The SAPL 3 Installation project (SF-1) would replace the existing Baden-Merced Pipeline, which was built in the late 1890s, and would construct a new pipeline extension of San Andreas Pipeline No. 3. Portions of the Baden-Merced Pipeline would be removed where its alignment merges with the San Andreas Pipeline No. 3 alignment. Because portions of the existing pipeline would be removed, this impact would be *potentially significant* if the pipeline were considered to be a historical resource for the purposes of CEQA compliance. The project's impact on these pipelines could be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #9 (cultural resources), as well as implementation of Measures 4.7-4a through 4.7-4f, which include historical documentation and compliance with the Secretary of the Interior's *Standards for the Treatment of Historic Properties*.

Because demolition under the Groundwater Projects (SF-2) would be limited to paved parking areas and playgrounds at the Francis Scott Key School Annex, and West and South Sunset Playgrounds, this impact would *not apply* to this project.

The Recycled Water Projects (SF-3) are not expected to affect historic water system facilities. If it is found after final facility locations are determined that historic resources could be adversely affected, implementation of SFPUC Construction Measure #9 (cultural resources) would ensure that impacts are *less than significant.*

Impact 4.7-5: Impacts on adjacent or nearby historic architectural resources.

Demolition, alteration, or other construction activities could also affect historic resources that are located near WSIP projects. These individual facilities or historic districts could include both SFPUC and non-SFPUC structures, and the types of impacts could be either direct or indirect. In particular, impacts on a nearby building associated with the Spring Valley Water Company could constitute significant impacts on potential historic districts united by plan and development. Impacts on non-SFPUC buildings near a WSIP project would not constitute significant impacts on the water system or its individual facilities, but would have to be evaluated in their own specific contexts at the project level.

Construction activities could cause indirect effects, such as damage due to vibration, staging and material storage, or the operation of construction equipment. With respect to vibration, construction activities could cause cosmetic or structural damage to buildings and structures (see Section 4.10, Noise and Vibration, for more discussion). Implementation of mitigation measures requiring the preparation of historic resources surveys and historic resource protection plans, vibration protection measures, and preconstruction surveys (Measures 4.7-4a through 4.7-4f), as appropriate, would reduce this potential impact to a less-than-significant level.

This analysis identifies historic SFPUC facilities that could be indirectly affected by the WSIP because they are located in or adjacent to the WSIP study area. The following information is based on project information presented in Chapter 3, Program Description, and Appendix C. It does not include all of the historic SFPUC and non-SFPUC resources in the WSIP study area. Implementation of SFPUC Construction Measure #9 (cultural resources) would require preconstruction screening to determine whether adjacent historic resources could be affected by the WSIP projects.

San Joaquin Region

Impact 4.7-5: Impacts on adjacent historic architectural resources		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	PSM

Two of the existing San Joaquin Pipelines were built in 1932 and 1953 (1932 for Pipeline No. 1, and 1953 for Pipeline No. 2). The SJPL System project (SJ-3) would add a new pipeline at the west and east ends of the San Joaquin right-of-way. The SJPL Rehabilitation project (SJ-4) would rehabilitate existing pipelines. While direct impacts on these pipelines are addressed in the previous impact (Impact 4.7-4), construction activities associated with both of these projects could indirectly affect the adjacent existing pipelines. Potential impacts associated with these two projects would be *potentially significant*. In addition to SFPUC Construction Measure #9 (cultural resources), implementation of mitigation measures requiring the preparation of historic resources surveys and protection plans, vibration protection measures, and preconstruction surveys (Measures 4.7-4a through 4.7-4f), as appropriate, would reduce this potential impact to a less-than-significant level.

The caretaker's residence associated with the Tesla Portal Disinfection project (SJ-5) could be altered or modified, depending on the design of proposed improvements. This residence is a potentially contributing feature to a historic district (San Francisco Planning Department, 2000), and impacts on this structure could be *potentially significant*. In addition to SFPUC Construction Measure #9 (cultural resources), implementation of mitigation measures requiring the preparation of historic resources surveys and protection plans, vibration protection measures, and preconstruction surveys (Measures 4.7-4a through 4.7-4f), as appropriate, would reduce this potential impact to a less-than-significant level.

The Advanced Disinfection (SJ-1) and Lawrence Livermore (SJ-2) projects would construct new facilities and would replace and upgrade existing non-historic facilities. With implementation of SFPUC Construction Measure #9 (cultural resources), requiring preconstruction screening for historic resources adjacent to these projects, the impact of these two projects would be *less than significant*.

Sunol Valley Region

Impact 4.7-5: Impacts on adjacent historic architectural resources		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	PSM
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	PSM

The Calaveras Dam project (SV-2) could affect the tender's (or watershed keeper's) residence, barn, and other historic structures, if any, at the dam site. The New Irvington Tunnel project (SV-4) could affect the historic components of the portals and tunnel, including the Irvington and Alameda West Portal Valve Houses and the caretaker's house. The SABUP project (SV-6) would conduct work within the area of the existing Alameda East Portal, which was built in 1934. The potential impacts associated with these projects would be *potentially significant*. In addition to SFPUC Construction Measure #9 (cultural resources), implementation of mitigation measures requiring the preparation of historic resources surveys and protection plans, vibration protection measures, and preconstruction surveys (Measures 4.7-4a through 4.7-4f), as appropriate, would reduce this potential impact to a less-than-significant level.

Implementation of SFPUC Construction Measure #9 (cultural resources), which would require preconstruction surveys to confirm the presence of historic resources adjacent to the Alameda Creek Fishery (SV-1), 40-mgd Treated Water (SV-3), and Treated Water Reservoirs (SV-5) projects as well as further investigation and protection as necessary, would ensure that impacts are *less than significant.*

Bay Division Region

Impact 4.7-5: Impacts on adjacent historic architectural resources		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	PSM
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSM

As described above, the Bay Division Pipeline system was built between 1925 and 1936. While direct impacts on these pipelines are addressed in the previous impact (Impact 4.7-4), construction activities associated with these projects could indirectly affect the adjacent existing pipelines. Potential impacts associated with these projects would be *potentially significant*. In addition to SFPUC Construction Measure #9 (cultural resources), implementation of mitigation measures requiring the preparation of historic resources surveys and protection plans, vibration protection measures, and preconstruction surveys (Measures 4.7-4a through 4.7-4f), as appropriate, would reduce this potential impact to a less-than-significant level.

Peninsula Region

Impact 4.7-5: Impacts on adjacent historic architectural resources		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	PSM
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	PSM
Pulgas Balancing Reservoir	PN-5	PSM

Facilities in the Lower Crystal Springs Dam vicinity were built during the historic period. The Lower Crystal Springs Dam was built in 1890. The Crystal Springs/San Andreas Pipeline was built between 1898 and 1932. The Crystal Springs Pump Station was built in 1933. In addition to potential direct impacts on these historic resources (addressed under Impact 4.7-4), the CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4), and Pulgas Balancing Reservoir (PN-5) projects could result in *potentially significant* impacts on adjacent historic resources, given the age of this portion of the regional water system. In addition to SFPUC Construction Measure #9 (cultural resources), implementation of mitigation measures requiring the preparation of historic resources surveys and protection plans, vibration protection measures, and preconstruction surveys (Measures 4.7-4a through 4.7-4f), as appropriate, would reduce this potential impact to a less-than-significant level.

The Baden and San Pedro Valve Lots (PN-1) and HTWTP Long-Term (PN-3) projects are upgrades of non-historic-era facilities. Implementation of SFPUC Construction Measure #9 (cultural resources), which would require preconstruction screening surveys to confirm the presence of historic resources adjacent to these projects as well as further investigation and protection as necessary, would ensure that impacts associated with these projects are *less than significant*.

San Francisco Region

Impact 4.7-5: Impacts on adjacent historic architectural resources		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	PSM

The facility locations for the Recycled Water Projects (SF-3) have not yet been determined. If the San Francisco Zoo is selected as a site for this recycled water treatment facility, the historic Fleishhacker Bath House, which was built in 1925, could be indirectly affected. Impacts of the Recycled Water Projects on this structure would be *potentially significant* and would be evaluated during separate, project-level CEQA review. In addition to SFPUC Construction Measure #9 (cultural resources), implementation of mitigation measures requiring the preparation of historic resources surveys and protection plans and historical documentation (Measures 4.7-4a through 4.7-4f), as appropriate, would reduce this potential impact to a less-than-significant level.

The SAPL 3 Installation project (SF-1) would extend an existing non-historic pipeline (San Joaquin Pipeline No. 3). This project would also remove or decommission portions of the existing Baden-Merced Pipeline, which was built in the late 1890s. Portions of the Baden-Merced Pipeline would be removed where its alignment merges with that of San Joaquin Pipeline No. 3. Where its alignment diverges from the San Joaquin Pipeline alignment, it would be capped and filled with slurry. Because portions of the existing Baden-Merced Pipeline would be removed and other portions decommissioned, the impact on the historical significance of the adjacent architectural resources would be *potentially significant*. In addition to SFPUC Construction Measure #9 (cultural resources), implementation of mitigation measures requiring the preparation of historic resources surveys and protection plans and historical documentation (Measures 4.7-4a through 4.7-4f), as appropriate, would reduce this potential impact to a less-than-significant level.

The Groundwater Projects (SF-2) would build new facilities or upgrade non-historic-era facilities. With implementation of SFPUC Construction Measure #9 (cultural resources), which would require preconstruction screening surveys to confirm the presence of historic resources near or adjacent to these projects as well as further investigation and protection as necessary, potential impacts on any adjacent or nearby historic resources would be *less than significant*.

4.8 Traffic, Transportation, and Circulation

4.8 Traffic, Transportation, and Circulation

4.8.1 Setting

This section presents the existing transportation network for the five WSIP regions. Preferred and alternative sites for WSIP projects are located in seven counties, including unincorporated areas within these counties and 25 cities (see Table 3.8, Chapter 3). The roadway network that would be used for project construction and/or as access routes for construction workers and construction vehicles include regional highways and freeways, local arterials, local residential streets, as well as rural roadways.

Many regional highways and freeways serve more than one WSIP region; depending on the origin and destination of the construction-related vehicles, vehicle trips associated with a particular WSIP project could travel on regional facilities in multiple regions. For each region, the location of interchanges and daily traffic volumes are presented for facilities in the vicinity of the WSIP projects in that region. Average daily traffic volumes on these facilities are based on the most recent data published by the California Department of Transportation (Caltrans). **Table 4.8-1** summarizes the average annual daily traffic volumes on regional facilities serving the five WSIP regions.

San Joaquin Region

Regional and Local Roadways

Regional access to the San Joaquin Region is provided by Interstate 5 (I-5) and Highway 99, both major north-south freeways containing between four and eight travel lanes. I-5 runs between the Canadian border in Washington State to the north and the Mexican border in San Diego to the south. Highway 99 connects with I-80 near Sacramento to the north and I-5 in Bakersfield to the south. The nearest interchanges with local access roadways to WSIP projects are Highway 132 at I-5 and Highway 120 at Highway 99.

In addition, I-580 provides east-west access between the San Francisco–Oakland Bay Bridge to the west and I-5 in San Joaquin County to the east. I-580 is a four-lane freeway in the San Joaquin Region, with an interchange at Highway 132. The average daily traffic volumes on the regional freeways in the vicinity of the WSIP projects are about 23,000 vehicles on I-5, 126,000 vehicles on Highway 99, and 38,000 vehicles on I-580.

Highway 132 (Vernalis Road), Highway 108/120, and Highway 120 serve as access routes for the WSIP projects in the San Joaquin Region. These roadways generally contain two to four travel lanes and do not provide on-street parking. Average daily traffic volumes on these roadways range between 20,000 and 30,000 vehicles. Local roadways in the immediate vicinity of the project sites are primarily two-lane rural roadways.

In the cities of Modesto and Riverbank, McHenry Avenue, Standiford Avenue, Prescott Road, Kiernan Avenue (Highway 219)/Claribel Road, and Ladd Road/Patterson Road (Highway 108), as well as a number of rural and local residential roadways, provide local access to the

TABLE 4.8-1
DAILY TRAFFIC VOLUMES ON REGIONAL ROADWAYS IN THE WSIP REGIONS

Regional Roadways	Location	Daily Traffic (Vehicles Per Day)
Highway 99	Modesto, Junction at Highway 132	126,000
Highway 101	Menlo Park, Willow Avenue	180,000
Highway 101	South San Francisco, Oyster Point Boulevard	200,000
Highway 101	San Francisco, Third Street	213,000
I-5	Modesto, Junction Highway 132	23,200
I-280	Redwood City, Edgewood Road	113,000
I-280	San Mateo, Junction at Highway 35, Bunker Hill	114,000
I-280	San Francisco, Geneva/Ocean Avenues	193,000
I-580	Modesto, Junction at Highway 132	37,500
I-680	Sunol, Junction at Highway 84 West	149,000
I-680	Fremont, Washington Boulevard	152,000
I-880	Fremont, Mowry Avenue	189,000

SOURCE: Caltrans, 2005.

San Joaquin Pipeline right-of-way. The roadways generally contain two to four lanes and do not provide on-street parking. Average daily traffic volumes on the above-noted roadways in Modesto range between 20,000 and 40,000 vehicles, while average daily traffic volumes on the roadways in Riverbank range between 10,000 and 25,000 vehicles (Caltrans, 2005).

Transit Service

The San Joaquin Region is served by a number of transit service providers, including Stanislaus Regional Transit, Modesto Area Express, and Riverbank–Oakdale Transit Authority Trolley. In the vicinity of the San Joaquin Pipeline in Modesto and Riverbank, one or more transit routes run along Kiernan Avenue, Standiford Avenue, McHenry Avenue, and Patterson Road. There are no transit routes in the immediate vicinity of the WSIP project sites outside of the cities of Modesto and Riverbank (MAX, 2006).

Bicycle and Pedestrian Network

There are a number of intercity/interregional bicycle routes on roadways that could serve as haul routes for the WSIP projects. The majority of these routes are Class III facilities (e.g., signed bike routes on roadways that allow shared use by bicycles and vehicles). Highway 120, Highway 108, and Willms Road are bicycle routes in the eastern portion of the region, and Highway 33 and Kasson Road are bicycle routes in the western portion of the region. There are limited pedestrian facilities on roadways in the vicinity of the WSIP project sites. In Modesto, the SFPUC right-of-way between Semallon Drive (west of McHenry Avenue and the Union Pacific railroad tracks) and Standiford Avenue contains a bicycle/pedestrian path (Class I facility). Bicycle lanes (Class II facilities) are provided on Standiford Avenue, Prescott Road, Tully Road, and Coffee Road (City of Modesto, 2002).

Sunol Valley Region

Regional and Local Roadways

Regional access to the Sunol Valley Region is provided by I-680. I-680 is an eight-lane, north-south freeway that connects I-80 near Fairfield to the north with I-280 in San Jose to the south. I-680 interchanges near the WSIP project sites are provided at Highway 237 in Milpitas and Highway 84 in Sunol. I-680 in the vicinity of Highway 84 carries about 149,000 vehicles per day.

Local access between the project sites in the western portion of the region and I-680 is via Calaveras Road. Calaveras Road between I-680 and Geary Road is generally a two-lane roadway with average daily traffic volumes of about 1,400 vehicles. South of Geary Road, Calaveras Road is a one to two-lane, rural roadway serving the Sunol Regional Wilderness and Calaveras Reservoir and Dam, and connects with Highway 237 and I-680 in Milpitas. Mission Boulevard (Highway 238), a four-lane divided arterial, provides local access to I-680 in the western portion of the Sunol Valley Region. Mission Boulevard (Highway 238) has an average daily traffic volume of about 32,000 vehicles (Caltrans, 2005).

Transit Service

Alameda County (AC) Transit is the principal bus service provider in the county, while Santa Clara Valley Transportation Authority (VTA) is the primary transit provider in Santa Clara County. There is no bus service provided by either AC Transit or VTA along Calaveras Road. A number of AC Transit bus lines (140, 141, 180, 217, and 520) provide service along Mission Boulevard (Highway 238) in Fremont (AC Transit, 2007; VTA, 2007).

Bicycle and Pedestrian Network

Neither Calaveras Road nor Mission Boulevard (north of I-680) are part of the designated Alameda countywide bicycle network. However, the East Bay Bicycle Coalition has identified Calaveras Road between I-680 and Milpitas, and Mission Boulevard as on-road routes recommended for bicycle travel. Calaveras Road experiences considerable recreational bicycle travel on weekends. There are no pedestrian facilities on Calaveras Road. Mission Boulevard has sidewalks on both sides of the street (Alameda County Congestion Management Agency, 2006; East Bay Bicycle Coalition, 2005).

Bay Division Region

Regional and Local Roadways

Regional access to the Bay Division Region is provided by I-680 and I-880 serving the eastern portion of the region in Alameda County, and Highway 101 and I-280 serving the western portion of the region in San Mateo County. Within the Bay Division Region, I-680 is a six-lane, east-west freeway, with interchanges at Mission Boulevard (Highway 238) and at Washington Street. I-880 is an eight-lane, north-south freeway that connects I-580 in Oakland to the north and I-280 in San Jose to the south. Within the region, I-880 has interchanges at Stevenson Boulevard and

Mowry Avenue. The average daily traffic volumes are about 152,000 vehicles on I-680, and 189,000 vehicles on I-880.

Highway 101 runs between I-5 near the Washington border to the north and the east Los Angeles interchange to the south. Highway 101 in the vicinity of the program area is an eight-lane, north-south freeway with interchanges at University Avenue, Willow Road, and Marsh Road. I-280 runs between San Francisco to the north and Highway 101/I-680 in San Jose to the south. In the Bay Division Region, I-280 has an interchange at Edgewood Road. Average daily traffic volumes in the Bay Division Region are about 180,000 vehicles on Highway 101, and 113,000 vehicles on I-280.

Woodside Road (Highway 84), El Camino Real (Highway 82) and Mission Boulevard (Highway 238) also serve as major regional access routes within the region. These roadways contain four to six travel lanes and generally do not provide on-street parking. Average daily traffic volumes on these facilities range between 36,000 and 46,000 vehicles (Caltrans, 2005).

WSIP projects are located in the vicinity of numerous residential and commercial streets in this region. Minor arterials and local residential streets generally contain two travel lanes and parking on both sides of the street.

Transit Service

The Bay Division Region is served by two transit agencies: AC Transit and San Mateo County Transit District (SamTrans). AC Transit is the principal bus service provider in the Alameda County portion of this region, with a number of local routes along the roadways in the vicinity of WSIP projects. SamTrans serves San Mateo County with a number of express and local routes in this region. Mission Boulevard, Paseo Padre Parkway, El Camino Real, and Edgewood Road are among this region’s roadways served by one or more AC Transit and SamTrans bus routes (AC Transit, 2007; SamTrans, 2007).

Bicycle and Pedestrian Network

There are a number of bicycle facilities on roadways in the vicinity of WSIP projects in this region. The eastern portion of the region in Alameda County has an established network of existing and proposed Class II (bike lanes striped within the paved area of roadways and established for the preferential use of bicycles) and Class III facilities. Many of the routes overlap with major arterials (e.g., Mission Boulevard, Paseo Padre Parkway). The East Bay Bicycle Coalition identifies most arterials as on-road bicycle routes. The western portion of the region in San Mateo County also has an established bicycle route network, primarily along major arterials (including Edgewood Road, Bay Road, El Camino Real, and Woodside Road) (Alameda County Congestion Management Agency, 2006).

The San Francisco Bay Trail has identified routes in both the eastern and western portions of the region. The Bay Trail is designed to create pathway links to the various commercial, residential, and industrial neighborhoods that surround San Francisco Bay. In the vicinity of WSIP projects in the Bay Division Region, the Bay Trail includes off-street paths along Highway 84, and on-road paths on University Avenue (Association of Bay Area Governments, 2003).

Most, but not all, roadways in the vicinity of the WSIP projects in the Bay Division Region have sidewalks on both sides of the street.

Peninsula Region

Regional and Local Roadways

Regional access to the Peninsula Region is provided by Highway 101 and I-280 in San Mateo County. Highway 101 in the Peninsula Region contains eight lanes and has interchanges at Millbrae Avenue and I-380. I-280 in the Peninsula Region contains eight lanes, with interchanges at Edgewood Road, Highway 92, Bunker Hill Drive, Hayne Road, and San Bruno Avenue. In the Peninsula Region, the average daily traffic volumes are about 200,000 vehicles on Highway 101, and 114,000 vehicles on I-280 (Caltrans, 2005).

El Camino Real (Highway 82) and Junipero Serra Boulevard also serve as access routes within the region, and Skyline Boulevard (Highway 35), Cañada Road, and Crystal Springs Road provide local access. These roadways contain two to four travel lanes. Skyline Boulevard is also part of the Scenic Highway System. El Camino Real and Junipero Serra Boulevard generally provide on-street parking.

Transit Service

Transit service in the Peninsula Region is primarily provided by the SamTrans, which offers a number of express and local routes along the arterials in the region, particularly along El Camino Real (Highway 82). There are no bus routes on Skyline Boulevard or Crystal Springs Road. The Peninsula Region is also served by the regional Bay Area Rapid Transit (BART) rail service to the San Francisco International Airport, and Caltrain commuter rail service between San Francisco and San Jose (SamTrans, 2007).

Bicycle and Pedestrian Network

The Peninsula Region has an established network of bicycle routes. The majority of these routes are Class III (signed routes only). Many of the routes overlap with major arterials (e.g., Mission Boulevard, Paseo Padre Parkway). Most, but not all, arterials and local streets in the vicinity of the WSIP projects in the Peninsula Region include sidewalks on both sides of the street (Alameda County Congestion Management Agency, 2006; San Mateo County, n.d.).

San Francisco Region

Regional and Local Roadways

Regional access to the San Francisco Region is provided by Highway 101 and I-280. Highway 101 in this region contains eight lanes and has interchanges at Millbrae Avenue, Oyster Point Boulevard, Third Street/Bayshore Boulevard, and Silver Avenue. I-280 in this region contains eight lanes, with an interchange at 19th Avenue/Highway 1. In the San Francisco Region, the average daily traffic volumes are about 213,000 vehicles on Highway 101, and 193,000 vehicles on I-280 (Caltrans, 2005).

A number of local roadways connect with the regional facilities, including El Camino Real (Highway 82) and Bayshore Boulevard in San Mateo County, as well as Ocean and Geneva Avenues in San Francisco. Local and regional access to the western portion of San Francisco is provided by 19th Avenue/Highway 1. These arterials generally contain four to six travel lanes, and most arterials provide for on-street parking on both sides of the street.

WSIP projects are located along and across numerous residential streets in both San Mateo and San Francisco Counties. Residential streets generally contain two travel lanes and on-street parking on one or both sides of the street.

Transit Service

Transit service in the San Francisco Region is primarily provided by the San Francisco Municipal Railway (Muni) (bus and light rail service in San Francisco), SamTrans, BART, and Caltrain. In the vicinity of the WSIP projects in this region, there are bus and/or light rail routes on 19th Avenue, Ocean Avenue, and Geneva Avenue. SamTrans provides a number of express and local bus routes along El Camino Real, and along local streets in Colma, San Bruno, Millbrae, and San Mateo. SamTrans provides some limited service in San Francisco (e.g., on Bayshore Boulevard) (Muni, 2005; SamTrans, 2007).

Bicycle and Pedestrian Network

The San Francisco Region has an established network of bicycle routes in both San Mateo and San Francisco Counties. In the vicinity of the WSIP project sites, most routes are Class III facilities (signed routes only) and overlap with major arterials (e.g., Geneva Avenue in San Francisco, and El Camino Real and Junipero Serra Boulevard in San Mateo County). Most, but not all, arterials and local streets in the vicinity of the WSIP projects in this region include sidewalks on both sides of the street (San Mateo County, n.d.).

Regulatory Framework

Transportation analysis in California is guided by policies and standards set at the state level by Caltrans as well as by local jurisdictions. There are no federal regulations that address transportation impacts associated with the WSIP projects.

Both Caltrans and local jurisdictions generally assess the impact of long-term, not short-term, traffic conditions. Plans and policies related to transportation aim to plan for and accommodate future growth and the vehicular, transit, pedestrian, and bicycle demand associated with that growth.

Policies regarding traffic service levels apply to long-term, not short-term, traffic conditions. These policies generally specify maintaining a level of service[1] (LOS) of LOS C or LOS D on major streets during the peak periods of traffic flow, and require mitigation measures when project-specific impacts would result in a level of service exceeding the threshold.

4.8.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to traffic, but generally considers that implementation of the proposed program would have a significant traffic impact if it were to:

- Cause an increase in traffic that is substantial in relation to the existing traffic load and capacity of the street system (i.e., result in a substantial increase in either the number of vehicle trips, the volume-to-capacity ratio on roads, or congestion at intersections) (Evaluated in this section)
- Exceed, either individually or cumulatively, a level of service standard established by the county congestion management agency for designated roads or highways (unless it is practical to achieve the standard through increased use of alternative transportation modes) (Not evaluated in this section, see Appendix B)
- Result in a change in air traffic patterns, including either an increase in traffic levels, an obstruction to flight, or a change in location, that results in substantial safety risks (Not evaluated in this section, see Appendix B)
- Substantially increase hazards due to a design feature (e.g., sharp curves at dangerous intersections) or incompatible uses, or interfere with existing transportation systems (including vehicular, pedestrian, and bicycle networks), causing substantial alterations to circulation patterns or major traffic hazards (Evaluated in this section)
- Result in inadequate emergency access (Evaluated in this section)
- Result in inadequate parking capacity that could not be accommodated by alternative solutions (Evaluated in this section)
- Conflict with adopted policies, plans, or programs supporting alternative transportation (e.g., conflict with policies promoting bus turnouts, bicycle racks, etc), or cause a substantial increase in transit demand that cannot be accommodated by existing or proposed transit capacity or alternative travel modes (Not evaluated in this section, see Appendix B)

Since many of the WSIP facilities are located in roadways or cross roadways, a significance criterion that relates to interference with existing transportation systems (second half of fourth

1 Level of service (LOS) is a qualitative description a facility's performance based on average delay per vehicle, vehicle density, or volume-to-capacity ratios. Levels of service range from LOS A, which indicates free-flow or excellent conditions with short delays, to LOS F, which indicates congested or overloaded conditions with extremely long delays.

bullet) has been added to the CCSF's standard list. This criterion has been applied in the past by the CCSF to development projects located in San Francisco.

Approach to Analysis

This program-level analysis presents a screening-level assessment of the potential transportation impacts associated with the WSIP projects. This assessment evaluates the potential for project-specific, short-term, construction-related impacts on roadways due to changes in roadway capacities or increases in construction-related traffic, as well as longer-term impacts due to the operation of WSIP facilities.

The impact assessment of construction-related impacts assumes that for all WSIP projects the contractor(s) would obtain any necessary road encroachment permits prior to construction and would comply with the conditions of approval attached to project implementation. In particular, the assessment assumes implementation of SFPUC Construction Measure #5 for traffic, which specifies that each contractor must prepare a traffic control plan to minimize traffic and on-street parking impacts on any streets affected by construction of a proposed project. As appropriate, the SFPUC or the contractor would consult with local traffic and transit agencies. The transportation impact assessment assumes that if multiple contracts for work within a project are issued, each individual project would prepare a traffic control plan, as applicable to the situation.

A number of the WSIP projects also include improvements to existing roads or construction of new temporary access roads between the project sites and public roadways serving as haul routes. The assessment assumes that any improvements at the intersection of existing or new temporary access roads with public roadways would be constructed to meet the applicable intersection design standards of the jurisdiction in which the facility is located. As appropriate, truck deceleration and acceleration lanes would be provided to facilitate truck access into and out of the project site, and to minimize conflicts between construction vehicles and adjacent traffic flow.

Impact Summary by Region

Table 4.8-2 presents a summary of the traffic and transportation impacts associated with implementation of the WSIP.

Construction-Related Impacts

Construction-related traffic impacts are not generally considered significant, because given their temporary nature, they are usually of limited duration. However, since construction of some WSIP projects could affect the transportation network for a longer duration (e.g., construction activities occurring for a two-year period), their impacts could be determined to be potentially significant. Construction activities that affect roadway operations are typically regulated through permits and construction requirements to ensure acceptable levels of traffic flow during the period of traffic disruption. Construction best management practices, including the preparation of a traffic control plan, are required to be in place to ensure the safety of construction workers, motorists, bicyclists, and pedestrians throughout project construction.

TABLE 4.8-2
POTENTIAL IMPACTS AND SIGNIFICANCE – TRAFFIC, TRANSPORTATION, AND CIRCULATION

Projects	Project Number	Impact 4.8-1: Temporary reduction in roadway capacity and increased traffic delays	Impact 4.8-2: Short-term traffic increases on roadways	Impact 4.8-3: Impaired access to adjacent roadways and land uses	Impact 4.8-4: Temporary displacement of on-street parking	Impact 4.8-5: Increased traffic safety hazards during construction	Impact 4.8-6: Long-term traffic increases during facility operation

LS = Less than Significant impact, no mitigation required
PSM= Potentially Significant impact, can be mitigated to less than significant
N/A = Not Applicable

The construction impacts identified below for each type of facility have been developed to allow a general assessment of the nature and magnitude of potential construction impacts associated with each individual facility. The final construction scheduling of specific projects could result in overlapping impacts due to simultaneous construction of more than one facility. Since most transportation impacts associated with each facility would be specific to each facility site, overlapping impacts would be limited to impacts at adjoining construction sites or along common haul routes, where overlapping schedules for two or more facilities could result in combined traffic impacts.

Short-Term Impacts of Construction Traffic

Impact 4.8-1: Temporary reduction in roadway capacity and increased traffic delays.

Impacts of WSIP project construction on the availability of travel lanes could result if facility construction occurs within or adjacent to a public roadway, and a portion of the pavement is required for construction purposes. Construction could then result in a temporary reduction in the number of travel lanes or the available width of travel lanes, and subject vehicles (including transit) using the affected roadways to increased congestion and delays. Road closures would require drivers to detour to other, potentially less convenient routes to access their destinations. Impacts would be significant and unavoidable if roadways would be closed and no detour routes provided, or if through-traffic or access to adjacent land uses would be restricted for a substantial duration. The actual impact of construction activities on roadway capacity and traffic operations would depend on the length of the affected roadway segment, the number of travel lanes that would be available for vehicular flow, and the duration of construction activities on the roadways.

Pipelines. Pipeline construction would occur both within the SFPUC right-of-way and within or adjacent to public roadway right-of-way.[2] Construction across minor roadways and some major roadways would be conducted via the cut-and-cover method, which would require construction activities to occur within the roadway pavement. Impacts on any particular segment of roadway would be limited in duration, as construction of pipelines generally progresses at an average rate of about 120 feet per day in urban and suburban areas, and 160 feet per day in rural areas. In general, multiple crews are expected to work on pipeline construction; therefore, for a particular pipeline project, construction at more than one segment of the pipeline could occur simultaneously. Cut-and-cover construction across some major roadways could result in substantial impacts on traffic flow, and trenchless construction techniques such as the jack-and-bore method may be selected by the contractor or required by local jurisdictions. Construction of pipelines across freeways, some major roadways, and railroads would be completed using the jack-and-bore or similar method, which would not affect operations on these facilities. (See Chapter 3, Section 3.10, for a description of the various proposed construction techniques.)

[2] For purposes of the transportation discussion, "SFPUC right-of-way" implies off-road areas through which the pipeline alignment travels, and "public roadway right-of-way" implies in-road areas. The SFPUC may have easements through the public roadway; however, construction activities in the public roadway right-of-way could encroach on vehicular, pedestrian, and bicycle access and on-street parking, if provided.

Pipeline construction within public roadways would result in greater traffic impacts, as construction activities would require the use of a portion of the roadway for excavation of the pipeline, and additional roadway area would be needed for construction staging, including materials storage and construction vehicle and construction worker parking. If the public roadway right-of-way is narrow (e.g., minor residential streets), then temporary roadway closures could be required.

Tunnels. Since tunnel construction would occur from tunnel portals and shafts within the tunnel alignment, WSIP projects involving new tunnel construction would generally not require the use of parking or travel lanes for construction activities. In some cases, however, haul trucks traveling to a facility site could result in the need to utilize shoulders or parking lanes for staging prior to accessing the construction site. In addition, some temporary roadway closures could be required for tunnel construction activities if they occur adjacent to a public roadway right-of-way.

Other Facilities. Construction of other types of facilities (vaults, valve lots, crossovers, pump stations, treatment facilities, and storage facilities) would generally occur at discrete locations along the alignment, and onsite parking would be provided within the designated construction staging area. Any travel lane closures would be of limited duration. At some urban locations, where the size of staging areas could be limited, construction worker parking demand might need to be accommodated on adjacent public streets.

San Joaquin Region

Impact 4.8-1: Temporary reduction in roadway capacity and increased traffic delays		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	LS

The SJPL System project’s (SJ-3) 6-mile eastern pipeline segment and crossover location west of Oakdale Portal would be sited in an undeveloped area, where the potential for traffic impacts would be low. The 10-mile western pipeline segment east of Tesla Portal would extend through a primarily agricultural area that contains a cluster of residences and a golf course.

Most construction on the SJPL System project (SJ-3) would occur within the SFPUC right-of-way, but this right-of-way would cross a number of local roadways, highways, and freeways as well as a railroad. Construction of the new pipeline across freeways (Highway 33, Highway 99, I-5, and I-580) and railroad tracks would be conducted using the jack-and-bore method, and disruption to traffic flow would be minimal. Construction across other roadways would be conducted primarily using the cut-and-cover method; however, since most roadways serving the project site are rural roadways with low volumes of traffic, disruption of traffic flow would also be minimal. Potential traffic impacts associated with the SJPL System project would be evaluated as part of separate, project-level CEQA review for this project. Implementation of SFPUC Construction Measure #5 (traffic control plan) and additional traffic control measures identified in Measure 4.8-1a is expected to be adequate to reduce any *potentially significant* traffic impacts to a less-than-significant level.

The SJPL Rehabilitation project (SJ-4) involves reconditioning of 48 miles of the existing San Joaquin Pipelines. While the eastern and western portions of the pipeline run through undeveloped and agricultural areas, where the potential for traffic impacts would be low, the central portion of the pipeline runs through the cities of Modesto and Riverbank, and largely through developed residential areas. Any construction through Modesto and Riverbank would be conducted using both the jack-and-bore and cut-and-cover methods and could result in temporary lane closures. Implementation of SFPUC Construction Measure #5 (traffic control plan) and additional traffic control measures identified in Measure 4.8-1a is expected to reduce any *potentially significant* traffic impacts to a less-than-significant level. When project elements and locations of the SJPL Rehabilitation project are defined, it would be subject to separate, project-level CEQA review.

Other WSIP projects could be located in the Tesla Portal vicinity (under Advanced Disinfection, SJ-1, and Tesla Portal Disinfection, SJ-5) or at the Thomas Shaft (under Lawrence Livermore, SJ-2) and would involve construction of new treatment facilities within the SFPUC right-of-way. No construction within public roadways is anticipated. Construction activities associated with these facilities would not result in a reduction in the number of travel lanes on roadways in the vicinity of the site. Therefore, traffic impacts are expected to be *less than significant* with implementation of SFPUC Construction Measure #5 (traffic control plans).

Sunol Valley Region

Impact 4.8-1: Temporary reduction in roadway capacity and increased traffic delays		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	PSM
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	LS
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	PSM

All WSIP projects in this region would be constructed within the SFPUC right-of-way. The Alameda Creek Fishery (SV-1), 40-mgd Treated Water (SV-3), New Irvington Tunnel (SV-4), and Treated Water Reservoirs (SV-5) projects would not require construction within or across public roadways, and therefore would not affect the number of travel lanes in the vicinities of these projects. With implementation of SFPUC Construction Measure #5 (traffic control plan), this impact would be *less than significant* for these projects.

The SABUP project (SV-6) would require crossing of Calaveras Road, a temporary but *potentially significant* impact on Calaveras Road. With implementation of SFPUC Construction Measure #5 (traffic control plan) and additional traffic control measures as part of Measure 4.8-1a, this impact would be reduced to a less-than-significant level.

Construction of Calaveras Dam (SV-2) would require temporary closure of a segment of Calaveras Road (between Geary and Felter Roads) to through-traffic during the two- to three-year construction period. Through-traffic using Calaveras Road would be required to find an alternate route for the duration of the construction period and would likely use I-680. Construction-related traffic impacts associated with Calaveras Dam would be evaluated as part of separate, project-level CEQA review. Implementation of SFPUC Construction Measure #5 (traffic control plan) and additional traffic control measures (including detour plans) as part of Measure 4.8-1a is expected to reduce the *potentially significant* impacts of the roadway closure to a less-than-significant level.

Bay Division Region

Impact 4.8-1: Temporary reduction in roadway capacity and increased traffic delays		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	LS
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSM

Within the Bay Division Region, the BDPL Reliability Upgrade (BD-1) project would primarily involve construction activities within the SFPUC pipeline right-of-way. However, since this project is located in an urbanized area, it may require construction across multiple roadways, highways, and freeways. Construction across roadways could potentially affect the number of available travel lanes as well as traffic flow on these roadways. The jack-and-bore method of construction is proposed to be used for crossing I-880 and Highway 101, while the cut-and-cover method would be employed to cross all other roadways. Use of cut-and-cover method for construction across a number of multiple-lane arterials, particularly in Fremont (e.g., Mission Boulevard, Paseo Padre Parkway, and Fremont Boulevard), could result in significant impacts on traffic operations. The impacts could be compounded if construction occurs simultaneously on more than one major arterial, and/or if the arterial is used as a haul route for other projects in the region. The BDPL Reliability Upgrade (BD-1) project would also require construction under the commuter and freight rail tracks at a number of locations; however, train movements would not be affected because the jack-and-bore method would be used. A more detailed traffic impact analysis for the BDPL Reliability Upgrade (BD-1) project would be completed as part of separate, project-level CEQA review. Implementation of SFPUC Construction Measure #5 (traffic control plan), additional traffic control measures identified in Measure 4.8-1a, and coordination of individual traffic control plans (Measure 4.8-1b) are expected to reduce *potentially significant* traffic impacts of the BDPL Reliability Upgrade (BD-1) project to a less-than-significant level.

BDPL 3 and 4 Crossovers (BD-2) would involve construction of new valve and vault structures and would not require construction within public roadways; therefore, potential traffic impacts on nearby roadways would be *less than significant* with implementation of SFPUC Construction Measure #5 (traffic control plan).

BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) includes a replacement pipeline between the new isolation valves**,** and would likely include work within public roadways. Implementation of SFPUC Construction Measure #5 (traffic control plan) and additional traffic control measures identified in Measure 4.8-1a are expected to reduce any *potentially significant* traffic impacts to a less-than-significant level.

Peninsula Region

Impact 4.8-1: Temporary reduction in roadway capacity and increased traffic delays		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	PSM
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	PSM
Pulgas Balancing Reservoir	PN-5	PSM

Within this region, the Baden and San Pedro Valve Lots (PN-1) and HTWTP Long-Term (PN-3) projects would be constructed at discrete locations within the SFPUC pipeline and tunnel alignments and would not require construction within public roadways. With implementation of SFPUC Construction Measure #5 (traffic control plan), this impact would be *less than significant* for these projects.

CS/SA Transmission (PN-2) facilities would be located on SFPUC property, except for repair work proposed on the Upper Crystal Springs Dam culverts under Highway 92. The Pulgas Balancing Reservoir project (PN-5) would include enlargement of the channel that crosses under Cañada Road. Both of these projects could require temporary closure of traffic lanes. Since these projects cross under public roadways, the potential for traffic disruption would be limited to the crossing location. For both of these projects, implementation of SFPUC Construction Measure #5 (traffic control plan) and additional traffic control measures identified in Measure 4.8-1a are expected to reduce any *potentially significant* traffic impacts to a less-than-significant level. The CS/SA Transmission project would be evaluated as part of separate, project-level CEQA review and a more detailed traffic analysis would be completed at that time.

Lower Crystal Springs Dam (PN-4) would require temporary closure of San Mateo County's Skyline Boulevard Bridge, which was built across the top of the dam. This section of Skyline Boulevard would be closed during the one-year construction period and would be reopened upon completion of the project. Implementation of SFPUC Construction Measure #5 (traffic control plan) and detour plans for the closure of Skyline Boulevard Bridge (Measure 4.8-1a) is expected to reduce *potentially significant* impacts of the roadway closure to a less-than-significant level. Potential traffic impacts associated with this project would be evaluated in more detail as part of separate, project-level CEQA review.

San Francisco Region

Impact 4.8-1: Temporary reduction in roadway capacity and increased traffic delays		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	PSM
Recycled Water Projects	SF-3	PSM

Within this region, the SAPL 3 Installation, (SF-1) project would have the greatest potential to affect roadway capacity as well as traffic and transit operations. The pipeline alignment would travel through densely populated areas, and pipelines would be located within public roadways. Pipeline replacement would necessitate partial or full temporary lane closures and could include closure of parking and/or travel lanes. Implementation of SFPUC Construction Measure #5 (traffic control plan), additional traffic control measures identified in Measure 4.8-1a, and coordination of individual traffic control plans (Measure 4.8-1b) is expected to reduce *potentially significant* impacts of this project to a less-than-significant level. Potential traffic impacts would be evaluated in more detail as part of separate, project-level CEQA review.

The Groundwater Projects (SF-2) and Recycled Water Projects (SF-3) could also require construction within or across local roadways, which could affect traffic operations. Implementation of SFPUC Construction Measure #5 (traffic control plan) and additional traffic control measures identified in Measure 4.8-1a is expected to reduce *potentially significant* impacts of each project to a less-than-significant level. Potential traffic impacts would be evaluated in more detail as part of separate, project-level CEQA review for both of these projects.

Impact 4.8-2: Short-term traffic increases on roadways due to construction-related vehicle trips.

Construction-related vehicles trips would include construction workers traveling to and from the project site, haul truck trips associated with excavation materials transfer and disposal, and materials and equipment deliveries. The number of construction-related vehicles traveling to and from WSIP project sites would vary on a daily basis, depending on the type of project, construction phase, planned activity, and material needs. The greatest number of construction-generated vehicle trips would generally occur during the excavation, concrete pouring, and backfilling stages of construction. Truck operations, including haul trucks and materials delivery trucks, would occur mostly during daytime hours, but could extend beyond these hours (see Section 4.10, Noise and Vibration for more discussion of construction hours).

Construction traffic could result in short-term increases in traffic volumes on roadways in the immediate vicinity of WSIP project sites and along haul routes. The addition of construction vehicle traffic to the existing roadway volumes, without increasing the capacity of the roadway, could result in increased congestion and delay for vehicles, including transit. The reduction in capacity of roadways through temporary lane closures could further increase congestion and delays for vehicles using the roadway. The presence of construction truck traffic could also temporarily reduce roadway capacities due to the slower travel speeds and larger turning radii of trucks. The actual impact of construction vehicle traffic on local and regional facilities would depend on the number and type of construction-related vehicles, the number of travel lanes on the roadways used as haul routes, existing traffic volumes on these roadways, as well as the terrain and other factors. Impacts of construction traffic would be most noticeable in the immediate vicinity of the WSIP projects, and less noticeable farther away and on regional facilities.

Haul routes for offsite disposal of excavated materials, and deliveries of concrete and other materials would include a combination of regional highways, local arterials, and residential and rural streets, depending on the geographic locations of WSIP projects. Offsite disposal of excavated materials would depend of the type of material to be disposed of, and could occur at any of the 17 active landfills located in Stanislaus, San Joaquin, Alameda, San Mateo, and Santa Clara counties. Depending on project location, regional freeways such as Highway 92, I-280, I-580, and I-680 would be used to access these facilities.

Due to the proximity of WSIP projects to each other, the use of common haul routes, and overlapping schedules, the number of daily truck trips on roadways serving as haul routes could increase substantially over existing conditions. The effect of such combined or collective increases in construction vehicle traffic, and particularly truck traffic, on roadways would be increased delays due to the trucks' slower travel speeds and larger turning radii. The impact of combined construction vehicle traffic increases on roadway operations would depend on a number of factors, including the number of daily and peak-period truck volumes, the duration of the overlapping phases of the construction projects, and the characteristics of the haul route (e.g., the number of travel lanes in each direction, existing traffic volumes, and terrain). Combined or collective traffic impacts are discussed in Section 4.16, Impact 4.16-7, Localized Collective Impacts.

Pipelines. Construction-vehicle activity associated with pipeline construction includes excavation, disposal of excavated materials, and materials delivery. Pipeline construction would proceed at an average rate of approximately 120 feet per day in urban and suburban areas, and 160 feet per day in rural areas; the haul routes would vary depending on the location of the segment of pipeline being constructed. At a minimum, there would be 20 truck trips (round-trips) per day, with a maximum of 10 truck trips per hour during the a.m. and p.m. peak hours. In addition, there would be approximately 30 to 40 workers per crew traveling to and from the site each day. Construction activities could occur six days per week and would generally occur between 7:00 a.m. and 5:00 p.m., although construction could extend beyond these hours.

Tunnels. Construction-vehicle activity associated with tunnel construction would include construction of the tunnel shaft, removal of excavated materials, and materials delivery. Construction staging and materials removal would occur at the tunnel entry and exit shafts or portals, and construction at the tunnel would typically be conducted 24 hours per day, seven days a week. Excavated materials would be disposed of onsite, or stored onsite and then disposed offsite. Offsite disposal of excavated materials would result in greater traffic impacts. If excavated materials were disposed of offsite on a daily basis, the number of haul trucks would be based on the amount of material that could be excavated per day. Typical tunnel excavation could result in between 20 and 40 truck trips (round-trips) per day. If excavation materials were stored onsite prior to offsite disposal, the number of truck trips would be limited to the amount of available staging area and could exceed the 20 to 40 truck trips per day. Truck activity associated with offsite disposal would occur on weekdays during the designated construction hours and, assuming between 20 and 40 truck trips per day, would result in a maximum of 10 truck trips during the a.m. or p.m. peak hours. Since tunnel activities would be conducted 24 hours a day, there would be three shifts of 10 construction workers per crew on a daily basis traveling to and from the project site.

Other Facilities. The number of construction vehicles associated with other types of WSIP projects would depend on the facility, and whether new facilities would be constructed or existing facilities upgraded. New treatment and storage facilities would generate the greatest number of construction vehicles, as these facilities would involve excavation and construction of new structures. The number of vehicle trips would depend on the amount of excavated materials;

however, during the a.m. and p.m. peak hours up to 180 truck trips could be expected. Construction of the new treatment and storage facilities would involve an average of 30 to 50 onsite construction workers per day. Other facilities such as valve vaults and pump stations would have substantially fewer construction vehicles and workers onsite per day. Construction activities could occur six days per week and would generally occur between 7:00 a.m. and 5:00 p.m., although construction could extend beyond these hours.

San Joaquin Region

Impact 4.8-2: Short-term traffic increases on roadways due to construction-related vehicle trips		
Advanced Disinfection	SJ-1	PSM
Lawrence Livermore	SJ-2	PSM
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	PSM

Of the five projects in the San Joaquin Region, pipeline construction associated with the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects would generate the greatest amount of construction traffic associated with construction crews and materials deliveries. Construction of the eastern pipeline segment of the SJPL System project (SJ-3) would increase traffic volumes on local highways, such as Highways 120 and 128, as well as on rural, two-lane roadways. Construction of the western pipeline segment of SJ-3 would increase traffic volumes on I-580, Vernalis Road (Highway 132), and Highway 33 as well as on rural, two-lane roadways. The traffic impacts of the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects would be evaluated in more detail during separate, project-level CEQA review. Implementation of SFPUC Construction Measure #5 (traffic control plan), additional traffic control measures as part of Measure 4.8-1a, and coordination of individual traffic control plans for projects in the Tesla Portal vicinity (Measure 4.8-1b) would reduce this *potentially significant* impact to a less-than-significant level.

Since the project elements and location of the SJPL Rehabilitation project (SJ-4) have not been defined, the potential exists that construction could occur at multiple locations along the existing 48-mile pipeline. Construction within Modesto could result in more than one construction project utilizing the same residential streets as haul routes and in partial or full closure of local streets, which could cause significant traffic impacts. Implementation of SFPUC Construction Measure #5 (traffic control plan for each individual project), additional traffic control measures identified in Measure 4.8-1a, and coordination of individual traffic control plans for nearby projects (Measure 4.8-1b) would reduce this *potentially significant* impact to a less-than-significant level.

Access routes for Tesla Portal (Advanced Disinfection, SJ-1, and Tesla Portal Disinfection, SJ-5) would include I-580, Chrisman Road, and Vernalis Road, while access routes for Thomas Shaft (Lawrence Livermore, SJ-2) would include I-580, Corral Hollow Road, and a dirt access road. The amount of activity associated with construction of these facilities has not yet been determined. With implementation of SFPUC Construction Measure #5 (traffic control plan) for these projects and additional traffic control measures identified in Measure 4.8-1a, *potentially significant* impacts of project-related increases in traffic would be reduced to a less-than-significant level.

Sunol Valley Region

Impact 4.8-2: Short-term traffic increases on roadways due to construction-related vehicle trips		
Alameda Creek Fishery	SV-1	PSM
Calaveras Dam	SV-2	PSM
40-mgd Treated Water	SV-3	PSM
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	PSM
SABUP	SV-6	PSM

Within this region, construction of the Calaveras Dam (SV-2) and Treated Water Reservoirs (SV-5) projects would require an extensive amount of excavation for dam replacement and construction of the new storage reservoirs at the Sunol Valley WTP. Of the six projects in the Sunol Valley Region, these projects would result in the greatest number of construction vehicles traveling to and from project sites. These trips would include disposal of excavated materials, and delivery of construction and filter materials. In addition, each project would have between 50 and 190 construction workers traveling to and from the site each day. The Calaveras Dam project would close Calaveras Road to through-traffic between Geary Road and Felter Road, requiring through-traffic using this section of Calaveras Road to divert to I-680. The traffic impacts associated with the Calaveras Dam and Treated Water Reservoirs projects would be evaluated in more detail as part of separate, project-level CEQA review.

The haul route for the New Irvington Tunnel (SV-4) exit portal would be via a new access road that would extend through a residential neighborhood and would connect the portal with Mission Boulevard (Highway 238) and the I-680 freeway. Due to the possible overlap in the construction schedules of the New Irvington Tunnel and BDPL Reliability Upgrade (BD-1) projects, there could be substantial increases in haul and delivery truck traffic in this area, which could substantially affect the operating conditions on Mission Boulevard. Combined or collective impacts associated with this overlap are discussed in Section 4.16, Impact 4.16-7.

For the six projects in the Sunol Valley Region, including Alameda Creek Fishery (SV-1), 40-mgd Treated Water (SV-3), and SABUP (SV-6), implementation of SFPUC Construction Measure #5 (traffic control plans) and additional traffic control measures identified in Measure 4.8-1a are expected to reduce any *potentially significant* traffic impacts to a less-than-significant level.

Bay Division Region

Impact 4.8-2: Short-term traffic increases on roadways due to construction-related vehicle trips		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	PSM
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSM

Of the three projects in the Bay Division Region, the pipeline construction projects (BDPL Reliability, BD-1, and BDPL 3 and 4 Seismic Upgrade at Hayward Fault, BD-3) would generate the greatest amount of construction traffic associated with construction crews, disposal of excavated materials, and materials deliveries. Haul routes would be along highways and freeways such as I-680, I-880, I-280, Highway 101, and Highway 238 (Mission Boulevard), major arterials such as El Camino Real, Paseo Padre Parkway, and

Edgewood Drive, as well as local commercial and residential streets. Potential construction traffic impacts would be evaluated in more detail as part of separate, project-level CEQA review for the BDPL Reliability Upgrade and BDPL 3 and 4 Seismic Upgrade at Hayward Fault projects. For the BDPL 3 and 4 Crossovers (BD-2) and BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) projects, it is expected that SFPUC Construction Measure #5 (traffic control plans) and additional traffic control measures (Measure 4.8-1a) would be adequate to reduce any *potentially significant* traffic impacts to a less-than-significant level.

However, for the BDPL Reliability project, significant traffic impacts could result from construction across major roadways as well as from multiple construction crews in this region using the same haul routes. Implementation of SFPUC Construction Measure #5 (traffic control plan), additional traffic control measures (Measure 4.8-1a), and coordination of individual traffic control plans (Measure 4.8-1b) would reduce *potentially significant* impacts to a less-than-significant level.

Construction of WSIP projects in the Bay Division Region is not expected to substantially overlap with other projects in this region or in other regions. In addition, due to the geographic distribution of the projects, construction traffic in this region would be dispersed over a number of roadways and freeways. The exception is the BDPL Reliability Upgrade and New Irvington Tunnel (SV-4) projects in the Sunol Valley Region as mentioned above.

Peninsula Region

Impact 4.8-2: Short-term traffic increases on roadways due to construction-related vehicle trips

Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	PSM
HTWTP Long-Term	PN-3	PSM
Lower Crystal Springs Dam	PN-4	PSM
Pulgas Balancing Reservoir	PN-5	PSM

Of the five projects in the Peninsula Region, the Lower Crystal Springs Dam (PN-4) project would generate the greatest amount of construction traffic associated with construction crews, disposal of excavated materials, and materials deliveries. Offsite disposal of excavated materials associated with the Lower Crystal Springs Dam project would result in increases in traffic volumes on Crystal Springs Road, I-280, Highway 92, and possibly Highway 101, depending on the disposal site. Haul routes for the Lower Crystal Springs Dam project would include Crystal Springs Road, Skyline Boulevard, and I-280. Crystal Springs Road and Skyline Boulevard are recreational facilities, and increases in construction traffic on these two-lane roadways could affect pedestrian and bicycle circulation. The CS/SA Transmission (PN 2) and HTWTP Long-Term (PN-3) projects would also use Crystal Springs Road and Skyline Boulevard as access routes. Implementation of SFPUC Construction Measure #5 (traffic control plan), additional traffic control measures (Measure 4.8-1a), and coordination of individual traffic control plans (Measure 4.8-1b) for the CS/SA Transmission, HTWTP Long-Term, and Lower Crystal Springs Dam projects would be adequate to reduce *potentially significant* traffic impacts to a less-than-significant level.

It is expected that construction vehicles associated with the Baden and San Pedro Valve Lots (PN-1) project would be dispersed among numerous roadways in the Peninsula Region, so potential impacts are expected to be *less than significant* with implementation of SFPUC Construction Measure #5 (traffic control plan).

The number of construction vehicles associated with the Pulgas Balancing Reservoir project (PN-5) has not yet been determined. However, improvements associated with this project are expected to occur over an extended period of time (about four years of construction occurring from 2007 to 2008 and 2010 to 2013), and trips to and from the facility would occur south of other SFPUC construction projects in the region. Implementation SFPUC Construction Measure #5 (traffic control plan) and additional traffic control measures identified in Measure 4.8-1a would be adequate to reduce any *potentially significant* traffic impacts to a less-than-significant level.

San Francisco Region

Impact 4.8-2: Short-term traffic increases on roadways due to construction-related vehicle trips		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	PSM

Of the three projects in the San Francisco Region, the SAPL 3 Installation (SF-1) and Recycled Water Projects (SF-3) projects would generate the greatest amount of construction vehicles. Haul routes would include Highway 1, Highway 101, and I-280 as well as numerous local arterials. Potential impacts associated with increased traffic volumes on roadways would be evaluated as part of separate, project-level CEQA review. For these two projects, implementation of SFPUC Construction Measure #5 (traffic control plans), additional traffic control measures identified in Measure 4.8-1a, and coordination of individual traffic control plans (Measure 4.8-1b) are expected to reduce any *potentially significant* impacts of construction-related traffic volume increases to a less-than-significant level.

The number of construction vehicles associated with Groundwater Projects (SF-2) has not yet been determined. However, improvements associated with these projects are expected to occur over an extended period of time, and trips to and from the facilities would likely be dispersed among numerous roadways in the San Francisco Region. Construction vehicles are not expected to substantially increase traffic volumes on the access routes to these facilities, and therefore potential impacts are expected to be *less than significant* with implementation of SFPUC Construction Measure #5 (traffic control plan).

Impact 4.8-3: Impaired access to adjacent roadways and land uses for both general and emergency response traffic as well as for bicycles and pedestrians.

Pipelines. Pipeline construction would be conducted within the SFPUC right-of-way or within public roadways. Trenching and paving activities within or across public roadways could result in a temporary reduction in parking and travel lanes or temporary road closures, could impede or block vehicular, pedestrian, and bicycle circulation and access to adjacent land uses, and could increase hazards. In addition, temporary road closures could affect access to adjacent land uses by emergency service providers. These impacts would occur mostly during the day when construction is ongoing, as vehicle access would be restored at the end of each workday through the use of steel trench plates or trench backfilling.

Pipeline construction could result in temporary full street closures if the required width of the construction zone would prevent maintenance of, at a minimum, alternate one-way traffic flow adjacent to the work zone. These road closures would be an inconvenience for motorists, bicyclists, and pedestrians, who would be required to detour onto other roadways.

Tunnels. Tunnel construction would occur from tunnel shafts or portals and adjacent staging areas. Impacts on access to adjacent uses would be limited, and would occur only if temporary access roads or staging areas would be required to gain access to public roads. If truck staging for access to construction sites occurs on public roadways, bicycle and pedestrian circulation could be impeded.

Treatment and Storage Facilities. Construction activities would occur at facility sites, and impacts on access to adjacent uses would be limited. Access impacts could occur if temporary access roads or staging areas are constructed across private land to gain access to public roads.

Other Facilities. The impact of other WSIP projects (such as installation of valves, vaults, standby power equipment, and monitoring equipment) on access to adjacent land uses and streets would vary depending on the type of project. Most projects would be at discrete locations along the pipeline alignments and would not require construction within roadways or other activities that could affect access to adjacent land uses or impede emergency access.

San Joaquin Region

Impact 4.8-3: Impaired access to adjacent roadways and land uses		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	LS

Construction of the treatment facilities (Advanced Disinfection, SJ-1; Lawrence Livermore, SJ-2; and Tesla Portal Disinfection, SJ-5) would occur at Tesla Portal and Thomas Shaft, and use of public roadways for construction staging and equipment parking would be minimal. Existing roadways would be used for construction worker and construction vehicle access. As a result, impacts on pedestrian and bicycle circulation and access to nearby land uses would be *less than significant* for these projects with implementation of SFPUC Construction Measure #5 (traffic control plans).

Pipeline construction associated with the SJPL System project (SJ-3) and SJPL Rehabilitation project (SJ-4) would occur primarily within the SFPUC right-of-way, and impacts on access to nearby land uses would be minimal. However, in some locations, the SFPUC right-of-way crosses agricultural lands, and access to some fields could be affected. In addition, in some locations, temporary construction access routes would cross private property, and construction access would need to be negotiated with local landowners. Some of the temporary construction access roads crossing private property could affect access to the uses, depending on the location of the access route. In addition, the SJPL System project would require crossing of local roadways and freeways, and construction activities associated with the roadway crossings (staging, parking for equipment and construction workers) could affect access to adjacent land uses as well as pedestrian and bicycle circulation. In addition, construction associated with the SJPL Rehabilitation project improvements along the existing pipeline through largely developed residential areas of Modesto and Riverbank could require crossing of local residential streets.

The SJPL System project (SJ-3) would be evaluated as part of separate, project-level CEQA review. When project elements of the SJPL Rehabilitation project (SJ-4) are defined, this project would also be subject to separate, project-level CEQA review. Implementation of SFPUC Construction Measure #5 (traffic control plan) and additional traffic control measures identified in Measure 4.8-1a would be adequate to ensure acceptable levels of traffic, pedestrian, and bicycle flow and to reduce any *potentially significant* circulation and access impacts to a less-than-significant level.

Sunol Valley Region

Impact 4.8-3: Impaired access to adjacent roadways and land uses		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	PSM
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	LS
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	LS

Construction of WSIP facilities in this region would occur on existing facility sites, and impacts on access to nearby land uses and on pedestrian and bicycle circulation would be minimal and generally *less than significant* with implementation of SFPUC Construction Measure #5 (traffic control plans) for all WSIP projects in this region except Calaveras Dam (SV-2). Existing roadways would be used for construction worker and construction vehicle access.

Construction of Calaveras Dam (SV-2) would require temporary closure of Calaveras Road between Geary Road and Felter Road to through-traffic during the two- to three-year construction period. Through-traffic using Calaveras Road would be required to find an alternate route for the duration of the construction period and would likely use I-680. Access to the East Bay Regional Park District's (EBRPD) Sunol Regional Wilderness would still be provided via Calaveras Road and Geary Road from the north, and emergency vehicles would continue to have access to temporarily closed roads. Direct access to the EBRPD Ohlone Wilderness Regional Trail may be restricted, including access to the Bay Area Ridge Trail connection from the west. There are no private residences or commercial uses on this segment of Calaveras Road. This project would be evaluated as part of separate, project-level CEQA review. Implementation of SFPUC Construction Measure #5 (traffic control plan) and additional traffic control measures identified in Measure 4.8-1a would be adequate to ensure acceptable levels of traffic, pedestrian, and bicycle flow and to reduce any *potentially significant* circulation and access impacts to a less-than-significant level.

Bay Division Region

Impact 4.8-3: Impaired access to adjacent roadways and land uses		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	PSM
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSM

All WSIP projects in this region would involve construction activities within the SFPUC right-of-way or construction at discrete locations along the alignments. However, within this region, the pipeline alignments traverse urbanized areas, cross numerous arterials and freeways, and extend along residential streets. Depending on the constraints associated with construction across roadways, construction activities could affect access to residences and local businesses as well as pedestrian and bicycle circulation. Of the three projects in the Bay Division Region, construction of the BDPL Reliability Upgrade (BD-1) project would have the greatest potential for impacts. Implementation of SFPUC Construction Measure #5 (traffic control plan) and additional traffic control identified in Measure 4.8-1a, would be adequate to ensure acceptable levels of traffic, pedestrian, and bicycle flow and to reduce any *potentially significant* circulation and access impacts associated with all three projects in this region to a less-than-significant level.

Peninsula Region

Impact 4.8-3: Impaired access to adjacent roadways and land uses		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	PSM
Pulgas Balancing Reservoir	PN-5	LS

All WSIP projects within the Peninsula Region would involve construction activities along the SFPUC right-of-way or construction at discrete locations along the pipeline alignments. Therefore, impacts on pedestrian and bicycle circulation and access to adjacent roadways and land uses would be minimal. With implementation of SFPUC Construction Measure #5 (traffic control plan), this impact would be *less than significant* for the Baden and San Pedro Valve Lots (PN-1), CS/SA Transmission (PN-2), HTWTP Long-Term (PN-3), and Pulgas Balancing Reservoir (PN-5) projects.

The Lower Crystal Springs Dam project (PN-4) would likely affect access to, and parking areas for, Sawyer Camp Trail near the intersection of Skyline Boulevard and Crystal Springs Road, in the vicinity of the dam. This project would require reconstruction of San Mateo County's Skyline Boulevard Bridge, which was built across the top of the dam. This section of Skyline Boulevard would be closed during construction of this project and would be reopened upon completion of the project. The Lower Crystal Springs Dam project would be evaluated as part of separate, project-level CEQA review. Implementation of SFPUC Construction Measure #5 (traffic control plan) and additional traffic control measures identified in Measure 4.8-1a would be adequate to ensure acceptable levels of traffic, pedestrian, and bicycle flow and to reduce any *potentially significant* circulation and access impacts to a less-than-significant level.

San Francisco Region

Impact 4.8-3: Impaired access to adjacent roadways and land uses		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	PSM
Recycled Water Projects	SF-3	PSM

All WSIP projects in this region (SAPL 3 Installation, SF-1; Groundwater Projects, SF-2; and Recycled Water Projects, SF-3) would have the potential to result in impacts on adjacent land uses and on pedestrian and bicycle circulation. These projects would be constructed within densely populated areas, and pipeline construction would occur within public roadways, many of which are narrow residential streets. Construction staging would likely necessitate the use of the on-street parking lane, which could temporarily restrict access to adjacent land uses. For these projects, impacts on local access would be evaluated as part of separate, project-level CEQA review.

Implementation SFPUC Construction Measure #5 (traffic control plan) and additional traffic control measures identified in Measure 4.8-1a would be adequate to ensure acceptable levels of traffic, pedestrian, and bicycle flow and to reduce any *potentially significant* circulation and access impacts to a less-than-significant level for all projects in this region.

Impact 4.8-4: Temporary displacement of on-street parking at some locations due to increased parking demand or construction within roadways.

Pipelines. Construction of pipelines would be conducted within the SFPUC right-of-way and within or adjacent to public roadways. Work within public roadways would temporarily displace on-street parking, if provided, along affected roadways. Pipeline construction would generally involve crews of 30 to 40 workers, who would park their vehicles in the identified parking areas within the designated construction zone. Temporary parking impacts on any particular segment of roadway would not be long in duration, since pipeline construction would generally proceed at an average rate of 120 feet per day in urban and suburban areas, and 160 feet per day in rural areas.

Other Facilities. Construction of other types of facilities (tunnels, vaults, valve lots, crossovers, pump stations, treatment facilities, and storage facilities) would occur at discrete locations along the alignment, and onsite parking would be provided within the designated construction staging area. At some urban locations, where the size of staging areas could be limited, construction worker parking demand might need to be accommodated on public streets. The number of construction workers would vary by facility type, and would range from 1 or 2 workers for minor repair work to up to 190 workers for dam replacement and water reservoirs.

San Joaquin Region

Impact 4.8-4: Temporary displacement of on-street parking at some locations due to increased parking demand or construction within roadways		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	LS

Of the five projects in this region, construction of the SJPL System project (SJ-3) and SJPL Rehabilitation project (SJ-4) would have the greatest potential to result in parking impacts. However, most of the pipeline construction would occur within the SFPUC right-of-way, and it is expected that construction vehicles and equipment would park within the construction zone, along access roads, and in offsite staging areas. Pipeline construction would cross roadway and freeway segments, which could result in the need for on-street parking of construction worker vehicles and equipment. For the SJPL System project (SJ-3), the majority of the roadways that would be affected are adjacent to agricultural uses that have limited on-street parking demand. With implementation of SFPUC Construction Measure #5 (traffic control plan), parking impacts would be *less than significant*.

Program elements and locations of the SJPL Rehabilitation project (SJ-4) have not yet been defined, and rehabilitation of the San Joaquin Pipeline through Modesto and Riverbank could affect local streets in developed residential areas. With implementation of SFPUC Construction Measure #5 (traffic control plan) and additional parking measures identified in Measure 4.8-1a, *potentially significant* parking impacts would be reduced to less-than-significant levels.

Other WSIP projects in this region would be located at Tesla Portal (Advanced Disinfection, SJ-1, and Tesla Portal Disinfection, SJ-5) and at Thomas Shaft (Lawrence Livermore, SJ-2). Construction staging areas that would accommodate construction worker vehicles and equipment would be provided onsite, and it is expected that parking impacts associated with these projects would be *less than significant* with implementation SFPUC Construction Measure #5 (traffic control plan).

Sunol Valley Region

Impact 4.8-4: Temporary displacement of on-street parking at some locations due to increased parking demand or construction within roadways		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	LS
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	LS

WSIP projects in this region would include onsite construction staging areas that would accommodate construction worker vehicles and equipment. Therefore, parking impacts for all projects within the Sunol Valley Region are expected to be *less than significant* with implementation of SFPUC Construction Measure #5 (traffic control plans).

Bay Division Region

Impact 4.8-4: Temporary displacement of on-street parking at some locations due to increased parking demand or construction within roadways		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	LS
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSM

Within this region, construction of the BDPL Reliability Upgrade (BD-1) and BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) would have the greatest potential to result in parking impacts. Most of the construction activity would occur within the SFPUC right-of-way, and construction vehicles and equipment are expected to be able to park within the construction zone; however, some segments of pipeline would be located within the public roadway right-of-way. In addition, pipeline construction would cross numerous local arterials and residential streets as well as I-680, which could result in the need for on-street parking of construction worker vehicles and equipment. The majority of the roadways that would be affected are urbanized and adjacent to commercial and residential land uses. These projects would be evaluated as part of separate, project-level CEQA review. Implementation of SFPUC Construction Measure #5 (traffic control plans) and additional parking measures identified in Measure 4.8-1a for these projects would be adequate to reduce any *potentially significant* parking impacts to a less-than-significant level.

The BDPL 3 and 4 Crossovers project (BD-2) would be located at discrete locations within the SFPUC right-of-way, with construction staging areas that would accommodate construction worker vehicles and equipment, as appropriate. Parking impacts associated with this project are therefore expected to be *less than significant* with implementation of SFPUC Construction Measure # 5 (traffic control plan).

Peninsula Region

Impact 4.8-4: Temporary displacement of on-street parking at some locations due to increased parking demand or construction within roadways		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	PSM
Pulgas Balancing Reservoir	PN-5	PSM

Within this region, all of the projects would be constructed at discrete locations within the SFPUC tunnel and pipeline alignments. It is anticipated that all projects in this region would include construction staging areas that would accommodate construction worker vehicles and equipment. For the Baden and San Pedro Valve Lots (PN-1), CS/SA Transmission (PN-2), and HTWTP Long-Term (PN-3) projects, staging areas are expected to be provided onsite, and therefore parking impacts are expected to be *less than significant* with implementation of SFPUC Construction Measure # 5 (traffic control plans).

The Lower Crystal Springs Dam project (PN-4) would likely affect the roadside parking areas used by visitors to Sawyer Camp Trail on Skyline Boulevard near the intersection with Crystal Springs Road. Pulgas Balancing Reservoir (PN-5) could affect parking used by visitors at the Pulgas Water Temple. Displacement of parking to public recreational areas where other nearby parking is not available could result in hazardous parking situations in the vicinity. These projects would be evaluated as part of separate, project-level CEQA review to ensure safe accommodation of visitor parking demand. Implementation of SFPUC Construction Measure # 5 (traffic control plan), additional parking measures identified in Measure 4.8-1a, and accommodation of displaced public parking supply for recreational visitors (Measure 4.8-4) would reduce any *potentially significant* parking impacts of these two projects to a less-than-significant level.

San Francisco Region

Impact 4.8-4: Temporary displacement of on-street parking at some locations due to increased parking demand or construction within roadways		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	PSM
Recycled Water Projects	SF-3	PSM

Within this region, the SAPL 3 Installation project (SF-1) would have the greatest potential to result in parking impacts. The pipeline alignment would travel through densely populated areas, and the pipeline would be located within roadways. Pipeline replacement would likely necessitate the use of the on-street parking lanes for construction staging of equipment and materials and for construction worker parking. Potentially significant parking impacts would be evaluated as part of separate, project-level CEQA review. With implementation of SFPUC Construction Measure #5 (traffic control plan) and additional parking measures identified in Measure 4.8-1a, *potentially significant* parking impacts associated with this project would be reduced to a less-than-significant level.

The Groundwater Projects (SF-2) and Recycled Water Projects (SF-3) projects could require construction within or across local roadways and could require on-street staging of equipment and materials, and parking for construction workers. The Groundwater and Recycled Water Projects would be evaluated as part of separate, project-level CEQA review. Implementation of SFPUC Construction Measure #5 (traffic control plan) and additional parking measures identified in Measure 4.8-1a is expected to reduce *potentially significant* parking impacts of these projects to a less-than-significant level.

Impact 4.8-5: Increased potential traffic safety hazards for vehicles, bicyclists, and pedestrians on public roadways during construction.

Since construction activities temporarily suspend the normal function of roadways, the potential exists for an increase in traffic safety hazards during construction of the WSIP projects. This increase in safety hazards would be due to the increased potential for:

- Conflicts between construction vehicles (with slower speeds and wider turning radii than autos) and vehicles, bicyclists, or pedestrians using the roadways
- Conflicts between the movement of traffic and the construction activities, particularly where traffic is routed into the travel lane adjacent to the work zone
- Confusion of drivers during one-lane, two-way traffic operation

- Confusion of bicyclists and pedestrians due to temporary alterations in bicycle and pedestrian circulation and on-street parking supply
- Distraction of drivers related to construction activities and nighttime lighting (at tunnel portals or shaft locations)

All Regions

Construction activities associated with the WSIP projects in all regions would increase the potential for safety hazards, which would be a *potentially significant* impact. In general, construction contractors for any projects affecting public rights-of-way (e.g., roadways, sidewalks, and walkways) are required to provide for continuity of traffic, pedestrians, and bicyclists; reduce the potential for traffic accidents; and ensure worker safety in construction zones. In addition, as part of project development, haul routes would be established to minimize truck traffic near schools, especially prior to school start times and following dismissal times, when students are on the roads traveling to and from schools. Implementation of SFPUC Construction Measure #5 (traffic control plan) and additional traffic control measures identified in Measure 4.8-1a (stipulating actions required of contractors) would reduce traffic safety impacts to a less-than-significant level for all WSIP projects.

It should be noted that, prior to construction of some WSIP projects, some roadways used to access the project sites could be improved to meet current safety standards, which would be a beneficial impact. For example, construction of the Treated Water Reservoirs project (SV-6) would bring a portion of Calaveras Road adjacent to the turnoff for the Sunol Valley WTP up to current Alameda County standards for safety both during and after construction.

Operational Impacts

Long-Term Traffic Increases

Impact 4.8-6: Increases in vehicle trips to and from the facility sites for operation and maintenance.

Operation of some of the WSIP facilities could result in an increase in the number of vehicles traveling to and from the facility site. The primary increase in vehicle trips would result from increases in the number of employees at an existing facility, increases in the number of deliveries to the facility, and new trips associated with operations, monitoring, inspection, and maintenance activities at new facilities. In most cases, there would be minimal increases over existing trips to the facility, and these vehicle trips would not result in a noticeable increase in traffic on adjacent streets.

Pipelines, Tunnels, and Crossovers. Operation of pipelines, tunnels, and crossovers would not result in new long-term trips. These facilities would be located underground and would not generate new vehicle trips.

Vaults, Valves, and Standby Power Facilities. Operation of these facilities would not result in a substantial number of new daily trips. These facilities require routine inspection and maintenance, but would not generate significant levels of new vehicle trips.

Storage Facilities, Treatment Facilities, and Pump Stations. Storage facilities include reservoirs and basins, and treatment facilities include basins, filters, and drains. These facilities could generate long-term vehicle trips associated with ongoing operations and monitoring of the facilities, and routine inspection and maintenance.

San Joaquin Region

Impact 4.8-6: Increases in vehicle trips to and from the facility sites for operation and maintenance		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	LS
Tesla Portal Disinfection	SJ-5	LS

Operation of WSIP facilities in the San Joaquin Region would result in minimal increases in long-term vehicle trips to these facilities. The Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) facilities at Tesla Portal and the Lawrence Livermore (SJ-2) facility at Thomas Shaft would be unmanned facilities and would require a daily visit to the site by an operations representative. The SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) pipelines would not in themselves result in an increase in vehicle trips, but would require occasional visits by operations representatives during flow rate changes. Overall, the vehicle trips generated by these facilities would not result in a noticeable increase in traffic on adjacent streets, and operational impacts are expected to be *less than significant*.

Sunol Valley Region

Impact 4.8-6: Increases in vehicle trips to and from the facility sites for operation and maintenance		
Alameda Creek Fishery	SV-1	N/A
Calaveras Dam	SV-2	N/A
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	N/A
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	N/A

The proposed treatment facilities at the Sunol Valley WTP (40-mgd Treated Water, SV-3, and Treated Water Reservoirs, SV-5) would result in an increased frequency of chemical deliveries to this facility. Overall, the increase in traffic volumes generated by operation of these facilities would not result in a noticeable increase in traffic on adjacent streets, and operational impacts are expected to be *less than significant*.

All remaining WSIP projects in this region (Alameda Creek Fishery, SV-1; Calaveras Dam, SV-2; New Irvington Tunnel, SV-4; and SABUP, SV-6) would involve upgrades to or replacement of existing facilities as well as construction of new tunnels and pipelines. At these facilities, the number of employees would remain the same as under existing conditions; therefore, the number of vehicle trips to and from the facilities is not expected to increase, and operational traffic impacts would not occur *(not applicable).* The tunnels and pipelines would not result in new employees or deliveries to facility sites.

Bay Division Region

Impact 4.8-6: Increases in vehicle trips to and from the facility sites for operation and maintenance		
BDPL Reliability Upgrade	BD-1	LS
BDPL 3 and 4 Crossovers	BD-2	LS
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	LS

All WSIP projects in this region (BDPL Reliability Upgrade, BD-1; BDPL 3 and 4 Crossovers, BD-2; and BDPL 3 and 4 Seismic Upgrade at Hayward Fault, BD-3) would include pipelines, tunnels, and crossovers, which would not generate any long-term vehicle trips. However, these projects would include existing and new vaults and valves, which would require periodic operations review and maintenance. Overall, any increase in traffic generated by operation and maintenance of these facilities would be minimal and would not result in a noticeable increase in traffic on adjacent streets, and operational impacts are expected to be *less than significant*.

Peninsula Region

Impact 4.8-6: Increases in vehicle trips to and from the facility sites for operation and maintenance		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS

WSIP projects in this region include repair, upgrades, and improvements to existing valves, vaults, and reservoirs (Baden and San Pedro Valve Lots, PN-1; Lower Crystal Springs Dam, PN-4; and Pulgas Balancing Reservoir, PN-5) and improvements to an existing water treatment plant (HTWTP Long-Term, PN-3). Only the HTWTP Long-Term project is expected to increase the number of employees (although not specified), and could require an increased frequency of chemical deliveries to the facility. Overall, long-term increases in traffic generated by operation of these facilities would be minimal and would not result in a noticeable increase in traffic on adjacent streets, and operational impacts are expected to be *less than significant*.

San Francisco Region

Impact 4.8-6: Increases in vehicle trips to and from the facility sites for operation and maintenance		
SAPL 3 Installation	SF-1	N/A
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	LS

New pipelines installed as part of the SAPL 3 Installation project (SF-1) would not result in any new employees or delivery trips to the facilities. Therefore, operational traffic impacts would not occur *(not applicable)*.

The Groundwater Projects (SF-2) include three projects in San Francisco and San Mateo, which would require an operations and maintenance check every day or two on average, as well as some increased chemical deliveries. These increases in trips would not result in a noticeable increase in traffic on adjacent streets. The Recycled Water Projects (SF-3) include recycled water projects at two locations in San Francisco, which would result in an increase of up to six employees as well as increased chemical deliveries to the site. Overall, the traffic generated by operation of these facilities would be minimal and would not result in a noticeable increase in traffic on adjacent streets, and operational impacts are expected to be *less than significant*.

4.9 Air Quality

4.9 Air Quality

4.9.1 Air Pollutant Properties, Effects, and Sources

Air quality conditions in the WSIP study area are indicated by six criteria air pollutants, as described below (BAAQMD, 1999; SJVAPCD, 2002a).

Ozone. Ozone is a secondary air pollutant produced in the atmosphere through a complex series of photochemical reactions involving reactive organic gases (ROG) and nitrogen oxide (NO_x). The main sources of NO_x and ROG, often referred to as ozone precursors, are combustion processes (including motor vehicle engines) and the evaporation of solvents, paints, and fuels. In the Bay Area, automobiles are the single largest source of ozone precursors. In San Joaquin Valley, primary sources of ozone precursors are mobile sources, solvents, farming operations, area sources (e.g., consumer products, fuel combustion, landscape maintenance equipment, etc.), and oil/gas production. Ozone is a regional air pollutant because its precursors are transported and diffused by wind concurrently with ozone production through the photochemical reaction process. Ozone causes eye irritation, airway constriction, and shortness of breath and can aggravate existing respiratory diseases such as asthma, bronchitis, and emphysema.

Carbon Monoxide (CO). CO is an odorless, colorless gas usually formed as the result of the incomplete combustion of fuels. The single largest source of CO is motor vehicles; the highest emissions occur during low travel speeds, stop-and-go driving, cold starts, and hard acceleration. Exposure to high concentrations of CO reduces the oxygen-carrying capacity of the blood and can cause dizziness and fatigue, impair central nervous system function, and induce angina in persons with serious heart disease.

Suspended Particulates (PM_{10} and $PM_{2.5}$). Particulate matter is a class of air pollutants that consists of solid and liquid airborne particles in an extremely small size range. Particulate matter is measured in two size ranges: PM_{10} for particles less than 10 microns in diameter, and $PM_{2.5}$ for particles less than 2.5 microns in diameter. In San Joaquin Valley, $PM_{2.5}$ sources tend to be combustion sources such as vehicles, power generation, industrial processes, and wood burning; PM_{10} sources include these same sources in addition to farming operations (23.2 percent) and road dust (36.6 percent). In the Bay Area, motor vehicles generate about half of the air basin's particulates, through tailpipe emissions as well as brake pad and tire wear. Wood burning in fireplaces and stoves, industrial facilities, and ground-disturbing activities such as construction are other sources of fine particulates in the Bay Area. Fine particulates are small enough to be inhaled into the deepest parts of the human lung can cause adverse health effects. Among the criteria pollutants that are regulated, particulates appear to represent the most serious overall health hazard. Studies have shown that elevated particulate levels contribute to the death of approximately 200 to 500 people per year in the Bay Area. High levels of particulates have also been known to exacerbate chronic respiratory ailments, such as bronchitis and asthma, and have been associated with increased emergency room visits and hospital admissions.

Diesel exhaust is a growing concern throughout California. The California Air Resources Board (CARB) identified diesel engine particulate matter as a toxic air contaminant. The exhaust from diesel engines includes hundreds of different gaseous and particulate components, many of which are toxic. Many of these toxic compounds adhere to the diesel particles, which are very small and can penetrate deeply into the lungs. Diesel engine particulate matter has been identified as a human carcinogen. Mobile sources such as trucks, buses, and automobiles are some of the primary sources of diesel emissions. Studies show that diesel particulate matter concentrations are much higher near heavily traveled highways and intersections. The cancer risk from exposure to diesel exhaust is much higher than the risk associated with any other toxic air pollutant routinely measured in the region. Diesel exhaust contains both pulmonary irritants and hazardous compounds that could affect sensitive receptors such as young children, senior citizens, or those susceptible to chronic respiratory disease such as asthma, bronchitis, and emphysema.

In 2001, the California Health Interview Survey (CHIS) found that California's lifetime asthma prevalence, at 11.5 percent of the population, is higher than the national lifetime asthma prevalence of 10.1 percent (UCLA Center for Health Policy Research, 2007).[1] When asthma symptom prevalence in 2001 is sorted by county, the CHIS found that people who live in rural areas have more frequent asthma symptoms. Asthma symptom prevalence by region ranged from 10.4 to 13.8 percent for all ages. The highest rates occurred in Northern California, Sierra, and Sacramento area counties (13.8 percent). The San Joaquin region had a rate of 12.9 percent, while the Bay Area region had a rate of 12.2 percent. These data indicate that asthma is a regional (not localized) problem. However, these regional statistics mask the fact that asthma rates are higher among African-Americans (16.2 percent) than among the rest of the population (7.0 to 13.1 percent), suggesting there may be asthma "hot spots" in some communities that are not well characterized by regional averages.

Nitrogen Dioxide (NO_2). NO_2 is a reddish brown gas that is a byproduct of combustion processes. Automobiles and industrial operations are the main sources of NO_2. Aside from its contribution to ozone formation, NO_2 can increase the risk of acute and chronic respiratory disease and reduce visibility. NO_2 may be visible as a coloring component on high pollution days, especially in conjunction with high ozone levels.

Sulfur Dioxide (SO_2). SO_2 is a colorless acidic gas with a strong odor. It is produced by the combustion of sulfur-containing fuels such as oil, coal, and diesel. SO_2 has the potential to damage materials and can cause health effects at high concentrations. It can irritate lung tissue and increase the risk of acute and chronic respiratory disease (BAAQMD, 1999).

Greenhouse Gases. Gases that trap heat in the atmosphere are often called greenhouse gases (GHGs). Both natural processes and human activities emit GHGs. The accumulation of GHGs in the atmosphere regulates the earth's temperature; however, emissions from human activities such as electricity production and vehicles have elevated the concentration of these gases in the atmosphere. This accumulation of GHGs has contributed to an increase in the temperature of the

1 "Lifetime asthma prevalence" includes people diagnosed with asthma at some point in their lives, while "asthma symptom prevalence" includes those who experience asthma symptoms at least once per year.

earth's atmosphere and contributed to climate change. The principal greenhouse gases are carbon dioxide, methane, nitrous oxide, ozone, and water vapor. Carbon dioxide is the reference gas for climate change.

4.9.2 Setting

The CARB has divided California into regional air basins according to topographic air drainage features. The WSIP study area spans two of these regional air basins: San Joaquin Valley Air Basin (SJVAB) and San Francisco Bay Area Air Basin (SFBAAB). The SJVAB, the second largest air basin in the state, is defined by the Sierra Nevada mountains to the east, the Coast Range mountains to the west, and the Tehachapi Mountains to the south. The SJVAB is a "bowl" that opens to the north at the Carquinez Strait, where the San Joaquin–Sacramento Delta empties into San Francisco Bay (SJVAPCD, 2002a). The SFBAAB lies west of the Coast Range. In the Bay Area, the Coast Range splits into western and eastern ranges, and San Francisco Bay lies between the two ranges. Air flows into the SFBAAB from the west at the Golden Gate and then flows out of the SFBAAB to the east at the Carquinez Strait (where it enters the SJVAB).

San Joaquin Valley Air Basin

Meteorology

The SJVAB has an "inland Mediterranean" climate averaging over 260 sunny days per year. The valley floor is characterized by warm, dry summers and cooler winters. Summer high temperatures often exceed 100 degrees Fahrenheit (ºF), averaging in the low 90s during summer. Winter highs average in the 50s, but highs in the 30s and 40s can occur on days with persistent fog and low clouds. Wind speed and direction data indicate that summer winds typically originate at the north end of the valley and flow in a south-southeasterly direction. Winter winds occasionally originate from the south end of the valley and flow in a north-northwesterly direction. During the winter months, the valley experiences light, variable winds of less than 10 miles per hour (mph).

The potential for high pollutant concentrations depends on two primary factors: (1) the quantity of pollutant emissions in the surrounding area and upwind of the area, and (2) topographic and climatological factors (e.g., winds, inversion potential, terrain, stability/vertical mixing, and solar radiation). San Joaquin Valley's "bowl" topography induces persistent temperature inversions. Persistent inversions combined with high summer temperatures and low wind speeds during the winter result in a high year-round potential for air pollution.

Ambient Air Quality

The San Joaquin Valley Air Pollution Control District (SJVAPCD) operates a regional monitoring network that measures the ambient concentrations of six criteria air pollutants: ozone, CO, PM_{10}, $PM_{2.5}$, NO_2, and SO_2. Existing air quality in the WSIP study area can generally be inferred from basinwide ambient air quality measurements. **Table 4.9-1** provides a five-year summary of monitoring data (2001–2005) compiled by the CARB and compares measured pollutant concentrations with the most stringent applicable standard.

TABLE 4.9-1
SAN JOAQUIN VALLEY AIR BASIN AMBIENT AIR QUALITY MONITORING SUMMARY (2001–2005)

Pollutant	Most Stringent Applicable Standard	Number of Days Standards were Exceeded and Maximum Concentrations Measured				
		2001	2002	2003	2004	2005
Ozone (ROG)						
- Days 1-hour Std. Exceeded	>0.09 ppm[a]	123	127	137	106	83
- Max. 1-hour Conc. (ppm)[b]		**0.149**	**0.164**	**0.156**	**0.155**	**0.134**
- Days 8-hour Std. Exceeded	>0.08 ppm[b]	109	125	134	109	72
- Max. 8-hour Conc. (ppm)[b]		**0.120**	**0.132**	**0.127**	**0.126**	**0.113**
Carbon Monoxide (CO)						
- Days 1-hour Std. Exceeded	>20 ppm[a]	0	0	0	0	0
- Max. 1-hour Conc. (ppm)		8.4	6.1	5.8	4.6	4.3
- Days 8-hour Std. Exceeded	>9 ppm[a]	0	0	0	0	0
- Max. 8-hour Conc. (ppm)		6.0	4.5	4.1	3.0	3.0
Suspended Particulates (PM_{10})						
- Days 24-hour Std. Exceeded[c]	>50 $\mu g/m^3$ [a]	168	256	167	113	146
- Max. 24-hour Conc. ($\mu g/m^3$)		**221**	**194**	**150**	**219**	**137**
Suspended Particulates ($PM_{2.5}$)						
- Days 24-hour Std. Exceeded	>65 $\mu g/m^3$ [b, d]	19	14	1	3	10
- Max. 24-hour Conc. ($\mu g/m^3$)		**154.7**	**104.3**	**84.5**	**77.0**	**102.0**
- Annual Average ($\mu g/m^3$)	>12 $\mu g/m^3$ [a]	**20.8**	**24.1**	**24.8**	**18.2**	**22.4**
Nitrogen Dioxide (NO_2)						
- Days 1-hour Std. Exceeded	>0.25 ppm[a]	0	0	0	0	0
- Max. 1-hour Conc. (ppm)[b]		0.115	0.107	0.092	0.083	0.087
Sulfur Dioxide (SO_2)						
- Days 1-hour Std. Exceeded	>0.25 ppm[a]	0	0	0	0	0
- Max. 1-hour Conc. (ppm)[b]		0.03	N/A	0.019	N/A	N/A

NOTES: **Bold** values are in excess of applicable standard. "N/A" indicates that data are not available.
conc. = concentration; ppm = parts per million; $\mu g/m^3$ = micrograms per cubic meter

[a] State standard, not to be exceeded.
[b] Federal standard, not to be exceeded.
[c] The first number represents measured exceedances but not all exceedances since PM_{10} is not sampled every day. The second number is the calculated days exceeding the standard, which is an estimate of days expected to exceed the standard if there was sampling every day. This estimate could be low if insufficient samples are collected.
[d] Sample days exceeding the standard, which would not represent all possible exceedances since not all days were sampled.

SOURCE: CARB, 2006a.

Ozone

Table 4.9-1 shows that, according to published data, the most stringent applicable ozone standards (the state 1-hour standard of 0.09 parts per million [ppm] and the federal 8-hour standard of 0.08 ppm) were exceeded approximately 20 to 40 percent of each year in the SJVAB between 2001 and 2005.

Carbon Monoxide

As shown in the table, no exceedances of state CO standards were recorded between 2001 and 2005. Measurements of CO indicate hourly maximums ranging between 20 and 40 percent of the more stringent state standard. Similarly, maximum 8-hour CO levels range between 35 and 65 percent of the allowable 8-hour standard.

Suspended Particulates (PM_{10} and $PM_{2.5}$)

Table 4.9-1 shows that exceedances of the state PM_{10} standard occur relatively frequently in the SJVAB. It is estimated that the state 24-hour PM_{10} standard was exceeded between 113 and 256 days per year between 2001 and 2005.

In 1997, the U.S. Environmental Protection Agency (U.S. EPA) adopted a standard for $PM_{2.5}$, the fine fraction of particulate matter (Table 4.9-1). California's standard went into effect in 2003. It is estimated that the federal 24-hour $PM_{2.5}$ standard was exceeded on 1 to 19 sample days per year between 2001 and 2005. The state annual average standard was exceeded every year between 2001 and 2005.

Other Criteria Air Pollutants

Table 4.9-1 shows that the standards for NO_2 and SO_2 are being met in the SJVAB, and pollutant trends suggest that the air basin will continue to meet these standards for the foreseeable future.

Greenhouse Gases

The SJVAPCD's emissions inventory identifies sources of criteria air pollutants but does not include GHGs, pollutants contributing to climate change. Sources of GHG emissions in the San Joaquin Valley include mobile sources (on-road motor vehicles, off-highway mobile sources, and aircraft) as well as stationary sources associated with agricultural, industrial, and commercial operations.

Sensitive Receptors

Land uses such as schools, children's daycare centers, hospitals, and convalescent homes are considered to be more sensitive than the general public to poor air quality because the population groups associated with these uses have increased susceptibility to respiratory distress. Persons engaged in strenuous work or exercise also have increased sensitivity to poor air quality. Residential areas are considered more sensitive to air quality conditions than commercial and industrial areas, because people generally spend longer periods of time at their residences, resulting in greater exposure to ambient air quality conditions. Recreational uses or parks are also considered sensitive due to the greater exposure to ambient air quality conditions, and because the presence of pollution detracts from the recreational experience.

Most of the areas adjacent to WSIP facilities in the SJVAB are undeveloped or used for agriculture. The city of Modesto, located in the center of the San Joaquin Region, includes residential, commercial, school, and park uses. There are also rural residential uses located south of Riverbank. In the western margin of this region (in the Tesla Portal vicinity), there is a private golf course (Tracy Golf and Country Club) and residential development.

San Francisco Bay Area Air Basin

Meteorology

Temperatures in the San Francisco Bay Area average 58 ºF annually, with summer highs in the mid-80s and winter lows in the mid-30s. However, since land tends to heat up and cool off more quickly than water, summer temperatures at the coast can be as much as 35 ºF cooler than temperatures 15 to 20 miles inland. At night, this contrast usually decreases to less than 10 ºF. During the winter, the relationship of minimum and maximum temperatures is reversed, with a small temperature contrast between the coast and inland areas during the day and a large temperature contrast at night.

Summer winds generally flow from the northwest through the Golden Gate, and, when they meet the East Bay Hills, split off to the northwest toward Richmond and to the southwest toward San Jose. In the late morning or early afternoon, air begins to flow onshore (from the coast to the Central Valley), increasing in depth and velocity while spreading inland. The depth of the onshore flow depends in large part on the height and strength of the inversion. During winter, the Bay Area frequently experiences stormy conditions with moderate to strong winds as well as periods of stagnation with very light winds. Winter stagnation episodes are characterized by nighttime drainage flows in coastal valleys. Drainage is a reversal of the usual daytime air-flow patterns; air moves from the Central Valley toward the coast and back down toward the Bay from the smaller valleys within the Bay Area.

The SFBAAB is divided into 11 climatological regions, and WSIP facilities would be located in four of these regions: Livermore Valley, West Alameda, Santa Clara Valley, and Peninsula. The air pollution potential in these areas is highest in the Livermore Valley and Santa Clara Valley, where high summer temperatures, stable air, and the surrounding mountains combine to promote ozone formation. There are also many emissions sources within and upwind of these areas. Although coastal areas of the Peninsula have a lower potential for air pollution due to the marine influence, the southeastern Peninsula area has a high air pollution potential because it is protected from the winds and fog associated with the marine layer. West Alameda has more of a marine influence than the inland valleys, but it also has a relatively high potential for air pollution during the summer and fall.

Ambient Air Quality

The Bay Area Air Quality Management District (BAAQMD) operates a regional monitoring network that measures the ambient concentrations of six criteria air pollutants: ozone, CO, PM_{10}, $PM_{2.5}$, NO_2, and SO_2. Existing air quality in the WSIP study area can be generally inferred from basinwide ambient air quality measurements. **Table 4.9-2** provides a five-year summary of monitoring data (2001–2005) compiled by the CARB and compares measured pollutant concentrations with the most stringent applicable standard.

TABLE 4.9-2
BAY AREA AIR BASIN AMBIENT AIR QUALITY MONITORING SUMMARY (2001–2005)

SOURCE: CARB, 2006a.

Ozone

Table 4.9-2 shows that, according to published data, the most stringent applicable standards (state 1-hour standard of 0.09 ppm and the federal 8-hour standard of 0.08 ppm) are exceeded in the SFBAAB approximately 2 to 5 percent of every year.

Carbon Monoxide

As shown in the table, no exceedances of state CO standards were recorded between 2001 and 2005. Measurements of CO indicate hourly maximums ranging between 20 and 40 percent of the more stringent state standard. Similarly, maximum 8-hour CO levels range between 30 and 60 percent of the allowable 8-hour standard.

Suspended Particulates (PM_{10} and $PM_{2.5}$)

Table 4.9-2 shows that exceedances of the state PM_{10} standard have occurred in the SFBAAB. It is estimated that the state 24-hour PM_{10} standard was exceeded between 18 and 48 days per year between 2001 and 2005.

The BAAQMD began monitoring $PM_{2.5}$ concentrations in 1999. The federal 24-hour $PM_{2.5}$ standard was exceeded on 1 to 4 days each year, for a total of 9 sample days between 2001 and 2005 (not exceeded in 2003 and 2005). The state annual average standard was exceeded in 2001 and 2002.

In 2004, the BAAQMD initiated the Community Air Risk Evaluation program, with the goal of sampling ambient levels of diesel particulate matter; however, the results are not yet available.

Other Criteria Air Pollutants

Table 4.9-2 shows that the standards for NO_2 and SO_2 are being met in the Bay Area, and pollutant trends suggest that the air basin will continue to meet these standards for the foreseeable future.

Greenhouse Gases

The BAAQMD has prepared an emissions inventory of GHGs, pollutants contributing to climate change. Fossil fuel consumption in the transportation sector (on-road motor vehicles, off-highway mobile sources, and aircraft) is the single largest source of Bay Area GHG emissions, accounting for approximately half of the Bay Area’s GHG emissions in 2002. Industrial and commercial sources were the second largest contributors of GHG emissions (with about one-fourth of total emissions), while power plants contribute approximately seven percent of total emissions (BAAQMD, 2006a).

Sensitive Receptors

Land uses considered most sensitive to air quality include residential uses, recreational/park uses, schools, children’s daycare centers, hospitals, and convalescent homes. All of these uses are present in the vicinity of WSIP facilities within the SFBAAB. Since the area surrounding WSIP facilities in the Sunol Valley contains only one residence, this region has the lowest sensitivity. WSIP facilities in the Bay Division Region would be located near residential, park, school, childcare, and convalescent/nursing home uses. WSIP facilities in the Peninsula Region would be located near residential, park, school, and hospital uses. Sensitive receptors near WSIP facilities in the San Francisco Region include residential and school uses.

Regulatory and Planning Framework

Federal Standards

The 1970 Clean Air Act (last amended in 1990, 42 United States Code 7401 et seq.) required that regional planning and air pollution control agencies prepare a regional air quality plan to outline the measures by which both stationary and mobile sources of pollutants will be controlled in order to achieve all standards by the deadlines specified in the Clean Air Act. The ambient air quality standards are intended to protect the public health and welfare, and they specify the concentration of pollutants (with an adequate margin of safety) to which the public can be exposed without adverse health effects. They are designed to protect those segments of the public most susceptible to respiratory distress, known as sensitive receptors, including asthmatics, the very young, the elderly, people weak from other illness or disease, or persons engaged in strenuous work or exercise. Healthy adults can tolerate occasional exposure to air pollution levels that are somewhat above the ambient air quality standards before adverse health effects are observed.

San Joaquin Valley Air Basin

The SJVAB includes the counties of San Joaquin, Stanislaus, Merced, Madera, Fresno, Kings, and Tulare, in addition to the valley portion of Kern County. For each nonattainment criteria pollutant (ozone and PM_{10}), the SJVAPCD is responsible for preparing attainment plans, which establish the strategies that the District will use to attain the federal standards. The SJVAB's current attainment status with respect to federal standards is summarized in **Table 4.9-3**. The SJVAB is currently not in compliance with federal ozone and PM_{10} standards and is designated as "severe nonattainment" for the federal ozone standard and "serious nonattainment" for the federal PM_{10} and $PM_{2.5}$ standards.

The SJVAPCD adopted the *Amended 2002 and 2005 Rate of Progress Plan for San Joaquin Valley Ozone* in December 2002. This ozone plan contains emission control strategies for various mobile and stationary sources, none of which pertain to construction projects. In response to the U.S. EPA's nonattainment designation of the 1-hour ozone standard, the *2004 Extreme Ozone Attainment Demonstration Plan* was prepared for this air basin and submitted to the U.S. EPA in November 2004. The plan set forth emissions reductions for attaining this standard by November 15, 2010. Because this standard (including associated designations and classifications) was revoked in June 2005, the U.S. EPA never approved the plan. However, preliminary work has begun on developing the *Eight-Hour Ozone Attainment Demonstration Plan* (OADP) for San Joaquin Valley. The OADP, which will be part of the State Implementation Plan, must demonstrate attainment of the new federal 8-hour ozone standard by 2013; it must also be adopted by the local air districts and the CARB, and be submitted to the U.S. EPA by June 15, 2007 (SJVAPCD, 2007a).

The SJVAPCD adopted the *2003 PM_{10} Plan* (PM_{10} Plan) in response to the SJVAB's nonattainment status for PM_{10}. The plan is designed to meet the requirements of the federal Clean Air Act and contains new control strategies for stationary, area, and mobile sources needed to attain the federal PM_{10} standards at the earliest possible date. The PM_{10} Plan does have control strategies related to construction projects. This plan became part of the State Implementation Plan for San Joaquin Valley when it was adopted by the CARB in August 2003. The U.S. EPA approved this plan in June 2004. In February 2006, the SJVAPCD adopted the *2006 PM_{10} Plan* and this plan is undergoing review by the CARB. The *2006 PM_{10} Plan* is due to the EPA by March 31, 2006. The *2006 PM_{10} Plan* is a continuation of the SJVAPCD's strategy for attaining federal PM_{10} standards.

TABLE 4.9-3
STATE AND FEDERAL AMBIENT AIR QUALITY STANDARDS AND ATTAINMENT STATUS

		(State) SAAQS[a]			(Federal) NAAQS[b]		
Pollutant	**Averaging Time**	**Standard**	**San Joaquin Attainment Status**	**Bay Area Attainment Status**	**Standard**	**San Joaquin Attainment Status**	**Bay Area Attainment Status**
Ozone (O_3)	1 hour	0.09 ppm	**N/Severe**	**N**	NA	See Note (c)	See Note (c)
	8 hour	0.07 ppm	See Note (d)	See Note (d)	0.08 ppm	**N/Serious**	**N/Marginal**
Carbon Monoxide (CO)	1 hour	20 ppm	A	A	35 ppm	U/A	A
	8 hour	9 ppm	A	A	9 ppm	U/A	A
Nitrogen Dioxide (NO_2)	1 hour	0.25 ppm	A	A	NA	NA	NA
	Annual	NA	NA	NA	0.053 ppm	U/A	A
Sulfur Dioxide (SO_2)	1 hour	0.25 ppm	A	A	NA	U	NA
	24 hour	0.04 ppm	A	A	0.14 ppm	U	A
	Annual	NA	NA	NA	0.03 ppm	U	A
Particulate Matter (PM_{10})	24 hour	50 $\mu g/m^3$	**N**	**N**	150 $\mu g/m^3$	**N/Serious**	U
	Annual[e]	20 $\mu g/m^3$ [f]	**N**	**N**	50 $\mu g/m^3$	**N/Serious**	A
Fine Particulate Matter ($PM_{2.5}$)	24 hour	NA	NA	NA	65 $\mu g/m^3$	**N/Serious**	A
	Annual	12 $\mu g/m^3$ [f]	**N**	**N**	15 $\mu g/m^3$	**N/Serious**	A
Sulfates	24 hour	25 $\mu g/m^3$	A	A	NA	NA	NA
Lead	30 day	1.5 $\mu g/m^3$	A	A	NA	NA	NA
	Quarter	NA	NA	NA	1.5 $\mu g/m^3$	ND	A
Hydrogen Sulfide	1 hour	0.03 ppm	U	U	NA	NA	NA
Visibility-Reducing Particles	8 hour	See Note (g)	U	A	NA	NA	NA

NOTES: A = Attainment; **N** = Nonattainment; U = Unclassified; NA = Not Applicable, no applicable standard; ND = no designation; ppm = parts per million; $\mu g/m^3$ = micrograms per cubic meter.

a SAAQS = state ambient air quality standards (California). SAAQS for ozone, carbon monoxide (except Lake Tahoe), sulfur dioxide (1-hour and 24-hour), nitrogen dioxide, particulate matter, and visibility-reducing particles are values that are not to be exceeded. All other state standards shown are values not to be equaled or exceeded.

b NAAQS = national ambient air quality standards. NAAQS, other than ozone and particulates, and those based on annual averages or annual arithmetic means, are not to be exceeded more than once a year. The 8-hour ozone standard is attained when the three-year average of the fourth highest daily concentration is 0.08 ppm or less. The 24-hour PM_{10} standard is attained when the three-year average of the 99th percentile of monitored concentrations is less than the standard. The 24-hour $PM_{2.5}$ standard is attained when the three-year average of the 98th percentile is less than the standard.

c The U.S. EPA revoked the national 1-hour ozone standard on June 15, 2005.

d This state 8-hour ozone standard was approved in April 2005 and became effective in May 2006. Attainment status in both districts is Unclassified.

e State standard = annual geometric mean; national standard = annual arithmetic mean.

f In June 2002, CARB established new annual standards for $PM_{2.5}$ and PM_{10}.

g Statewide visibility-reducing particle standard (except Lake Tahoe Air Basin): Particles in sufficient amount to produce an extinction coefficient of 0.23 per kilometer when the relative humidity is less than 70 percent. This standard is intended to limit the frequency and severity of visibility impairment due to regional haze and is equivalent to a 10-mile nominal visual range.

SOURCES: BAAQMD and SJVAPCD standards, and attainment status as of February 2007 (BAAQMD 2007; SJVAPCD 2007b).

The U.S. EPA is currently developing implementation guidance for fine particulate matter ($PM_{2.5}$). Air districts will be designated as attainment or nonattainment for this new standard in the near future. The SJAPCD has been designated as nonattainment for the $PM_{2.5}$ standard, and the *$PM_{2.5}$ Plan* is due to the U.S. EPA in April 2008. Air districts that are designated as nonattainment will be subject to more stringent air quality planning requirements.

San Francisco Bay Area Air Basin

The SFBAAB's current attainment status with respect to federal standards is summarized in Table 4.9-3. In general, the Bay Area experiences low concentrations of most pollutants when compared to federal standards, except for ozone and particulate matter (PM_{10} and $PM_{2.5}$), for which standards are exceeded periodically. The Bay Area's attainment status for ozone has changed several times over the past decade, first from "nonattainment" to "attainment" in 1995, then back to "unclassified nonattainment" in 1998 for the 1-hour federal ozone standard. In June 2004, the Bay Area was designated as "marginal nonattainment" for the 8-hour ozone standard. In 1998, after many years without violations of any CO standards, the attainment status for CO was upgraded to "attainment."

The BAAQMD's *Clean Air Plan* (CAP), last adopted in 2000, applies control measures to stationary and mobile sources and outlines transportation control measures. Although the 2000 CAP is an ozone plan, it includes PM_{10} attainment planning as an informational item. The 1997 CAP and 2000 CAP included 19 transportation control measures, many of which were partially implemented between 1998 and 2000. The 2000 CAP continues to implement and expand key mobile-source programs included in the 1997 CAP.

In response to the U.S. EPA redesignation of the basin for the 1-hour federal ozone standard to nonattainment, the BAAQMD, Association of Bay Area Governments (ABAG), and Metropolitan Transportation Commission (MTC) were required to develop an ozone attainment plan to meet this standard. The *1999 Ozone Attainment Plan* (OAP) was prepared and adopted by these agencies in June 1999. However, in March 2001, the U.S. EPA proposed and took final action to approve portions of the 1999 OAP and disapprove other portions, while also making the finding that the Bay Area had not attained the national 1-hour ozone standard. As a result, a revised OAP was prepared and adopted in October 2001. The 2001 OAP amends and supplements the 1999 OAP. The 2001 OAP contains control strategies for stationary and mobile sources. The adopted mobile-source control program was estimated to significantly reduce volatile organic compound and NOx emissions between 2000 and 2006, reducing emissions from on- and off-road diesel engines (including construction equipment). In addition to emission reduction requirements for engines and fuels, the OAP identified 28 transportation control measures to reduce automobile emissions, including improved transit service and transit coordination, new carpool lanes, signal timing, freeway incident management, and increased state gas tax and bridge tolls. In June 2005, the U.S. EPA revoked the federal 1-hour ozone standard, although the 8-hour standard is still in effect. The attainment deadline for "marginal nonattainment" areas for the 8-hour federal ozone standard is June 2007.

State Standards

The Clean Air Act Amendments of 1970 established national ambient air quality standards, and individual states retained the option to adopt more stringent standards and to include other pollution sources. California had already established its own air quality standards when federal standards were established, and because of the unique meteorological problems in California, there is considerable diversity between the state and national ambient air quality standards, as shown in Table 4.9-3. California ambient standards tend to be at least as protective as national ambient standards and are often more stringent. Currently, there are no federal or state ambient air quality standards for any of the six greenhouse gases.[2]

In 1988, California passed the California Clean Air Act (California Health and Safety Code Sections 39600 et seq.), which, like its federal counterpart, called for the designation of areas as attainment or nonattainment, but based on state ambient air quality standards rather than the federal standards.

In 2005, in recognition of California's vulnerability to the effects of climate change, Governor Schwarzenegger established Executive Order S-3-05, which sets forth a series of target dates by which statewide emission of GHG would be progressively reduced, as follows:

- By 2010, reduce GHG emissions to 2000 levels;
- By 2020, reduce GHG emissions to 1990 levels; and
- By 2050, reduce GHG emissions to 80 percent below 1990 levels.

In 2006, California passed the California Global Warming Solutions Act of 2006 (Assembly Bill No. 32; California Health and Safety Code Division 25.5, Sections 38500, et seq., or AB 32), which requires the CARB to design and implement emission limits, regulations, and other measures, such that feasible and cost-effective statewide GHG emissions are reduced to 1990 levels by 2020 (representing a 25 percent reduction in emissions).

California Air Resources Board

The CARB is the state agency responsible for regulating air quality. The CARB's responsibilities include establishing state ambient air quality standards, emissions standards, and regulations for mobile emissions sources (e.g., autos, trucks, etc.), as well as overseeing the efforts of countywide and multi-county air pollution control districts, which have primary responsibility over stationary sources. The emission standards most relevant to proposed WSIP facilities are those related to automobiles and on- and off-road heavy-duty diesel engines. The CARB also regulates vehicle fuels with the intent to reduce emissions; it has set emission reduction performance requirements for gasoline (California reformulated gasoline) and limited the sulfur and aromatic content of diesel fuel to make it burn cleaner. The CARB also sets the standards used to pass or fail vehicles in smog check and heavy-duty truck inspection programs.

[2] The six GHGs are carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons (HFC), perfluorocarbons (PFC), and sulfur hexafluoride (SF_6).

Diesel Idling Limits. In 2005, the CARB approved a regulatory measure to reduce emissions of toxic and criteria pollutants by limiting the idling of new heavy-duty diesel vehicles, which altered five sections of Title 13 of the California Code of Regulations. The relevant changes with respect to the WSIP are Sections 2480 and 2485. The pertinent requirements of Section 2480, Airborne Toxic Control Measure to Limit School Bus Idling and Idling at Schools, include the following:

(c)(2) A driver of a commercial motor vehicle:

(A) must turn off the bus or vehicle engine upon stopping at a school and must not turn the bus or vehicle engine on more than 30 seconds before beginning to depart from a school; and

(B) must not cause or allow a bus or vehicle to idle at any location within 100 feet of, but not at, a school for:

(i) more than five consecutive minutes; or
(ii) a period or periods aggregating more than five minutes in any one hour.

(c)(4) A motor carrier of a commercial motor vehicle must ensure that:

(A) the bus or vehicle driver, upon employment and at least once per year thereafter, is informed of the requirements in (c)(2), and of the consequences, under this section and the motor carrier's terms of employment, of not complying with those requirements;

(B) all complaints of non-compliance with, and enforcement actions related to, the requirements of (c)(2) are reviewed and remedial action is taken as necessary; and

(C) records of (4) (A) and (B) are kept for at least three years and made available or accessible to enforcement personnel as defined in subsection (g) within three business days of their request.

Pertinent requirements of Section 2485, Airborne Toxic Control Measure to Limit Diesel-Fueled Commercial Motor Vehicle Idling, include the following:

(c) The driver of any vehicle subject to this section:

(1) shall not idle the vehicle's primary diesel engine for greater than five minutes at any location, except as noted in subsection (d); and

(2) shall not operate a diesel-fueled auxiliary power system (APS) to power a heater, air conditioner, or any ancillary equipment on that vehicle during sleeping or resting in a sleeper berth for greater than five minutes at any location when within 100 feet of a restricted area, except as noted in subsection (d).

"Restricted area" means any real property zoned for individual or multifamily housing units that has one or more such units. There are 12 exceptions to this requirement (e.g., emergency situations, military, adverse weather conditions, etc.), including: when a vehicle's power takeoff is being used to run pumps, blowers, or other equipment; when a vehicle is stuck in traffic, stopped at a light, or under direction of a police officer; when a vehicle is queuing beyond 100 feet from any restricted area; or when an engine is being tested, serviced, or repaired.

Greenhouse Gas Emissions Limits. The California Global Warming Solutions Act of 2006 establishes a timetable for the CARB to adopt emission limits, rules, and regulations designed to achieve the intent of the Act, as follows (CARB, 2006b):

- Publish a list of discrete early action GHG emission reduction measures by June 30, 2007.
- Establish a statewide GHG emissions cap for 2020, equivalent to the 1990 emissions level by January 1, 2008.
- Adopt mandatory reporting rules for significant sources of GHGs by January 1, 2008.
- Adopt a scoping plan by January 1, 2009, indicating how GHG emission reductions will be achieved from significant GHG sources via regulations, market-based compliance mechanisms and other actions, including the recommendation of a *de minimus* threshold for GHG emissions, below which emission reduction requirements would not apply.
- Adopt regulations by January 1, 2011 to achieve the maximum technologically feasible and cost-effective reductions in GHGs, including provisions for using both market-based and alternative compliance mechanisms.
- Establish January 1, 2012 as the date by which all regulations adopted prior to January 1, 2010 are to become operative (enforceable).

The CARB is proposing "Early Action Measures" in three groups; together, these measures will make a substantial contribution to the overall 2020 statewide GHG emission reduction goal of approximately 174 million metric tons of carbon dioxide equivalent gases (CARB, 2007). (The term "carbon dioxide equivalent" is used to account for the differences in global warming potential [GWP] among the six greenhouse gases.) These measures are summarized as follows:

> *Group 1*: Three new GHG-only regulations are proposed to meet the narrow legal definition of "discrete early action GHG reduction measures": a low-carbon fuel standard, reduction of refrigerant losses from motor vehicle air conditioning system maintenance, and increased methane capture from landfills. These regulations are expected to take effect by January 1, 2010.
>
> *Group 2*: The CARB is initiating work on 23 other GHG emission-reducing measures in the 2007 to 2009 time period with rulemaking to occur as soon as possible, where applicable. These GHG measures relate to the following sectors: agriculture, commercial, education, energy efficiency, fire suppression, forestry, oil and gas, and transportation.
>
> *Group 3*: The CARB is initiating work on 10 conventional air pollution controls aimed at criteria and toxic air pollutants, but with concurrent climate co-benefits through reductions in carbon dioxide or non-Kyoto pollutants (i.e., diesel particulate matter, other light-absorbing compounds, and/or ozone precursors) that contribute to global warming.

With the exception of the low-carbon fuel standard,[3] none of the Group 1 measures specifically relate to construction or operation of water infrastructure projects, such as the WSIP facility

[3] Feasiblity of this measure is currently unknown depending on availability and suitability of low-carbon fuel for construction equipment and proximity to construction site.

improvement projects. Proposed Groups 2 and 3 measures that could become effective during implementation of the WSIP and could pertain to construction-related equipment operations or specific WSIP facility design include the following actions:

- Measure 2-6, Education: Guidance/protocols for local governments to facilitate GHG emission reductions
- Measure 2-9, Energy Efficiency: Light-covered paving, cool roofs and shade trees
- Measures 2-14, 3-2, 3-4, Transportation: emission reductions for heavy-duty vehicles, on-road diesel trucks, and off-road diesel equipment (non-agricultural); efficiency improvements
- Measure 2-20, Transportation: Tire inflation program
- Measure 3-10, Fuels: Evaporative standards for aboveground tanks

Some proposed measures will require new legislation to implement, some will require subsidies, some have already been developed, and some will require additional effort to evaluate and quantify. Applicable early action measures that are ultimately adopted from Groups 2 and 3 will become effective during implementation of the WSIP and some WSIP facility projects might be subject to these requirements, depending on their timing.

In consultation with the CARB and California Public Utilities Commission, the California Energy Commission (CEC) is currently establishing a GHGs emission performance standard for local, public-owned electric utilities (pursuant to Senate Bill No. 1368). This standard will limit the rate of GHGs emissions to a level that is no higher than the rate of emissions of GHGs for combined-cycle natural gas baseload generation. The rulemaking shall consider, but not necessarily be limited to, establishing a GHGs emission performance standard for baseload generation facilities by June 30, 2007, a process for calculating the emissions of GHGs from baseload facilities and enforcing the standard, and a process for reevaluating and revising as necessary the GHGs emission performance standard. This standard must take into consideration the effect of the standard on rates, reliability, and financial resources, while recognizing the Legislature's intent to encourage use of renewable resources and its goal of environmental improvement.

San Joaquin Valley Air Basin

The SJVAPCD is the regional agency responsible for air quality regulation within the SJVAB. The SJVAPCD regulates air quality through its control of stationary sources of pollution such as industrial processes and equipment, but also implements indirect source control programs to reduce mobile-source emissions (including transportation control measures). The SJVAB also provides the CARB with local strategies for sources under its jurisdiction for inclusion in the State Implementation Plan. (See the discussion above under Federal Standards for the SJVAB.)

Table 4.9-3 presents a summary of the SJVAB's attainment status with respect to state standards. As indicated in the table, the SJVAB is designated as "severe nonattainment" for the state ozone standard and "nonattainment" for the state PM_{10} and $PM_{2.5}$ standards. The SJVAB is designated as "attainment" for all other criteria pollutants listed in Table 4.9-3.

San Francisco Bay Area Air Basin

The BAAQMD is the regional agency responsible for air quality regulation within the SFBAAB. The BAAQMD regulates air quality through its planning and review activities. The BAAQMD has permit authority over most types of stationary emission sources and can require stationary sources to obtain permits; it can also impose emission limits, set fuel or material specifications, or establish operational limits to reduce air emissions. The BAAQMD regulates new or expanding stationary sources of toxic air contaminants.

In September 2005, the BAAQMD, in cooperation with the MTC and ABAG, prepared the draft *Bay Area 2005 Ozone Strategy*. The Ozone Strategy is a roadmap showing how the San Francisco Bay Area will achieve compliance with the state 1-hour ozone standard as expeditiously as practicable, and how the region will reduce transport of ozone and ozone precursors to neighboring air basins. The control strategy includes stationary-source control measures to be implemented through BAAQMD regulations; mobile-source control measures to be implemented through incentive programs and other activities; and transportation control measures to be implemented through transportation programs in cooperation with the MTC, local governments, transit agencies, and others.

Table 4.9-3 presents a summary of the BAAQMD's attainment status with respect to state standards. As indicated in the table, the SFBAAB is designated as "nonattainment" for state ozone, PM_{10}, and $PM_{2.5}$ standards. The SFBAAB is designated as "attainment" for all other criteria pollutants listed in the table.

Climate Action Plan for San Francisco. In February 2002, the San Francisco Board of Supervisors passed the *Greenhouse Gas Emissions Reduction Resolution* (Number 158-02) committing the City and County of San Francisco to a greenhouse gas (GHG) emissions reductions goal of 20 percent below 1990 levels by the year 2012. The resolution also directs the San Francisco Department of the Environment, the SFPUC, and other appropriate City agencies to complete and coordinate an analysis and planning of a local action plan targeting GHG emission reduction activities. In September 2004, the San Francisco Department of the Environment and the SFPUC published the *Climate Action Plan for San Francisco: Local Actions to Reduce Greenhouse Emissions* (Plan) (SFDE and SFPUC, 2004). Although the San Francisco Board of Supervisors has not formally committed the City to perform the actions addressed in the Plan, and many of the actions require further development and commitment of resources, it serves as a blueprint for GHG emission reductions, and several actions are now in progress.

The Plan presents estimates of San Francisco's baseline GHG inventory and reduction targets. It states that burning fossil fuels in vehicles and for energy use in buildings and facilities are the major contributors to San Francisco's GHG emissions; in 1990, these activities produced approximately 9.1 million tons of carbon dioxide (CO_2). The Plan also describes recommended emissions reduction actions in the key target sectors – transportation, energy efficiency, renewable energy, and solid waste management – to meet stated goals by 2012.

The Plan presents proposals to reduce annual carbon dioxide emissions by 2.5 million tons by 2012, a 20 percent reduction below 1990 emissions, such as greening vehicle fleets, increasing energy efficiency in public and private buildings, developing renewable energy technologies like solar, wind, fuel cells and tidal power, and expanding residential and commercial recycling programs. The roadmap to achieving these goals requires the cooperation of a number of City, regional and State agencies as well as private sector partners.

Greenhouse Gas Reduction Ordinance

In May 2008, San Francisco adopted an ordinance amending its Environment Code to establish greenhouse gas emission targets and action plans, to authorize the Department of the Environment to coordinate efforts to meet these targets, and to make environmental findings (CCSF, 2008). The ordinance establishes the following greenhouse gas emission reduction limits for San Francisco and the target dates to achieve them:

- Determine 1990 City greenhouse gas emissions by 2008, the baseline level with reference to which target reductions are set;
- Reduce greenhouse gas emissions by 25 percent below 1990 levels by 2017;
- Reduce greenhouse gas emissions by 40 percent below 1990 levels by 2025; and
- Reduce greenhouse gas emissions by 80 percent below 1990 levels by 2050.

The ordinance also specifies requirements for City departments to prepare Climate Action Plans that assess and report GHG emissions and prepare recommendations to reduce emissions. As part of this, the San Francisco Planning Department is required to: (1) update and amend the City's applicable General Plan elements to include the emissions reduction limits set forth in this ordinance and policies to achieve those targets; (2) consider a project's impact on the City's GHG reduction limits specified in this ordinance as part of its review under CEQA; and (3) work with other City departments to enhance the "transit first" policy to encourage a shift to sustainable modes of transportation thereby reducing emissions and helping to achieve the targets set forth by this ordinance.

Existing CCSF GHG Reduction Actions. The City is already implementing a wide range of actions related to the reduction of GHG emissions. Some of these actions are described below (SFDE and SFPUC, 2004) and additional actions are described in the Plan.

***Transportation*.** The San Francisco Board of Supervisors passed a Resolution No. 728-97 supporting increased Corporate Average Fuel Economy (CAFE) standards in the early 1990s. In 1999, the Board adopted the Healthy Air and Smog Prevention Act, which became Chapter 4 of the City's Environment Code. This ordinance requires that all new purchases or leases of passenger vehicles and light duty trucks must either be rated as ultralow emission vehicle (ULEV) or zero emission vehicles (ZEV) (at least 10 percent were to be ZEV by July 1, 2000). Requirements were also set forth for medium and heavy-duty vehicles and motorized equipment, and for phasing out all highly polluting vehicles and equipment (SFDE and SFPUC, 2004).

The City has also contributed grant funds towards the development of three alternate fueling facilities. It continues to seek funds to expand alternate fueling infrastructure and has also been successful in developing a number of electric vehicle charging stations both in San Francisco and throughout the Bay Area. In addition, the City encourages car sharing. Several car sharing organizations in the City provide a community-wide solution to vehicle fleets. By providing a network of vehicles in locations around the city, available for reservation on an as-needed basis, residents can utilize small, fuel-efficient and electric vehicles and reduce car ownership. Car sharing is also available for use by businesses and public entities. The City requires the provision of car share parking spaces in large new residential buildings (City Planning Code Section 166). The City also limits the amount of parking allowed in new downtown residential developments (City Planning Code Section 151.1).

Solar and Energy Efficiency. San Francisco elected officials and voters have expressed strong support for renewable energy in several ways. The City funds municipal energy efficiency programs through a combination of the SFPUC's Hetch Hetchy Water and Power revenues, state grants and loans, and the City's General Fund at approximately $5.5 million annually. Alternative renewable energy funding mechanisms, which can take advantage of private investor incentives including the 30 percent federal tax credit and accelerated depreciation through acquisition of renewable power from Power Purchase Agreements, are currently being explored. In 2001, the City's Department of Environment received $7.8 million of state funds to manage an energy efficient lighting retrofit program for small businesses in San Francisco. Also in 2001, the voters approved Proposition B and H. Proposition B authorized $100 million in revenue bonds to develop solar, wind and energy efficiency projects in City facilities and Proposition H authorized the City to issue revenue bonds for private sector as well as municipal projects.

City ordinances include the Green Building Ordinance for City Buildings, and Residential Energy Conservation Ordinance (RECO); and City energy policies include those such as set forth in the Energy Policy of the City's General Plan, the 1997 Sustainability Plan, and the 2002 Electricity Resource Plan. One of the goals of the Electricity Resource Plan is to maximize energy efficiency in San Francisco. The Plan recommends that the City "periodically review and set annual targets for increasing the efficiency of electricity use and the amount of electricity produced by renewable sources of energy so that ultimately all of San Francisco's electricity needs are met with zero GHG emissions and minimal impacts on the environment." Increased energy efficiency goals included in the Climate Action Plan include 107 megawatts of electric demand reduction and 759 gigawatt-hours of energy efficiency by 2012.

The San Francisco Department of Environment (SF Environment) is developing streamlined permitting and public information systems to pave the way for accelerated construction of solar in San Francisco for both hot water heating and electricity. Permit fees are being reduced and requirements standardized (SFDE and SFPUC, 2004).

SF Environment is also promoting the integration of solar into the construction of new City facilities through its Green Building program. The SFPUC and SF Environment are cooperating to implement the Generation Solar program to facilitate the installation of solar electric systems on residential and commercial rooftops in San Francisco SFPUC provides overall oversight of the program, technical assistance, and contractor screening. SF Environment has responsibility for program marketing and proposing changes to building and planning codes, procedures, permitting and fees. See below for additional SFPUC-specific GHG emissions reduction measures (SFDE and SFPUC, 2004).

Existing SFPUC-Specific GHG Reduction Actions. As stated throughout this PEIR, the SFPUC owns and operates a gravity-driven water system. The SFPUC is also developing and energy-efficiency and renewable generation projects. To date, several renewable generation projects have been constructed and many more are in the planning, design or construction phases. For instance, in 2002, the SFPUC installed a small reciprocating engine to use biogas recovered from the Oceanside Water Treatment Control Plant. In 2003, a 2 megawatt biogas plant began operation at the Southeast Water Treatment Control Plant. Both of these plants use sewage-produced methane gas that would otherwise be flared-off. In addition, the SFPUC has completed several solar electric projects for City facilities. The first project, a 675-kilowatt solar electric photovoltaic (PV) system is located on the Moscone Convention Center's roof. This project generates 826,000 kilowatt-hours of electricity per year and provides a solar showplace for visitors. Additional solar PV projects in operation include a 255-kilowatt project that the Southeast Water Pollution Control Plant and a 245-kilowatt project at Pier 96, the Norcal recycling facility. Five other solar PV projects are currently under construction. The SFPUC has also installed pyranometers at 19 sites on City buildings and schools to collect data about the availability of sunlight, as well as instruments to measure wind speed and ambient temperature. The variability in solar incidence is based on microclimate and geography, and when used in conjunction with availability of appropriate space suggests potential future solar PV project sites.

The SFPUC also manages and implements energy efficiency projects in municipal buildings and facilities. SFPUC provides energy efficiency services such as energy audits, design, and construction management. Energy retrofit technologies include installing energy efficient equipment such as lighting, HVAC, motors, controls and energy management systems.

Municipal energy efficiency and renewable generation projects are funded by Hetch Hetchy power sales net revenue as well as state grants and loans, among other funding mechanisms. Funds that the SFPUC designates for energy projects are appropriated in a project account called The Mayor's Energy Conservation Account (MECA). MECA provides a financing mechanism whereby a loan can be made by the SFPUC to a department for the purpose of funding an energy project. For energy efficiency projects, loans can be paid back though City departments' energy savings. As of 2007, the SFPUC has invested $24 million in energy efficiency projects and estimates that it has reduced peak demand by approximately 3,800 kW and CO_2 emissions by approximately 11,000 tons/year. Municipal solar PV projects have been funded by SFPUC Power Enterprise such that client departments pay the same rate for solar power as they would normally pay for that power from Hetch Hetchy generation. To date, 2 megawatts of municipal solar plants have been installed or are under construction for an investment (before rebates) of about $20 million.

Municipal energy efficiency projects recently completed or underway include: lighting retrofits at Moscone Convention Center (North and South), San Francisco General Hospital, Mental Health Clinics, City parking garages, Golden Gate Park and West Portal Library; Department of Parking and Traffic LED traffic signal conversions; efficient refrigerators at Housing Authority facilities; motor replacements at the Southeast Wastewater Treatment Plant; and efficient lighting, HVAC, building shell, and energy management controls upgrades at the new Moscone West Convention Center (SFDE and SFPUC, 2004).

The SFPUC is also looking at several sites around the Bay Area for wind power development. The SFPUC has installed wind monitoring equipment at five sites in and around the City and additional data are being obtained for City property in the Sierra foothills.

SFPUC GHG Reduction Actions as Part of the WSIP. In addition to the actions set forth above, the SFPUC is committed to the following GHG reduction actions as part of the WSIP program.

A. The SFPUC will include the first two measures in all WSIP contractor specifications and will implement the third during project planning and design, which in addition to having other environmental benefits, would also help reduce GHG emissions.

    1. The SFPUC will require that all contractors maintain tire inflation to the manufacturers' inflation specifications.
    2. The SFPUC will implement a construction worker education program for all WSIP projects.
    3. WSIP projects that include construction of new buildings will consult with the SFPUC Power Enterprise's Energy Efficiency Group to incorporate all applicable energy efficiency measures into project design. Projects with buildings components will

attempt to maximize energy efficiency by exceeding Title 24 minimum requirements by at least 20 percent. Projects with buildings components will attempt to meet or exceed LEED Silver certification as required by the City's Green Building Ordinance.

B. Chapter 6 presents mitigation measures that would be implemented as part of the WSIP and some of these measures would also help reduce GHG emissions. They include exhaust controls (Measures 4.9-1b, 4.9-1d and 4.16-7a), waste reduction measures (Measure 4.11-2) and energy efficiency measures (Measure 4.15-2). In addition, CARB regulations (Title 13 of the California Code of Regulations, Sections 2480 and 2485), which limit idling of diesel-fueled commercial motor vehicles, would help to limit greenhouse gas emissions associated with WSIP-related construction vehicles.

4.9.3 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to air quality, but generally considers that implementation of the proposed program would have a significant air quality impact if it were to:

- Conflict with or obstruct implementation of the applicable air quality plan (Evaluated in this section)
- Violate any air quality standard or contribute substantially to an existing or projected air quality violation (Evaluated in this section)
- Conflict with the state goal of reducing GHG emissions in California to 1990 levels by 2020, as set forth by the timetable established in AB 32, California Global Warming Solutions Act of 2006, such that the project's GHG emissions would result in a substantial contribution to global climate change (Evaluated in this section).
- Result in a cumulatively considerable net increase of any criteria pollutant for which the project region is in nonattainment under an applicable federal or state ambient air quality standard (including releasing emissions that exceed quantitative thresholds for ozone precursors) (Evaluated in this section and Section 4.16, Collective WSIP Impacts; cumulative increases are evaluated in Section 4.17, Cumulative WSIP Impacts)
- Expose sensitive receptors to substantial pollutant concentrations (Evaluated in this section)
- Create objectionable odors affecting a substantial number of people (Evaluated in this section)

Approach to Analysis

The air quality impact analysis considers construction and operational impacts associated with the proposed WSIP. Construction air emissions are evaluated in accordance with the SJVAPCD and BAAQMD guidelines for assessing and mitigating air quality impacts (SJVAPCD, 2002b; BAAQMD, 1999). Both the SJVAPCD and BAAQMD guidelines indicate that the significance of a project's impact should be evaluated based on the effectiveness of proposed measures to reduce construction-related emissions (e.g., whether control measures are implemented as part of construction). If appropriate mitigation measures are implemented for each project to control

PM_{10} emissions, both air districts consider the potentially significant project-related and cumulative impacts to be less than significant.

Both the SJVAPCD and BAAQMD guidelines also provide significance thresholds for criteria pollutant emissions associated with project operation. However, water storage, transmission, and treatment facilities are not typically a source of "traditional" air pollution emissions. Therefore, direct and secondary emissions associated with operation of the WSIP facilities are discussed qualitatively. The significance of the WSIP's cumulative operational impacts is determined based on the consistency of the WSIP with pertinent air quality plans.

Impact Summary by Region

Table 4.9-4 provides a summary of the air quality impacts associated with implementation of the WSIP.

Construction Impacts

Short-Term Increases in Pollutant Emissions

Impact 4.9-1: Construction emissions of criteria pollutants.

Construction of all WSIP facilities would generate fugitive dust[4] (including PM_{10} and $PM_{2.5}$) and other criteria pollutants, primarily as a result of a variety of construction activities, including excavation, grading, demolition, vehicle travel on paved and unpaved surfaces, and vehicle exhaust. With respect to construction-related emissions, PM_{10} is the pollutant of greatest concern to the SJVAPCD and BAAQMD. Construction-related emissions could cause substantial increases in localized concentrations of PM_{10} and could affect PM_{10} compliance with ambient air quality standards on a regional basis. Particulate emissions from construction activities could also lead to adverse health effects and nuisance concerns (e.g., reduced visibility and soiling of exposed surfaces).

Combustion emissions from construction equipment and vehicles (i.e., heavy equipment and delivery/haul trucks, worker commute vehicles, air compressors, and generators) would be generated during project construction. Emissions from construction worker commute trips would be minor compared to the emissions generated by construction equipment. Criteria pollutant emissions of ROG and NO_x from these emission sources would incrementally add to regional atmospheric loading of ozone precursors during project construction. The *BAAQMD CEQA Guidelines* recognize that construction equipment emits ozone precursors, but indicate that such emissions are included in the emission inventory that is the basis for regional air quality plans, and that construction emissions are not expected to impede the attainment or maintenance of ozone standards in the Bay Area (BAAQMD, 1999). However, the SJVAPCD indicates that

4 "Fugitive" emissions generally refer to those emissions that are released to the atmosphere by some means other than through a stack or tailpipe.

LS = Less than Significant impact, no mitigation required
PSM= Potentially Significant impact, can be mitigated to less than significant
N/A = Not Applicable

construction projects lasting for many months in the SJVAB could exceed the air district's annual threshold for NOx emissions. In addition, sensitive receptors could be subject to elevated levels of diesel particulate matter (DPM). These impacts would be temporary but would span the duration of construction for each project, mostly one to four years depending on the project. Construction emissions associated with implementation of all the WSIP projects would span seven or eight years (approximately 2008 to 2014). Due to the long overall duration of WSIP-related construction activities and the regional extent of WSIP facilities, this PEIR quantifies construction-phase emissions by region to demonstrate the combined or collective construction impact in each region that could result from WSIP implementation.

Air pollutant emissions were estimated for each region, as shown in **Table 4.9-5**. While much of the estimated emissions are attributable to the largest WSIP projects: SJPL System (SJ-3), Calaveras Dam (SV-2), and BDPL Reliability Upgrade (BD-1), other WSIP projects would incrementally contribute to emissions listed in this table. For purposes of a worst-case analysis, simultaneous construction of all WSIP projects (listed in Table 3.10) were assumed to occur during any given year, which is unlikely to occur.

Given the length of time that construction-related emissions would occur, this PEIR compares estimated exhaust emissions to the SJVAPCD's operational significance criteria (10 tons/year, equivalent to 55 pounds per day, for ROG and NOx; 9 ppm averaged over 8 hours and 20 ppm over 1 hour for CO) and the BAAQMD's operational significance criteria (80 pounds/day for ROG, NOx, and PM_{10}; 550 pounds/day for CO).

San Joaquin Region

Impact 4.9-1: Construction emissions of criteria pollutants		
Advanced Disinfection	SJ-1	PSM
Lawrence Livermore	SJ-2	PSM
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	PSM

Construction activities associated with all projects in the San Joaquin Region would result in short-term increases in suspended particulates and other criteria pollutants. This would be a *potentially significant* impact.

Table 4.9-5 shows the estimated average daily earthmoving quantities and correlating fugitive PM_{10} and equipment exhaust emissions that could occur on any given day in the San Joaquin Region. Most of the estimated construction-related air pollutant emissions in this region are attributable to the SJPL System project (SJ-3), since the majority of the surface disturbance/ excavation in this region would be associated with this project. The SJPL Rehabilitation project (SJ-4) also could contribute substantial additional emissions, but the amount cannot be quantified at this time because the extent of disturbance has not yet been determined. Emissions associated with haul truck traffic for both of these projects would add to estimated emissions (including DPM). Although the SJVAPCD has no construction significance criteria, these estimates indicate the SJVAPCD's annual threshold for NOx could be exceeded, primarily due to the long construction duration (almost three years) for the SJPL System project. Construction of the SJPL Rehabilitation project would further increase estimated emissions and the potential for exceedance of the NOx threshold. Potential air quality impacts associated with these projects

TABLE 4.9-5
WSIP CONSTRUCTION-RELATED AIR POLLUTANT EMISSIONS

Region	Average Daily Area of Disturbance (acres/day)	Average Daily Fugitive PM10 Emissions [a] (pounds/day)	Average Daily Excavation/ Spoils Volume (cubic yards)	Average Daily Equipment Emissions Associated with Earthmoving Equipment (pounds per day)[b]

BAAQMD Significance Thresholds	NA	80	NA	80	550	80	80	NA	NA

NOTE: **Bold** values are in excess of SJVAPD or BAAQMD significance thresholds. Fugitive PM_{10} emissions are estimated using the CARB's construction-related emission factor of 51 pounds/acre/day of PM_{10}, as presented by the BAAQMD (1999). Equipment emissions represent a composite fleet of heavy- and light-duty construction equipment in the Bay Area, and estimates are based on BAAQMD emissions factors (1999). NA = not applicable or not available.

[a] Fugitive particulate matter (PM_{10}) emissions for all regions (except the Sunol Valley and Peninsula Regions) are based on typical trench dimensions of pipeline projects and average length of pipeline that can be constructed in one day. Since a larger construction area would result in surface disturbance (and fugitive dust) along segments that are unpaved, additional disturbance area was included for pipelines in the San Joaquin and Bay Division Regions. For the Sunol Valley and Peninsula Regions, fugitive PM_{10} emissions are estimated based on the maximum total excavation/spoils volume (see Table 3.12 in Chapter 3) that could occur on any given day due to overlapping construction schedules.

[b] Equipment emissions for all regions are based on the maximum total excavation/spoils volume that could occur on any given day due to overlapping construction schedules, averaged over each project's estimated construction duration (see Table 4.16-1). Since these estimates are daily emissions averaged over the entire construction period, actual emissions on any given day could be higher or lower than these estimates.

[c] Equipment PM_{10} exhaust emissions estimates include DPM, but do not include emissions associated with haul truck traffic.

[d] Does not include methane which is a greenhouse gas.

[e] Does not include nitrous oxide which is a greenhouse gas.

[f] Carbon dioxide equivalent greenhouse gas emissions. The calculation assumes that each cubic yard of cut and fill requires the expenditure of 0.27 gallons of diesel fuel, and that each gallon of diesel fuel combustion produces 22.15 pounds of CO2-equivalent emissions (CO2 + CH4 [GWP=21] + N2O [GWP=310]) based upon Tables C.3 and C.4 of the California Climate Action Registry. GWP is "global warming potential" which recognizes that each GHG differs in its ability to absorb heat in the atmosphere. Methane traps 21 times more heat per molecule than carbon dioxide, and nitrous oxide absorbs 310 times more heat per molecule. All GHG emissions have been quantified and weighted according to their GWP to create a CO_2-equivalent emission rate.

[g] Estimated emissions are based on the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects only, because these projects represent most of this region's emissions. It is assumed that two construction crews would work on SJ-3 and one construction crew would work on SJ-4 simultaneously.

[h] As noted previously, there are no established standards or thresholds applicable to GHG emissions.

[i] Estimated emissions are based on the BDPL Reliability Upgrade project (BD-1) only, because this project represents most of this region's emissions. It is assumed that four construction crews would work simultaneously.

[j] Estimated emissions are based on construction of the SAPL 3 Installation (SF-1) and Recycled Water Projects (SF-3), because these projects represent most of this region's emissions. It is assumed that four construction crews would work simultaneously. It is possible that construction activities associated with these two projects could overlap in 2010.

would be evaluated during separate, project-level CEQA review. SFPUC Construction Measure #3, which requires preparation of a dust control plan and implementation of several dust control measures, would reduce these potentially significant impacts. However, the SJVAPCD considers construction-related emissions from all projects in this region to be mitigated to a less-than-significant level if SJVAPCD-recommended PM_{10} fugitive dust rules (collectively called Regulation VIII and included as Measure 4.9-1a) and equipment exhaust emission controls (outlined in Measure 4.9-1b) are implemented. Therefore, implementation of SFPUC Construction Measure #3 for air quality in addition to applicable SJVAPCD dust and exhaust control measures (Measures 4.9-1a and 4.9-1b) would reduce potential air quality impacts to a less-than-significant level.

Sunol Valley Region

Impact 4.9-1: Construction emissions of criteria pollutants		
Alameda Creek Fishery	SV-1	PSM
Calaveras Dam	SV-2	PSM
40-mgd Treated Water	SV-3	PSM
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	PSM
SABUP	SV-6	PSM

Construction activities associated with all projects in the Sunol Valley Region would result in short-term increases in suspended particulates and other criteria pollutants. This would be a *potentially significant* impact.

Table 4.9-5 shows the estimated average daily earthmoving quantities and correlating fugitive PM_{10} and equipment exhaust emissions that could occur between approximately 2009 and 2010 during simultaneous construction of six WSIP projects in the Sunol Valley Region (Alameda Creek Fishery, SV-1; Calaveras Dam, SV-2; 40-mgd Treated Water, SV-3; New Irvington Tunnel, SV-4; Treated Water Reservoirs, SV-5; and SABUP, SV-6). Most of the estimated construction-related air pollutant emissions in this region are attributable to the Calaveras Dam project, since the majority of the surface disturbance/excavation in this region would be associated with this project. Emissions associated with haul truck traffic would add to estimated emissions (including DPM; see Impact 4.9-2). Although the BAAQMD has no construction significance criteria, these estimates indicate the BAAQMD's operational thresholds for ROG, NO_x, PM_{10}, and CO could be exceeded. Potential air quality impacts associated with the Calaveras Dam project would be evaluated in more detail in a separate, project-level EIR. SFPUC Construction Measure #3, which requires preparation of a dust control plan and implementation of several dust control measures, would reduce these potentially significant impacts. However, the BAAQMD considers construction-related emissions from all projects in this region to be mitigated to a less-than-significant level if BAAQMD-recommended dust and equipment exhaust emission controls (outlined in Measures 4.9-1c and 4.9-1d) are implemented. Therefore, it is expected that implementation of SFPUC Construction Measure #3 for air quality in addition to applicable BAAQMD dust and exhaust control measures (Measures 4.9-1c and 4.9-1d) would reduce potential air quality impacts to a less-than-significant level.

Bay Division Region

Impact 4.9-1: Construction emissions of criteria pollutants		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	PSM
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSM

Construction activities associated with all projects in the Bay Division Region would result in short-term increases in suspended particulates and other criteria pollutants. This would be a *potentially significant* impact.

Table 4.9-5 shows the estimated average daily earthmoving quantities and correlating fugitive PM_{10} and equipment exhaust emissions that could occur on any given day in the Bay Division Region. Most of the estimated construction-related air pollutant emissions in this region are attributable to the BDPL Reliability Upgrade project (BD-1), since the majority of the surface disturbance/excavation in this region would be associated with this project. Emissions associated with haul truck traffic would add to estimated emissions (including DPM; see Impact 4.9-2). These estimates indicate the BAAQMD's operational thresholds for PM_{10}, CO, and NOx could be exceeded. Potential air quality impacts associated with the BDPL Reliability Upgrade project would be evaluated in more detail in a separate, project-level EIR. SFPUC Construction Measure #3, which requires preparation of a dust control plan and implementation of several dust control measures, would reduce these potentially significant impacts. However, the BAAQMD considers construction-related emissions from all projects in this region to be mitigated to a less-than-significant level if BAAQMD-recommended dust and equipment exhaust emission controls (outlined in Measures 4.9-1c and 4.9-1d) are implemented. Therefore, it is expected that implementation of SFPUC Construction Measure #3 for air quality in addition to applicable BAAQMD dust and exhaust control measures (Measures 4.9-1c and 4.9-1d) would reduce potential air quality impacts to a less-than-significant level.

Peninsula Region

Impact 4.9-1: Construction emissions of criteria pollutants		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS

Construction activities associated with all projects in the Peninsula Region would result in short-term increases in suspended particulates and other criteria pollutants.

Table 4.9-5 shows the estimated average daily earthmoving quantities and correlating fugitive PM_{10} and equipment exhaust emissions that could occur on any given day within the Peninsula Region. Construction activities associated with WSIP projects in this region as well as emissions associated with haul truck traffic would contribute air pollutant emissions (including DPM; see Impact 4.9-2). SFPUC Construction Measure #3, which requires preparation of a dust control plan and implementation of several dust control measures, would reduce emission of criteria pollutants. These estimates indicate the BAAQMD's operational thresholds for ROG, NO_X, PM_{10}, and CO would not likely be exceeded in this region, and impacts would therefore be *less than significant*. However, it should be noted that construction of these five projects would add to the WSIP's combined or collective emissions contributions to the SFBAAB (see Section 4.16, Collective WSIP Impacts, for more discussion).

San Francisco Region

Impact 4.9-1: Construction emissions of criteria pollutants		
SAPL 3 Installation	SF-1	LS
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	LS

Construction activities associated with all projects in the San Francisco Region would result in short-term increases in suspended particulates and other criteria pollutants.

Table 4.9-5 shows the estimated average daily earthmoving quantities and correlating fugitive PM_{10} and equipment exhaust emissions that could occur on any given day within the San Francisco Region. Most of the estimated construction-related air pollutant emissions in this region are attributable to simultaneous construction of the SAPL 3 Installation (SF-1) and Recycled Water Projects (SF-3). Construction activities associated with the Groundwater Projects (SF-2) as well as emissions associated with haul truck traffic (see Impact 4.9-2) would contribute additional air pollutant emissions. SFPUC Construction Measure #3, which requires preparation of a dust control plan and implementation of several dust control measures, would reduce emission of criteria pollutants. These estimates indicate the BAAQMD's operational thresholds for ROG, NO_x, PM_{10}, and CO would not likely be exceeded in this region, and impacts would therefore be *less than significant*. However, it should be noted that construction of these three projects would add to the WSIP's combined or collective emissions contributions to the SFBAAB (see Section 4.16, Collective WSIP Impacts, for more discussion).

Impact 4.9-2: Exposure to diesel particulate matter (DPM) during construction.

Combustion emissions from construction equipment and vehicles (i.e., heavy equipment and delivery/haul trucks, worker commute vehicles, air compressors, and generators) would be generated during project construction. Onsite construction emissions are evaluated above under Impact 4.9-1. Offsite emissions would include those generated by worker vehicles as well as by diesel haul/delivery trucks used during construction, particularly trucks used to transport excavated materials from WSIP facility sites. Emissions from construction worker commute trips would be minor compared to the emissions generated by construction equipment and haul/delivery trucks. Construction emissions would result in an increase in $PM_{2.5}$ emissions in addition to PM_{10} and ozone precursors. $PM_{2.5}$ emissions of concern would be associated primarily with DPM, since particulates generated by excavation, grading, and other soil-disturbance activities are normally outside the $PM_{2.5}$-size range. Diesel exhaust particulates contain substances that are suspected carcinogens. Diesel exhaust contains both pulmonary irritants and hazardous compounds that could affect sensitive receptors such as young children, senior citizens, or those susceptible to chronic respiratory disease such as asthma, bronchitis, and emphysema.

In 2000, the CARB approved a comprehensive *Diesel Risk Reduction Plan* to reduce diesel emissions from both new and existing diesel-fueled engines. The plan focuses on reducing emissions from diesel-fueled engines (through new standards and retrofitting) and reducing the sulfur content of diesel fuel to enable the use of advanced DPM emission controls. The plan's goals are to achieve a 75 percent reduction in DPM by 2010 and an 85 percent reduction by 2020 (from the 2000 baseline). While many of the new regulations are source-based controls, in 2005 the CARB approved a regulatory measure (Section 2485 of the California Health and Safety Code) to reduce emissions of toxic and criteria pollutants by limiting the idling of new heavy-duty diesel vehicles. Idling limits are specified in Measure 4.9-1d, and WSIP projects would be required to comply with these requirements.

The SJVAPCD and BAAQMD do not have methodologies for estimating impacts from diesel exhaust or determining the significance of a project's contribution. However, a DPM air monitoring study was conducted during another water treatment facility construction project in the Bay Area (URS Corporation, 2004). This study found the average downwind exposure during the hauling of 41 loads of material (82 one-way trips) to be 1.44 micrograms per cubic meter ($\mu g/m^3$) of DPM. The upwind concentration was 0.92 $\mu g/m^3$. Therefore, 41 loads of material (82 trips) are estimated to increase the DPM exposure by 0.52 $\mu g/m^3$ over an eight-hour period. To convert this to a daily exposure, it would be approximately one-third of this value. The accumulated health risk to children and residents can be calculated as follows under a number of conservative assumptions:

RISK = (0.52 / 3) * 300 in a million * (loads/day / 41) * (days of hauling / 25,550 days in 70 years)

= DPM * Cancer Risk * daily hauling * lifetime fraction over which risk applies

A risk of 1 in a million is considered insignificant by the BAAQMD, while a risk of 10 in a million would be significant.[5] For purposes of this PEIR, a risk between 1 and 10 in a million is conservatively considered to be potentially significant. The number of loads that would cause these thresholds to be exceeded over the hauling lifetime would be as follows:

1 in a million – 20,000 loads (40,000 trips)

10 in a million – 200,000 loads (400,000 trips)

These estimates are based on very conservative assumptions, including the following:

- The receptor remains outside their home for eight hours per day for every day of hauling.
- The receptor location is downwind of and adjacent to the haul route.
- Emissions from the haul truck fleet remain at 2004 emission rates, and no cleaner, lower emission trucks are ever added to the fleet; this assumption results in very conservative estimates since DPM emission rates are estimated to decrease by nearly 50 percent between 2004 and 2012.

[5] The BAAQMD's Regulation 2, Rule 5, *New Source Review of Toxic Air Contaminants*, specifies that a cancer risk of 1 in a million or less over a 70-year-lifetime exposure period is an insignificant risk, and no further review of health-related impacts is required. If a project has a risk greater than 1 in a million, it must be further evaluated in order to determine acceptability. Factors that affect acceptability include the presence of controls on the rate of emissions, the location of the site in relation to residential areas and schools, and contaminant reductions in other media such as water. In general, projects with risks greater than 1 in a million, but less than 10 in a million, are approved if other determining factors are acceptable. Projects with risks greater than 10 in a million are generally not approved. Projects that are not approved may be reevaluated if emissions are reduced, thus reducing their risks.

Table 4.9-6 presents a range of truck trips for each WSIP project that could be associated with the hauling of excavated spoils to offsite locations for reuse or disposal. Development of the above hauling thresholds serves as a basis for this program-level analysis, and also provides guidance for a project-level assessment of impacts related to truck hauling. These thresholds clearly include a high degree of conservatism (large margin of safety). Nevertheless, there could be unique, site-specific project features (e.g., proximity to sensitive receptor(s), a combination of onsite equipment emissions and haul trucks, or high levels of other air toxics creating cumulative exposure issues) that would prompt the need for a project-level health risk assessment, even if the above thresholds were not exceeded.

TABLE 4.9-6
OFFSITE DIESEL PARTICULATE MATTER EMISSIONS

Project Number	Project Name	Excavation/ Spoils Volume (cubic yards)	Total Truck Trips (if 80% Hauled Offsite)	Exceeds 10 in a Million Threshold?	Total Truck Trips (if 50% Hauled Offsite)	Exceeds 10 in a Million Threshold?

	Total Truck Trips for Peninsula Region		4,700+	No	2,900+	No
San Francisco Region						
SF-1	San Andreas Pipeline No. 3 Installation	44,170 cy	5,889	No	3,681	No
SF-2	Groundwater Projects – Local & Regional	TBD	TBD	TBD	TBD	TBD
SF-3	Recycled Water Projects	47,200 cy	6,293	No	3,933	No
	Total Truck Trips for San Francisco Region		12,183+	No	7,614+	No

NOTE: Estimated truck trips assume each haul truck would accommodate 12 cubic yards, and 50 to 80 percent of excavation spoils would be hauled offsite for reuse or disposal. See Sections 4.16 and 4.17 for discussion of collective and cumulative DPM impacts associated with total truck trips and overlapping impacts in each region.

Air pollution studies indicate a high correlation between traffic emissions and health impacts within 1,000 feet, with the strongest association within 300 to 500 feet. Studies also show that concentrations of traffic emissions decline with distance from the road, with a dramatic decrease in the first 300 to 500 feet (up to a 70 percent decrease in one study). Based on these studies, the CARB and BAAQMD recommend that new sensitive land uses not be located within 500 feet of freeways, urban roads carrying 100,000 vehicles/day, or rural roads carrying 50,000vehicles/day (Cal-EPA and CARB, 2005). Therefore, if sensitive receptors are located more than 500 feet from a haul route, potential health effects associated with elevated DPM are considered less than significant.

San Joaquin Region

Impact 4.9-2: Exposure to DPM during construction		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	N/A
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	LS
Tesla Portal Disinfection	SJ-5	LS

Within the San Joaquin Region, access to most of the WSIP facility sites would be provided by rural roadways, highways, or freeways. As shown in Table 4.9-6, total DPM emissions generated by haul truck traffic associated with the SJPL System project (SJ-3) as a whole would be potentially significant, since the total truck trips for the whole project indicate excess cancer risk would be greater than 1 in a million but less than 10 in a million. However, health risks associated with DPM exposure would be *less than significant*, because haul trucks would use different haul routes along the pipeline alignment and only a portion of the total number of truck trips listed in Table 4.9-6 would occur along the same route. Since DPM emissions would be dispersed along the pipeline alignment (approximately one-third along the eastern pipeline segment and two-thirds on the western pipeline segment), it is expected that the excess cancer risk at any specific receptor would be less than 1 in a million (i.e., less than 40,000 truck trips would occur over the entire construction period at a specific receptor).

The SJPL Rehabilitation project (SJ-4) would not generate significant DPM levels along haul routes since disposal of excavation spoils is not expected to be required. Potential DPM emissions associated with the Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) projects are expected to be *less than significant* due to the limited surface disturbance associated with these projects (approximately two acres of surface disturbance is expected at each site).

The Lawrence Livermore project (SJ-2) would be located near Thomas Shaft, and there are no residential uses or other sensitive receptors in the area. Therefore, this impact would *not apply* to this project.

Sunol Valley Region

Impact 4.9-2: Exposure to DPM during construction		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	PSM
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	LS
Treated Water Reservoirs	SV-5	PSM
SABUP	SV-6	LS

As indicated in Table 4.9-6, DPM emissions generated by haul truck traffic would be *less than significant* (excess cancer risk would be less than 1 in a million) for all WSIP projects in this region,[6] except for the Calaveras Dam project (SV-2) and possibly for the Treated Water Reservoirs project (SV-5). Since most of the excavation spoils associated with the Calaveras Dam project would be hauled to disposal sites in the dam vicinity or the Sunol Valley, all haul truck trips would not necessarily use the entire length of Calaveras Road in the Sunol Valley. If 50 percent of the spoils were hauled offsite via the lower section of Calaveras Road, DPM emissions would remain below the significant "10 in a million" threshold but would exceed the potentially significant "1 in a million" threshold. If 80 percent of the excavation spoils were hauled offsite under the Treated Water Reservoirs project, the excess cancer risk would exceed the potentially significant "1 in a million" threshold.

DPM emissions from haul trucks would be considered *potentially significant* for the Calaveras Dam (SV-2) and Treated Water Reservoirs (SV-5) projects. However, these DPM emissions must also be evaluated at the project level to determine whether sensitive receptors could be affected by increased DPM emissions. The primary haul route for all projects in this region would be Calaveras Road in the Sunol Valley. There is one residential receptor located approximately 2,000 feet west of Calaveras Road; at this distance, potential health risks associated with DPM would be less than significant. However, there are two SFPUC Land Managers' residences, one near Calaveras Dam and the other near Alameda East Portal. Occupants of these residences could include children or the elderly, which are considered sensitive receptors. Therefore, DPM impacts from the individual and combined truck traffic associated with the Calaveras Dam and Treated Water Reservoirs projects would be *potentially significant* at these two residences. A health risk assessment would need to be completed or the residences vacated during construction of these two projects (Measure 4.9-2b) to reduce this impact to a less-than-significant level.

Bay Division Region

Impact 4.9-2: Exposure to DPM during construction		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	LS
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	LS

Since the majority of this region is urbanized and many of the WSIP projects are located in or near residential neighborhoods and schools, there is a high potential for sensitive receptors to be exposed to increased DPM levels from truck traffic on haul routes associated with all three WSIP projects in this region. As indicated

6 Although an excavation/spoils volume is not specified for the Alameda Creek Fishery project, the size of this project would indicate preliminary that DPM emissions generated by haul truck traffic would not likely exceed cancer risk of 1 in a million.

in Table 4.9-6, DPM emissions generated by haul truck traffic would be *less than significant* (excess cancer risk would be less than 1 in a million) for the BDPL 3 and 4 Crossovers (BD-2) and BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) projects.

As indicated in Table 4.9-6, total DPM emissions generated by haul truck traffic associated with the pipeline and tunnel components of the BDPL Reliability Upgrade project (BD-1) would be potentially significant, since excess cancer risk would be greater than the "1 in a million" threshold but less than the "10 in a million" threshold. For the pipeline portion of this project, health risks associated with DPM exposure would be less than significant, because haul trucks would use different haul routes along the pipeline alignment and only a portion of the total number of truck trips listed in Table 4.9-6 would occur along the same route. However, truck traffic associated with the tunnel component would generate DPM emissions in the tunnel portal vicinities over the entire construction period, affecting the same sensitive receptors. Therefore, DPM emissions associated with the tunnel component of this project would be *potentially significant*, and use of soot filters on haul trucks (Measure 4.9-2a) could be required for this component (depending on the proportion of excavation spoils that would be hauled offsite) to reduce impacts to a less-than-significant level.

Peninsula Region

Impact 4.9-2: Exposure to DPM during construction		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS

Table 4.9-6 indicates that DPM emissions generated by haul truck traffic would be *less than significant* (excess cancer risk would be less than 1 in a million) for the CS/SA Transmission (PN-2) and Lower Crystal Springs Dam (PN-4) projects. Although the volume of excavation spoils has not been determined for the other three projects in this region (Baden and San Pedro Valve Lots, PN-1; HTWTP Long-Term, PN-3; and Pulgas Balancing Reservoir, PN-5), potential DPM emissions associated with each of these projects are expected to be *less than significant* (excess cancer risk would be less than 1 in a million or 40,000 total truck trips) due to the limited surface disturbance generally associated with these types of facilities. In addition, the Pulgas Balancing Reservoir project would be located on the west side of Interstate 280 (I-280), so possible haul routes to the I-280 freeway for this project would be more than 500 feet from residential receptors to the east of the freeway.

San Francisco Region

Impact 4.9-2: Exposure to DPM during construction		
SAPL 3 Installation	SF-1	LS
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	LS

All of the WSIP projects in this region would be located near or adjacent to sensitive receptors, and DPM increases associated with haul and delivery truck traffic could adversely affect sensitive receptors along these routes. However, as indicated in Table 4.9-6, DPM emissions generated by haul truck traffic would be *less than significant* (excess cancer risk would be less than 1 in a million) for the SAPL 3 Installation (SF-1) and Recycled Water Projects (SF-3) projects, and it is expected that the volume of excavation spoils for the Groundwater Projects (SF-2) would not be greater than estimated volumes for SF-1 or SF-3.

Impact 4.9-3: Exposure to emissions (possibly including asbestos) from tunneling.

Methane and hydrogen sulfide gases could be encountered during proposed tunneling. These gases are generated during the decomposition of organic material. Because methane is odorless, it is not expected to generate nuisance odor problems. However, if hydrogen sulfide gas is encountered, it could cause nuisance odor problems at nearby receptors. Diesel exhaust would be generated by tunnel boring equipment and the muck removal system (if muck trains are used), and diesel exhaust odors would be released into the atmosphere through the tunnel ventilation system. The potential for exposure of any nearby sensitive receptors would depend on the proximity of receptors to tunnel shafts or portals and their ventilation exhaust systems. If gases were present, Occupational Health and Safety Administration standards would require the tunnel ventilation system to reduce gas levels within the tunnel to protect workers. Residential receptors would be exposed to even lower levels of these gases, since dispersion into the atmosphere would reduce levels in the tunnel by more than tenfold, ensuring that residential exposure would be well below exposure within the tunnel. Therefore, impacts related to the exposure of nearby residential receptors to tunnel gases is expected to be less than significant.

If ultramafic rock deposits are encountered during tunneling, there would be a potential for asbestos (chrysotile) emissions from the tunnel ventilation system. If tunnel ventilation systems are required in jack-and-bore pits used in pipeline crossings (where pipelines cross under freeways, major roadways, railroads, waterways) and ultramafic rock occurs along this pipeline segment, there also would be a potential for asbestos (chrysotile) emissions from the ventilation system. Geologic mapping indicates a low potential for encountering such rock along various WSIP facility alignments (see Section 4.14, Hazards, Impact 4.14-2 for more discussion). Wherever demolition is proposed as part of WSIP implementation, asbestos could be released if any asbestos-containing building materials are present. Airborne asbestos fibers could pose a serious health threat if adequate control techniques are not carried out when the material is disturbed (see Section 4.14, Impact 4.14-5 for more discussion of this potential impact).

San Joaquin Region

Impact 4.9-3: Exposure to emissions (possibly including asbestos) from tunneling		
Advanced Disinfection	SJ-1	N/A
Lawrence Livermore	SJ-2	N/A
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	N/A

The Advanced Disinfection (SJ-1), Lawrence Livermore (SJ-2), and Tesla Portal Disinfection (SJ-5) projects would not involve any tunneling or jack-and-bore construction techniques. Therefore, this impact is *not applicable* to these projects.

Construction of the SJPL System project (SJ-3) would employ jack-and-bore or microtunneling techniques where the pipeline would cross under major facilities such as freeways and aqueducts, and potentially where the pipeline would cross wetlands. Pipeline rehabilitation work under the SJPL Rehabilitation project (SJ-4) could also require the use of jack-and-bore or microtunneling techniques. If a tunnel ventilation exhaust system is required in jack-and-bore pits and is located near any residential receptors, they could be exposed to nuisance odors associated with tunnel gases or diesel exhaust. Although impacts related to health risk would be less than significant (as described above), nuisance odors (if they occur) would be *potentially significant*, but could be mitigated to a less-than-significant level through the use of water scrubbers on the tunnel ventilation system (Measure 4.9-3). No other tunneling activities would occur under the WSIP projects in this region.

Sunol Valley Region

Impact 4.9-3: Exposure to emissions (possibly including asbestos) from tunneling		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	N/A
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	N/A
SABUP	SV-6	LS

The Calaveras Dam (SV-2) and Treated Water Reservoirs (SV-5) would not involve any tunneling or jack-and-bore construction techniques. Therefore, this impact is *not applicable* to these projects.

Construction of the New Irvington Tunnel project (SV-4) would require the use of a tunnel ventilation exhaust system at both tunnel portals in the Sunol Valley and Fremont. The Alameda Creek Fishery (SV-1), 40-mgd Treated Water (SV-3), and SABUP (SV-6) projects could require jack-and-bore techniques where any pipelines cross creeks or roads. In the Sunol Valley, there is one residential receptor (located west of Alameda Creek and south of the Alameda West Portal). Impacts related to health risk would be less than significant (as described above) for this receptor; it is also unlikely that tunnel-related nuisance odors associated with jack-and-bore crossings related to any of these projects would affect this receptor since there would be adequate area to provide sufficient setbacks, so this impact would be *less than significant*. However, nuisance odors associated with the New Irvington Tunnel project (if they occur) could affect this receptor. If they occur, nuisance odors would be *potentially significant*, but could be mitigated to a less-than-significant level through implementation of tunnel gas odor control measures (Measure 4.9-3). No other tunneling activities would occur under the WSIP projects in this region.

Bay Division Region

Impact 4.9-3: Exposure to emissions (possibly including asbestos) from tunneling		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	N/A
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSM

Construction of the BDPL Reliability Upgrade project (BD-1) would require use of a tunnel ventilation exhaust system at both tunnel shafts in Newark and east of East Palo Alto. Tunnel ventilation systems could also be required for the BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3), wherever jack-and-bore or microtunneling techniques are employed for major roadway and creek crossings. Residential receptors located near or adjacent to these facilities could be exposed to nuisance odors associated with tunnel gases or diesel exhaust. Impacts related to health risk would be less than significant (as described above), and nuisance odors associated with these two projects (if they occur) would be *potentially significant*, but could be mitigated to a less-than-significant level through implementation of tunnel gas odor control measures (Measure 4.9-3).

No tunneling activities would occur under the BDPL 3 and 4 Crossovers (BD-2) project, so this impact is *not applicable*.

Peninsula Region

Impact 4.9-3: Exposure to emissions (possibly including asbestos) from tunneling		
Baden and San Pedro Valve Lots	PN-1	N/A
CS/SA Transmission	PN-2	PSM
HTWTP Long-Term	PN-3	N/A
Lower Crystal Springs Dam	PN-4	N/A
Pulgas Balancing Reservoir	PN-5	N/A

Except for the CS/SA Transmission project (PN-2), no tunneling activities would occur under any other WSIP projects in this region, so this impact is *not applicable* to these projects. If jack-and-bore or microtunneling techniques are used where only pipeline facilities associated with the CS/SA Transmission project cross roadways or waterways and they are located near any sensitive receptors, they could be exposed to nuisance odors associated with tunnel gases or diesel exhaust. Implementation of gas odor control measures (Measure 4.9-3) as necessary would reduce nuisance odor impacts to a less-than-significant level.

San Francisco Region

Impact 4.9-3: Exposure to emissions (possibly including asbestos) from tunneling		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	PSM
Recycled Water Projects	SF-3	PSM

Pipeline construction under the SAPL 3 Installation project (SF-1) would employ jack-and-bore or microtunneling techniques where pipelines cross under major roadways or creeks. If a tunnel ventilation exhaust system is required in jack-and-bore pits and is located near any sensitive receptors, they could be exposed to nuisance odors associated with tunnel gases or diesel exhaust. In addition, it is possible that pipelines proposed under the Groundwater Projects (SF-2) and Recycled Water Projects (SF-3) could require the use of jack-and-bore construction. Impacts related to health risk would be less than significant (as described above), and nuisance odors (if they occur) would be *potentially significant,* but could be mitigated to a less-than-significant level through implementation of tunnel gas odor control measures (Measure 4.9-3).

Operational Impacts

Facility Emissions

Impact 4.9-4: Air pollutant emissions during project operation.

Long-term operation of the WSIP facilities would result in minimal increases in air emissions, including criteria pollutants. Most of the power provided to WSIP projects by the SFPUC would be hydroelectric power. Since all proposed facilities would be connected to grid power, emission sources during project operations would be limited to emergency generators, use of refrigerants, and minor increases in traffic due to project operation and maintenance. Operation of emergency generators at WSIP facilities would result in an incremental short-term increase in criteria air pollutants, but only infrequently during power outages and when equipment is tested.

San Joaquin Region

Impact 4.9-4: Air pollutant emissions during project operation		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	LS
Tesla Portal Disinfection	SJ-5	LS

Proposed treatment and pipeline facilities in this region would be enclosed, and the potential for increases in criteria pollutants during project operations would be *less than significant*. Three of the WSIP facilities in this region (Advanced Disinfection, SJ-1; Lawrence Livermore, SJ-2; and Tesla Portal Disinfection, SJ-5) would be unmanned facilities (continuously monitored by the SCADA System), but would require a daily visit to the site by an operations representative. The SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects would require occasional visits by operations representatives during flow rate changes, and associated air pollutant emissions would be *less than significant*.

Sunol Valley Region

Impact 4.9-4: Air pollutant emissions during project operation		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	LS
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	N/A

Except for WSIP facilities at the Sunol Valley WTP, operation of all proposed WSIP facilities in this region (associated with Alameda Creek Fishery, SV-1; Calaveras Dam, SV-2; 40-mgd Treated Water, SV-3; New Irvington Tunnel, SV-4; and Treated Water Reservoirs, SV-5) would use grid power; therefore, potential increases in criteria pollutants during project operations would be *less than significant.* No system changes would occur under the SABUP project, so potential changes in emissions during project operation would *not apply* to this project.

Operation of proposed facilities in this region would generate minor increases in maintenance-related and chemical delivery traffic; however, such minor increases in traffic would result in *less-than-significant* increases in criteria air pollutant emissions.

Bay Division Region

Impact 4.9-4: Air pollutant emissions during project operation		
BDPL Reliability Upgrade	BD-1	LS
BDPL 3 and 4 Crossovers	BD-2	LS
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	N/A

Proposed WSIP facilities in this region under the BDPL Reliability Upgrade (BD-1) and BDPL 3 and 4 Crossovers (BD-2) projects would use grid power as necessary, so potential increases in criteria pollutants during project operations would be *less than significant.* However, propane-powered emergency generators would be used to power actuators at isolation valves along the BDPL Reliability Upgrade pipeline alignment in the event that valves need to be operated during a power failure (e.g., after a major earthquake event). As stationary point sources, the emergency generators proposed under this project would require authority to construct permits and permits to operate from the BAAQMD. The permit review process would ensure that air emissions associated with these generators comply with applicable air quality standards; therefore, potential increases in criteria pollutants during project operations would be *less than significant*.

Since the overall increase in maintenance-related traffic at proposed WSIP facilities would be minimal, WSIP-related increases in criteria air pollutant emissions in this region would be *less than significant*.

The BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) would not result in criteria air pollutant emissions because this project involves construction of enclosed pipelines; therefore, this impact is *not applicable*.

Peninsula Region

Impact 4.9-4: Air pollutant emissions during project operation		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS

Proposed WSIP facilities in this region (Baden and San Pedro Valve Lots, PN-1; CS/SA Transmission, PN-2; HTWTP Long-Term, PN-3; Lower Crystal Springs Dam, PN-4; and Pulgas Balancing Reservoir, PN-5) would use grid power as necessary and thus would not directly emit criteria air pollutants. During power outages, short-term increases in criteria pollutants would result from existing diesel-powered emergency generators at the Harry Tracy WTP (PN-3). The CS/SA Transmission project (PN-2) would also include use of an existing emergency generator in the event of a power outage. As stationary point sources, the existing emergency generators at the Harry Tracy WTP (under PN-3) and Crystal Springs Pump Station (under PN-2) already have permits to operate from the BAAQMD, and these permits would ensure that air emissions associated with these generators are *less than significant*.

Since the overall increase in maintenance-related traffic at proposed WSIP facilities in this region would be minimal, WSIP-related increases in criteria air pollutant emissions in this region would be *less than significant*.

San Francisco Region

Impact 4.9-4: Air pollutant emissions during project operation		
SAPL 3 Installation	SF-1	LS
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	LS

Proposed WSIP storage, pipeline, and well facilities in this region (SAPL 3 Installation, SF-1; Groundwater Projects, SF-2; and Recycled Water Projects, SF-3) would use grid power as necessary and thus would not directly emit criteria air pollutants. During power outages, short-term increases in criteria pollutants would result from operation of an emergency generator at the Recycled Water treatment facility (SF-3). As a stationary point source, this generator would require an authority to construct permit and permit to operate from the BAAQMD. The permit review process would ensure that air emissions associated with this facility comply with applicable air quality standards; therefore, potential increases in criteria pollutants during project operations would be *less than significant.*

Since the overall increase in maintenance-related traffic at proposed WSIP facilities in this region would be minimal, WSIP-related increases in criteria air pollutant emissions in this region would be *less than significant*.

Odors

Impact 4.9-5: Odors generated during project operation.

Nuisance odor problems are not expected to result from operation of WSIP facilities due to the low biological content (and consequent anaerobic activity) of the water as well as the enclosed nature of most proposed facilities. With the exception of filters and some basins at water treatment facilities, existing treatment, conveyance, and storage facilities are enclosed.

Filters at water treatment facilities are not typically a source of odors; odors associated with anaerobic activity do not occur since the water is aerated. However, open basins associated with backwash water processing can sometimes be sources of odor. Odors can derive from organic material suspended in the water, from outgassing of dissolved gases used for disinfection, or from sludge that has been removed from the water during treatment.

Two BAAQMD regulations prohibit the creation of an odor nuisance. Rule 1-301 prohibits the discharge of any contaminants that causes annoyance for a considerable number of people of normal sensitivity. Regulation 7 specifies odor limits for public exposure and identifies specific dilution levels that must be achieved as a function of odor emission strength. If odors were generated during the operation of any WSIP facility, enforcement of these regulations would be adequate to protect the public from impacts related to odorous emissions.

San Joaquin Region

Impact 4.9-5: Odors generated during project operation		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	N/A
SJPL Rehabilitation	SJ-4	N/A
Tesla Portal Disinfection	SJ-5	LS

Proposed WSIP treatment facilities in this region (Advanced Disinfection, SJ-1; Lawrence Livermore, SJ-2; and Tesla Portal Disinfection, SJ-5) would be enclosed, and the odor potential would be *less than significant*. Enclosed pipelines, such as those under the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects, are not a source of odors, and this impact is *not applicable*.

Sunol Valley Region

Impact 4.9-5: Odors generated during project operation		
Alameda Creek Fishery	SV-1	N/A
Calaveras Dam	SV-2	N/A
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	N/A
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	N/A

Except for WSIP facilities at the Sunol Valley WTP, all proposed WSIP facilities in this region would have a low potential for odor generation. These projects involve storage (Calaveras Dam, SV-2) or transmission facilities (Alameda Creek Fishery, SV-1; New Irvington Tunnel, SV-4; and SABUP, SV-6), which are not typically associated with odor generation (due to the low biological content of the water or the enclosed nature of the facility). Therefore, this impact is *not applicable* to these projects.

Proposed backwash system improvements at the Sunol Valley WTP (40-mgd Treated Water, SV-3, and Treated Water Reservoirs, SV-5) could be a source of odor, depending on the design of these facilities. However, if any odors were generated by the backwash system, they would have a *less-than-significant* impact given the absence of nearby sensitive receptors (the closest and only receptor is a residence located 1.6 miles to the north).

Bay Division Region

Impact 4.9-5: Odors generated during project operation		
BDPL Reliability Upgrade	BD-1	N/A
BDPL 3 and 4 Crossovers	BD-2	N/A
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	N/A

Proposed WSIP facilities in this region (BDPL Reliability Upgrade, BD-1; BDPL 3 and 4 Crossovers, BD-2; and BDPL 3 and 4 Seismic Upgrade at Hayward Fault, BD-3) would involve pipelines and valves and would be enclosed. Therefore, there is no odor potential in this region, and this impact is *not applicable* to these projects.

Peninsula Region

Impact 4.9-5: Odors generated during project operation		
Baden and San Pedro Valve Lots	PN-1	N/A
CS/SA Transmission	PN-2	N/A
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	N/A
Pulgas Balancing Reservoir	PN-5	N/A

Except at the Harry Tracy WTP, all proposed WSIP facilities in this region would have a low potential for odor generation. These projects involve valve upgrades (Baden and San Pedro Valve Lots, PN-1), pipelines/tunnels (CS/SA Transmission, PN-2), or storage upgrades (Lower Crystal Springs Dam, PN-4; Pulgas Balancing Reservoir, PN-5), which are not typically associated with odor generation (due to the low biological content of the water or the enclosed nature of the facility). This impact is *not applicable* to these projects.

The Harry Tracy WTP does not currently generate odors, but proposed sludge-handling facility improvements at the plant under the HTWTP Long-Term project (PN-3) could be a source of odor, depending on the design of these facilities. The odor potential of proposed facilities would be assessed as part of subsequent, project-level CEQA review when project design has been completed. With compliance with BAAQMD odor control regulations (Rule 1-301 and Regulation 7), this potential impact would be *less than significant*.

San Francisco Region

Impact 4.9-5: Odors generated during project operation		
SAPL 3 Installation	SF-1	LS
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	LS

Proposed WSIP storage, pipeline, and well facilities in this region (SAPL 3 Installation, SF-1; Groundwater Projects, SF-2; and Recycled Water Projects, SF-3) would be enclosed, and the odor potential would be *less than significant*. No odor problems are expected at proposed Recycled Water treatment facilities (SF-3) due to the low biological content of treated/recycled water. However, if the emergency generator at this treatment facility were diesel-powered, there would be a potential for short-term nuisance diesel odors at the adjacent San Francisco Zoo during a power outage. With compliance with BAAQMD odor control regulations (Rule 1-301 and Regulation 7), this potential impact would be *less than significant*.

Secondary Emissions from Increased Electricity Demand

Impact 4.9-6: Secondary emissions at power plants.

Operation of new and expanded WSIP facilities could result in secondary emissions associated with electricity generation. Electricity is supplied by SFPUC Power Enterprise, which operates 400 megawatts of hydroelectric power generation plants. Pacific Gas and Electric Company provides transmission and distribution services. Energy production varies by season and by year, depending on hydrologic conditions. SFPUC Power Enterprise purchases power as necessary to ensure reliable electricity supply.

At present, SFPUC Power Enterprise is working with WSIP staff to identify energy efficiency in two areas: pumping energy optimization and efficient pump station design. Pumping energy optimization is aimed at designing pumping systems that reduce on-peak energy requirements for water pumping operations. With optimized pumping, pumping would shift to the off-peak and part-peak periods of each day to reduce on-peak energy consumption, while at the same time maintaining uninterrupted water delivery to end-users. This measure is projected to reduce on-peak electricity demand by 6 megawatts. Efficient pump station design focuses on incorporating efficient motors, pumps, lighting, and ventilation systems. SFPUC Power Enterprise is developing energy efficiency design guidelines to be used by WSIP staff in designing energy-efficient buildings and pump stations. Energy savings resulting from this measure are determined based on these guidelines.

All Regions

Operation of WSIP facilities proposed in all five regions would increase demand for electricity. Power is generated primarily from hydroelectric sources, although purchased power is derived from a variety of sources (hydroelectric, alternative energy, and fossil fuels). With respect to purchased power, power generation is regional in nature and could occur outside the air basin or outside California; therefore, the WSIP's incremental increase in power demand during project operations (the portion that is not from hydroelectric or alternative energy sources) is not expected to create a significant secondary air quality impact on criteria air pollutant levels specifically within the SJVAB or SFBAAB, a *less-than-significant* impact for each WSIP facility project.

Regional Air Quality Plans and Goals

Impact 4.9-7: Conflict with implementation of applicable regional air quality plans addressing criteria air pollutants and state goals for reducing GHG emissions.

Air quality planning is accomplished through regional air quality plans that address measures to reduce criteria air pollutants. Air quality planning efforts by the SJAPCD and BAAQMD would pertain to construction and operation of the WSIP. Potential increases in criteria air pollutants during construction and operation of the WSIP are quantified and consistency with state and federal standards for criteria pollutants are evaluated under Impacts 4.9-1 and 4.9-2. While construction-related emissions were determined to be potentially significant in some regions when compared to air district thresholds of significance, criteria pollutant emissions associated with operation of the WSIP were determined to be less than significant. Consistency of the WSIP with regional air quality planning efforts is discussed below by region.

State planning efforts to reduce GHG emissions (pursuant to the California Global Warming Solutions Act of 2006) would also pertain to construction and operation of the WSIP, as discussed below.

GHG Emissions During Project Construction. The WSIP's incremental increases in GHG emissions associated with construction-related traffic and off-road construction equipment would contribute to regional increases in GHG emissions and associated climate change effects (see Table 4.9-5 for GHG emission estimates by region). However, no state or regional air quality agency has adopted a methodology or quantitative threshold that can be applied to a specific development or construction project to evaluate the significance of an individual project's contribution to GHG emissions, such as the ones that exist for priority pollutants. Therefore, this analysis considers the quantity of GHGs that would be emitted with WSIP implementation in relation to the total GHG emissions in the Bay Area and the state. It also considers steps that the State intends to take to reduce GHG emissions and the actions that the CCSF and SFPUC are actively taking steps to reduce GHG emissions, such that implementation of the WSIP would not conflict with the State's goals of reducing GHG emissions to 1990 levels by 2020.

The *Bay Area Greenhouse Gas Emission Inventory Projections* (BAAQMD, 2006a) indicates that construction and mining equipment emissions currently account for approximately 4 percent of total mobile-source emissions and will continue to account for about the same proportion into the future (projected to 2016). The WSIP's combined GHG emissions from simultaneous construction projects in the San Joaquin Valley and the Bay Area Air Basins identified above would generate approximately 79,260 pounds of CO_2-equivalent GHG each work day during the construction period. For an assumed 260 work days per year, this translates into approximately 9,400 metric tons per year. The current statewide annual GHG inventory is estimated at 427,000,000 metric tons (California Energy Commission, 2006). Peak project construction activities would represent 0.0022 percent of the statewide total during the time these peak construction activities are carried out. This amount reflects peak GHG emissions from all of the WSIP projects; it is evident that GHG emissions from individual project would be extremely small.

Existing CARB regulations (Title 13 of the California Code of Regulations, Sections 2480 and 2485), which limit idling of diesel-fueled commercial motor vehicles, would help to limit GHG emissions associated with WSIP-related construction vehicles. In addition, CARB's proposed Early Action Measures (pursuant to the California Global Warming Solutions Act of 2006) include other emission reduction measures for diesel trucks and diesel off-road equipment. The CARB will review and adopt Early Action Measures by January 1, 2010, and equipment used for construction of WSIP facility improvement projects after 2010 could be subject to these requirements. Once such measures go into effect, SFPUC and construction contractors on SFPUC projects would be subject to these requirements, and the SFPUC will implement these measures are required; emissions from SFPUC construction activities would be reduced accordingly. Given the small amount of GHGs that would be emitted from individual WSIP projects during construction, continuing implementation of GHG reduction actions by the CCSF and SFPUC and additional GHG reductions actions that SFPUC would implement as part of the WSIP (see above under “Existing Setting”), the WSIP projects would not conflict with the State’s goals of reducing GHG emissions to 1990 levels by 2020.

As stated above, as part of implementation of the WSIP, the SFPUC will also be required to implement mitigation measures related to exhaust controls (Measures 4.9-1b, 4.9-1d and 4.16-7a) to address criteria pollutant emissions, waste reduction (Measure 4.11-2) to address solid waste disposal, and energy efficiency (Measure 4.15-2) to address energy use, which would further reduce GHG emissions from SFPUC construction activities.

GHG Emissions During Project Operation. Operation of WSIP facilities could result in a minor increase in the use of refrigerants and number of employee trips and chemical deliveries to facility sites and these actions could result in a minor increase in GHG emissions over current levels. These new activities and sources of GHGs would be minimal, however, because most of the WSIP facility projects involve improvements to existing operations and not entirely new operations. No state or regional air quality agency has adopted a methodology or quantitative threshold that can be applied to evaluate the significance of an individual project’s contribution to GHG emissions, such as the ones that exist for priority pollutants. The increase in GHG emissions at individual WSIP facilities during long-term operation occasioned by a small increase in vehicle trips would be a fraction of the statewide total inventory, and well below the estimated 0.0022 percent represented by construction emissions. Therefore, it is expected that increased GHG emissions from each WSIP facility operation would generally be minimal in nature.

The CARB will review and adopt Early Action Measures (pursuant to the California Global Warming Solutions Act of 2006) by January 1, 2010, and equipment used during operation of WSIP facility improvement projects after 2010 would be subject to these requirements. For example, future WSIP-related truck or vehicle operation will be required to comply with any future emissions reduction measures adopted by CARB as part of the California Global Warming Solutions Act of 2006, which would reduce the WSIP’s contribution to GHG emissions. As CARB’s Early Action Measures become effective, the SFPUC will implement them as required to reduce GHG emissions from the WSIP project operations. It is also expected that actions that the CCSF and SFPUC are taking to reduce GHG emissions may reduce GHG emissions associated with SFPUC operations and offset the minimal increases in GHG emissions associated with new operations.

Given the minimal increase in the amount of GHGs that could be emitted from the operation of individual WSIP projects, continuing implementation of GHG reduction actions by the CCSF and SFPUC, and additional GHG reductions actions that SFPUC will take as part of the WSIP project (see above under “Existing Setting”), the WSIP projects would not conflict with the State’s goals of reducing GHG emissions to 1990 levels by 2020.

As stated above, as part of implementation of the WSIP, the SFPUC will also be required to implement mitigation measures related to energy efficiency (Measure 4.15-2) to address energy use, which would further reduce GHG emissions from operation of WSIP facilities.

Secondary GHG Emissions at Power Plants. Implementation of the WSIP would also result in secondary operational increases in GHG emissions as a result of electricity generated to meet the WSIP's increase in energy demand. Although electricity for the WSIP projects would be derived primarily from hydroelectric sources, power would need to be purchased from the grid or other sources by customers of the SFPUC Power Enterprise from a variety of nonrenewable sources when less hydroelectric power is available, particularly during the summer and fall months. Electricity in the Bay Area occurs mainly at natural-gas-fired power plants, which produce about 7 percent of total GHG emissions in the Bay Area (BAAQMD, 2006a). However, since California imports about 20 to 30 percent of its total electricity (mainly from the northwestern and southwestern states), GHG emissions associated with electricity generation also occur outside the SJVAB or SFBAAB or outside of California. Therefore, the WSIP's incremental increase in power demand during project operations (the portion that is not from hydroelectric or renewable energy sources) would indirectly serve to sustain rather than reduce current GHG emissions from these emission sources.

The additional annual energy demand for all proposed WSIP projects is estimated at 39,000 megawatt-hours (MWH; see Impact 4.16-13 in Section 4.16, Collective Impacts, for more discussion). Although there would be an overall increase in demand associated the WSIP implementation, it should be noted that many individual WSIP projects would result in no increase in energy demand. The hydroelectric generating capacity of the SFPUC Power Enterprise is approximately 400 MW. The total increase in energy demand for all of the proposed WSIP projects would be met in approximately 98 hours of hydroelectric generation annually at full capacity. Except in the summer and fall when water is being stored and not being replenished, WSIP projects would be more than adequately supplied by the system. However, the 39,000 MWH used by WSIP projects would no longer be available to provide GHG-free electricity to California users. The "lost" 39,000 MWH would be offset by increased generation from fossil-fueled resources and other sources, such as hydroelectric power generated by Modesto and Turlock Irrigation Districts.

Tables C.1 and C.2 of the California Climate Action Registry (CCAR) Protocol document (CCAR, 2007) show that California power plants create approximately 806 pounds of CO_2-equivalent GHG emissions per MWH of power generated. For simplicity, it was assumed that the WSIP-diverted power would be generated somewhere within California at the above GHG-generation rate. The WSIP projects at completion are estimated to result in approximately 14,260 metric tons of CO_2-equivalent emissions by consuming hydroelectric power that is no longer available to current users. Compared to the current annual inventory of 427,000,000 metric tons in California (California Energy Commission, 2006), this represents 0.0033 percent of that inventory. Planned increases in water distribution and treatment system efficiencies will offset a limited portion of the increased power demand, but not enough to eliminate the increase in GHG emissions that would result from WSIP-diverted electrical power. Nevertheless, the total increased power demand associated with the operation of the WSIP projects is a small fraction of total state demand.

As stated above, no state or regional air quality agency has adopted a methodology or quantitative threshold that can be applied to evaluate the significance of an individual project's contribution to GHG emissions, such as the ones that exist for priority pollutants. However, it is apparent from the above analysis that the indirect effect of increased GHG emissions from power generation associated with operation of all of the proposed WSIP facilities would be minimal. It is apparent that the individual facility impacts would be even less.

As the CARB's Early Action Measures and CEC's greenhouse gases emission performance standard for local, public-owned electric utilities become effective (see discussion under Regulatory Framework, Greenhouse Gas Emissions Limits), the SFPUC will implement them as required to reduce GHG emissions from the WSIP project operations. With continuing implementation of GHG reduction actions by the CCSF and SFPUC and additional GHG reductions actions that SFPUC will take as part of the WSIP project (see above under "Existing Setting"), the WSIP projects would not conflict with the State's goals of reducing GHG emissions to 1990 levels by 2020.

As part of implementation of the WSIP, the SFPUC will also be required to implement feasible energy efficiency measures in applicable WSIP projects to address energy impacts, consistent with the *Energy Action Plan II* priorities for reducing energy usage (as specified in Measure 4.15-2).

San Joaquin Region

Although the WSIP includes facility improvement projects located in the San Joaquin Valley, operation of the WSIP would not serve future growth in the San Joaquin Valley since it is outside the SFPUC service area. Projected growth assumptions in the SFPUC service area would not be relevant to regional air quality planning efforts in the San Joaquin Valley. Therefore, consistency with SJVAPCD air quality plans related to criteria pollutants would be not applicable to this project.

Given the small amount of GHGs that would be emitted from WSIP projects in this region during construction and operation, continuing implementation of GHG reduction actions by the CCSF and SFPUC and additional GHG reductions actions that SFPUC would implement as part of the WSIP (see above under "Existing Setting"), the WSIP projects in this region would not conflict with the State's goals of reducing GHG emissions to 1990 levels by 2020 (*less than significant*).

Sunol Valley, Bay Division, Peninsula, and San Francisco Regions

The WSIP would be consistent with the BAAQMD's *Bay Area 2005 Ozone Strategy* (BAOS) (BAAQMD, 2006b), the most recently adopted regional air quality plan that pertains to the WSIP.[7] The consistency of the WSIP with the BAOS was determined by comparing the WSIP's growth assumptions with BAOS growth assumptions, which are based on ABAG population projections. Since the population growth assumed in the WSIP demand projections is generally

[7] Although the WSIP includes projects located in the San Joaquin Valley, operation of the WSIP would serve future Bay Area growth, not growth in the San Joaquin Valley. Therefore, long-term operation of the WSIP would have no direct or indirect effects on air quality planning efforts in the San Joaquin Valley.

consistent[8] with the 2030 population projections for the SFPUC service area in ABAG's *Projections 2005*, the WSIP would also be consistent with the BAOS (see Chapter 7, Growth Inducement Potential and Indirect Effects of Growth, for more discussion on the comparison of WSIP growth assumptions with ABAG projections). Therefore, the WSIP would have a *less-than-significant* impact on regional air quality planning efforts related to criteria pollutants in the Bay Area.

Given the small amount of GHGs that would be emitted from WSIP projects in these regions during construction and operation, continuing implementation of GHG reduction actions by the CCSF and SFPUC and additional GHG reductions actions that SFPUC would implement as part of the WSIP (see above under "Existing Setting"), the WSIP projects in this region would not conflict with the State's goals of reducing GHG emissions to 1990 levels by 2020 (*less than significant*).

4.10 Noise and Vibration

4.10 Noise and Vibration

4.10.1 Noise Descriptors

dB, dBA

Sound is characterized by various parameters that describe the rate of oscillation of sound waves, the distance between successive troughs or crests, the speed of, and the pressure level or energy content of a given sound. The sound pressure level has become the most common descriptor used to characterize the loudness of an ambient sound, and the decibel (dB) scale is used to quantify sound intensity. Because sound can vary in intensity by over 1 million times within the range of human hearing, a logarithmic loudness scale is used to keep sound intensity numbers at a convenient and manageable level. Since the human ear is not equally sensitive to all sound frequencies within the entire spectrum, human response is factored into sound descriptions in a process called “A-weighting,” expressed as “dBA.” The dBA, or A-weighted decibel, refers to a scale of noise measurement that approximates the range of sensitivity of the human ear to sounds of different frequencies. On this scale, the normal range of human hearing extends from about 0 dBA to about 140 dBA. A 10-dBA increase in the level of a continuous noise represents a perceived doubling of loudness. The noise levels presented herein are expressed in terms of dBA, unless otherwise indicated. **Table 4.10-1** shows some representative noise sources and their corresponding noise levels in dBA.

Planning for acceptable noise exposure must take into account the types of activities and corresponding noise sensitivity in a specified location for a generalized land use type. Some general guidelines (U.S. EPA, 1974) are as follows: sleep disturbance can occur at levels above 35 dBA; interference with human speech begins at about 60 dBA; and hearing damage can result from prolonged exposure to noise levels in excess of 85 to 90 dBA.

Leq, CNEL, Ldn

Time variations in noise exposure are typically expressed in terms of a steady-state energy level (called Leq) that represents the acoustical energy of a given measurement. Leq (24) is the steady-state energy level measured over a 24-hour period. Because community receptors are more sensitive to unwanted noise intrusion during the evening and at night, state law requires that, for planning purposes, an artificial dBA increment be added to “quiet time” noise levels to form a 24-hour noise descriptor called the Community Noise Equivalent Level (CNEL). CNEL adds a 5-dBA “penalty” during the evening hours (7:00 p.m. to 10:00 p.m.) and a 10-dBA penalty during the night hours (10:00 p.m. to 7:00 a.m.). Another 24-hour noise descriptor, called the day-night noise level (Ldn), is similar to CNEL. While both add a 10-dBA penalty to all nighttime noise events between 10:00 p.m. and 7:00 a.m., Ldn does not add the evening 5-dBA penalty. In practice, Ldn and CNEL usually differ by less than 1 dBA at any given location for transportation noise sources.

TABLE 4.10-1
TYPICAL SOUND LEVELS MEASURED IN THE ENVIRONMENT

Examples of Common, Easily Recognized Sounds	Decibels (dBA)	Subjective Evaluations
Near Jet Engine	140	Deafening
Threshold of Pain	130	
Threshold of Feeling – Hard Rock Band	120	
Accelerating Motorcycle (at a few feet away)	110	
Loud Horn (at 10 feet away)	100	Very Loud
Noisy Urban Street	90	
Noisy Factory	85[a]	
School Cafeteria with Untreated Surfaces	80	Loud
Stenographic Room	70[b]	
Near Freeway Auto Traffic	60[b]	Moderate
Average Office	50[b]	
Soft Radio Music in Apartment	40	Faint
Average Residence Without Stereo Playing	30	
Average Whisper	20	Very Faint
Rustle of Leaves in Wind	10	
Human Breathing	5	
Threshold of Audibility	0	

[a] Continuous exposure above 85 dBA is likely to degrade the hearing of most people.
[b] Range of speech is 50 to 70 dBA.

SOURCE: U.S. Department of Housing and Urban Development, Office of Community Planning and Development, 1985.

Vibration

Vibrations caused by construction activities can be interpreted as energy transmitted in waves through the soil mass. These energy waves generally dissipate with distance from the vibration source (e.g., pile driving or sheetpile driving). Since energy is lost during the transfer of energy from one particle to another, vibration that is distant from a source is usually less perceptible than vibration closer to the source. However, actual human and structure response to different vibration levels is influenced by a combination of factors, including soil type, distance between source and receptor, duration, and the number of perceived events.

If great enough, the energy transmitted through the ground as vibration can result in structural damage. To assess the potential for structural damage associated with vibration, the vibratory ground motion in the vicinity of the affected structure is measured in terms of peak particle velocity (PPV) in the vertical and horizontal directions (vector sum), typically in units of inches per second (in/sec). A freight train passing at 100 feet can cause vibrations of 0.1 in/sec PPV, while a strong earthquake can produce vibrations in the range of 10 in/sec PPV. In general, cosmetic or threshold damage to residential buildings can occur at peak particle velocities over 0.5 in/sec. The term “threshold damage vibration” is defined as the highest vibration amplitude at which no cosmetic, minor, or major damage occurs, which includes “threshold cracks” or “hair-sized” cracks in room walls that occur at the lowest vibration amplitudes. Field data suggest a probability of 5 percent for cosmetic damage or threshold damage at 0.5 in/sec PPV, with the probability falling to 0 percent for vibration below 0.5 in/sec PPV (Wilson Ihrig & Associates, 2005).

An active family may produce strains in walls and ceilings that are comparable to those produced by blast vibration at 0.1 to 0.5 in/sec PPV. However, vibrations of 0.012 in/sec PPV can cause residential annoyance (Wilson Ihrig & Associates, 2005). Monitoring data for an unrelated tunnel/pipeline project in San Francisco indicated that the associated vibration was below the level of annoyance for most residents when vibration levels were maintained at 0.1 in/sec PPV or less (i.e., no complaints were received) (ESA, 1997).

Vibration thresholds vary depending on the nature of the vibration and frequency range. Controlled detonations do not generate structural damage if they produce vibrations of less than 0.5 in/sec PPV (measured at the residential building setback line at the ground surface). This level is consistent with the U.S. Bureau of Mines’ threshold cracking criteria of 0.5 in/sec PPV for low frequencies and 2.0 in/sec PPV for high frequencies. Continuous vibration caused by vibratory pile drivers, impact pile drivers, and large vibratory rollers/compactors can cause annoyance but do not cause structural damage if the continuous vibration is less than 0.2 in/sec PPV. This criterion is less than the controlled detonation vibration limit, reflecting the longer exposure time and the potential effect of structural resonances. Vibratory mechanical equipment may be operated over many minutes several times per day, and the associated response of structures can build up over several seconds due to resonance of the structure, especially during startup and shutdown of vibratory compactors. Impact pile driving, while impulsive in nature, involves repeated impacts of several hundred per day, much more than occurs for controlled detonations. Thus, the vibration limit for impact pile driving is the same as the threshold for continuous vibration (0.2 in/sec PPV) (Wilson Ihrig & Associates, 2005).

4.10.2 Setting

Existing Noise Environment and Sensitive Receptors

Human response to noise varies from individual to individual and depends on the ambient environment in which the noise is perceived. The same noise that would be highly intrusive to a sleeping person or in a quiet park might be barely perceptible at an athletic event or in the middle of a freeway at rush hour. Effects of noise at various levels can include interference with sleep, concentration, and communication; physiological and psychological stress; and hearing loss. Given these effects, some land uses are considered more sensitive to ambient noise levels than others. In general, residences and schools are among the uses considered to be the most sensitive to noise.

Certain land uses, such as residences, schools, childcare centers, churches, hospitals, and nursing homes, are considered to be sensitive receptors. The proximity of such receptors to WSIP facilities would vary with each project.

San Joaquin Region

The primary sources of noise in the vicinity of SFPUC facilities in the San Joaquin Region include traffic on state highways and major county roadways, railroad operations, airport operations, and farm equipment associated with agricultural activities. Noise levels in this region were measured to be in the range of 37 to 60 dBA (Ldn), with quieter areas located away from these noise sources (Stanislaus County, 1994).

Most of the areas adjacent to WSIP facilities in this region are undeveloped or are used for agriculture. The city of Modesto, located in the center of this region, has mainly residential, commercial, school, and park uses. There are also rural residential uses located south of Riverbank. In the western margin of this region (in the Tesla Portal vicinity), there is a private golf course (Tracy Golf and Country Club) and residential development. These residential areas as well as school uses in Modesto are considered sensitive noise receptors.

Sunol Valley Region

The southern portion of Sunol Valley and the area surrounding Calaveras Reservoir are mostly undeveloped, with a relatively quiet noise environment typical of rural areas. However, the northern portion of Sunol Valley is subject to higher noise levels due to traffic on regional roads as well as the presence of commercial nurseries and aggregate quarries. The primary sources of noise in Sunol Valley include traffic on I-680, Highway 84, and Calaveras Road, commercial nurseries along Calaveras Road, and aggregate quarries located south of I-680. Other minor sources of noise within this valley include the SFPUC's existing San Antonio Pump Station and Sunol Valley WTP. In general, noise levels exceed 75 dBA (CNEL) within approximately 200 feet of the I-680 freeway and 65 dBA (CNEL) within approximately 200 feet of Highway 84 (Alameda County, 1996).

There are no sensitive receptors in Sunol Valley, except for one residence located about a quarter mile southeast of the existing Alameda West Portal. In addition, there are rural residential uses scattered through the hills between Sunol Valley and Fremont. Residential uses on the east side of Mission Boulevard (Highway 238) are adjacent to the westernmost existing SFPUC facilities (Irvington Tunnel Portal) located in this region.

Bay Division Region

Most SFPUC facilities in the Bay Division Region are located in urbanized areas of the East Bay, South Bay, and Peninsula. The primary sources of noise in this region include traffic on freeways and local roads, aircraft, railroad operations, and stationary (industrial) sources. Major freeways that traverse this region include I-680, I-880, I-280, Highway 84 (Dumbarton Bridge), and Highway 101. There are major arterials located throughout this region. In general, noise levels adjacent to the freeways exceed 70 dBA (Ldn), while noise levels adjacent to major local roadways are generally between 60 and 70 dBA (Ldn) (City of Newark, 1992).

SFPUC facilities also cross the southern portion of San Francisco Bay and San Francisco National Wildlife Refuge. Some special-status species that use the refuge are considered to be noise-sensitive receptors during nesting or breeding season. Sensitive receptors near SFPUC facilities in this region include residential uses, schools, childcare centers, churches, and nursing homes.

Peninsula Region

The Peninsula Region spans the urbanized areas located between the Bay and I-280, but also includes the SFPUC Peninsula watershed, which is the area surrounding the Upper and Lower Crystal Springs Reservoirs and San Andreas Reservoirs. The watershed area is undeveloped, and ambient noise levels are relatively low. The primary sources of noise in this region include traffic on freeways and local roads, aircraft, railroad operations, and stationary (industrial) sources. Major freeways and highways that traverse this region include I-280, Highway 101, Highway 92, Highway 84 (Dumbarton Bridge/Woodside Road), Highway 35 (Skyline Boulevard), and Highway 82 (El Camino Real). There are major arterials throughout this region. The San Mateo County General Plan (San Mateo County, 1986) includes a Community Noise Map, which indicates noise levels exceed 60 dBA (CNEL) in areas adjacent to I-280, Highway 92, Highway 35 (Skyline Boulevard), and Edgewood Road. Sensitive receptors near existing SFPUC facilities in this region include residential uses, schools, churches, and hospitals.

San Francisco Region

Most SFPUC facilities in the San Francisco Region are located in urbanized areas of the west and south sides of the city. Proposed WSIP facilities are located as far north as Golden Gate Park, as far south as Lake Merced. The ambient noise environment within the city is dominated by traffic on freeways and local roads. A city-wide noise map prepared by the San Francisco Department of Public Health (2006) indicate that noise levels generally exceed 60 dBA (Ldn) in areas adjacent to or near major roadways such as I-280, Highway 101, Highway 1 (19th Avenue), and various arterial roadways extending through the city. While many areas in the northeastern part of the city are subject to noise levels over 60 dBA (Ldn), residential neighborhoods in the western and southern portions of the city (away from arterials and freeways) generally experience noise levels of less than 60 dBA (Ldn). Sensitive receptors near WSIP facilities in this region include residential uses, schools, and churches.

Of the proposed WSIP facilities south of San Francisco (in northern San Mateo County), there is one WSIP facility (Baden Valve Lot, SF-1) near the San Francisco International Airport and airport noise contours indicate that this site would be located near the 65-dBA CNEL noise contour (San Francisco Aircraft Noise Abatement Office, 2007).

Regulatory Framework

Local noise issues are addressed through implementation of general plan policies, including noise and land use compatibility guidelines, and through enforcement of noise ordinance standards. General plan policies provide guidelines for determining whether a noise environment is appropriate for a proposed or planned land use. Noise ordinances regulate noise sources, such as mechanical equipment and amplified sounds, as well as prescribe hours of heavy equipment operation. In most cases, noise ordinances are part of local building and zoning ordinances of other jurisdictions; these building and zoning ordinances do not apply to SFPUC projects (see Section 4.2, Plans and Policies). However, time and noise limits prescribed in local noise ordinances are used in this PEIR as criteria to determine the significance of project impacts under CEQA.

WSIP facilities (including alternative sites) would be located 7 counties and 27 cities. Noise ordinance standards that are relevant to the construction of WSIP facilities are incorporated into the significance criteria and summarized in **Table 4.10-2**.

Construction and Operational Time and Noise Limits

San Joaquin Region

WSIP projects in the San Joaquin Region would be located in unincorporated areas of Tuolumne, Stanislaus, and San Joaquin Counties, and incorporated areas of Riverbank and Modesto. Tuolumne and Stanislaus Counties do not have a noise ordinance and do not enforce any noise limits or time restrictions for construction activities. San Joaquin County limits construction activities to specific hours of the day. As shown in Table 4.10-2, noise ordinances for these counties specify noise limits for operation of stationary equipment.

Sunol Valley Region

WSIP projects in the Sunol Valley Region would be located mostly in unincorporated areas of Alameda County, but portions of two facilities would be located in Santa Clara County and the City of Fremont. As shown in Table 4.10-2, noise ordinances for these counties and cities specify time limits for construction activities and noise limits for operation of stationary equipment in or near residential zones.

Bay Division Region

WSIP projects in the Bay Division Region would be located in unincorporated areas of San Mateo County. Project facilities in this region would also be located within the following incorporated areas: Fremont, Newark, San Jose, Santa Clara, Palo Alto, East Palo Alto, Menlo Park, Atherton, Redwood City, and San Carlos. Alternative sites for some of these facilities would be located in the following incorporated areas: Milpitas, Sunnyvale, Mountain View, Los Altos, Redwood City, and Woodside. As shown in Table 4.10-2, noise ordinances for these counties and cities specify time limits for construction activities and noise limits for operation of stationary equipment in or near residential zones.

TABLE 4.10-2
PERTINENT ORDINANCE TIME LIMITS AND NOISE STANDARDS

Jurisdiction	Construction Time Limits			Ordinance Noise Limits for Various Activities in Residential Zones (dBA)[a]	
	Weekdays	Saturdays	Sundays	Day (Leq) 7 a.m. to 10 p.m.	Night (Leq) 10 p.m. to 7 a.m.
Tuolumne and Stanislaus Counties[b]	–	–	–	50	45
San Joaquin County[c]	6 a.m. to 9 p.m.	6 a.m. to 9 p.m.	6 a.m. to 9 p.m.	50	45
Alameda County[d]	7 a.m. to 7 p.m.	8 a.m. to 5 p.m.	8 a.m. to 5 p.m.	58	53
Santa Clara County[e]	7 a.m. to 7 p.m.	7 a.m. to 7 p.m.	Prohibited	60	50
San Mateo County[f]	7 a.m. to 6 p.m.	9 a.m. to 5 p.m.	Prohibited	63	58
City of Riverbank[g]	6 a.m. to 6:30 p.m.	8 a.m. to 5 p.m.	8 a.m. to 5 p.m.	50	45
City of Modesto[h]	7 a.m. to 9 p.m.	9 a.m. to 9 p.m.	9 a.m. to 9 p.m.	–	–
City of Fremont[i]	7 a.m. to 7 p.m.	9 a.m. to 6 p.m.	Prohibited	60 (Ldn)	
City of Newark[j]	7 a.m. to 6 p.m.	–	–	75 or 80 (Lmax) at 50 feet depending on equipment type; 95 (Lmax) at 50 feet for pile drivers	
City of Milpitas[k]	7 a.m. to 7 p.m.	7 a.m. to 7 p.m.	7 a.m. to 7 p.m.	–	–
City of San Jose[l]	7 a.m. to 7 p.m.	Prohibited	Prohibited	55	55
City of Santa Clara[m]	7 a.m. to 6 p.m.	9 a.m. to 6 p.m.	Prohibited	55	50
City of Sunnyvale[n]	7 a.m. to 6 p.m.	8 a.m. to 5 p.m.	Prohibited	60	45/50
City of Mountain View[o]	7 a.m. to 6 p.m.	Prohibited	Prohibited	55	50
City of Los Altos[p]	7 a.m. to 5:30 p.m.	9 a.m. to 3 p.m.	Prohibited	55	45/50
City of Palo Alto[q]	8 a.m. to 6 p.m.	9 a.m. to 6 p.m.	Prohibited	–	–
City of East Palo Alto[r]	7 a.m. to 8 p.m.	7 a.m. to 8 p.m.	7 a.m. to 8 p.m.	63	58
City of Menlo Park[s]	8 a.m. to 6 p.m.	Prohibited	Prohibited	60	50
Town of Atherton[t]	8 a.m. to 6 p.m.	Prohibited	Prohibited	60	50
City of Redwood City[u]	7 a.m. to 8 p.m.	Prohibited	Prohibited	–	–
City of San Carlos[v]	7 a.m. to 6 p.m.	9 a.m. to 5 p.m.	9 a.m. to 5 p.m.	10 dBA above ambient	
City of San Mateo[w]	7 a.m. to 7 p.m.	8 a.m. to 5 p.m.	12 p.m. to 4 p.m.	60	50 or 55
Town of Woodside[x]	7:30 a.m. to 5:30 p.m.	8 a.m. to 1 p.m.	Prohibited	55 (Ldn)	
Town of Hillsborough[y]	8 a.m. to 5 p.m.	10 a.m. to 5 p.m.	Prohibited	70 at 25 feet	–
City of Burlingame[z]	8 a.m. to 7 p.m.	8 a.m. to 7 p.m.	10 a.m. to 6 p.m.	–	–
City of Millbrae[aa]	7:30 a.m. to 7 p.m.	8 a.m. to 6 p.m.	8 a.m. to 6 p.m.	–	–
City of San Bruno[bb]	7 a.m. to 10 p.m. (85 dBA limit at 100 feet) 10 p.m. to 7 a.m. (60 dBA limit at 100 feet)			60	45
City of South San Francisco[cc]	8 a.m. to 8 p.m.	9 a.m. to 8 p.m.	10 a.m. to 6 p.m.	60	50
City of Colma[dd]	–	–	–	–	–
City of Brisbane[ee]	7 a.m. to 7 p.m.	9 a.m. to 7 p.m.	9 a.m. to 7 p.m.		
City of Daly City[ff]	6 a.m. to 10 p.m.	6 a.m. to 10 p.m.	6 a.m. to 10 p.m.	–	–
City/County of San Francisco[gg]	7 a.m. to 8 p.m. (80 dBA limit at 100 feet)			55 or 60	50 or 55

TABLE 4.10-2 (Continued)
PERTINENT ORDINANCE TIME LIMITS AND NOISE STANDARDS

– not specified
[a] In addition to residential zones, these limits could apply to school, hospital, church, or public library uses depending on the jurisdiction. These limits generally apply to operation of stationary noise sources except in the cities of Newark, Hayward, and San Bruno, where limits apply to construction noise.
[b] Noise limits specified in Tuolumne County Noise Element (Table 5.4) and Stanislaus County General Plan Noise Element (Policy Two, Table II) and apply to stationary noise sources. These counties do not have construction time limits.
[c] Section 1025.9(c)(3) of the San Joaquin County Title 9 Development Title specifies hourly limits for construction. Section 1025.9(b)(2) of the San Joaquin County Development Title specifies Leq limits for stationary noise sources.
[d] Alameda County Municipal Code, Title 6, Health and Safety, Chapter 6.60, Section 6.60.070(E) specifies hourly limits for construction. Noise limits are based on specified noise, duration, and timing limits in Section 6.60.040.
[e] Santa Clara County Code Chapter VII, Section B11-154(b)(6), Noise/Demolition.
[f] Noise limits are based on specified noise, duration, and timing limits in San Mateo County Code, Title 4, Chapter 4.88, Section 4.88.330, Exterior Noise Standards*.* Time limits are specified in San Mateo County Code, Title 4, Chapter 4.88, Section 4.88.360(e), Exemptions.
[g] Time and noise limits specified in Riverbank Municipal Code, Title IX, Chapter 93, Section 93.07(C).
[h] Modesto Municipal Code, Title 4, Chapter 9, Article 4-9.103. Although the code does not contain noise limits, the Environmental Resources Element of the Modesto General Plan specifies a maximum outdoor noise level of 60 dBA (CNEL or Ldn) in single-family residential areas or 65 dBA in multifamily residential areas.
[i] Fremont Municipal Code, Section 8-2205 specifies the above time limits for construction activities within 500 feet of residences, lodging facilities, nursing homes, or inpatient hospitals. Beyond 500 feet of these uses, construction hours are extended to 6 a.m. to 10 p.m. on weekdays and 8 a.m. to 8 p.m. on weekends. When a project is located in a right-of-way or easement or on public-owned property, these hours can be modified by the City, on balance, to minimize disruption to the community as a whole, such as to facilitate orderly flow of traffic or to reduce negative impacts on commercial or residential activity.
[j] The Noise Element of the City of Newark's General Plan serves as the City's noise ordinance, which includes peak noise (Lmax) limits for specific types of construction equipment, but no time restrictions for construction activities. However, the City limits construction to the above weekday hours for most projects requiring permits, although exceptions can be granted by the City (Fujikawa, 2006).
[k] Time limits are specified in the Milpitas Municipal Code, Title V, Chapter 213, Section V-213-3(b), Site Construction Regulations, but no noise limits are specified.
[l] Time limits specified by the San Jose Municipal Code (Chapter 20.100, Section 20.100.450) apply to any construction activity on a site located within 500 feet of a residential unit. Specified noise limit is the performance standard for residential zoning districts (Section 20.30.700).
[m] Time and noise limits specified in Santa Clara City Code, Title 9, Chapter 9.10.
[n] Time and noise limits specified in the Sunnyvale Municipal Code, Sections 16.08.110 and 19.42.030.
[o] Mountain View City Code specifies time limits in Chapter 8, Article I, Section 8.23, and noise limits for stationary equipment in Chapter 21, Article I, Section 21.26.
[p] Los Altos Municipal Code specifies time limits in Title 6, Chapter 6.16, Section 6.16.070, and exterior noise limits in Section 6.16.050. Section 6.16.070 specifies construction maximum noise levels of 75 or 80 dBA (7 a.m. to 7 p.m.) and 50 or 55 dBA (7 p.m. and 7 a.m.), depending on the residential zoning district noise limits.
[q] Construction time limits apply to residential properties and are specified in Title 9, Chapter 9.10 of the Palo Alto Municipal Code. This ordinance also limits noise from any individual piece of equipment to 110 dBA at 25 feet or outside the property plane.
[r] Time and noise limits specified in East Palo Alto Municipal Code, Title 8, Chapter 8.52.
[s] Time and noise limits specified in Menlo Park Municipal Code, Title 8, Section 8.06.030.
[t] Time and noise limits specified in Atherton Municipal Code*,* Title 8, Section 8.16.
[u] Time and noise limits specified in Redwood City Municipal Code, Chapter 24, Article II. Noise levels generated by construction activities (including demolition, alteration, repair, or remodeling) shall not exceed 110 dBA on any adjacent residential property or at 25 feet.
[v] Time and noise limits specified in the San Carlos Municipal Code, Chapter 9.3, Sections 9.30.030 and 9.30.070.
[w] Time and noise limits specified in San Mateo Municipal Code, Title VII, Chapter 7.30, Sections 7.30.040 and 7.30.060. Noise levels generated by construction activities (including demolition, alteration, repair, or remodeling) shall not exceed 90 dBA at 25 feet or outside the property plane.
[x] Time limits specified in Woodside Code of Ordinances, Chapter 151, Section 151.55. Noise limits specified in Town of Woodside General Plan Noise Element.
[y] Time limits specified in Section 8.32.040 of Hillsborough Municipal Code. This code limits construction equipment noise to 100 dBA at a distance of 25 feet from the source, and noise levels from all sources shall not exceed 100 dBA at 25 feet outside the property line plane. On Saturdays, the combined noise level from all construction activity is limited to 70 dBA at 25 feet outside the property line plane. The code limits general noise levels to 70 dBA outside the property plane on weekdays, 7 a.m. to 5 p.m.
[z] Burlingame Municipal Code, Title 10, Chapter 10.40, Section 10.40.037. Although the code does not contain noise limits, the Noise Element of the Burlingame General Plan specifies a maximum outdoor noise level of 60 dBA (CNEL) in residential areas.
[aa] Time limits specified in Millbrae Municipal Code, Title 6, Chapter 6.25, Section 6.25.050(F)(9).
[bb] San Bruno Municipal Code, Title 6, Chapter 6.16, Section 6.16.030 for noise limits in residential zone and Section 6.16.070 for construction limits.
[cc] Time and noise limits specified in South San Francisco Municipal Code, Chapter 8.32, Sections 8.32.030 and 8.32.050. Construction activities allowed during these hours if each piece of equipment produces a noise level of 90 dBA or less at 25 feet or outside of the property plane.
[dd] There is no noise ordinance for the Town of Colma. Instead, it uses the California Penal Code Section 415, "Disturbing the Peace," which prohibits any person from maliciously and willfully disturbing another person by loud and unreasonable noise.
[ee] Brisbane Municipal Code, Title 8, Chapter 8.28, Section 8.28.060 specifies time limits, and no piece of equipment shall produce a noise level of more than 83 dBA or more at 25 feet or 86 dBA outside of the property plane.
[ff] Time limits specified in Daly City Municipal Code, Title 9, Chapter 9.22, Section 9.22.030.
[gg] Time and noise limits specified in San Francisco Police Code, Article 29, Sections 2907 through 2909. Except for impact tools and equipment, powered construction equipment cannot generate noise levels in excess of 80 dBA at 100 feet. Noise limits are for fixed noise sources, with the lower limit applying to R-1 and R-2 residential zoning districts and the higher limit applying to all other residential zoning districts.

Peninsula Region

WSIP projects in the Peninsula Region would mainly be located in unincorporated areas of San Mateo County. Project facilities in this region would also be located within the following incorporated areas: South San Francisco and Daly City. Although most of these facilities would be located in unincorporated areas, a number of them would be sited adjacent to or near the cities of San Mateo, Hillsborough, Burlingame, Millbrae, and San Bruno. As shown in Table 4.10-2, noise ordinances for these counties and cities specify time limits for construction activities and noise limits for operation of stationary equipment in or near residential zones.

San Francisco Region

Most WSIP projects in the San Francisco Region would be located in San Francisco. However, two projects would have facilities located in unincorporated areas of northern San Mateo County as well as in the following incorporated areas on the Peninsula: Burlingame, Millbrae, San Bruno, South San Francisco, Colma, Brisbane, and Daly City. As shown in Table 4.10-2, noise ordinances for these counties and cities specify time limits for construction activities and noise limits for operation of stationary equipment in or near residential zones.

4.10.3 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to noise, but generally considers that implementation of the proposed program would have a significant noise impact if it were to:

- Expose people to or generate noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies (Evaluated in this section)
- Expose people to or generate excessive groundborne vibration or groundborne noise levels (Evaluated in this section)
- Create a substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project (Evaluated in this section)
- Create a substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project (Evaluated in this section)
- For a project located within an area covered by an airport land use plan (or, where such a plan has not been adopted, within two miles of a public airport or public use airport), expose people residing or working in the project area to excessive noise levels (Not evaluated in this section, see Appendix B)
- For a project within the vicinity of a private airstrip, expose people residing or working in the project area to excessive noise levels (Not evaluated in this section, see Appendix B)
- Be substantially affected by existing noise levels (Not evaluated in this section, see Appendix B)

Approach to Analysis

This program-level analysis presents a screening-level analysis to determine areas of potential noise impacts based on two factors: (1) the proximity of sensitive receptors in the site vicinities; and (2) the potential for proposed activities to occur during the more sensitive nighttime hours. Both of these factors are used to define the potential for impact and the need for or feasibility of mitigation. For construction noise, the potential for impact is defined by the proximity of sensitive receptors, typical noise levels associated with construction equipment, the potential for construction noise levels to interfere with daytime and nighttime activities, and whether construction noise audible to nearby receptors will occur outside of construction time limits specified in local ordinances. For operational noise, the potential for impact is defined by the proximity of sensitive receptors to a proposed facility, and the potential for operational noise to remain within noise ordinance limits at the nearest receptors.

This section focuses on the program-level impacts that would be associated with the various types of facilities as well as each WSIP project. The final construction scheduling of specific WSIP projects could lead to combined or collective impacts resulting from construction of more than one facility. This potential effect is assessed in Section 4.16, Collective Impacts.

Another relevant factor to consider in assessing whether a noise impact is significant or not is the frequency with which noise levels associated with project construction might exceed the established standards. If exceedance of a noise standard might happen only very rarely and/or briefly, this may not constitute a significant impact. This factor of noise frequency is not considered as part of this program-level impact analysis of the WSIP projects since there is not yet enough detailed information about the construction scenario for each project to assess the potential frequency of project noise levels that might established standards. This factor will be considered as part of the separate project-level impact analysis to be conducted as appropriate for each WSIP project. Based on more detailed information about project construction activities and schedule, and site-specific information on the proximity of sensitive receptors, project-level analysis may determine that impacts considered to be potential significant and unavoidable at this program-level of review are instead significant but mitigable or less than significant.

Impact Summary by Region

Table 4.10-3 provides a summary of the noise and vibration impacts associated with implementation of the WSIP.

Construction Impacts

Short-Term Noise Increases

Impact 4.10-1: Disturbance from temporary construction-related noise increases.

Construction activities associated with implementation of the WSIP would result in temporary noise increases at sensitive receptors near facility sites. Construction noise levels would fluctuate at any given receptor depending on the type of project, construction phasing, equipment

TABLE 4.10-3
POTENTIAL IMPACTS AND SIGNIFICANCE – NOISE AND VIBRATION

Projects	Project Number	Impact 4.10-1: Disturbance from temporary construction-related noise increases	Impact 4.10-2: Temporary noise disturbance along construction haul routes	Impact 4.10-3: Disturbance due to construction-related vibration	Impact 4.10-4: Disturbance due to long-term noise increases

PSU = Potentially Significant Unavoidable impact
N/A = Not Applicable

type/duration of use, distance between the noise source and receptor, and the presence or absence of barriers between the noise source and receptor. Typical construction equipment generates maximum noise levels ranging from about 76 to 88 dBA at a distance of 50 feet from the source, with slightly higher levels of about 88 to 91 dBA for certain types of earthmoving and impact equipment. The rate of attenuation (i.e., reduction) is about 6 dBA for every doubling of distance from a point source. Noise levels from pile drivers can generate noise peaks of approximately 101 dBA at 50 feet. **Table 4.10-4** indicates noise levels at 25, 50, and 100 feet from the noise source for typical construction equipment.

[a] Estimated levels can be obtained by selecting quieter procedures or machines and implementing noise-control features that do not require major redesign or extreme cost (e.g., improved mufflers, equipment redesign, use of silencers, shields, shrouds, ducts, and engine enclosures).

SOURCE: U.S. Environmental Protection Agency, 1971; U.S. Department of Transportation, Federal Transit Administration, 1995.

As stated in the first significance criterion above, a noise impact is considered significant if noise levels are in excess of the standards established in local noise ordinances. However, WSIP projects are located in over 20 different jurisdictions, each with its own limits. Some jurisdictions have noise limits but do not have time limits. Others have time limits but no construction noise limits. Given the variation in time and noise limits among jurisdictions, combined with the undetermined nature of construction hours and specific construction activities for the WSIP projects, it is not possible at the program level to accurately determine whether each WSIP project would generate noise in excess of local noise ordinance standards. This project-specific analysis will be undertaken as part of separate, project-level CEQA review.

For construction noise, a “substantial” noise increase (as stated in the fourth significance criterion) can be defined as interference with activities during the day and night. One indicator that construction noise could interfere with daytime activities would be speech interference, and an indicator that construction noise could interfere with nighttime activities would be sleep interference. This analysis uses the following criteria to define the significance of potential noise impacts:

- *Speech Interference*. Speech interference is an indicator of impact on typical daytime and evening activities. A speech interference criterion, in the context of impact duration and time of day, is used to identify substantial increases in noise from temporary construction activities. Noise peaks generated by construction equipment could result in speech interference in adjacent buildings if the noise level in the interior of the building exceeds 45 to 60 dBA.[1] A typical building can reduce noise levels by 25 dBA with the windows closed (U.S. EPA, 1974). This noise reduction could be maintained only on a temporary basis in some cases, since it assumes windows must remain closed at all times. Assuming a 25-dBA reduction with the windows closed, an exterior noise level of 70 dBA (Leq) at receptors would maintain an acceptable interior noise environment of 45 dBA. It should be noted that such noise levels would be sporadic rather than continuous in nature, because different types of construction equipment would be used throughout the construction process.

- *Sleep Interference*. Based on available sleep criteria data, an interior nighttime level of 35 dBA is considered acceptable (U.S. EPA, 1974). Assuming a 25-dBA reduction with the windows closed, an exterior noise level of 60 dBA at receptors would maintain an acceptable interior noise environment of 35 dBA. Since a 15-dBA reduction would occur with windows open, an exterior noise level of 50 dBA (Leq) would be required to maintain an acceptable interior noise environment of 35 dBA.

In general, most construction noise would exceed the speech interference criterion when heavy equipment is operated within approximately 500 feet of a sensitive receptor (distance ranges between 150 and 500 feet depending on the type of equipment operated). The sleep interference criterion would be exceeded at distances closer than approximately 3,000 feet with windows open or 900 feet with the windows closed (with operation of most types of construction equipment; greater setback distances would be required if trucks and impact equipment were to be operated at night).[2] If feasible noise controls are implemented (see Mitigation Measure 4.10-1a), most construction noise levels could be reduced to below the speech interference criterion, except when receptors are approximately 75 feet or less from construction equipment. For nighttime construction, implementation of noise controls would reduce most construction noise to below the sleep interference criterion except when construction equipment were operated within 300 feet (windows closed) or 900 feet (windows open) of sensitive receptors or when impact equipment were operated within 600 feet (windows closed) or 1,700 feet (windows open) of sensitive receptors. Estimates of typical construction noise levels at these distances (mitigated and unmitigated) are included in Appendix F and they are compared to the speech and sleep interference criteria.

1 For indoor noise environments, the highest noise level that permits relaxed conversation with 100 percent intelligibility throughout the room is 45 dBA. Speech interference is considered to become intolerable when normal conversation is precluded at 3 feet, which occurs when background noise levels exceed 60 dBA. For outdoor environments, the highest noise level that permits normal conversation at 3 feet with 95 percent sentence intelligibility is 66 dBA (U.S. EPA, 1974).

2 Whether windows can remain closed at night would depend on local climate conditions as well as duration of nighttime construction.

The construction impacts identified below for each type of facility have been developed to allow a general assessment of the nature and magnitude of potential impacts associated with the WSIP.

Pipelines. For pipelines, sensitive receptors tend to be located closer to construction activities than at facility sites (as close as 25 to 50 feet of proposed alignments in urbanized areas), and construction noise levels would exceed the speech interference criterion at distances closer than 100 feet, with or without feasible noise controls. However, because pipeline construction progresses along an alignment (rather than persisting at one location) at an average rate of approximately 120 to 160 feet per day, any given sensitive receptor would typically be subject to construction noise for about two weeks and not for the entire duration of the construction schedule. In some cases, the limited duration of exposure at a given sensitive receptor could reduce the adverse effects of these temporary noise increases to a less-than-significant level, even if noise controls cannot reduce estimated noise levels to below the speech interference criterion. However, if pipeline construction were prolonged at any one location, localized impacts could be potentially significant and unavoidable. While it is expected that most pipeline construction activities would occur during daytime hours (generally within with applicable noise ordinance time limits), the SFPUC has indicated that nighttime construction could occur at specific locations due to special construction requirements (e.g., water service must be temporarily discontinued when proposed facilities are connected to existing facilities).

Construction of jack-and-bore pits for pipeline crossings of railroads, freeways, and streets that are more than four lanes wide would pose additional noise impacts if tunnel ventilation fans, dewatering pumps, and generators are required. If any sensitive receptors are located near these pits, they could be subject to construction-related noise increases for longer durations as well as nighttime noise increases if fans, pumps, and generators are required to be operated 24 hours per day. Twenty-four-hour operation of ventilation fans, generators, and/or pumps could exceed ordinance time or noise limits, and noise controls would be required to minimize speech interference and sleep disturbance effects.

Tunnels. Noise impacts associated with tunnel construction would primarily occur at tunnel entry and exit shafts or portals, where construction staging would occur. Since tunnel construction might have to occur 24 hours per day, seven days per week, activities at these shafts/portals would often involve nighttime activities. If nighttime activities occur in tunnel portal vicinities, it could be appropriate to apply ordinance noise limits (listed in Table 4.10-2) in addition to the sleep interference criterion to evaluate the potential significance of construction noise increases. In addition to activities at tunnel shafts/portals, noise increases could occur along haul routes, since tunnel construction would entail off-hauling of materials excavated from tunnels (tunnel spoils), as well as equipment and material (e.g., tunnel lining) deliveries.

Within tunnels, the primary noise sources are typically the tunnel boring machine and tunnel muck removal system (conveyor belt and rail cars), but these sources would not be audible at the surface. However, these underground tunnel-related activities could generate groundborne noise within any overlying structures, which could result in sleep disturbance.

The primary sources of airborne noise associated with tunnel construction would be activities at tunnel shafts or portals, which could include the following with a tunnel shaft design:

- Excavation of the tunnel entry and exit shafts, which could include pile driving
- Handling and removal of excavated materials (shaft and tunnel spoils) at the tunnel entry shaft, which could include operation of a crane at the surface and a skip hoist system that moves muck from the bottom of the shaft to the surface, and front loaders that load muck into haul trucks
- Operation of a crane to lower tunnel support segments into the shaft
- Continuous operation of a ventilation fan (which could be located at the bottom of the shaft or at the surface) and dewatering pumps (at the bottom of the shaft) at the entry shaft site (24 hours per day, seven days per week)
- Continuous operation of ventilation equipment and a grout batching plant at the exit shaft (24 hours per day, seven days per week during the tunnel lining phase only)
- Operation of compressors or generators at night at the entry and exit shafts
- Possible controlled detonations during shaft construction

Potential tunnel-related noise impacts would depend on the tunnel design (below-ground shaft or surface portal), the type of tunneling and muck removal system ultimately used (dictated by whether the tunnel is gassy or potentially gassy), the extent of nighttime surface activities in the vicinity of tunnel portals/shafts (e.g., equipment repair, heavy equipment operation associated with muck removal), and the proximity of the shaft or portal (including ventilation fans, dewatering pumps, and/or generators) to sensitive receptors. Outside of the tunnel portal/shaft vicinities, the primary source of noise during tunnel construction would be haul trucks and material delivery trucks.

Other Facilities. Compared to pipeline construction noise, noise impacts associated with construction of other types of water facilities (vault, valve lot, crossover, pump station, treatment, and storage facilities) would generally affect fewer receptors because such construction would occur at discrete locations (involving smaller areas than pipelines), and many of these facilities would be located within or adjacent to existing SFPUC water facilities. Construction at some existing facilities could involve fewer earthmoving activities, limiting the potential for noise impacts associated with operation of heavy equipment and off-hauling of excavated material. The exception would be dam replacement/reconstruction projects, which could involve extensive earthmoving activities. The potential for temporary construction noise impacts would depend on the proximity of sensitive receptors, construction duration, time of day construction occurs, and extent of earthmoving activities (excavation, shoring, stockpiling of excavated materials). Installation of any above-ground facilities could also involve temporary noise increases.

San Joaquin Region

Impact 4.10-1: Disturbance from temporary construction-related noise increases		
Advanced Disinfection	SJ-1	PSU
Lawrence Livermore	SJ-2	PSU
SJPL System	SJ-3	PSU
SJPL Rehabilitation	SJ-4	PSU
Tesla Portal Disinfection	SJ-5	PSU

Within this region, construction of the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects would have the potential to result in significant, short-term noise impacts. The SJPL System project's six-mile eastern pipeline segment (west of Oakdale Portal) and eastern crossover would be located in an undeveloped area, where the potential for noise impacts would be low. However, the 9.7-mile western pipeline segment located east of Tesla Portal would extend through a residential area and golf course (Tracy Golf and Country Club). These residences are located west of I-580, and the golf course spans the freeway. Residences could be within 50 feet of the pipeline alignment, depending on the pipeline location within the existing SFPUC right-of-way. (Golf course users are not considered noise-sensitive receptors.) Construction noise impacts could also occur at crossover facility sites proposed as part of this project, depending on their locations and proximity to noise-sensitive receptors.

Potential construction-related noise impacts associated with the SJPL System project would be potentially significant and evaluated in greater detail in a separate, project-level EIR. At most locations along the pipeline alignment where construction would be short in duration (two weeks or less at any given receptor), construction noise impacts could be reduced to a less-than-significant level by limiting construction activities to the daytime hours or reducing construction noise levels to meet ordinance nighttime noise limits (Measure 4.10-1a). However, because sensitive receptors could be within 50 feet of a pipeline alignment, it is possible that construction noise impacts could not be reduced to a less-than-significant level if the construction duration along this segment of the pipeline alignment lasted for longer than two weeks or occurred during nighttime hours adjacent to a residential receptor (e.g., crossover facilities, jack and bore pits). If this occurs, construction noise would be temporary but *potentially significant and unavoidable*.

Similar construction-related noise impacts could result during rehabilitation of the existing San Joaquin pipelines (SJ-4). In Modesto and Riverbank, segments of the existing pipelines are located within 25 feet of existing homes. If the pipeline segments being rehabilitated were within 25 feet of residences and the construction duration were prolonged or occurred during the nighttime hours at any such locations, it is possible that construction noise levels could not be reduced to a less-than-significant level. Therefore, this project would result in temporary but potentially significant construction noise impacts. At locations where construction would be short in duration (two weeks or less at any given receptor), daytime construction noise impacts could be reduced to a less-than-significant level by implementing noise controls to meet the speech interference criterion (Measure 4.10-1a). However, if construction activities would occur within 25 feet of a receptor for a prolonged period (over two weeks at any given receptor) or construction occurred during the nighttime hours, noise impacts would be temporary but *potentially significant and unavoidable*. When project elements and locations are defined, this project would be subject to separate, project-level CEQA review to analyze potential construction noise impacts for specific facility locations and determine if impacts could be mitigated to a less-than-significant level.

Other WSIP facilities within this region would be located at Tesla Portal (under Advanced Disinfection, SJ-1, and Tesla Portal Disinfection, SJ-5) or at Thomas Shaft (under Lawrence Livermore, SJ-2). There are no sensitive receptors located in the vicinity of Thomas Shaft and therefore, construction noise levels would result in less than significant noise impacts. The closest receptors to Tesla Portal include the SFPUC caretaker's residence at Tesla Portal and private residences located approximately 3,500 feet to the south. Since the caretaker's residence would be located adjacent to both these projects, occupants of this residence would be subject to construction noise levels in excess of speech and sleep interference criteria. Vacating this residence (Measure 4.10-1b) would reduce potentially significant noise impacts to a less-than-significant level. At private residences located at least 3,500 feet to the south, construction noise from most types of equipment would not exceed speech or sleep interference criteria. However, nighttime construction noise could still exceed the San Joaquin County nighttime ordinance limit of 45 dBA, a potentially significant impact for the Advanced Disinfection and Tesla Portal Disinfection projects. Given the distance to the nearest receptors, it is possible that this impact could be reduced to a less-than-significant level (avoiding sleep disturbance effects or reducing noise to ordinance noise limits) with implementation of noise controls (Measure 4.10-1a).

At this stage of program planning, proposed construction hours have not been determined for each WSIP project in this region, and it is possible that construction noise (audible to nearby receptors) associated with any WSIP project in this region could extend beyond the typical daytime hours (i.e., could occur during the evening or nighttime hours on weekends as well as weekdays). Therefore, the PEIR errs on the conservative side and identifies *potentially significant and unavoidable* noise impacts for any WSIP project in this region that will generate construction noise audible to nearby receptors beyond the hours specified in local noise ordinances or that cannot meet local noise limits for these hours. However, when construction hours and activities are defined for each WSIP project, separate, project-level CEQA review will be conducted to determine potential construction noise impacts for specific facility locations and whether impacts can be mitigated to a less-than-significant level.

Sunol Valley Region

Impact 4.10-1: Disturbance from temporary construction-related noise increases		
Alameda Creek Fishery	SV-1	PSU
Calaveras Dam	SV-2	PSU
40-mgd Treated Water	SV-3	PSU
New Irvington Tunnel	SV-4	PSU
Treated Water Reservoirs	SV-5	PSU
SABUP	SV-6	PSU

Most of the projects in this region would be located in Sunol Valley, which contains one private residence, two SFPUC Land Manager's residences (one adjacent to Alameda East Portal and one adjacent to Calaveras Dam), various water facilities, commercial nurseries, and quarries. The private residence is about 1,200 feet or more from the existing Alameda West Portal, and 2,000 feet from Calaveras Road.

Since the proposed New Irvington Tunnel (SV-4) entrance portal would be located closer to the private residence than the existing Alameda West Portal, there is a potential that noise impacts could occur at this residence. Depending on the type of equipment that would be operated at the tunnel portal, construction activities within 1,000 to 3,000 feet of this residence could result in potentially significant noise impacts at this residence. Although it is possible to limit nighttime use of certain types of equipment as well as require use of engine controls and sound barriers around the tunnel portal area (Measure 4.10-1a) so that construction noise levels do not cause sleep disturbance, the effectiveness of such measures cannot be determined until portal and equipment design details are determined and therefore, this impact is conservatively considered to be *potentially significant and unavoidable* in this PEIR. The SFPUC Land Manager's residence would be approximately 3,000 feet from the tunnel portal area, and this setback distance would allow construction noise levels generated beyond the time limits to be reduced by noise controls (Measure 4.10-1a) to meet ordinance nighttime noise limits (ensuring that sleep disturbance effects do not occur), reducing impacts to a less-than-significant level. The potential for noise impacts on the private residence and the SFPUC Land Manager's residence, as well as the need for noise controls would be evaluated in more detail in a separate, project-level EIR.

The New Irvington Tunnel (SV-4) exit portal would be located outside of Sunol Valley. The western exit portal of this tunnel in Fremont has the potential to cause noise impacts because it could be located near sensitive receptors. Tunnel-related noise impacts, as described above, would be associated with this project. Due to the proximity of sensitive receptors to the exit portal (less than 500 feet) and possibility of nighttime construction, it is possible that construction noise could result in sleep disturbance effects and possibly exceed the Fremont Noise Ordinance nighttime noise limit of 60 dBA (Ldn) at the closest receptors. This impact would be temporary but *potentially significant and unavoidable*. The New Irvington Tunnel project would be evaluated in a separate, project-level EIR, which would identify potential construction noise impacts at the tunnel exit portal and determine if impacts could be mitigated to a less-than-significant level.

Other WSIP projects in this region with components that could be located within 500 feet of the private residence in Sunol Valley include the pipeline proposed to extend from the Sunol Valley WTP to the Irvington Tunnel or Alameda Siphons as part of the 40-mgd Treated Water project (SV-3). If this pipeline passed closer than 500 feet from this residence, pipeline-related construction noise impacts could occur, as described above. It is also possible that facilities associated with the Alameda Creek Fishery project (SV-1) could extend through the area within 500 feet east of the residence. The potential for significant construction noise impacts on this residence due to these projects would depend on the proximity of these facilities to this residence and construction hours, and therefore, is conservatively considered potentially significant in this PEIR. Since there appears to be available space to provide sufficient setbacks from this residence, implementation of appropriate noise controls (Measure 4.10-1a) would likely reduce potentially significant noise impacts to a less-than-significant level. If nighttime construction occurs, this potentially significant impact could be reduced to a less-than-significant level by providing adequate setbacks and implementing feasible noise controls so as to reduce any construction noise levels below the sleep disturbance criterion (Measure 4.10-1a).

The Calaveras Dam project (SV-2) is located at the south end of Sunol Valley and extends southward into Calaveras Valley, where one borrow area is located at the south end of Calaveras Reservoir. There are private residences located more than 2,000 feet from the southernmost borrow area and the SFPUC Land Manager's residence is located adjacent to the Calaveras Dam. Nighttime construction activities over a two-year period would pose potentially significant noise impacts on these residential receptors. The SFPUC Land Manager's residence is proposed to be vacated, avoiding noise impacts on this receptor. Given the residential setback distances of more than 2,000 feet from project facilities, implementation of noise controls (Measure 4.10-1a) would likely be adequate to reduce potentially significant noise impacts to a less-than-significant level (avoiding sleep disturbance effects or reducing noise to meet ordinance limits). However, it should be noted that mitigated construction noise could, at times, still be noticeable to some of the closest residential receptors during the nighttime hours because ambient noise levels are so low in this area and ordinance limits are higher than ambient noise levels.

The Treated Water Reservoirs (SV-5) and SABUP (SV-6) projects are located more than 500 feet from the private residence in Sunol Valley and 300 feet from the SFPUC Land Manager's residence near Alameda East Portal. At such distances, construction noise impacts associated with this project would be potentially significant, but it is possible that these impacts could be reduced to a less-than-significant level (avoiding sleep disturbance effects or reducing noise to ordinance noise limits) with implementation of noise controls (Measure 4.10-1a).

At this stage of program planning, proposed construction hours have not been determined for each WSIP project in this region, and it is possible that construction noise (audible to nearby receptors) associated with any WSIP project in this region could extend beyond the typical daytime hours (i.e., could occur during the evening or nighttime hours on weekends as well as weekdays). Therefore, the PEIR errs on the conservative side and identifies *potentially significant and unavoidable* noise impacts for any WSIP project in this region that will generate construction noise audible to nearby receptors beyond the hours specified in local noise ordinances or that cannot meet local noise limits for these hours. However, when construction hours and activities are defined for each WSIP project, separate, project-level CEQA review will be conducted to determine potential construction noise impacts for specific facility locations and whether impacts can be mitigated to a less-than-significant level.

Bay Division Region

Impact 4.10-1: Disturbance from temporary construction-related noise increases		
BDPL Reliability Upgrade	BD-1	PSU
BDPL 3 and 4 Crossovers	BD-2	PSU
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSU

All of the WSIP projects in this region would involve construction activities along existing pipeline alignments or construction at discrete locations along these alignments. Pipeline-related noise impacts, as described above, would be associated with the BDPL Reliability Upgrade (BD-1) and BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) projects. At receptor locations along pipeline alignments where construction would be short in duration (two weeks or less at any given receptor), construction noise impacts could likely be reduced to a less-than-significant level by implementing applicable noise controls (Measure 4.10-1a). However, because sensitive receptors would be less than 75 feet from the BDPL Reliability Upgrade (BD-1) and BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) pipeline alignments, it is possible that construction noise impacts could not be reduced to a less-than-significant level if the construction duration along the pipeline alignment lasted for longer than two weeks at any one location (e.g., jack-and-bore pits) or if nighttime construction occurs. Such effects would be temporary but *potentially significant and unavoidable*. With setbacks of less than 75 feet, noise controls (Measure 4.10-1a) would not reduce nighttime construction noise to below the sleep interference criterion or ordinance nighttime noise limits.

Tunnel-related noise impacts would also occur at tunnel shafts proposed as part of the BDPL Reliability Upgrade (BD-1) in Newark and East Palo Alto. Tunnel shafts would be located 900 feet or more from the closest residential receptors; with such setbacks, it is expected that sleep disturbance effects from nighttime tunnel construction noise levels near the shafts could be reduced to a less-than-significant level by limiting equipment/truck operations or erecting sound barriers (Measure 4.10-1a) to meet nighttime ordinance noise limits at the closest receptors. However, the effectiveness of such measures cannot be determined until portal and equipment design details are determined and therefore, this impact is conservatively considered to be *potentially significant and unavoidable* in this PEIR.

Under the BDPL 3 and 4 Crossovers (BD-2) project, construction would occur at discrete locations along the pipeline alignments. Since most of the Bay Division Region is urbanized, it is possible that noise impacts could adversely affect adjacent school or residential receptors. The SFPUC has indicated that construction hours could extend beyond the daytime hours. If facilities are located within 75 feet of noise-sensitive receptors, any prolonged construction activities (longer than two weeks) and/or any nighttime construction activities would result in *potentially significant and unavoidable* noise impacts. With setbacks of less than 75 feet, noise controls (Measure 4.10-1a) would not reduce construction noise to below the sleep interference criterion or ordinance nighttime noise limits.

At this stage of program planning, proposed construction hours have not been determined for each WSIP project in this region, and it is possible that construction noise (audible to nearby receptors) associated with any WSIP project in this region could extend beyond the typical daytime hours (i.e., could occur during the evening or nighttime hours on weekends as well as weekdays). Therefore, the PEIR errs on the conservative side and identifies *potentially significant and unavoidable* noise impacts for any WSIP project in this region that will generate construction noise audible to nearby receptors beyond the hours specified in local noise ordinances or that cannot meet local noise limits for these hours. However, when construction hours and activities are defined for each WSIP project, separate, project-level CEQA review will be conducted to determine potential construction noise impacts for specific facility locations and whether impacts can be mitigated to a less-than-significant level.

Peninsula Region

Impact 4.10-1: Disturbance from temporary construction-related noise increases		
Baden and San Pedro Valve Lots	PN-1	PSU
CS/SA Transmission	PN-2	PSU
HTWTP Long-Term	PN-3	PSU
Lower Crystal Springs Dam	PN-4	PSU
Pulgas Balancing Reservoir	PN-5	PSU

The Baden and San Pedro Valve Lots project (PN-1) would be located at existing valve lots in South San Francisco and Daly City. There are residential receptors adjacent to the Baden Valve Lot in South San Francisco (PN-1), but no residential receptors in the vicinity of the San Pedro Valve Lot in Daly City (PN-1). Sensitive receptors could be less than 100 feet from proposed construction in Baden Valve Lot. While daytime construction could be mitigated to less than significant with implementation of noise controls (Measure 4.10-1a), any nighttime construction activities could result in *potentially significant and unavoidable* noise impacts if they occur within 75 feet of noise-sensitive receptors. With setbacks of less than 75 feet, noise controls (Measure 4.10-1a) would not reduce construction noise to below the sleep interference criterion (and ordinance nighttime noise limits) at the closest receptors.

One WSIP project in the Peninsula Region would be located at the Harry Tracy WTP (PN-3). The closest residential receptors are approximately 500 feet east and southeast of existing WTP facilities and 300 feet to the south. If construction activities occurred within 500 feet of existing residences, construction-related noise impacts would be potentially significant. However, implementation of appropriate noise controls (Measure 4.10-1a) would be adequate to reduce construction noise impacts to a less-than-significant level. With setbacks of 300 to 500 feet or more from these residences, it is possible that construction noise could be reduced to a less-than-significant level (reducing noise to below the sleep interference criterion or ordinance nighttime noise limits) with implementation of noise controls (Measure 4.10-1a).

Two WSIP projects in this region (CS/SA Transmission, PN-2, and Lower Crystal Springs Dam, PN-4) would be located in the vicinity of the Crystal Springs Reservoirs, west of and across I-280 from the westernmost residential neighborhoods in Belmont, Hillsborough, and Millbrae as well as unincorporated areas of San Mateo County. Residential receptors would be over 1,000 feet east of these two projects (and across a freeway), but a few residences are located approximately 500 feet to the northeast of the Crystal Springs Pump Station, at the base of Lower Crystal Springs Dam. Construction activities in this vicinity could occur under these two projects, and could extend beyond the daytime hours. With minimum residential setback distances of approximately 500 feet from these two projects, potentially significant noise impacts could be reduced to a less-than-significant level (reducing noise to below the sleep interference criterion or ordinance nighttime noise limits) with implementation of noise controls (Measure 4.10-1a).

The Pulgas Balancing Reservoir project (PN-5) would be over 6,000 feet from the closest residential receptors to the east. Given such large residential setback distances, potential noise impacts would be less than significant. However, project construction could adversely affect scheduled activities (e.g., weddings, etc.) at the nearby Pulgas Water Temple, a potentially significant impact. If the SFPUC chooses to schedule activities during project construction, appropriate noise controls (Measure 4.10-1a) could be required to reduce noise impacts to a less-than-significant level. However, this potential impact could be avoided if no Temple activities were scheduled during construction hours.

At this stage of program planning, proposed construction hours have not been determined for each WSIP project in this region, and it is possible that construction noise (audible to any nearby receptors) associated with any WSIP project in this region could extend beyond the typical daytime hours (i.e., could occur during the evening or nighttime hours on weekends as well as weekdays). Therefore, the PEIR errs on the conservative side and identifies *potentially significant and unavoidable* noise impacts for any WSIP project in this region that will generate construction noise audible to nearby receptors beyond the hours specified in local noise ordinances or that cannot meet local noise limits for these hours. However, when construction hours and activities are defined for each WSIP project, separate, project-level CEQA review will be conducted to determine potential construction noise impacts for specific facility locations and whether impacts can be mitigated to a less-than-significant level.

San Francisco Region

Impact 4.10-1: Disturbance from temporary construction-related noise increases		
SAPL 3 Installation	SF-1	PSU
Groundwater Projects	SF-2	PSU
Recycled Water Projects	SF-3	PSU

Pipeline-related noise impacts, as described above, would be associated with the SAPL 3 Installation (SF-1) project. At receptor locations along the pipeline alignment where construction would be short in duration (two weeks or less at any given receptor), construction noise impacts could likely be reduced to a less-than-significant level by implementing applicable noise controls (Measure 4.10-1a). However, because sensitive receptors would be less than 25 feet on some residential streets, it is possible that construction noise impacts could not be reduced to a less-than-significant level if the construction duration along the pipeline alignment lasted for longer than two weeks at any one location (e.g., jack-and-bore pits) or if construction occurred during the night. Such effects would be temporary but *potentially significant and unavoidable*. With setbacks of less than 75 feet, noise controls (Measure 4.10-1a) would not reduce construction noise to below the sleep interference criterion at the closest receptors.

The primary construction noise issue associated with the local and regional Groundwater Projects (SF-2) would be 24-hour drilling required as part of proposed well construction. Continuous operation of drilling equipment could exceed the sleep interference criterion (with windows closed) if sensitive receptors were located within approximately 900 feet of well sites. At setback distances of 300 feet or more, implementation of noise controls (Measure 4.10-1a) could reduce drilling noise to less than significant. However, if setbacks are less than 300 feet, sleep disturbance could still occur (with Measure 4.10-1a) and this impact, although temporary, would be *potentially significant and unavoidable*. The Groundwater Projects would be evaluated in more detail as part of separate, project-level CEQA review, which would determine if construction noise impacts could be mitigated to a less-than-significant level.

Both pipeline and facility construction noise impacts, as described above, would be associated with the Recycled Water Projects (SF-3). Sensitive receptors are located near or adjacent to proposed treatment facilities and pipelines, and therefore, construction noise impacts on these receptors would be potentially significant. If facilities are located within 75 feet of noise-sensitive receptors, construction noise (occurring for longer than two weeks or at night) could be a *potentially significant and unavoidable* impact. With setbacks of less than 75 feet, noise controls (Measure 4.10-1a) would not reduce construction noise to below the sleep interference criterion at the closest receptors.

At this stage of program planning, proposed construction hours have not been determined for each WSIP project in this region, and it is possible that construction activities and construction noise associated with any WSIP project in this region could extend beyond the typical daytime hours (i.e., could occur during the evening or nighttime hours on weekends as well as weekdays). Therefore, the PEIR errs on the conservative side and identifies *potentially significant and unavoidable* noise impacts for any WSIP project in this region that will generate construction noise audible to nearby receptors beyond the hours specified in local noise ordinances or that cannot meet local noise limits for these hours. However, when construction hours and activities are defined for each WSIP project, separate, project-level CEQA review will be conducted to determine potential construction noise impacts for specific facility locations and whether impacts can be mitigated to a less-than-significant level.

Impact 4.10-2: Temporary noise disturbance along construction haul routes.

Truck noise levels depend on vehicle speed, load, terrain, and other factors. The effects of construction-related truck traffic would depend on the level of background noise already occurring at a particular receptor site. In quiet noise environments (Leq averaging 50 dBA), one truck per hour would be noticeable, even though such a low volume would not measurably increase noise levels. In slightly noisier environments (Leq averaging 60 dBA), the threshold level is higher, and it would take 10 trucks per hour to noticeably increase the noise exposure. In moderately noisy environments (Leq averaging 70 dBA), a noise increase would be perceptible with the addition of 100 trucks per hour (Caltrans, 1998).

In quiet environments or during quieter times of the day, truck noise is mainly a single-event disturbance because, although the hourly average associated with short, single events is not very high, individual noise peaks of 80 to 85 dBA at 50 feet are common during a truck passage. In noisy environments or during less noise-sensitive hours, truck noise would be perceived as a part of the total noise environment rather than as an individual disturbance. It is important to note that haul truck volumes associated with the WSIP projects would vary from day to day, with the highest volumes generally occurring during the excavation, concrete placement, and backfilling stages of construction. When haul truck noise is considered on an hourly basis rather than as a single noise event, noise levels generated by hourly truck volumes of 80 trucks per hour or more would exceed the 70-dBA speech interference criterion at 50 feet. Any truck volume greater than 1 truck per hour would exceed the 50-dBA sleep interference criterion at 50 feet. At greater distances, higher hourly truck volumes could occur without exceeding these criteria. For example, hourly truck volumes of up to approximately 10 trucks per hour could occur at distances of approximately 200 feet or more from a receptor while not exceeding the 50-dBA sleep interference criterion.

The hours for hauling excavated materials and for deliveries have not yet been specified for several of the WSIP projects that are still under development; however, the SFPUC has indicated that truck operations could occur beyond noise ordinance time limits.

San Joaquin Region

Impact 4.10-2: Temporary noise disturbance along construction haul routes		
Advanced Disinfection	SJ-1	PSU
Lawrence Livermore	SJ-2	N/A
SJPL System	SJ-3	PSU
SJPL Rehabilitation	SJ-4	PSU
Tesla Portal Disinfection	SJ-5	PSU

Within the San Joaquin Region, access to most of the WSIP facility sites is provided by rural roadways, highways, or freeways. Depending on where pipeline rehabilitation would occur along the existing pipeline alignment, haul trucks associated with the SJPL Rehabilitation project (SJ-4) might have to use residential streets in Modesto or Riverbank to access the pipeline. For the Advanced Disinfection (SJ-1), SJPL System (SJ-3), SJPL Rehabilitation (SJ-4), and Tesla Portal Disinfection (SJ-5) projects, haul trucks would use Chrisman and Vernalis Roads to access Tesla Portal from I-580, and residential receptors along this route could be subject to noise increases from haul truck and delivery traffic. Potential haul truck noise impacts would be evaluated in more detail as part of separate, project-level CEQA review these projects. In general, if residences could be set back 50 feet or less along haul routes and any nighttime truck operations exceeded 1 truck per hour, truck noise levels could exceed the sleep interference criterion. It is possible that limiting hourly truck volumes to the daytime hours (Measure 4.10-2a) and restricting nighttime truck operations (Measure 4.10-2b) could reduce this impact to a less-than-significant level. However, since haul routes, truck volumes, and hours of truck operations are undetermined for these projects, potential noise impacts on any residential receptors located along haul routes for these four projects are conservatively considered to be *potentially significant and unavoidable*.

Haul routes to and from the Lawrence Livermore (SJ-2) project site are not located near sensitive receptors, so this impact would *not apply*.

Sunol Valley Region

Impact 4.10-2: Temporary noise disturbance along construction haul routes		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	LS

The haul routes for most of the projects in this region would be Calaveras Road and I-680 in Sunol Valley. There is one private residence (located approximately 2,000 feet from Calaveras Road and possibly as close as 1,000 feet from the proposed tunnel portal associated with the New Irvington Tunnel project, SV-4). There is also one SFPUC Land

Manager's residence that is located approximately 200 feet from Calaveras Road, but its location uphill of this road allows topography to provide additional noise attenuation. To the south of the Sunol Valley, there are a few private residences located in Calaveras Valley at the south end of Calaveras Reservoir, more than approximately 3,000 feet from possible haul routes. With such large setback distances and expected average hourly volumes of up to 12 trucks per hour for each project, it is unlikely that noise generated by haul and delivery trucks along Calaveras Road would exceed speech or sleep interference criteria at these receptors. Therefore, this impact would be *less than significant* for all projects in this region: Alameda Creek Fishery (SV-1), Calaveras Dam (SV-2), 40-mgd Treated Water (SV-3), Treated Water Reservoirs (SV-5), and SABUP (SV-6).

The Irvington Tunnel project (SV-4) would generate substantially higher haul and delivery truck volumes than other WSIP projects in this region. Expected average hourly volumes of up to 36 trucks per hour would generate noise levels along the access road and Calaveras Road that would not exceed the speech interference criterion, but could exceed the sleep interference criterion at the SFPUC Land Manager's residence, a *potentially significant* impact. Implementation of Measure 4.10-2c, requiring this residence to be vacated during construction of this project, would reduce this impact to a less-than-significant level. Truck-related noise levels along these two roads is not expected to exceed the 50-dBA sleep interference criterion at the private residence to the south, but truck noise could increase ambient noise levels in the vicinity of this residence, which would be noticeable.

Bay Division Region

Impact 4.10-2: Temporary noise disturbance along construction haul routes		
BDPL Reliability Upgrade	BD-1	PSU
BDPL 3 and 4 Crossovers	BD-2	PSU
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSU

Since the majority of this region is urbanized and many of the WSIP projects are located in or near residential neighborhoods and schools, haul routes for most WSIP projects in this region could adversely affect sensitive receptors. Construction of the BDPL Reliability Upgrade project (BD-1) would expose the greatest number of residential and school receptors to noticeable noise increases due to haul truck traffic; these increases could be potentially significant if residential streets were used as haul routes. Haul routes for the BDPL 3 and 4 Crossovers (BD-2) and BDPL 3 and 4 Seismic Upgrade at Hayward Fault projects could also affect residential streets. Potential haul truck noise impacts would be evaluated in more detail as part of separate, project-level CEQA review for all projects in this region. In general, residences are set back less than 50 feet from most residential streets in this region, and any nighttime truck operations greater than 1 truck per hour could exceed the sleep interference criterion. It is possible that limiting hourly truck volumes during the day (Measure 4.10-2a) and restricting nighttime truck operations (Measure 4.10-2b) could reduce this impact to a less-than-significant level. However, since haul routes, truck volumes, and hours of truck operations are undetermined for these projects, potential noise impacts on any residential receptors located along haul routes for all projects in this region are conservatively considered to be *potentially significant and unavoidable*.

Peninsula Region

Impact 4.10-2: Temporary noise disturbance along construction haul routes		
Baden and San Pedro Valve Lots	PN-1	PSU
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	PSU
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS

Three of the five WSIP projects in this region would be located primarily on the west side of I-280 (CS/SA Transmission, PN-2; Lower Crystal Springs Dam, PN-4; and Pulgas Balancing Reservoir, PN-5), so haul routes to the I-280 freeway would likely be more than 225 feet from the closest residential receptors. With such large setback distances, it is unlikely that noise generated by haul and delivery trucks along haul routes would exceed speech or sleep interference criteria at the closest receptors, and noise impacts would be *less than significant*.

The remaining two projects in this region (Baden and San Pedro Valve Lots, PN-1 and HTWTP Long-Term, PN-3) would involve construction sites located in or near residential neighborhoods or schools. Noise increases associated with haul and delivery truck traffic could adversely affect sensitive receptors along these routes. In general, residences are set back less than 50 feet from most residential streets in these two neighborhoods, and any nighttime truck operations greater than 1 truck per hour could exceed the sleep interference criterion. It is possible that limiting hourly truck volumes during the day (Measure 4.10-2a) and restricting nighttime truck operations (Measure 4.10-2b) could reduce this impact to a less-than-significant level. However, since haul routes, truck volumes, and hours of truck operations are undetermined for these projects, potential noise impacts on any residential receptors located along haul routes for these two projects are conservatively considered to be *potentially significant and unavoidable*.

San Francisco Region

Impact 4.10-2: Temporary noise disturbance along construction haul routes		
SAPL 3 Installation	SF-1	PSU
Groundwater Projects	SF-2	PSU
Recycled Water Projects	SF-3	PSU

All of the WSIP projects in this region would be located near or adjacent to noise-sensitive receptors, and noise increases associated with haul and delivery truck traffic could adversely affect sensitive receptors along haul truck routes. In general, residences along most streets where project facilities would be located are set back less than 50 feet, and any nighttime truck operations greater than 1 truck per hour could exceed the sleep interference criterion. It is possible that limiting hourly truck volumes during the day (Measure 4.10-2a) and restricting nighttime truck operations (Measure 4.10-2b) could reduce this impact to a less-than-significant level. However, since haul routes, truck volumes, and hours of truck operations are undetermined for these projects, potential noise impacts on any residential receptors located along haul routes for these two projects are conservatively considered to be *potentially significant and unavoidable*.

Impact 4.10-3: Disturbance due to construction-related vibration.

Construction of WSIP facilities could cause vibration that could disturb local residents and cause cosmetic damage to buildings and structures. The second significance criterion above identifies “excessive groundborne vibration” as a significance impact. For this programmatic analysis, the following criteria were used to determine the significance of construction-related vibration effects:

- The potential for building damage, including cosmetic damage
- The exposure of people to vibration in terms of sleep disturbance or interruption of normal living activity

In general, cosmetic or threshold damage to residential buildings can occur at vibrations over 0.5 in/sec PPV, and controlled detonations would not generate structural damage if they produce vibrations of less than 0.5 in/sec PPV (measured at the residential building setback line at the ground surface). This level is consistent with the U.S. Bureau of Mines’ threshold cracking criteria of 0.5 in/sec PPV for low frequencies and 2.0 in/sec PPV for high frequencies (Wilson, Ihrig & Associates, 2005). Continuous vibration caused by vibratory pile drivers and large vibratory rollers/compactors may cause annoyance, but would not cause structural damage if the continuous vibration were less than 0.2 in/sec PPV (Wilson, Ihrig & Associates, 2005). This level is consistent with the Federal Transit Administration’s (U.S. Department of Transportation, Federal Transit Administration, 1995) recommended vibration threshold criterion of 0.2 in/sec for fragile buildings.

Much lower vibration levels (levels exceeding 0.012 in/sec PPV) can cause disturbance or annoyance and this threshold is typically applied to construction activities that occur during the more sensitive nighttime hours. Exceedance of this annoyance threshold during the nighttime hours could result in sleep disturbance, depending on proximity to the receptor.

Based on these criteria, vibration exceeding the following limits would be considered significant:

- Controlled detonations: 0.5 in/sec PPV
- Vibratory equipment and impact pile drivers: 0.2 in/sec PPV
- Activities causing annoyance (pertains to nighttime construction only): 0.012 in/sec PPV

Pipelines and Other Facilities. Table 4.10-5 presents vibration levels that could be expected at distances of 25, 50, and 100 feet from vibration sources and assumes typical construction activities and normal propagation conditions.

A threshold of 0.2 in/sec PPV is appropriate to apply to any construction activities occurring during the daytime hours. Both San Francisco and FTA measurement data presented in Table 4.10-5 demonstrate that vibration levels generated by most types of construction equipment would not exceed the 0.2 in/sec PPV threshold for continuous vibration at a distance of 25 feet, while pile-driving activities could exceed this threshold within approximately 50 feet. Impact pile-driving activities could exceed this threshold if it occurs closer than 100 feet from a receptor.

TABLE 4.10-5
VIBRATION LEVELS FOR CONSTRUCTION EQUIPMENT AT 25, 50, AND 100 FEET

	Peak Particle Velocity (PPV)		
Equipment[a]	**PPV at 25 Feet (in/sec)**	**PPV at 50 Feet (in/sec)**	**PPV at 100 Feet (in/sec)**
Pile Driver (Impact) – Upper Range	1.518	0.537	0.190
Pile Driver (Impact) – Typical	0.644	0.228	0.081
Pile Driver (Sonic) – Upper Range	0.734	0.260	0.092
Pile Driver (Sonic) – Typical	0.170	0.060	0.021
Clam Shovel Drop (Slurry Wall)	0.202	0.071	0.025
Large Bulldozer	0.089	0.031	0.011
Loaded Trucks	0.076	0.027	0.010
Jackhammer	0.035	0.012	0.004
Small Bulldozer	0.003	0.001	0.000

NOTES: Vibration levels for construction equipment at 25 feet are based on measured data near various types of equipment and assume normal propagation conditions. The following propagation adjustment was applied to estimate vibration levels at 50 and 100 feet:

$PPV_{equip} = PPV_{ref} \times (25/D)^{1.5}$

where:
PPV (equip) is the peak particle velocity in in/sec of the equipment adjusted for distance
PPV (ref) is the reference vibration levels in in/sec at 25 feet as listed above
D is the distance from the equipment to the receiver.

It should be noted that vibration propagation characteristics would depend on a number of factors, including the type and condition of geologic materials, depth of construction, and type of construction equipment and activity.

SOURCE: U.S. Department of Transportation Federal Transit Administration, 1995.

For any nighttime construction activities, it is more appropriate to apply the annoyance threshold of 0.012 in/sec PPV. Table 4.10-5 indicates that operation of most types of construction equipment at distances within 50 to 100 feet from a receptor could exceed the annoyance threshold.

Excavation activities associated with facility construction (including clearwells at treatment plants, reservoirs, and pipelines) could require sheetpile driving for shoring, which could generate perceptible vibration levels. Although vibration potential from sheetpile driving as well as other construction activities would depend on soil type and proximity to receptors, the measurements presented in Table 4.10-5 demonstrate that construction equipment can generate a wide range of vibration levels (0.003 to 1.518 in/sec, PPV at 25 feet) and can be operated in a manner that minimizes the potential for structural damage at the closest residential receptors. Measurements collected during various excavation-related construction activities (including pavement breaking, vibratory sheetpile driving, sheetpile driving by an excavator shovel, vibratory soil compaction, and earth excavation) at an unrelated project in San Francisco determined that vibration levels ranged between 0.03 to 0.38 in/sec PPV at 30 to 35 feet (ESA, 1997). When compared to vibration data presented in this table, vibration levels for sheetpile driving would be less than for pile driving (impact or sonic), but greater than levels generated by other types of construction equipment such as bulldozers, trucks, and jackhammers.

It is possible that vibration would be perceptible and could temporarily annoy the closest residents during construction of some of the WSIP projects, particularly if impact pile driving or sheetpile driving occurs. In many of the jurisdictions where WSIP projects are located, code requirements would limit vibration levels at the property line to the vibration perception threshold. Although it might not be feasible to maintain vibration levels below the perception threshold level at all receptors (even with mitigation measures), the limited duration of exposure at a given sensitive receptor[3] and restriction of construction activities to the daytime hours could help reduce such vibration annoyance effects to a less-than-significant level.

Tunnels. The primary sources of vibration associated with tunnel construction would include heavy construction equipment (e.g., bulldozers, vibratory compaction equipment, impact breakers) and mining equipment (e.g., a roadheader or a tunnel boring machine), tunnel train operations, and controlled detonations. Measurements for an unrelated tunnel project indicate that a roadheader can produce vibration levels of 0.0015 to 0.0022 in/sec PPV at 100 feet, while a tunnel train (operating at an estimated 10 miles per hour) can produce vibration levels of 0.0004 to 0.0008 in/sec PPV at 100 feet (ESA, 2003). Since tunnel construction would occur 24 hours per day, there would be a potential for annoyance, particularly during the nighttime hours. So, the lower 0.012 in/sec PPV annoyance threshold is applied as a significance threshold for tunnel construction. The potential for annoyance due to vibration would depend on the strength of rock encountered and the depth of the tunnel below ground. If receptors are located 100 feet or more from the proposed tunnel, vibration levels associated with operating tunneling equipment would likely remain below the 0.012 in/sec PPV threshold level for noticeability or annoyance.

Controlled detonations, which are produced by blasting techniques involving explosives, can be more noticeable to the public than mechanical excavation because of the intermittent, higher level noise and vibrations caused by blasting activities. Controlled detonation is performed by drilling holes in the rock face of a tunnel excavation and packing the holes with small amounts of explosive and primer. The explosives are detonated in one hole at a time, using a time delay between successive detonations; delay periods often range from 10 to 100 milliseconds, with the entire detonation event lasting no more than a few seconds. Detonations typically occur infrequently (once or twice per day), and the vibration produced by such detonations can be controlled by the delay time and the charge per delay (the amount of explosive per delay in each hole) so that cosmetic or structural damage does not occur. With vibration controls (Measures 4.10-3a and 4.10-1a), vibration levels generated by controlled detonations would be restricted so as not to cause cosmetic or structural damage, while the hours when controlled detonations could occur would be limited to the daytime hours.

---

3 It is anticipated that pipeline construction would progress along an alignment (rather than persisting at one location) at a rate of approximately 120 to 160 feet per day, so that any given sensitive receptor would typically be subject to construction vibration for about two weeks.

San Joaquin Region

Impact 4.10-3: Disturbance due to construction-related vibration		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	PSU
SJPL Rehabilitation	SJ-4	PSU
Tesla Portal Disinfection	SJ-5	LS

Pipeline construction for the SJPL System project (SJ-3) would require sheetpile driving to shore the pipeline trench, and pipeline-related vibration effects, as described above, could occur at residences located along the western pipeline segment near Tesla Portal or near crossover facilities. It is possible that rehabilitation of the existing San Joaquin Pipeline under the SJPL Rehabilitation project (SJ-4) would also require sheetpile driving for shoring. Since residences could be located as close as approximately 50 feet from the SJPL System alignment and 25 feet from the SJPL Rehabilitation project (depending on what pipeline segments were rehabilitated), vibration associated with sheetpile driving would be potentially significant. Implementation of vibration controls (Measures 4.10-3a and 4.10-3b) would reduce this potential impact to a less-than-significant level. However, if any construction activities were to generate vibration during the nighttime hours and within 100 feet of a receptor, it is possible that these measures could not reduce vibration levels sufficiently and sleep disturbance or annoyance could occur; therefore, this analysis conservatively considers this impact to be *potentially significant and unavoidable*. The potential for vibration effects would be evaluated in more detail as part of separate, project-level CEQA review for these projects.

Vibration could result if sheetpile driving is required to shore any excavations associated with proposed facilities at Tesla Portal for the Advanced Disinfection and Tesla Portal Disinfection projects (SJ-1 and SJ-5) or at Thomas Shaft for the Lawrence Livermore project (SJ-2); however, there are no sensitive receptors adjacent to these locations. Therefore, vibrations effects associated with construction of these projects would be *less than significant*.

Sunol Valley Region

Impact 4.10-3: Disturbance due to construction-related vibration		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	PSU
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	LS

There is one private residence and one SFPUC Land Manager's residence in the Sunol Valley Region, and construction activities associated with all but one of the WSIP projects in this region would be located more than 300 feet from these residences (Alameda Creek Fishery, SV-1; Calaveras Dam, SV-2; SVWTP – Treated Water Reservoirs, SV-5; and SABUP, SV-6). At distances over 100 feet, construction-related vibration effects would be *less than significant*. The only WSIP component in this region that could be implemented within 300 feet of the Sunol Valley residence is the pipeline proposed to extend from the Sunol Valley WTP to the Irvington Tunnel or Alameda Siphons under the 40-mgd Treated Water project (SV-3). If this pipeline passed within 100 feet of this residence, pipeline-related construction vibration impacts, as described above, could occur at this residence. However, it is unlikely that this pipeline alignment would pass that close to the residence. While vibration effects on this residence are expected to be less than significant if located more than 100 feet from this residence, for purposes of this analysis, this impact is considered potentially significant (since distance is currently undetermined), but could be reduced to a less-than-significant level with vibration controls (Measures 4.10-3a and 4.10-3b). However, if any construction activities were to generate vibration during the nighttime hours and within 100 feet of this residence, it is possible that these measures could not reduce vibration levels sufficiently and sleep disturbance or annoyance could occur; therefore, this analysis conservatively considers this impact to be *potentially significant and unavoidable*. The potential for vibration impacts would be evaluated in more detail as part of separate, project-level CEQA review for the 40-mgd Treated Water project, once the specific pipeline location has been determined.

The New Irvington Tunnel project (SV-4) exit portal would be located near residential receptors in Fremont, and tunnel-related construction activities would be located as close as approximately 200 to 300 feet from the nearest receptors, depending on location of staging areas, etc. At distances of 100 feet or greater, potential tunnel-related vibration effects would likely remain below the annoyance threshold and therefore, would be less than significant. Potential vibration and noise disturbance associated with tunnel-related controlled detonation activities would be *potentially significant* but reduced to a less-than-significant level by restricting these activities to the daytime hours (Measure 4.10-1a) and limiting charges to ensure that vibration does not cause cosmetic or structural damage (Measure 4.10-3a). However, potential vibration effects associated with this project would be evaluated in more detail as part of separate, project-level CEQA review to identify potential vibration impacts and ensure that impacts are adequately mitigated.

Bay Division Region

Impact 4.10-3: Disturbance due to construction-related vibration		
BDPL Reliability Upgrade	BD-1	PSU
BDPL 3 and 4 Crossovers	BD-2	PSU
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSU

Pipeline construction for the BDPL Reliability Upgrade project (BD-1) would require sheetpile driving to shore the pipeline trench, and pipeline-related vibration effects, as described above, could occur at residences and other structures located within 100 feet of the pipeline alignment; some residences are located as close as 10 to 25 feet from pipeline construction. Tunnel-related vibration could also occur if pile driving is required, although the proposed setbacks of 900 feet or more from the closest residential structures would minimize the potential for tunnel-related vibration impacts. Implementation of vibration controls (Measures 4.10-3a and 4.10-3b) would reduce this potential impact to a less-than-significant level. However, if any construction activities were to generate vibration during the nighttime hours and within 100 feet of a receptor, it is possible that these measures could not reduce vibration levels sufficiently and sleep disturbance or annoyance could occur; therefore, this analysis conservatively considers this impact to be *potentially significant and unavoidable*. Potential vibration and noise disturbance associated with tunnel-related controlled detonation activities would be potentially significant but reduced to a less-than-significant level by restricting these activities to the daytime hours (Measure 4.10-3c) and limiting charges to ensure that vibration does not cause cosmetic or structural damage

(Measure 4.10-3a). Potential vibration impacts would be evaluated in more detail as part of separate, project-level CEQA review.

Vibration could also result if sheetpile driving is required to shore any excavations associated with the BDPL 3 and 4 Crossovers (BD-2) and BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) projects. Adverse vibration effects could result if sensitive receptors are located within 100 feet of construction. Implementation of vibration controls (Measures 4.10-3a and 4.10-3b) would reduce potentially significant vibration effects to a less-than-significant level at adjacent or nearby sensitive receptors. However, if any construction activities were to generate vibration during the nighttime hours and within 100 feet of a receptor, it is possible that sleep disturbance or annoyance could occur and therefore, this analysis conservatively considers this impact to be *potentially significant and unavoidable*. Potential vibration impacts would be evaluated in more detail as part of separate, project-level CEQA review.

Peninsula Region

Impact 4.10-3: Disturbance due to construction-related vibration		
Baden and San Pedro Valve Lots	PN-1	PSU
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS

The Baden and San Pedro Valve Lots project (PN-1) would be located at the existing Baden and San Pedro Valve Lots in South San Francisco and Daly City, and proposed facilities would be located in proximity to existing adjacent structures. Vibration impacts could result if sheetpile driving is required within 100 feet of an existing sensitive receptor to shore any excavations associated with these projects. Implementation of vibration controls (Measures 4.10-3a and 4.10-3b) would reduce this potential impact to a less-than-significant level. However, if any construction activities were to generate vibration during the nighttime hours and within 100 feet of a receptor, it is possible that these measures could not reduce vibration levels sufficiently and sleep disturbance or annoyance could occur; therefore, this analysis conservatively considers this impact to be *potentially significant and unavoidable*. Potential vibration impacts would be evaluated in more detail as part of separate, project-level CEQA review.

Improvements at the Harry Tracy WTP (HTWTP Long-Term, PN-3) could generate vibration if sheetpile driving is required to shore any excavations associated with this project. However, sensitive receptors are located 300 to 500 feet from the closest receptors, which reduces the potential for annoyance due to vibration. At this distance, vibration effects would be *less than significant*.

The remaining three WSIP projects in this region (CS/SA Transmission, PN-2; Lower Crystal Springs Dam, PN-4; and Pulgas Balancing Reservoir, PN-5) would be located in the vicinity of the Crystal Springs Reservoirs, west of and across I-280 from the westernmost residential neighborhoods in Belmont, Hillsborough, Millbrae, and unincorporated areas of San Mateo County. Since the closest residential receptors would be located over 1,000 feet east of these three projects (and across a freeway), potential vibration impacts would be *less than significant*.

San Francisco Region

Impact 4.10-3: Disturbance due to construction-related vibration		
SAPL 3 Installation	SF-1	PSU
Groundwater Projects	SF-2	PSU
Recycled Water Projects	SF-3	PSU

Pipeline construction for the SAPL 3 Installation project (SF-1) could require sheetpile driving to shore the pipeline trenches or pipeline-related facilities (e.g., jack-and-bore pits), and pipeline-related vibration effects, as described above, could occur at residences and other structures located along the pipeline alignment. Due to the close proximity of sensitive receptors to sections of this pipeline alignment (potentially less than 25 feet on some residential streets), vibration effects could be perceptible and therefore potentially significant. Implementation of vibration controls (Measures 4.10-3a and 4.10-3b) would reduce this potential impact to a less-than-significant level. However, if any construction activities were to generate vibration during the nighttime hours and within 100 feet of a receptor, it is possible that these measures could not reduce vibration levels sufficiently and sleep disturbance or annoyance could occur; therefore, this analysis conservatively considers this impact to be *potentially significant and unavoidable*. Potential vibration impacts would be evaluated in more detail as part of separate, project-level CEQA review.

Vibration could also result if sheetpile driving is required to shore any excavations associated with the Groundwater Projects (SF-2) and Recycled Water Projects (SF-3). Potentially significant vibration effects could result if there are any sensitive receptors located within 100 feet of proposed facilities, and implementation of vibration controls (Measures 4.10-3a and 4.10-3b) would reduce this potential impact to a less-than-significant level. However, if any construction activities were to generate vibration during the nighttime hours and within 100 feet of a receptor, it is possible that these measures could not reduce vibration levels sufficiently and sleep disturbance or annoyance could occur; therefore, this analysis conservatively considers this impact to be *potentially significant and unavoidable*. Potential vibration impacts would be evaluated in more detail as part of separate, project-level CEQA review.

Operational Impacts

Long-Term Noise Increases

Impact 4.10-4: Disturbance due to long-term noise increases associated with operation of project facilities.

Operation of some of the WSIP facilities would result in long-term noise increases. The primary sources of noise associated with facility operation are pumps and electrical facilities (substations, transformers, and emergency generators). Such noise sources are most often associated with water treatment plants and pumping plants. The degree of impact would vary with each project and would depend on pump sizes, transformer sizes, proximity to sensitive receptors, and the extent of noise attenuation incorporated into the facility design.

For operational noise, a substantial noise increase (as stated in the first significance criterion) can be defined by whether operational noise levels are within local ordinance noise limits (see Table 4.10-2). Operational noise levels would be estimated as part of separate, project-level CEQA review for those facilities, and the potential for operational noise impacts would be assessed at that time. Potential impacts would depend on existing ambient noise levels in the project vicinities, proposed facility design, and pertinent ordinance noise limits.

Pump Stations. Operation of some WSIP facilities would include new pump stations or upgrades of existing pump stations. The primary sources of noise associated with pump stations are pumps and electrical facilities (substations, transformers, and emergency generators). As indicated in Table 4.10-4, a pump (not enclosed) typically generates noise levels of 76 dBA at 50 feet. Noise levels associated with pump stations would depend on four factors: (1) characteristics of the noise source (e.g., technology type, rated horsepower, revolutions per minute, presence or absence of pure tones, directional characteristics of the noise source, presence or absence of acoustical design features); (2) the number of noise sources clustered together; (3) the type and effectiveness of the building enclosure; and (4) operational characteristics (steady 24-hour operation, intermittent operation, variable settings at different times, etc.). Typical noise levels associated with pump stations are as follows:

- Pumps (enclosed with baffled vents): 45 to 60 dBA (Leq) at 50 feet, depending on the number and sizes of pumps (based on noise measurements collected at various pump stations)
- Transformers: 50 to 70 dBA at 50 feet, depending on the size and number (NEMA, 1994)

Treatment Facilities. Treatment facilities typically include basins, filters, and drains, which would not be major sources of noise. Noise generated by water flowing through pipes or drains would be limited to areas in the vicinity of openings or vents; since noise levels from flowing water would generally be less than ambient noise levels, these facilities would not increase noise levels beyond the treatment plant boundaries. Chemical feed systems typically operate with very small pumps and are enclosed; therefore, they typically do not affect ambient noise levels. However, if pumping facilities are located within the treatment facility, noise from pumping facilities would be a principal source of operational noise.

Storage Facilities. Storage facilities include reservoirs or basins, which are typically located entirely or partially below grade. These facilities are sometimes filled by gravity flow, although pumping facilities can be required to fill basins or reservoirs. For the WSIP, major pumping systems are considered separately when they are located at different locations (e.g., the San Antonio Pump Station is considered separate from Calaveras Dam or Sunol Valley WTP). Noise sources within these facilities could include internal pumping systems, filters, chemical feed systems, piping, valves, and electrical and instrumentation facilities. Since this equipment is typically enclosed within the facility, it does not contribute significantly to the surrounding ambient noise environment.

Pipelines, Tunnels, and Crossovers. Operation of pipelines, tunnels, crossovers, or storage facilities would not generate noise. Pipelines, tunnels, and crossovers would be located underground and/or enclosed, and these facilities generally do not include any noise-generating equipment. While there could be electrical facilities associated with some of these facilities, they are generally housed within control buildings, and these enclosed facilities are not a major source of noise.

Vaults and Valve Lots. Vaults are structures (typically concrete) that are normally partially underground and enclosed either by hatch covers or valve house buildings. Various piping and valves are located within these vaults, and the valves allow operators to control water flows through the system. Since valves are typically electric-powered, standby power must be provided so they remain operational at all times, even during power outages. Other than emergency generators, there are no major noise sources (e.g., motors, pumps, transformers) associated with these facilities.

Standby Power. WSIP implementation would include provision of standby power (propane- or diesel-fueled emergency generators) at a number of existing, proposed, and upgraded facilities to keep facilities operating during power outages, thereby reducing the potential for interruption of supply to customers. Standby power, which could be provided by permanent or portable emergency generators, is proposed at various treatment facilities, pump stations, wells, vaults, and valve lots. Emergency generators typically generate noise levels of 85 dBA at 50 feet (see Table 4.10-4). An enclosure with baffled vents for permanent standby generators could reduce generator noise by 25 to 30 dBA. These generators would be used infrequently (only during power outages and for periodic testing during the day).

San Joaquin Region

Impact 4.10-4: Disturbance due to long-term noise increases		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	N/A
Tesla Portal Disinfection	SJ-5	LS

Primary sources of operational noise within this region would be standby power facilities associated with the SJPL System project (SJ-3, if required for valve house, crossovers, or possible pump station) and the Tesla Portal Disinfection project (SJ-5). Transformers or substations for power generation would also be a source of operational noise associated with the Advanced Disinfection project (SJ-1). The degree of impact would depend on the locations and designs of these facilities (e.g., proximity of sensitive receptors, use of enclosures or sound barriers). Given the rural or undeveloped nature of the areas surrounding these facility sites and the distance to the closest sensitive receptors, it is expected that operational noise could be maintained at acceptable levels (within local ordinance limits) through appropriate location and design (enclosure if necessary). Standby power facilities would be operated infrequently (only during power outages and for periodic testing during the day), limiting the potential for significant noise impacts. Enclosure of these facilities typically reduces potential impacts to a less-than-significant level. With implementation of SFPUC Construction Measure #6 (compliance with local noise ordinances to the extent feasible), potential noise impacts on any affected residential receptors would be *less than significant* for these three projects. However, it should be noted that the location of power facilities for the SJPL System project have not been determined, potential operational noise impacts would be evaluated in more detail as part of separate, project-level CEQA review for this project to define design measures needed to ensure operational noise levels are maintained at acceptable levels.

The Lawrence Livermore project (SJ-2) is not located near any noise sensitive land uses; therefore, noise associated with any Lawrence Livermore facilities would be *less than significant*. No facilities under the SJPL Rehabilitation project (SJ-4) would generate noise; therefore, this impact would *not apply* to this project.

Sunol Valley Region

Impact 4.10-4: Disturbance due to long-term noise increases		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	N/A
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	LS
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	N/A

Potential increases in operational noise in the Sunol Valley Region could occur as a result of new pumping facilities possibly associated with the Alameda Creek Fishery project (SV-1); new pumping facilities at the Sunol Valley WTP for filter backwashing, chemical feed, etc. proposed under the 40-mgd Treated Water and Treated Water Reservoirs projects (SV-3 and SV-5); and electrical supply upgrades associated with the 40-mgd Treated Water project (SV-3). The possible provision of additional standby power facilities at a new Alameda East Portal (under New Irvington Tunnel, SV-4) would also introduce a new source of noise (emergency generators) during periodic daytime testing and power outages. The SFPUC Land Manager's residence is located approximately 300 feet north of the Alameda East Portal, while a private residence is located about a half mile to the west. With implementation of SFPUC Construction Measure #6 (compliance with local noise ordinances to the extent feasible), potential noise impacts on these residential receptors would be *less than significant.* Given the distance between noise sources and residential receptors, it is expected that operational noise could be maintained at acceptable levels (within local ordinance limits) through appropriate location and design (including enclosure, if necessary).

The Calaveras Dam (SV-2) and SABUP (SV-5) projects would essentially have no operational noise, and this impact would *not apply*.

Bay Division Region

Impact 4.10-4: Disturbance due to long-term noise increases		
BDPL Reliability Upgrade	BD-1	LS
BDPL 3 and 4 Crossovers	BD-2	N/A
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	N/A

Operational noise increases within this region would be associated with standby power for the BDPL Reliability Upgrade project (BD-1). Since these facilities could be located near noise-sensitive receptors, there would be a potential for operational noise impacts. However, operational noise sources would be limited to backup power systems, including emergency generators, which would operate only during power outages and for periodic daytime testing. With implementation of SFPUC Construction Measure #6 (compliance with local noise ordinances to the extent feasible), potential noise impacts would be *less than significant,* given the limited noise sources associated with operation of this project. Potential operational noise impacts would be evaluated in more detail as part of separate, project-level CEQA review for the BDPL Reliability Upgrade project to define design measures needed to minimize noise levels during emergency and testing conditions.

The BDPL 3 and 4 Crossovers project (BD-2) would consist of crossovers and valves, partially underground and enclosed; these facilities would not generate noise. Similarly, the BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) project, as a pipeline project, would not generate operational noise. Therefore, this impact would *not apply* to these two projects.

Peninsula Region

Impact 4.10-4: Disturbance due to long-term noise increases		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission Upgrade	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	N/A
Pulgas Balancing Reservoir	PN-5	LS

Primary sources of operational noise within this region would be upgrades to existing pumping facilities (CS/SA Transmission, PN-2, and HTWTP Long-Term, PN-3), and possible electrical upgrades at the Harry Tracy WTP. The Baden and San Pedro Valve Lots project (PN-1) would consist of valves located partially underground and enclosed. Residential or school receptors are located near the HTWTP Long-Term (PN-3) and Baden Valve Lot projects. Proposed facilities at the Baden Valve Lot would also have a limited potential for noise impacts since the facilities would be enclosed. With implementation of SFPUC Construction Measure #6 (compliance with local noise ordinances to the extent feasible), potential noise impacts on these residential receptors would be *less than significant,* given the setback distances between sources and receptors or the limited noise potential associated with operation of proposed facilities. Potential operational noise impacts would be evaluated in more detail as part of separate, project-level CEQA review for these three projects to define design measures needed to ensure operational noise levels are maintained at acceptable levels.

Potential operational noise increases resulting from the provision of new chemical feed systems at the Pulgas Balancing Reservoir (PN-5) would be *less than significant* due to the absence of sensitive receptors in this vicinity and the small size of pumps that are typically associated with such facilities.

The Lower Crystal Springs Dam (PN-4) project would not generate operational noise, and operational noise impacts are *not applicable* to this project.

San Francisco Region

Impact 4.10-4: Disturbance due to long-term noise increases		
SAPL 3 Installation	SF-1	N/A
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	LS

Potential increases in operational noise in the San Francisco Region would be associated with wells for the Groundwater Projects (SF-2), the pumping facility for the Recycled Water Projects (SF-3), and standby power (under both the Groundwater and Recycled Water Projects). Potential impacts associated with standby power would be limited, since emergency generators would only operate during periodic daytime testing and power outages. Enclosure of these facilities typically reduces potential impacts to a less-than-significant level. With implementation of SFPUC Construction Measure #6 (compliance with local noise ordinances to the extent feasible), potential noise impacts would be *less than significant*. However, it should be noted that the location of these facilities have not yet been determined, and potential operational noise impacts would be evaluated in more detail as part of separate, project-level CEQA review for both the Groundwater and Recycled Water Projects to define design measures needed to ensure operational noise levels are maintained at acceptable levels.

Pipelines under the SAPL 3 Installation (SF-1) project would not generate operational noise. This impact would *not apply* to this project.

4.11 Public Services and Utilities

4.11 Public Services and Utilities

This section addresses potential impacts on public services and utilities that could occur as a result of implementation of the WSIP projects. This analysis is conducted on a program level, and each WSIP project would be subject to separate, project-level CEQA review. Public utilities discussed in this section include water, natural gas, and electricity conveyance facilities. Public services addressed in this section include law enforcement services, fire protection services, and solid waste disposal. Potential impacts on emergency response or access (i.e., disruption of emergency services due to access restrictions) are addressed in Section 4.8, Traffic, Transportation, and Circulation, and potential energy and power issues are addressed in Section 4.15, Energy Resources. Projects implemented under the WSIP that would affect school facilities are addressed in Section 4.3, Land Use and Visual Quality.

This section discusses the county and city jurisdictions where WSIP project construction would occur, or those within close proximity. Potential secondary or indirect impacts on utilities and public services that could occur as a result of population growth attributed to the WSIP projects are presented in Chapter 7.

4.11.1 Setting

The SFPUC regional water system consists of a network of facilities covering a geographic range of approximately 170 miles across central California, from the Sierra Nevada on the east to San Francisco on the west. WSIP projects are proposed within or in close proximity to the jurisdictional boundaries of the following seven counties: Alameda, San Francisco, San Joaquin, San Mateo, Santa Clara, Stanislaus, and Tuolumne. Project construction would occur in 27 cities within these counties. A detailed description of the SFPUC regional system, including facilities, locations, and operations, is provided in Chapter 3.

Water Service

The SFPUC provides water delivery services to retail and wholesale customers, primarily in San Francisco, San Mateo, Santa Clara, and Alameda Counties. The SFPUC serves about one-third of its water supplies directly to retail customers in San Francisco, and about two-thirds of its water supplies to 27 wholesale customers by contractual agreement. The wholesale customers consist of 25 cities and water districts and two private utilities in San Mateo, Santa Clara, and Alameda Counties, represented by the Bay Area Water Supply and Conservation Agency (BAWSCA). Some of these customers have sources of water in addition to what they receive from the SFPUC regional system. The SFPUC also provides service to some isolated regional retail customers along the water system, including customers in Tuolumne County. Chapter 3 provides detailed information regarding the SFPUC's overall water supply service.

Table 4.11-1 lists the major regional system customers and indicates the wholesale customers that have available water supplies from sources other than the SFPUC.

TABLE 4.11-1
SFPUC REGIONAL WATER SYSTEM CUSTOMERS

Wholesale Regional Customers[a] (BAWSCA Members)		
Peninsula	**South Bay**	**Other Major Customers**
California Water Service Company (South San Francisco* and Mid-Peninsula)	Alameda County Water District*	City and County of San Francisco
City of Brisbane	Mid-Peninsula Water District	Presidio Trust*
Guadalupe Valley Municipal Improvement District	California Water Service Company (Bear Gulch)*	San Francisco County Jail (San Bruno)
City of Burlingame	City of Hayward	San Francisco International Airport (San Mateo County)
City of Daly City*	City of Menlo Park*	Lawrence Livermore National Laboratory (Site 200/300)
City of Millbrae	City of Milpitas*	National Aeronautics and Space Administration (Santa Clara County)
City of San Bruno*	City of Mountain View*	Town of Sunol (Alameda County)
Coastside County Water District*	City of Palo Alto*	Groveland Community Services District (Tuolumne County)
Estero Municipal Improvement District (Foster City)	City Redwood City*	
North Coast County Water District	City of San Jose (North San Jose Service Area)*	
Town of Hillsborough	City of Sunnyvale*	
Westborough County Water District	City of Santa Clara*	
	City of East Palo Alto	
	Purissima Hills Water District	
	Skyline County Water District	
	Stanford University*	

* Indicates customers that currently receive additional water supplies from sources other than the SFPUC.

[a] Not shown on the table because they are not a BAWSCA member, the Cordilleras Mutual Water Association is also a wholesale customer receiving water from the SFPUC. It is a small water association serving 18 single-family homes located in San Mateo County.

SOURCES: CDM, 2005; URS, 2004a.

Natural Gas

Natural gas customers in California, including the WSIP study area, are served by a network of regional natural gas pipelines that traverse the state, crossing the state line to the southeast via San Bernardino and Riverside Counties, or to the north via Modoc County. Within northern California, natural gas pipelines are primarily owned by Pacific Gas and Electric Company (PG&E). Additional natural gas pipelines in the state are owned by Southern California Gas, San Diego Gas and Electric Company (SDG&E), Kern/Mojave, and other utility providers. Regional pipelines generally range from 2 to 42 inches in diameter. Large natural gas pipelines (33 to 42 inches in diameter), of which there are four, travel through much of the state.

PG&E owns the regional natural gas pipelines in the WSIP study area. PG&E operates natural gas and electrical transmission lines in two corridors west of the Calaveras Reservoir, and three high-pressure natural gas transmission lines in the San Antonio Valley, which is located along the Diablo Range in eastern Santa Clara County on the border of Alameda and Stanislaus Counties (SFPUC, 2001). The diameters of regional pipelines within proximity or traveling through proposed WSIP construction areas vary widely, from 2 and 42 inches (California Energy Commission, 2007a).

Petroleum

California is a major refining center for petroleum markets on the West Coast, with a combined crude oil distillation capacity of more than 1.9 million barrels per day, ranking the state third highest in the nation. California petroleum refineries are located in the San Francisco Bay Area, the Los Angeles area, and the Central Valley. A large network of crude oil pipelines connects producing areas with the major ports in Northern and Southern California. These ports receive Alaska North Slope and foreign crude oil for processing in many of the state's 21 refineries (California Energy Commission, 2007b).

The Chevron Pipeline Company operates a pipeline in the WSIP study area for the transport of refined petroleum products. The pipeline travels through the San Antonio Reservoir watershed, which is within the Alameda Creek watershed, and then crosses Alameda Creek in the Sunol Valley, for a distance of about eight miles within the Alameda watershed (SFPUC, 2001).

Electricity

A number of regional electricity transmission lines with varying levels of capacity serve the state's electricity demand. Most of California's electricity transmission lines, not including distribution lines, are owned by PG&E (approximately 58 percent of the state's transmission line mileage). Other transmission line owners in the state include Southern California Edison, SDG&E, municipal utilities, and the Western Area Power Administration.

Generally, PG&E provides electricity in the WSIP study area and also operates electrical transmission lines in two corridors west of Calaveras Reservoir (SFPUC, 2001). The Modesto and Turlock Irrigation Districts also serve Stanislaus County, while some customers choose to maintain contracts with independent power generators. Through the seven counties where WSIP project construction could occur, regional electricity transmission lines have capacities of 110 to 161 kilovolts, and 220 to 287 kilovolts (California Energy Commission, 2007a).

Law Enforcement Services

Law enforcement services in the WSIP study area are provided by a combination of county sheriff departments as well as citywide police departments (see **Table 4.11-2**). Sheriff departments typically provide law enforcement and jail services within their respective counties. In addition to law enforcement jurisdiction over unincorporated county areas, some sheriff departments, including the Stanislaus, San Joaquin, Alameda, and San Mateo County Sheriff Departments, also provide law enforcement services to certain cities within the county on a contract basis.

Fire Protection Services

Fire protection services in the WSIP study area are provided by a number of agencies, including county fire departments, city fire departments, and fire districts (see Table 4.11-2). A number of the counties also have volunteer fire departments. The California Department of Forestry and Fire Protection (CDF) provides fire protection services for both wildland and residential/commercial areas, in addition to responding to other types of emergencies, ranging from automobile accidents to lost hikers to earthquakes. The CDF is responsible for the protection of over 31 million acres of California's privately owned wildlands and provides emergency services within 36 of California's 58 counties through local government contracts. Within the counties that would be affected by WSIP projects, the CDF has three units: the San Mateo/Santa Cruz Unit, the Santa Clara Unit, and the Tuolumne/Calaveras Unit.

Solid Waste Management

With the exception of San Francisco and Tuolumne Counties, each of the counties within the WSIP study area has active landfills. Active landfills by county include: Alameda County with two landfills (Altamont Landfill and Resource Recovery, and Vasco Road Sanitary Landfill); San Joaquin County with three landfills (Foothill Sanitary Landfill, Forward Landfill, Inc., and North County Landfill); San Mateo County with one landfill (Ox Mountain Sanitary Landfill); Santa Clara County with seven landfills (City of Palo Alto Refuse Disposal Site, Guadalupe Sanitary Landfill, Kirby Canyon Recycling and Disposal Facility, Newby Island Sanitary Landfill, Zanker Material Processing Facility, and Zanker Road Resource Recovery Operations Landfill); and Stanislaus County with two landfills (Bonzi Sanitary Landfill and Fink Road Landfill). The California Integrated Waste Management Board (CIWMB) maintains facility information and waste stream profiles for all counties and jurisdictions in the state (see Table **4.11-3**). The CIWMB, the state entity that administers the California Integrated Waste Management Act (described below), found that these jurisdictions achieved the 50 percent goal or approved their good faith effort to achieve the 50 percent goal[1] for 2002 (CIWMB, 2007a). Jurisdictions within the WSIP study area have prepared and adopted the necessary planning documents to implement the act.

Regulatory Framework

California Public Utilities Commission

The California Constitution vests the California Public Utilities Commission (CPUC) with exclusive power and sole authority to regulate privately owned and investor-owned public utilities. This exclusive power extends to all aspects of the location, design, construction, maintenance, and operation of regulated utility facilities. The CPUC has provisions that require regulated utilities to work closely with local governments and to give due consideration to their concerns.

1 The California Integrated Waste Management Act of 1989 is discussed under Regulatory Framework.

[a] Capacity information from 2000 (CIWMB, 2007b). The remaining capacity of landfills in the WSIP study area that were recently closed, or that will be closed in the near future, were not included in this analysis. They are: Tri-Cities Recycling and Disposal Facility (Alameda County), Hillside Class III Disposal Site (San Mateo County), and NORCAL Waste Systems Pacheco Pass (Santa Clara County).
[b] Calculated using CIWMB 2007 data.
[c] Remaining capacity date provided by the CIWMB or local landfill operator.

California Integrated Waste Management Act of 1989

The California Integrated Waste Management Act of 1989 (Public Resources Code [PRC], Division 30), enacted through Assembly Bill (AB) 939 and modified by subsequent legislation, requires all California cities and counties to implement programs to reduce, recycle, and compost at least 50 percent of wastes by the year 2000 (PRC Section 41780). The state determines compliance with this mandate to divert 50 percent of generated waste (which includes both disposed and diverted waste) through a complex formula. This formula requires cities and counties to conduct empirical studies to establish a “base year” waste generation rate against which future diversion is measured. The actual determination of the diversion rate in subsequent years is arrived at through deduction, not direct measurement: instead of counting the amount of material recycled and composted, the city or county tracks the amount of material disposed at landfills, then subtracts the disposed amount from the base-year amount. The difference is assumed to be diverted (PRC Section 41780.2).

In the original determination of their base-year generation rate, cities and counties may not count certain diverted materials, including agricultural wastes, scrap metals, discarded major appliances, or inert solids such as rock, concrete, brick, sand, soil, fines, asphalt, and unsorted construction and demolition waste, unless the city or county can demonstrate that these materials had previously been disposed in a landfill and were now being diverted through a specific action of the city or county (PRC Section 41781.2). In subsequent years, these materials only have an impact on a city’s or county’s attainment of the diversion mandate if the materials are disposed in landfills. If they continue to be diverted, they are never accounted for.

Regulations Governing Utility Safety and Service at Construction Sites

Excavation activities are regulated through the California Occupational Health and Safety Administration Trench Construction Safety Orders. In addition, California Department of Health Services (DHS) standards require: (1) a 10-foot horizontal separation between parallel sewer and water mains; (2) a 1-foot vertical separation between perpendicular water and sewer line crossings; and (3) encasement of sewer mains in protective sleeves where a new water line crosses under or over an existing wastewater main. In the event that separation requirements cannot be maintained, the SFPUC or its contractors would obtain a DHS variance by providing sewer encasement or other measure deemed suitable by the DHS.

4.11.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to public services and utilities, but generally considers that implementation of the proposed program would have a significant impact if it were to:

- Result in substantial adverse physical impacts associated with the provision of, or the need for, new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times, or other performance objectives for any public services such as fire protection, police protection, schools, parks, or other services (Not evaluated in this section, see Appendix B)

- Exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board (Not evaluated in this section, see Appendix B)

- Require or result in the construction of new water or wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects (Evaluated in this section)

- Require or result in the construction of new storm water drainage facilities or expansion of existing facilities, the construction of which could cause significant environmental effects (Not evaluated in this section, see Appendix B)

- Not have sufficient water supply available to serve the project from existing entitlements and resources, or require new or expanded water supply resources or entitlements (Evaluated in this section)

- Result in a determination by the wastewater treatment provider that would serve the project that it has inadequate capacity to serve the project's projected demand in addition to the provider's existing commitments (Not evaluated in this section, see Appendix B)

- Be served by a landfill with insufficient permitted capacity to accommodate the project's solid waste disposal needs (Evaluated in this section)

- Be out of compliance with federal, state, and local statutes and regulations related to solid waste (Evaluated in this section)

Impacts from construction of new water facilities are discussed by impact topic throughout Chapter 4. The provision of adequate water supply is discussed in Chapters 3 and 5. Storm water drainage issues as they relate to effects on hydrology are addressed in Section 4.5, Hydrology and Water Quality.

This section specifically addresses impacts on public utilities and landfills. Due to the nature of the proposed program, this PEIR also applies the following additional criteria and considers implementation of WSIP to have a significant effect on services and utilities if it were to:

- Disrupt operation of or require relocation of regional or local utilities (Evaluated in this section)

Approach to Analysis

For this program-level analysis, one area of focus is the temporary construction-related impacts on utility services. In general, implementation of the WSIP projects would not have direct, long-term impacts on the demand for public utilities, with the exception of water supply service (discussed in Chapter 3) and electricity (discussed in Section 4.15, Energy Resources). Long-term electricity use would increase as needed to power new or expanded facilities. Short-term, temporary disruption of service could occur if existing utilities required relocation. The presence of existing utility systems in the vicinity of proposed WSIP projects is used as an indicator of potential impact on utilities.

The second focus of analysis is the potentially adverse temporary impact on landfill capacity due to the disposal of WSIP construction waste. The largest potential source of solid waste would be excavated soil. While it is expected that most clean soil would be recycled, reused offsite, or stockpiled and reused as backfill, this analysis assumes that a portion of soil would be disposed in landfills. The analysis includes an estimate of the available capacity of landfills in the counties within the WSIP study area and expected construction waste quantities.

Impact Summary by Region

Table 4.11-4 presents a summary of potential impacts on utilities and landfills associated with the WSIP projects. For each impact, the summary presents the expected level of significance of each potential impact for each WSIP project.

Construction Impacts

Impact 4.11-1: Potential temporary damage to or disruption of existing regional and local public utilities.

Implementation of the WSIP projects would result in new construction of or improvements to pipelines, tunnels, vaults, valve lots, crossovers, treatment facilities, and storage facilities. Construction activities associated with the WSIP projects could result in unintentional utility service disruptions, including water, sewer, storm drain, and natural gas pipelines, and electricity, telephone, and television cable service. Construction activities that could affect utilities are addressed by facility type below.

Pipelines. The open-cut or cut-and-cover construction methods for pipeline installation, repair, or replacement would have the greatest potential for disrupting existing utility services. Depending on the location of the proposed pipeline and associated staging areas, construction activities could disrupt utility services.

Regional utility lines as well as local utility connections of varying sizes traverse the WSIP study area. Given that utility corridors generally include multiple utility lines (i.e., natural gas, water, and sewer lines), construction of pipelines could interfere with existing utility services. If the specific locations of existing utilities are not identified prior to construction activities, damage to utility lines and temporary disruption of utility services could occur.

TABLE 4.11-4
SUMMARY OF IMPACTS AND SIGNIFICANCE – PUBLIC SERVICES AND UTILITIES

Projects	Project Number	Impact 4.11-1:Potential temporary damage to or disruption of existing regional or local public utilities	Impact 4.11-2 : Temporary adverse effects on solid waste landfill capacity	Impact 4.11-3: Impacts related to compliance with statutes and regulations related to solid waste	Impact 4.11-4: Impacts related to the relocation of utilities
San Joaquin Region					
Advanced Disinfection	SJ-1	LS	PSM	PSM	PSM
Lawrence Livermore Supply Improvements	SJ-2	LS	PSM	PSM	PSM
San Joaquin Pipeline System	SJ-3	PSM	PSM	PSM	PSM
Rehabilitation of Existing San Joaquin Pipelines	SJ-4	LS	PSM	PSM	PSM
Tesla Portal Disinfection Station	SJ-5	LS	PSM	PSM	PSM
Sunol Valley Region					
Alameda Creek Fishery Enhancement	SV-1	PSM	PSM	PSM	PSM
Calaveras Dam Replacement	SV-2	PSM	PSM	PSM	PSM
Additional 40-mgd Treated Water Supply	SV-3	PSM	PSM	PSM	PSM
New Irvington Tunnel	SV-4	PSM	PSM	PSM	PSM
SVWTP – Treated Water Reservoirs	SV-5	LS	PSM	PSM	PSM
San Antonio Backup Pipeline	SV-6	PSM	PSM	PSM	PSM

San Francisco Region					
San Andreas Pipeline No. 3 Installation	SF-1	PSM	PSM	PSM	PSM
Groundwater Projects	SF-2	PSM	PSM	PSM	PSM
Recycled Water Projects	SF-3	PSM	PSM	PSM	PSM

LS = Less than Significant impact, no mitigation required
PSM= Potentially Significant impact, can be mitigated to less than significant

All utility lines that could be disrupted during pipeline construction would be identified during the project design phase. As a condition of approval for either a utility excavation permit or an encroachment permit, the SFPUC would prepare a detailed engineering and construction plan that identifies construction techniques and protective measures to minimize impacts on utilities.

Tunnels. Unlike pipeline projects, tunnel projects are generally not expected to interfere with utility services, since new tunnels would not be constructed within utility corridors. However, potential impacts on utilities associated with tunnel construction could occur at the tunnel entry and exit portal locations, which would serve as the construction staging areas. Utilities could be adversely affected if portals were located within existing utility corridors.

Vaults, Valve Lots, and Crossover Facilities. The WSIP includes the construction of vaults, valve lots, and crossover facilities at isolated locations near existing SFPUC facilities. These new facilities would be partially or completely buried. Impacts on utilities could occur during project construction, as subsurface activity has the potential to interfere with existing utilities and could result in interruptions in service.

Pump Stations. The WSIP projects would include the construction of new pump stations and upgrades to existing pump stations. New pump stations could result in an adverse effect on the provision of utilities if construction interfered with established utility lines and interrupted services. Typically, construction would be scheduled such that service to customers could be maintained without interruption.

Treatment Facilities. The WSIP would upgrade and expand treatment facilities at two existing treatment plants as well as at the system's primary disinfection facility, in addition to constructing a new secondary disinfection facility. Upgrades at existing treatment plants would occur within the property boundaries and would not affect offsite utility services. Potential impacts associated with the provision of utilities would depend on site locations in relation to established utility lines. Typically, construction would be scheduled such that service to customers could be maintained without interruption.

Storage Facilities. WSIP projects related to water storage facilities include improvements to reservoirs and dams. For most reservoirs, construction activities would be limited to the installation of new pumping and electrical equipment; however, for the Pulgas Balancing Reservoir project (PN-5), rehabilitation work would include replacing the Pulgas Channel. Dam improvement projects include raising the dam parapet wall at Lower Crystal Springs Dam (PN-4) and replacing Calaveras Dam (SV-2). During construction at storage facilities, interruptions in water service to SFPUC customers are not expected, as the SFPUC would plan for alternative water service during project planning and construction phasing, as necessary. Also, construction would be scheduled such that service to customers could be maintained without interruption. Thus, the level of service during a planned outage would remain unchanged from existing conditions.

San Joaquin Region

Impact 4.11-1: Potential temporary damage to or disruption of existing regional and local public utilities		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	LS
Tesla Portal Disinfection	SJ-5	LS

Of the projects in this region, the SJPL System project (SJ-3) would have the greatest potential to result in temporary adverse impacts on utility services. The SJPL System project would entail construction of a new pipeline and two crossover facilities. Pipeline construction (and associated staging areas) could temporarily interrupt the provision of utility services, resulting in *potentially significant* impacts. Potential impacts on services and utilities would be evaluated in more detail as part of separate, project-level CEQA review for this project. Implementation of SFPUC Construction Measure #1 (neighborhood noticing) and identification of public utility lines prior to commencing construction (Measures 4.11-1a through 4.11-1h) would reduce this impact to a less-than-significant level.

The proposed water treatment projects (Advanced Disinfection, SJ-1; Lawrence Livermore, SJ-2; and Tesla Portal Disinfection, SJ-5) and SJPL Rehabilitation project (SJ-4), would replace existing facilities with new facilities to increase system reliability and improve the supply of water to SFPUC retail and wholesale customers. These facilities would be constructed within the SFPUC's existing right-of-way on sites that already have power connections. The SFPUC would phase construction to ensure that operations would not be interrupted during construction. With implementation of SFPUC Construction Measure #1 (neighborhood noticing), potential impacts on existing regional and local public utilities from these four projects would be *less than significant*.

Sunol Valley Region

Impact 4.11-1: Potential temporary damage to or disruption of existing regional and local public utilities		
Alameda Creek Fishery	SV-1	PSM
Calaveras Dam	SV-2	PSM
40-mgd Treated Water	SV-3	PSM
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	PSM

Four of the five WSIP projects in the Sunol Valley Region (Alameda Creek Fishery, SV-1; Calaveras Dam, SV-2; the pipeline portion of the 40-mgd Treated Water project, SV-3; New Irvington Tunnel, SV-4; and SABUP, SV-6) could conflict with existing local and regional utilities. Although these water improvement projects also have the potential to disrupt water services delivered to SFPUC customers, appropriate measures would be incorporated into these projects to ensure that construction activities would not result in service interruption. While these projects have various components, the pipeline component would have the greatest potential to conflict with existing utilities. Underground utility lines in this region include the Chevron pipeline, which transports refined petroleum products, and PG&E natural gas and underground electrical transmission lines.

Construction of these four WSIP projects could cause temporary service disruptions of these water and utility lines (as described above) or potential safety hazards, resulting in *potentially significant* impacts. Implementation of SFPUC Construction Measure #1 (neighborhood noticing) and identification of public utility lines prior to commencing construction (Measures 4.11-1a through 4.11-1h) would reduce these impacts to a less-than-significant level.

The Treated Water Reservoirs project (SV-5) would be constructed in a previously undisturbed area adjacent to the Sunol Valley Water Treatment Plant, and this project is not expected to result in water or utility service interruptions. With implementation of SFPUC Construction Measure #1 (neighborhood noticing), potential impacts on existing regional and local public utilities would be *less than significant*.

Bay Division Region

Impact 4.11-1: Potential temporary damage to or disruption of existing regional and local public utilities		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	PSM
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSM

Construction in this region associated with pipelines, tunnels, and valve lots or vaults (as described above) would result in potential impacts on utility service. Although most construction would occur within SFPUC rights-of-way or within existing SFPUC facilities, all of the projects in this region (BDPL Reliability Upgrade, BD-1; BDPL 3 and 4 Crossovers, BD-2; and BDPL 3 and 4 Seismic Upgrade at Hayward Fault, BD-3) have the potential to traverse or encroach on existing utility corridors because much of this area is urbanized. The project could result in *potentially significant* (although temporary) service disruptions where such conflicts occur. Implementation of SFPUC Construction Measure #1 (neighborhood noticing) and identification of public utility lines prior to commencing construction (Measures 4.11-1a through 4.11-1h) would reduce these impacts to a less-than-significant level.

Peninsula Region

Impact 4.11-1: Potential temporary damage to or disruption of existing regional and local public utilities		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	PSM
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	PSM
Pulgas Balancing Reservoir	PN-5	LS

The CS/SA Transmission (PN-2) and Lower Crystal Springs Dam (PN-4) projects could cause temporary utility disruptions, a *potentially significant* impact. Implementation of SFPUC Construction Measure #1 (neighborhood noticing) and identification of public utility lines prior to commencing construction (Measures 4.11-1a through 4.11-1h) would reduce this impact to a less-than-significant level.

The other projects in this region (Baden and San Pedro Valve Lots, PN-1; HTWTP Long-Term, PN-3; and Pulgas Balancing Reservoir, PN-5) would involve repair, improvement, or expansion of existing water facilities and would occur in areas that are already developed with SFPUC water facilities. Therefore, these projects are not expected to cause impacts on offsite utility systems. With implementation of SFPUC Construction Measure #1 (neighborhood noticing), potential impacts on existing regional and local public utilities from these three projects would be *less than significant*.

San Francisco Region

Impact 4.11-1: Potential temporary damage to or disruption of existing regional and local public utilities		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	PSM
Recycled Water Projects	SF-3	PSM

All three projects in this region (SAPL 3 Installation, SF-1; Groundwater Projects, SF-2; and Recycled Water Projects, SF-3) have the potential to result in temporary adverse impacts on utility services. Some components of the Groundwater and Recycled Water Projects, such as wells, storage facilities, etc., would be located in developed areas, where the potential exists for encroachment on existing utilities. Project construction (and associated staging areas) could temporarily disrupt utility services, resulting in *potentially significant* impacts. Implementation of SFPUC Construction Measure #1 (neighborhood noticing) and identification of public utility lines prior to commencing construction (Measures 4.11-1a through 4.11-1h) would reduce these impacts to a less-than-significant level.

Impact 4.11-2: Temporary adverse effects on solid waste landfill capacity.

Construction of the WSIP projects could result in the generation of a large volume of waste materials; if the total amount were disposed of in local landfills, these materials could potentially exceed the daily tonnage limit of these landfills and/or adversely affect landfill capacity. These waste materials include construction debris, demolition materials, and excavated spoils. The largest potential source of solid waste would be excavated soil. Every landfill listed in Table 4.11-3 is permitted to accept construction/demolition waste, including clean soil. Four landfills (Newby Island Landfill in Santa Clara County, Altamont Landfill and Resource Recovery and Vasco Road Sanitary Landfill in Alameda County, and Forward Landfill, Inc. in San Joaquin County) are permitted to accept contaminated soil. The specific quantity and quality of solid waste to be disposed would be determined during a condition assessment for each project. Due to the economic value of clean excavated soil and the cost of landfill disposal, this analysis assumes at least 50 percent of excavation/spoils would be diverted from landfills and reused as landfill or agricultural cover, backfilled onsite, or recycled.[2]

---

[2] This rate of diversion from landfills would be consistent with the California Integrated Waste Management Act of 1989, which requires all California cities and counties to implement programs to reduce, recycle, and compost at least 50 percent of wastes by the year 2000 and divert at least 75 percent by 2010. These are general guidelines, and percentages would vary depending on waste types, etc. Also, diversion rates for the WSIP projects could vary substantially, since some projects, like Calaveras Dam (SV-2), provide for onsite disposal of most of their own spoils.

Table 4.11-5 indicates the estimated amount of excavated soils in cubic yards (whether or not demolition would be required for each project) and provides additional information on disposal. Assuming a 50 percent diversion rate, the estimated total volume of excavated material to be disposed of offsite for all WSIP projects combined would be approximately 2,903,157 cubic yards. There would be approximately 374,229,941 cubic yards of remaining capacity in nearby landfills, as identified in Table 4.11-3. The proposed volume of excavated material under the WSIP is less than approximately 1 percent of the total existing landfill capacity in the WSIP study area. Furthermore, when the estimated disposal amount for the Central Valley projects is compared to the available capacity of landfills in San Joaquin and Stanislaus Counties, these projects would account for 1 to 2 percent of capacity. The WSIP projects in the four Bay Area counties would similarly account for 1 to 2 percent of the landfill capacity in the Bay Area. However, since the exact quantity and quality of disposed material and the daily disposal rates have not yet been determined for each project, the impacts on permitted landfill capacity are conservatively considered to be *potentially significant*. Development of a waste management or recycling plan (Measure 4.11-2) would reduce this impact to a less-than-significant level.

San Joaquin Region

Impact 4.11-2: Temporary adverse effects on solid waste landfill capacity		
Advanced Disinfection	SJ-1	PSM
Lawrence Livermore	SJ-2	PSM
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	PSM

Of the projects in this region, the SJPL System project (SJ-3) has the greatest potential to result in temporary adverse impacts on landfill capacity. This project would create approximately 424,000 cubic yards of excavation/spoils. Assuming a 50 percent diversion rate, the SJPL Rehabilitation project (SJ-4) could generate approximately 100,000 cubic yards. Due to the economic value of clean excavated soil, the cost of landfill disposal, and the availability of alternative receptor sites such as agricultural fields, this analysis assumes at least 50 percent of excavation/spoils generated in the San Joaquin Region would be reused onsite or used by nearby agricultural industries. This analysis also assumes that any solid waste disposal necessitated by the projects within this region would utilize nearby landfills, while spoils in other regions would use landfills in the Bay Area.

The estimated 262,000 cubic yards of solid waste generated in the San Joaquin Region would only use 1 to 2 percent of the existing regional landfill capacity in San Joaquin and Stanislaus Counties. However, since the exact quantity and quality of disposed material and daily disposal rates have not yet been determined, the impacts on permitted landfill capacity from all of the projects in the San Joaquin Region are conservatively considered to be *potentially significant*. Development of a waste management or recycling plan (Measure 4.11-2) would reduce this impact to a less-than-significant level.

TABLE 4.11-5
WSIP SPOIL ESTIMATES AND DISPOSAL SITE INFORMATION

Project No.	Project Name	Excavation/ Spoils (cubic yards)[a]	Demolition Required[a]	Disposal Information[a,b]	Offsite Disposal Estimate (cubic yards)[c]
SJ-1	Advanced Disinfection	TBD	TBD	No additional borrow or disposal sites.	Part or all of the spoils to be disposed onsite or used in nearby agricultural operations.
SJ-2	Lawrence Livermore Supply Improvements	TBD	TBD	TBD	Part or all of spoils to be disposed onsite or used in nearby agricultural operations.
SJ-3	San Joaquin Pipeline System	424,000	TBD	Clean spoils might be stockpiled on right-of-way, and adjacent owners could be allowed to move spoils to adjacent agricultural uses.	Part or all of spoils to be disposed onsite or used in nearby agricultural operations. Estimate for analysis: 50% disposed offsite = 212,000 cubic yards
SJ-4	San Joaquin Pipeline Rehabilitation	100,000	None	No additional borrow or disposal sites.	Part or all of spoils to be disposed onsite or used in nearby agricultural operations. Estimate for analysis: 50% disposed offsite = 50,000 cubic yards
SJ-5	Tesla Portal Disinfection Station	TBD	TBD	TBD	Part or all of spoils to be disposed onsite or used in nearby agricultural operations.
SV-1	Alameda Creek Fishery Enhancement	TBD	TBD	TBD	—
SV-2	Calaveras Dam Replacement	4,000,000	Yes	Seven borrow areas (totaling over 222 acres).	Most or all of spoils to be disposed of onsite. Estimate for analysis: 50% disposed offsite = 2,000,000 cubic yards
SV-3	Additional 40-mgd Treated Water Supply	100,000	No	TBD	Estimate for analysis: 50% disposed offsite = 50,000 cubic yards
SV-4	New Irvington Tunnel	186,175	Yes	Up to four spoils disposal areas are proposed. Spoils could be transported to one of these areas by conveyor belt.	Most or all of spoils to be disposed of onsite. Estimate for analysis: 50% disposed offsite = 93,087 cubic yards
SV-5	SVWTP – Treated Water Reservoirs	300,000	No	TBD	Estimate for analysis: 50% disposed offsite = 150,000 cubic yards
SV-6	San Antonio Backup Pipeline	37,000	No	Borrow/disposal sites could be located on undeveloped SFPUC land.	Estimate for analysis: 50% disposed offsite = 18,500 cubic yards

TABLE 4.11-5 (Continued)
WSIP SPOIL ESTIMATES AND DISPOSAL SITE INFORMATION

Project No.	Project Name	Excavation/ Spoils (cubic yards)[a]	Demolition Required[a]	Disposal Information[a,b]	Offsite Disposal Estimate (cubic yards)[c]
BD-1	Bay Division Pipeline Reliability Upgrade	434,000	Yes	Portions of the section of Bay Division Pipeline No. 1 between Edgewood Valve Lot and Pulgas Valve Lot would be removed. Potential disposal sites for tunnel muck include salt ponds near Dumbarton Strait and South Bay Salt Pond Restoration Project and nearby landfills.	Estimate for analysis: 50% disposed offsite = 217,000 cubic yards
BD-2	BDPL Nos. 3 and 4 Crossovers	43,500	TBD	TBD	Estimate for analysis: 50% disposed offsite = 21,750 cubic yards
BD-3	Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault	55,300	No	No additional borrow or disposal sites.	Estimate for analysis: 50% disposed offsite = 27,650 cubic yards
PN-1	Baden and San Pedro Valve Lots Improvements	4,970	Yes	TBD	Estimate for analysis: 50% disposed offsite = 2,485 cubic yards
PN-2	Crystal Springs/San Andreas Transmission Upgrade	Up to 9,000 cubic yards	TBD	TBD	Estimate for analysis: 50% disposed offsite = 4,500 cubic yards
PN-3	HTWTP Long-Term Improvements	Not specified	Not specified	TBD	Unknown
PN-4	Lower Crystal Springs Dam Improvements	21,000	Yes	TBD	Estimate for analysis: 50% disposed offsite = 10,500 cubic yards
PN-5	Pulgas Balancing Reservoir Rehabilitation	TBD	TBD	N/A	Unknown
SF-1	San Andreas Pipeline No. 3 Installation	44,170	Yes	N/A	Estimate for analysis: 50% disposed offsite = 22,085 cubic yards
SF-2	Groundwater Projects	TBD	TBD	N/A	Unknown
SF-3	Recycled Water Projects	47,200	TBD	TBD	Estimate for analysis: 50% disposed offsite = 23,600 cubic yards
TOTAL					**2,903,157 cubic yards**

TBD = To be determined; N/A = Not Available or Not Applicable

[a] Information from Table C.4 in Appendix C.
[b] Information from Table C.1 in Appendix C.
[c] For this analysis, a conservative estimate was made that 50 percent of the excavated soil would be disposed of in landfills.

SOURCES: SFPUC, 2006; ESA, 2006.

Sunol Valley Region

Impact 4.11-2: Temporary adverse effects on solid waste landfill capacity		
Alameda Creek Fishery	SV-1	PSM
Calaveras Dam	SV-2	PSM
40-mgd Treated Water	SV-3	PSM
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	PSM
SABUP	SV-6	PSM

The construction of a number of the WSIP projects within the Sunol Valley Region (Calaveras Dam, SV-2; 40-mgd Treated Water, SV-3; New Irvington Tunnel, SV-4; and Treated Water Reservoirs, SV-5; SABUP, SV-6) would require offsite disposal in nearby landfills. Due to the economic value of clean excavated soil and the cost of landfill disposal, the following estimates assume at least 50 percent of excavation/spoils would be diverted from landfills to be reused as landfill cover, backfill, or recycled for further use.

The Calaveras Dam project (SV-2) would generate approximately 4,000,000 cubic yards of excavation/spoils. Although most of the spoils are proposed for onsite disposal in the dam vicinity, this analysis conservatively assumes up to 2,000,000 cubic yards could be disposed of in a nearby landfill. The 40-mgd Treated Water project (SV-3) would create approximately 100,000 cubic yards of excavation/spoils, of which up to 50,000 cubic yards could be disposed of in a nearby landfill. The New Irvington Tunnel project (SV-4) would create approximately 186,175 cubic yards of excavation/spoils, of which up to 93,087 cubic yards could be disposed in a nearby landfill. The Treated Water Reservoirs (SV-5) would create approximately 300,000 cubic yards of excavation/spoils, of which up to 150,000 cubic yards could be disposed in a nearby landfill. The SABUP project (SV-6) would create approximately 37,000 cubic yards of excavation/spoils, of which up to 18,500 cubic yards could be disposed in a nearby landfill. Individual landfill disposal requirements and potential impacts of these projects would be evaluated in more detail as part of separate, project-level CEQA review. More detailed project design information would be necessary to determine the expected excavation/spoils quantities and disposal information for the Alameda Creek Fishery project (SV-1).

The estimated 2.3 million cubic yards of solid waste that would be generated from the Sunol Valley Region projects would use approximately 1 to 2 percent of the existing landfill capacity in the four Bay Area counties. However, since the exact quantity and quality of disposed material and daily disposal rates have not yet been determined, the impacts on permitted landfill capacity are conservatively considered to be *potentially significant*. However, development of a waste management or recycling plan (Measure 4.11-2) would reduce this impact to a less-than-significant level.

Bay Division Region

Impact 4.11-2: Temporary adverse effects on solid waste landfill capacity		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	PSM
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSM

The construction of all three WSIP projects within the Bay Division Region (BDPL Reliability Upgrade, BD-1; BDPL 3 and 4 Crossovers, BD-2; and BDPL 3 and 4 Seismic Upgrade at Hayward Fault, BD-3) would require offsite disposal in nearby landfills. Due to the economic value of clean excavated soil and the cost of landfill disposal, the following estimates assume at least 50 percent of excavation/spoils would be diverted from landfills to be reused as landfill cover, backfill, or recycled for further use.

The BDPL Reliability Upgrade project (BD-1) would create approximately 434,000 cubic yards of excavation/spoils, of which up to 217,000 cubic yards could be disposed of in a nearby landfill. The BDPL 3 and 4 Crossovers project (BD-2) would create approximately 43,500 cubic yards of excavation/spoils, of which up to 21,750 cubic yards could be disposed of in a nearby landfill. The BDPL 3 and 4 Seismic Upgrade at Hayward Fault project (BD-3) would create approximately 55,300 cubic yards of excavation/spoils, of which up to 27,650 cubic yards could be disposed of in a nearby landfill. Individual landfill disposal requirements and potential impacts of these projects would be evaluated in more detail as part of separate, project-level CEQA review for each project.

The estimated 266,400 cubic yards of solid waste generated from the Bay Division Region projects would use only 1 to 2 percent of the existing landfill capacity in the four Bay Area counties. However, since the exact quantity and quality of disposed material and daily disposal rates have not yet been determined, the impacts on permitted landfill capacity are conservatively considered to be *potentially significant*. Development of a waste management or recycling plan (Measure 4.11-2) would reduce this impact to a less-than-significant level.

Peninsula Region

Impact 4.11-2: Temporary adverse effects on solid waste landfill capacity		
Baden and San Pedro Valve Lots	PN-1	PSM
CS/SA Transmission	PN-2	PSM
HTWTP Long-Term	PN-3	PSM
Lower Crystal Springs Dam	PN-4	PSM
Pulgas Balancing Reservoir	PN-5	PSM

The construction of three WSIP projects in the Peninsula Region (Baden and San Pedro Valve Lots, PN-1; CS/SA Transmission, PN-2; and Lower Crystal Springs Dam, PN-4) would require offsite disposal in nearby landfills. Due to the economic value of clean excavated soil and the cost of landfill disposal, the following estimates assume at least 50 percent of excavation/spoils would be diverted from landfills to be reused as landfill cover, backfill, or recycled for further use.

The Baden and San Pedro Valve Lots project would create approximately 4,970 cubic yards of excavation/spoils, of which approximately 2,485 cubic yards could be disposed of in a nearby landfill. The CS/SA Transmission project would create up to 9,000 cubic yards of excavation/spoils, of which up to 4,500 cubic yards could be disposed of in a nearby landfill. The Lower Crystal Springs Dam project would create approximately 21,000 cubic yards of excavation/spoils, of which up to 10,500 cubic yards could be disposed of in a nearby landfill. Individual landfill disposal requirements and potential impacts of these projects would be evaluated in more detail as part of separate, project-level CEQA review. More detailed project design information is necessary to determine the expected excavation/spoils quantities and disposal information for the HTWTP Long-Term (PN-3) and Pulgas Balancing Reservoir (PN-5) projects.

The estimated 15,000 cubic yards of solid waste generated from the Peninsula Region projects would use only 1 to 2 percent of the existing landfill capacity in the Bay Area. However, since the exact quantity and quality of disposed material and daily disposal rates have not yet been determined, the impacts on permitted landfill capacity are conservatively considered to be *potentially significant*. Development of a waste management or recycling plan (Measure 4.11-2) would reduce this impact to a less-than-significant level.

San Francisco Region

Impact 4.11-2: Temporary adverse effects on solid waste landfill capacity		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	PSM
Recycled Water Projects	SF-3	PSM

Two projects in the San Francisco Region (SAPL 3 Installation, SF-1, and Recycled Water Projects, SF-3) would require offsite disposal in nearby landfills. Due to the economic value of clean excavated soil and the cost of landfill disposal, the following estimates assume at least 50 percent of excavation/spoils would be diverted from landfills to be reused as landfill cover, backfill, or recycled for further use.

The SAPL 3 Installation project would create up to 44,170 cubic yards of excavation/spoils, of which up to 22,085 cubic yards could be disposed of in a nearby landfill. The Recycled Water Projects would create approximately 47,200 cubic yards of excavation/spoils, of which up to 23,600 cubic yards could be disposed of in a nearby landfill. Individual landfill disposal requirements and potential impacts of these projects would be evaluated in more detail as part of separate, project-level CEQA review. More detailed project design information is necessary to determine the expected excavation/spoils quantities and disposal information for the Groundwater Projects (SF-2).

The estimated 45,685 cubic yards of solid waste generated from the San Francisco Region projects would use only 1 to 2 percent of the existing regional landfill capacity. However, since the exact quantity and quality of disposed material and daily disposal rates have not yet been determined, the impacts on permitted landfill capacity are conservatively considered to be *potentially significant*. Development of a waste management or recycling plan (Measure 4.11-2) would reduce this impact to a less-than-significant level.

Impact 4.11-3: Impacts related to compliance with federal, state, and local statutes and regulations related to solid waste.

All Regions

The CIWMB found that the jurisdictions within the WSIP study area achieved or nearly achieved the 50 percent solid waste diversion goal for 2002 (CIWMB, 2007a). Construction of the WSIP projects would result in the generation of a large volume of waste materials; if the total amount were disposed of in local landfills, these materials could potentially exceed the daily tonnage limit of these landfills or lower diversion rates for the purpose of calculating compliance with the California Integrated Waste Management Act. The exact quantity of waste materials to be disposed of in nearby landfills (which includes construction debris, demolition materials, and excavation spoils) would not be known until each project undergoes a detailed evaluation as part of separate, project-level CEQA review. In the absence of exact disposal quantities, WSIP compliance with local plans, policies, programs, and ordinances regarding solid waste management cannot be determined. Therefore, impacts related to compliance with federal, state, and local statutes are conservatively considered to be *potentially significant*. Development of a waste management or recycling plan (Measure 4.11-2) would reduce this impact to a less-than-significant level.

Siting Impacts

Need for Relocation

Impact 4.11-4: Impacts related to the relocation of utilities.

Implementation of the WSIP would result in new construction or improvements to existing pipelines, tunnels, vaults, valve lots, crossovers, and water treatment and storage facilities. Many of these projects would occur at existing SFPUC facility sites or within SFPUC rights-of-way. Construction activities associated with the WSIP projects could affect utility infrastructure by requiring the relocation of existing facilities. The relocation of facilities could result in adverse effects related to the following environmental resource topics: hydrology, biological resources, cultural resources, traffic, and air quality, among others. All subsurface and aboveground utility lines and cables requiring relocation during construction of the WSIP projects would be identified during the predesign and permitting stages for each project.

Pipelines. Of the WSIP project types, pipeline projects have the greatest potential to require the relocation of utility lines, since construction activity would encroach on existing utility corridors. Utility corridors generally include multiple utility lines (i.e., water, sewer, storm drain, and natural gas pipelines, and electricity, telephone, and television cables). All utility lines that require relocation as a result of WSIP construction would be identified during project design.

Tunnels. Tunnel projects could require the relocation of utility lines near the tunnel entry and exit shaft/portal locations, which would serve as construction staging areas.

Vaults, Valve Lots, and Crossover Facilities. The construction of vaults, valve lots, and crossover would occur at isolated locations near existing SFPUC facilities. These facilities could require the relocation of utility lines, depending on project siting.

Other Facilities. The WSIP projects that would occur at discrete locations include pump stations, treatment facilities, and storage facilities. Upgrades at existing facilities are not expected to require the relocation of offsite utilities, since the projects would be located at existing facility sites or within the SFPUC right-of-way. These sites already include development and utility connections. For new project siting, potential impacts could result if utility lines needed to be relocated.

All Regions

All of the WSIP projects have the potential to require the relocation of subsurface or aboveground utilities and cables during construction. The extent of utility relocation cannot be determined until that time, but would be identified during the predesign and permitting stages for each project. The impact associated with the relocation of utilities could be temporary or permanent, thereby resulting in *potentially significant* impacts. Implementation of SFPUC Construction Measure #1 (neighborhood noticing) and identification of public utility lines prior to commencing construction (Measures 4.11-1a through 4.11-1h) would reduce this impact to a less-than-significant level.

4.12 Recreational Resources

4.12 Recreational Resources

4.12.1 Setting

Regional Overview

This section provides an overview of the distribution and type of park and recreational facilities within the WSIP study area (which extends from Oakdale Portal on the SFPUC regional water system in western Tuolumne County, west to San Francisco) and describes the specific recreational facilities that lie in the immediate vicinity of WSIP projects. This section also identifies goals and policies aimed at protecting and enhancing recreational resources (including parks and recreational facilities) that have been adopted by the local jurisdictions in which portions of the WSIP projects would be located. (Chapter 5, WSIP Water Supply and System Operations, describes recreation areas, facilities, and activities east of the WSIP study area in the Tuolumne River system and the eastern end of the SFPUC regional water system.)

There is a wide variety of recreational resources in the region, from small neighborhood parks designed for local residents to large regional parks that attract tourists from across the nation or around the world. Recreational resources also include formally designated parks and trails, open spaces where dispersed activities such as hiking and bird watching can take place, as well as bodies of water where boating, fishing, or swimming can be enjoyed. The WSIP study area also includes regional amenities such as San Francisco Bay and the Bay Trail, and numerous parks and recreational facilities managed by local jurisdictions, including cities, counties, and special park and open space districts. **Figure 4.12-1** shows the locations of major parks, local parks, and other recreational resources that could be affected by the WSIP.

Description of Recreational Resources by Region

San Joaquin Region

Tuolumne County

In Tuolumne County, the existing Oakdale Portal and the easternmost portion of the proposed SJPL System project (SJ-3) are located within the San Joaquin Region. However, no significant recreational resources are located near this segment of the regional system. Chapter 5 presents more information on recreational resources in areas farther east in Tuolumne County, where the regional system begins.

Stanislaus County

Stanislaus County manages 25 park and recreational areas, including five regional parks, eight fishing access points, and 11 neighborhood parks in the unincorporated portions of the county (Stanislaus County, 2007). Only two WSIP projects—the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4)—would involve construction in Stanislaus County (segments of the San Joaquin Pipeline west of Oakdale Portal). Chapter 5 describes recreational resources along the lower Tuolumne River in Stanislaus County that could be affected by the proposed WSIP water supply or system operations.

San Joaquin County

San Joaquin County manages numerous parks and recreational facilities, including nine regional parks and 11 community and neighborhood parks. There are also two state parks in the county, as well as the San Joaquin National Wildlife Refuge. The refuge, located where the Tuolumne and Stanislaus Rivers meet the San Joaquin River, is an important wintering ground for migratory birds (San Joaquin County Parks and Recreation, 2007a; 2007b; USFWS, 2007b).

City of Modesto. The SJPL Rehabilitation project (SJ-4) could involve work on segments of pipeline that run beneath a three-mile-long linear park. This park, which extends from Semallon Drive to Sisk Road, has a developed asphalt bike path and greenway that follows the SFPUC right-of-way (Hetch Hetchy Trail). Two other city parks abut this trail: Wesson Ranch Park near the eastern end and Chrysler 99 Park near the western end. Facilities at Wesson Ranch Park include baseball and soccer fields, trails, a playground, and restrooms. Facilities at Chrysler 99 Park include a full basketball court, bleachers, and trails. Tracy Golf and Country Club. The private Tracy Golf and Country Club is located on South Chrisman Road near Tesla Portal. I-580 passes over this 18-hole golf course, creating a unique design (The Golf Courses.net, 2007). The SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects could affect this facility.

Sunol Valley Region

Regional Parks and Open Space

Alameda Watershed. The SFPUC-managed portion of the Alameda watershed encompasses approximately 36,000 acres of land, with 23,000 acres in Alameda County and 13,000 acres in Santa Clara County. The City and County of San Francisco (CCSF) owns about 30 percent of the watershed, including the San Antonio and Calaveras Reservoirs, where no public access is allowed. The CCSF leases some watershed land to the East Bay Regional Park District (EBRPD) for public recreational use, as described below. Policy WA10 in the SFPUC's *Alameda Watershed Management Plan* specifies certain day-use activities that are allowed by permit, including use of the Sunol Water Temple for events and supervised public access to roads and trails (SFPUC, 2001). The following projects would be located in the Alameda watershed: Alameda Creek Fishery, SV-1; Calaveras Dam, SV-2; 40-mgd Treated Water, SV-3; Treated Water Reservoirs, SV-5; and SABUP; SV-6. A portion of the Irvington Tunnel runs through Alameda watershed lands, but the New Irvington Tunnel project (SV-4) would be located outside the watershed lands. Section 5.4, Alameda Creek Watershed Streams and Reservoirs, also discusses recreational resources in the Alameda watershed.

East Bay Regional Parks. The EBRPD has jurisdiction over numerous regional parks located in Alameda and Contra Costa Counties. Several major EBRPD facilities encompassing thousands of acres of parks and open space are clustered in the East County/Sunol Valley area, including Del Valle Regional Park, Ohlone Regional Wilderness, Sunol Regional Wilderness, Vargas Plateau Regional Preserve, and Mission Peak Regional Park. The long-term goal of the EBRPD is to adopt land use plans to guide the management and use of all of its facilities. The EBRPD has adopted a land use plan for Del Valle Regional Park; other land use plans are in draft form at various stages of planning.

Figure 4.12-1c
Parks and Recreational Resources, Hetch Hetchy Region

THIS PAGE INTENTIONALLY LEFT BLANK

The 6,858-acre Sunol Regional Wilderness lies between San Antonio Reservoir and Calaveras Reservoir, with Alameda Creek running through it. Recreational activities in this wilderness area include hiking, bike riding, and horseback riding (EBRPD, 2007). Part of the Sunol Regional Wilderness is located on Alameda watershed lands leased from the CCSF. The Calaveras Dam project (SV-2) could affect this recreational area.

San Francisco Bay Area

San Francisco Bay and the Bay Trail span multiple WSIP regions.

San Francisco Bay. San Francisco Bay offers a wide variety of dispersed recreational opportunities for residents of and visitors to the counties and cities surrounding the bay. Approximately 40 publicly and privately owned marinas ring the bay, and there are numerous designated and informal access or launching points for boating, windsurfing, kayaking, jet-skiing, and swimming, as well as piers and other access locations for fishing. The preferred pipeline alignment for the BDPL Reliability Upgrade (BD-1) crosses the southern portion of San Francisco Bay, in an area used for recreational activities such as boating, kayaking, fishing, swimming, bird watching, and sightseeing.

The Bay Trail. Senate Bill 100, passed in 1987, directed the Association of Bay Area Governments (ABAG) to identify an alignment and develop a plan to create a public trail system encircling San Francisco Bay. The *Bay Trail Plan*, adopted by ABAG in 1989, proposed a continuous 400-mile corridor that would eventually link the shorelines of all nine Bay Area counties and 47 cities around San Francisco and San Pablo Bays. Since its adoption, the *Bay Trail Plan* has received widespread public support as a means of preserving and enhancing public access to the San Francisco Bay waterfront. Most of the jurisdictions along the proposed trail alignment have adopted the plan and incorporated the appropriate Bay Trail segments into their local plans and policies. When complete, the Bay Trail corridor will be 500 miles long.

Development of the Bay Trail is overseen by the Bay Trail Project, a nonprofit organization established in 1990. The Bay Trail Project does not own land or easements; instead, it encourages local jurisdictions to construct and maintain segments of the Bay Trail, often in partnership with other local nonprofit groups. Approximately 290 miles, or just over half of the envisioned trail, has been completed. Some portions of the Bay Trail are paved pathways, while others consist of dirt trails or sidewalks. The main trail, referred to as the “spine trail,” follows the San Francisco Bay shoreline to the extent possible. Where it is not able to follow the shoreline, “spur trails” provide access from the spine trail to points of interest along the waterfront. In addition, “connector trails” provide links to other nearby recreational facilities, residential neighborhoods and employment centers (Association of Bay Area Governments Bay Trail Project, 2005). Segments of the Bay Trail exist near the proposed pipeline alignments for the BDPL Reliability Upgrade (BD-1) project.

Bay Division Region

Regional Parks and Open Space

San Francisco Bay and the Bay Trail spans the WSIP's Bay Division, Peninsula, and San Francisco Regions.

Don Edwards San Francisco Bay National Wildlife Refuge. The Don Edwards San Francisco Bay National Wildlife Refuge, located on the eastern shore of San Francisco Bay, was the first urban national wildlife refuge in the United States. The refuge, established in 1974 and managed by the U.S. Fish and Wildlife Service, is located along the Pacific Flyway, which attracts millions of shorebirds and waterfowl annually. It encompasses 30,000 acres of open bay, salt pond, salt marshes, mudflats, and upland and vernal pool habitats in portions of San Mateo, Santa Clara, and Alameda Counties. The area attracts hundreds of thousands of visitors annually and offers hiking trails, boating, fishing, and hunting as well as interpretive programs, an environmental education center, and a visitor center (USFWS, 2007a). The preferred pipeline alignment for the BDPL Reliability Upgrade project (BD-1) crosses this refuge.

City of Fremont

The City of Fremont manages several recreational facilities located in or adjacent to the proposed alignment for the BDPL Reliability Upgrade project (BD-1), including Central Park, Azeveda Park, Noll Park, and Mission San Jose Park. The popular Central Park has playground areas, picnic sites, softball fields, snack bars, soccer fields, tennis courts, fishing, boat rentals, a boat launch, boat storage, walking trails, a golf driving-range, dog park, basketball courts, and a skate park. Central Park encompasses 450 acres, and Lake Elizabeth covers an additional 83 acres (City of Fremont, 2007a). Azeveda Park, located at 39450 Royal Palm Drive, is a neighborhood park and playground (City of Fremont, 2007b; Fremont Online.org, 2007a). Noll Park and Mission San Jose Parks are also neighborhood parks, located at 39600 Sundale Drive and 43545 Bryant Street, respectively. Mission San Jose Park, located behind Mission San Jose Elementary School, includes a playing field and baseball diamond (Fremont Online.org, 2007b). The BDPL Reliability Upgrade project could affect these parks. The Warm Springs Recreation Center, located at 47300 Fernald Street in Fremont, is a 6,000-square-foot center in a 12-acre park. It contains a multipurpose room and meeting room, and also has an outdoor gazebo (City of Fremont, 2007c). The BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) and New Irvington Tunnel (SV-4) projects would also be located in Fremont.

City of Newark

There are 272 acres of park and recreational areas within Newark city limits and three important regional recreational areas adjacent to the city: Don Edwards San Francisco Bay National Wildlife Refuge, Coyote Hills Regional Park, and Ardenwood Regional Preserve (City of Newark, 1992). The BDPL Reliability Upgrade project (BD-1) could affect two community parks in Newark—Birch Grove Park and Ash Street Park. Birch Grove Park is located at 38080 Birch Street and contains approximately 15 acres. Facilities include play structures, a water element, a fenced softball playing field, basketball court, lighted tennis courts, picnic facilities, and restrooms (City of Newark, 2007). Ash Street Park, located at 37365 Ash Street, encompasses approximately six acres and includes play structures, softball practice fields, a basketball court, picnic facilities, restroom facilities, and a horseshoe pit. The privately operated Viola Blythe Community Center and a Head Start preschool facility are also situated on the park grounds (City of Newark, 2007). The BDPL Reliability Upgrade project could affect Birch Grove and Ash Street Parks.

Santa Clara County General Plan

The Santa Clara County General Plan envisions a “necklace of parks” composed of regional parks and community parks linked by recreational trails and scenic highways. Agencies working to achieve this goal include the Midpeninsula Regional Open Space District, the County Parks Department, the California Department of Parks and Recreation, and the Don Edwards San Francisco Bay National Wildlife Refuge (Santa Clara County, 1994). An overview of the recreational resources in Santa Clara County cities that could be affected by the WSIP projects is provided below.

City of Milpitas

Milpitas has approximately 160 acres of park and recreational facilities in the form of community, neighborhood, special-use, regional, and school parks as well as private recreational facilities. The 1,539-acre Ed R. Levin County Park, which lies on the border between Alameda and Santa Clara Counties, is partially within the city of Milpitas. This park offers areas for picnicking, fishing, hiking, cycling, horseback riding, and hang gliding (Santa Clara County Parks, 2007). An alternative site for the BDPL 3 and 4 Crossovers project (BD-2) would be located in Milpitas.

City of San Jose

San Jose has over 16,300 acres of public parkland within its sphere of influence. These parklands include federal, county, and city lands, the majority of which are County-owned hillside open space, creekside park chains, and the federally owned Don Edwards San Francisco Bay National Wildlife Refuge. The City manages approximately 4,000 acres of parks that form a “greenbelt” of open space around the urban area. Utility corridors and water supply reservoirs are an integral part of San Jose’s recreational resources (City of San Jose, 2005). The Lower Guadalupe River Trail is a six-mile trail along the Guadalupe River. The trail program is governed by the City of San Jose; however, portions of the trail extend into Santa Clara. Developed and planned portions of the trail are in the vicinity of the BDPL 3 and 4 Crossovers project (BD-2) (City of San Jose and Santa Clara Valley Water District, 2006).

City of Santa Clara

Santa Clara has 39 parks and playgrounds, providing 277 acres of municipal parkland and 458 acres of open space (City of Santa Clara, 2007). The largest park is the 52-acre Central Park. The City supports plans for a regional “park chain” along the Guadalupe River. A portion of the Hetch Hetchy Aqueduct traverses the northern part of the city, and this right-of-way corridor is designated as open space. A BDPL 3 and 4 Crossovers (BD-2) crossover facility would be located along the Guadalupe River in the vicinity of several small neighborhood parks, including Lick Mill Park and Fairway Glen Park (City of Santa Clara, 2002).

City of Sunnyvale

Sunnyvale has approximately 838 acres of parks and open space, of which 351 acres are owned by the City and 177 acres are owned by Santa Clara County (City of Sunnyvale, 1997). Sunnyvale's largest park is Baylands Park, which adjoins the Don Edwards San Francisco Bay National Wildlife Refuge. An alternative site for BDPL 3 and 4 Crossovers project (BD-2) would be located in the vicinity of this park. The Baylands Park encompasses approximately 200 acres of preserved wetlands and community park features. Over 70 acres are developed parkland, and the remainder is protected wetland. The Bay Trail passes along the north and eastern sides of the park (City of Sunnyvale, 2007).

City of Mountain View

Mountain View has 21 recreational facilities encompassing 768 acres, the largest of which is the Shoreline at Mountain View Regional Park (consisting of 662 acres). The Hetch Hetchy Aqueduct runs through the city, and Rex Manor mini-park is located along this right-of-way corridor (City of Mountain View, 1992). An alternative site for BDPL 3 and 4 Crossovers project (BD-2) would be located in Mountain View.

City of Los Altos

Los Altos has 32 acres of parks and an additional 127 acres of open space (City of Los Altos, 2002). An alternative location for one of the BDPL 3 and 4 Crossovers (BD-2) crossover facilities would be located near Adobe Creek in Los Altos, where there is a bike trail along the Hetch Hetchy Aqueduct.

City of Palo Alto

According to the City of Palo Alto, the city has a total of 4,358 acres of parkland and open space areas, including 32 urban parks encompassing approximately 200 acres and several large open-space and nature preserves. Foothill Park is approximately 1,400 acres and the Arastradero Preserve is approximately 610 acres (City of Palo Alto, 2007). The City of Palo Alto owns the wetlands south of Cooley Landing (in East Palo Alto) in the vicinity of the BDPL Reliability Upgrade (BD-1) pipeline alignment (City of Palo Alto, 1998). A BDPL Nos. 3 and 4 Crossovers (BD-2) crossover facility would be adjacent to the sports fields at Gunn High School.

City of East Palo Alto

The City of East Palo Alto owns and operates three parks, encompassing of a total of 14 acres. These parks include Jack Farrell Park, Bell Street Park, and Martin Luther King Jr. Park. Jack Farrell Park is the closest city park to the Hetch Hetchy Aqueduct (City of East Palo Alto, 1999); however, Costano School and Cesar Chavez School are also located near the aqueduct as well as near the proposed BDPL Reliability Upgrade (BD-1) alignment.

City of Menlo Park

The City of Menlo Park owns and operates approximately 231 acres of parkland. Most of its recreational facilities are concentrated at the Burgess Park Complex within the Civic Center. The largest City-maintained park is Bayfront Park, which provides 155 acres for passive recreational use (City of Menlo Park, 1994). The BDPL Reliability Upgrade project (BD-1) would be located in Menlo Park.

City of Redwood City

Redwood City owns and operates 30 parks, including small neighborhood parks, larger multi-use parks, a dog park, a skate park, and two outdoor pools (City of Redwood City, 2007a). The BDPL Reliability Upgrade project (BD-1) is in the vicinity of Fleishman Park, Hawes Park, and Red Morton Park. The 0.64-acre Fleishman Park has play equipment, a play area, picnic area, barbeque pits, and restrooms (City of Redwood City, 2007b). Hawes Park contains ball fields and restroom facilities on 1.59 acres (City of Redwood City, 2007b). Red Morton Park encompasses 30.89 acres and has pools, ball fields, play areas and equipment, picnic areas, barbeque pits, tennis courts, basketball courts, and restroom facilities (City of Redwood City, 2007b). An alternative site for the BDPL 3 and 4 Crossovers project (BD-2) could also be located in Redwood City (City of Redwood City, 1991).

Town of Atherton

The BDPL 3 and 4 Crossovers project (BD-2) would be located in Atherton.

Peninsula Region

The Peninsula Region offers numerous park and recreational facilities, including the SFPUC-managed Peninsula watershed lands, state and county parks, city parks, and numerous regional facilities managed by the Midpeninsula Regional Open Space District. Major regional recreational resources are described below, followed by brief descriptions of the park and recreational facilities in cities potentially affected by WSIP projects. (Section 5.5, San Francisco Peninsula Streams and Reservoirs, discusses recreational resources and activities within the Peninsula watershed that could be affected by the proposed WSIP water supply and system operations.)

Regional Parks and Open Space

SFPUC Peninsula Watershed and Crystal Springs Park. The 23,000-acre SFPUC-managed portion of the Peninsula watershed has limited public access but offers several popular recreational opportunities, including Crystal Springs Golf Course and two popular trails (Fifield-Cahill Ridge Trail and Sawyer Camp Trail). Since 2003, Fifield-Cahill Ridge Trail has been open to the public on a reservation-only basis, with groups of up to 20 people led by docents three days a week. When the SFPUC fenced off the watershed lands in the vicinity of Crystal Springs Reservoir, it left the six-mile Sawyer Camp Trail open to the public for non-motorized recreational use. This trail, once a notable travel route along the Peninsula, is visited by approximately 300,000 people each year (San Mateo County, 2007a). Several other public trails border the watershed area, including Sweeny Ridge Trail, San Andreas Trail, and Crystal Springs Trail (SFPUC, 2007c). Sweeny Ridge Trail is open to the public and crosses Fifield-Cahill Ridge Trail (SFPUC, 2007a). The CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4), and Pulgas Balancing Reservoir (PN-5) projects are located in this watershed.

Coyote Point. Coyote Point Recreational Area is a popular waterfront regional park managed by the San Mateo County Parks and Recreation Department. The park is located on San Francisco Bay in the city of San Mateo, and portions of the Bay Trail traverse the park. Activities include picnicking, swimming, kayaking, windsurfing, bicycling, jogging, fishing, boating, and sailing, as well as watching airplanes take off and land at nearby San Francisco International Airport. The Coyote Point Museum, located in the park, provides environmental education programs (San Mateo County, 2007b).

Junipero Serra Park. San Mateo County also manages the 108-acre Junipero Serra Park, located between Millbrae and San Bruno on Crystal Springs Road. Facilities include picnic areas, campsites, shelter buildings, and trails. The park is known for its spectacular views as well as spring wildflowers (San Mateo County, 2007e). The HTWTP Long-Term project (PN-3) would be adjacent to this park.

San Bruno Mountain State and County Park. San Bruno Mountain State and County Park has eight trails traversing 2,326 acres of land and 12 miles of hiking, horseback riding, and jogging trails. The park is jointly operated by the California Department of Parks and Recreation and the County Parks Department (San Mateo County, 2007f). The Groundwater Projects (SF-2) could be located near this park.

Ravenswood Open Space Preserve. Ravenswood Open Space Preserve is managed by the Midpeninsula Regional Open Space District, which manages approximately 50,000 acres of open space in 25 preserves in San Mateo and Santa Clara Counties (Midpeninsula Regional Open Space District, 2007a). Ravenswood Open Space Preserve consists of 373 acres of marshland and trails located south of the Dumbarton Bridge on San Francisco Bay, in the vicinity of the BDPL Reliability Upgrade (BD-1) pipeline alignment (Midpeninsula Regional Open Space District, 2007c).

Flood Park. Flood Park, located in Menlo Park and managed by San Mateo County, offers 21 acres of parkland, with many large native oak and bay trees. Picnicking, softball, tennis, horseshoes, volleyball, and petanque are popular activities in the park (San Mateo County, 2007d). Flood Park is adjacent to the BDPL Reliability Upgrade (BD-1) alignment.

Edgewood Park Nature Preserve. Edgewood Park Nature Preserve, managed by San Mateo County, is located in Redwood City at Edgewood and Old Stage Roads. This 467-acre park offers hiking and sightseeing and is well known for its spring wildflower blooms (San Mateo County, 2007c). This park is in the vicinity of the BDPL Reliability Upgrade (BD-1) alignment.

Pulgas Ridge Open Space Preserve. The Pulgas Ridge Open Space Preserve, managed by the Midpeninsula Open Space Regional District, is located near San Carlos, northwest of Edgewood County Park and across the Junipero Serra freeway from Pulgas Water Temple. The preserve encompasses 366 acres with three miles of trails. Some lands adjacent to Pulgas Ridge are not open to the public (Midpeninsula Regional Open Space District, 2007b).

City Parks and Recreational Facilities

City of East Palo Alto. See description under Bay Division Region, above.

City of Menlo Park. See description under Bay Division Region, above.

City of Redwood City. See description under Bay Division Region, above.

City of San Carlos. San Carlos has 15 parks totaling 143 acres. Fourteen are developed parks, providing ball diamonds, basketball courts, dog exercise areas, hiking trails, horseshoe pits, jogging paths, picnic tables, play equipment, recreation centers, soccer fields, and tennis courts. One park, the Chilton Property, is open space land. The general plan identifies three community parks and 12 neighborhood parks (City of San Carlos, 1992; 2007). The BDPL Reliability Upgrade project (BD-1) would be located in San Carlos.

Town of Woodside. A portion of the SFPUC's Peninsula watershed land lies adjacent to the town of Woodside. Woodside sponsors recreational programs and classes, but has no publicly owned recreational facilities in the vicinity of any proposed program features. An alternate site for the BDPL 3 and 4 Crossovers project (BD-2) would be located in Woodside.

City of San Mateo. The City of San Mateo owns 30 park sites, three open space areas, and two inaccessible open space areas, for a total of over 500 acres of parkland (City of San Mateo, 1991).

Town of Hillsborough. There are limited public parks and recreational facilities within Hillsborough, including two parks and a water conservation garden. The town also has 258 acres of open space that cannot be developed, improved, or sold (Town of Hillsborough, 2007b). Open space areas are not available for public access (Town of Hillsborough, 2007a). Private facilities such as the 110-acre Burlingame County Club and the Hillsborough Racquet Club provide additional recreational facilities, and many town residents have large lots with private recreational amenities. Nearby regional recreational areas and open space include Crystal Springs Reservoir and Coyote Point County Recreation Area. The CS/SA Transmission project (PN-2) would be located near the town of Hillsborough.

City of Burlingame. Burlingame has 17 parks and playgrounds, some of which are located near the CS/SA Transmission project (PN-2) (City of Burlingame, 2007). The 1.9-acre Village Park on Eastmoor Road has restroom facilities, a playground, picnic facilities, and basketball courts. The 5.9-acre Ray Park on Balboa Way provides a playground, picnic area, basketball courts, softball fields, tennis courts, and restroom facilities. The Groundwater Projects (SF-2) could also be located in Burlingame.

City of Millbrae. The City of Millbrae owns and operates 12 parks encompassing approximately 44 acres of parkland. Over 165 acres of parkland are available to city residents, when the Civic Center, the unimproved Spur Property, a portion of Junipero Serra Park, and school playgrounds and playfields are included. Millbrae's shoreline parks provide significant links to the Bay Trail (McElroy, 2001).Green Hills Park, on the corner of Ludeman Lane and Magnolia Avenue, provides picnic tables and benches, barbeque pits, and a group picnic area; other amenities include restrooms, par course, jogging path, children's play equipment, open playing field, conversation place, horseshoe pit, bocce ball court, and open space (City of Millbrae, 2007). Although the CS/SA Transmission project (PN-2) and HTWTP Long-Term (PN-3) would not be located in Millbrae, they would be close to its city limits. The Groundwater Projects (SF-2) could also be located in Millbrae.

City of San Bruno. San Bruno has 18 parks encompassing approximately 90 acres. City residents also use Junipero Serra Park and some local school grounds, although not all school grounds are available for public use (City of San Bruno, 1984). Forest Lane Park, located near I-380 and Huntington Avenue has a grassy area, basketball court, play area, and picnic and barbeque area (City of San Bruno, 2007). Although the CS/SA Transmission (PN-2) and HTWTP Long-Term (PN-3) projects would not be located in San Bruno, they would be close to its city limits. The Groundwater Projects (SF-2) could also be located in San Bruno.

City of South San Francisco. South San Francisco has approximately 320 acres of parks and open space, 70 acres of which are developed, 169 acres of open space, and 81 acres of school lands (City of South San Francisco, 1999). According to the Parks, Public Facilities and Services Element of the general plan, the overall amount of open space in the city appears adequate to meet the community's needs, but the amount of developed parkland is inadequate. The general plan proposes an additional 108 acres of parkland, including a six-acre SFPUC Linear Park in the Winston-Serra area of the city. The corridor is already under development as a linear park, from the city's western boundary to Hickey Boulevard (City of South San Francisco, 1999). The 21-acre Orange Memorial Park, located on Orange Avenue and Tennis Drive, contains a children's play area, community building, restrooms, picnic tables, picnic shelter, five tennis courts, ball fields, basketball courts, walking trails, soccer fields, an indoor swimming pool, sculpture garden, and bocce ball courts (City of South San Francisco, 2006). Paradise Valley Park provides 1.2 acres, including a children's play area, Boys Club, restrooms, picnic tables, ball fields, and basketball courts. The park is located on Hillside Boulevard (City of South San Francisco, 2006). The Baden and San Pedro Valve Lots (PN-1) and Groundwater Projects (SF-2) could affect recreational facilities in South San Francisco.

Town of Colma. Colma has three public recreational facilities occupying 0.5 acres of land. The largest is the Sterling Park Community Center. The private Cypress Hills Golf Course adds an additional 76 acres of parkland. The town's eastern border is adjacent to the San Bruno Mountain State and County Park, and the town supports access to all trails along this border. The Colma General Plan states that a pedestrian path should be considered along the San Francisco Water Company right-of-way between Serramonte Boulevard and Collins Avenue (Town of Colma, 2000). The Groundwater Projects (SF-2) would be located in Colma.

City of Brisbane. Brisbane owns very few recreational facilities, but the city is surrounded by open space for outdoor recreation (City of Brisbane, 1994). The Open Space Element of the general plan states that, although Brisbane meets or exceeds current standards for parks and open space based on acreage per thousand persons, residents desire additional open space facilities. There are numerous goals and policies in the Open Space Element, as well as in the Recreation and Community Services Element, aimed at maximizing the use of existing recreational and open spaces and developing new recreational and open spaces. The City proposes to use the lagoon, bayfront, and marsh for recreational and educational purposes, consistent with the sensitivity of the resources. The plan also states the goal of extending the trail system to include aquatic areas, creating a shoreline recreational trail along San Francisco Bay from Sierra Point to the Candlestick Point State Recreation Area, in cooperation with regional efforts. Once the water environment is determined to be safe, development of water-related passive recreation is encouraged at the Brisbane Lagoon, including public access facilities adjacent to the lagoon. Richard Firth Memorial Park, located on Glen Park Way, contains several concrete statues and a picnic area. Community Park, located at Old County Road and San Francisco Street, contains four picnic areas, restrooms, and a children's playground (City of Brisbane, 2007; Carmick, 2006). The Groundwater Projects (SF-2) could be located in Brisbane.

City of Daly City. Daly City has 71 acres of public recreation land and over 180 acres of private recreation lands. The general plan encourages the National Park Service to incorporate City-owned property along the coast into the Golden Gate National Recreation Area (City of Daly City, 1987). David R. Rowe Park on Midway Avenue provides ball fields, basketball courts, and recreational facilities for rent (Daly City Online, 2007). On the west side of I-280, a City-owned skate park on Sullivan Avenue provides skateboarding ramps and rails (SFGoKids.com, 2007). The Baden and San Pedro Valve Lots (PN-1), SAPL 3 Installation (SF-1), and Groundwater Projects (SF-2) could affect Daly City's recreational facilities.

San Francisco Region

City of San Francisco

The city, state, and federal property permanently dedicated to open space uses in San Francisco encompasses approximately 4,090 acres, or 5.5 acres per 1,000 San Francisco residents. The Recreation and Open Space Element of the San Francisco General Plan (CCSF, 1998) states a goal to increase the per capita supply of public open space within the city, but acknowledges that this is a challenge given existing development patterns, high population density, and relatively small land mass (28,918 acres). About half of the City-owned recreational and open space acreage is composed of a few large open space areas, which are enjoyed by residents throughout the city and region as well as by tourists. The other half is made up of smaller open spaces distributed throughout the city and used by residents of the immediate area. The SAPL 3 Installation (SF-1), Groundwater Projects (SF-2), and Recycled Water Projects (SF-3) would be located in San Francisco. Parks that could be affected by the WSIP projects are described below.

Golden Gate National Recreation Area (Lake Merced). The recreational areas of the Golden Gate National Recreation Area at Lake Merced are managed by the San Francisco Recreation and Park Department under an agreement with the SFPUC. This agreement was created in 1950, naming the SFPUC to manage the water aspects of Lake Merced. Lake Merced is located near Skyline and Lake Merced Boulevards and is composed of four interconnected freshwater lakes. Recreational activities include walking, jogging, and boating. Developed facilities include the Lake Merced Sports Center, the 18-hole public Harding Park Golf Course (Harding Park, 2007), the 18-hole Jack Fleming Municipal Golf Course, and the Pacific Rod and Gun Club, with skeet and trap ranges (SFPUC, 2007b). There are several other private golf clubs in the Lake Merced vicinity, including Olympic Country Club to the south, Lake Merced Golf & Country Club to the southeast, and San Francisco Golf Club to the east, as well as athletic facilities associated with San Francisco State University. The alignment for the SAPL 3 Installation (SF-1) through the San Francisco Golf Course and adjacent to the Lake Merced Golf & Country Club, and the Groundwater Projects (SF-2) could affect Harding Park Golf Course.

West Sunset Playground and Recreation Center and South Sunset Playground. The West Sunset Playground and Recreation Center, located at Ortega Street and 39th Avenue, provides two baseball fields, a softball field, basketball and tennis courts, and a soccer field. This unique, bi-level playground is heavily used by the community (Go City Kids, 2007b). The South Sunset Playground could also be affected. The Groundwater Projects (SF-2) could affect these playgrounds.

Golden Gate Park. San Francisco's Golden Gate Park provides 1,017 acres of parkland, including tennis courts, playgrounds, biking and skating facilities, a rose garden, casting ponds for anglers, the Buffalo Paddock in the northwest corner of the park, and boating facilities at Stow Lake. The park is heavily used by city residents and is also popular with regional residents and visiting tourists. Various SFPUC wells and the Golden Gate Storage Tank, involved in the Groundwater Projects (SF-2) and Recycled Water Project (SF-3), are located in the park (CCSF, 2007b; Go City Kids, 2007a).

As indicated in the Golden Gate Park Master Plan, the former Richmond-Sunset Treatment Plant, which is currently a staging area for the Recreation and Park Department, would be restored to include an additional soccer field, a picnic area, a small parking area, log storage, and reforestation areas. The site is located in the western area of Golden Gate Park (CCSF, 2007a). A Recycled Water Project (SF-3) alternative could affect this area.

San Francisco Zoo. San Francisco Zoo is one of the Bay Area's most popular cultural and recreational attractions. Recreational facilities include a carousel, a miniature steam train, several cafes, and open space. The San Francisco Recreation and Park Department works in partnership with the San Francisco Zoological Society to maintain and govern the zoo (San Francisco Zoo, 2007). The Groundwater Projects (SF-2) could affect an overflow parking lot at the zoo.

Pine Lake Park/Stern Grove. Pine Lake Park and Stern Grove, a 64-acre open space area, forms a long valley that drops 100 feet in elevation from the city street above. There are numerous recreational activities, including summer concerts, receptions, picnic events, tennis, horseshoes, and croquet. The popular "Sundays at the Grove" concert series is attended annually by more than 175,000 patrons. The park has plans for improvements, including redesign of the outdoor concert area, restoration of buildings (including historic structures), enhancement of disabled access to park facilities, lake and wildlife habitat restoration, playground and tennis courts repairs, and utility and infrastructure improvements (CCSF, 2007c). The Groundwater Projects (SF-2) could affect the park.

Lincoln Park Golf Course. Lincoln Park Golf Course was constructed in 1928 and provides the public with an 18-hole course on a native landscape of rolling hills forested with cypress and pine trees. The Recycled Water Projects (SF-3) would affect the golf course.

Regulatory Framework

Local Plans and Policies

Refer to Section 4.2, Plans and Policies, regarding the application of local land use plans and policies to implementation of the WSIP.

4.12.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to recreation, but generally considers that implementation of the proposed program would have a recreational impact if it were to:

- Increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated (Secondary impacts of growth are evaluated in Chapter 7, Growth-Inducement Potential and Indirect Effects of Growth)
- Include recreational facilities or require the construction or expansion of recreational facilities that might have an adverse physical effect on the environment (Secondary impacts of growth are evaluated in Chapter 7)
- Physically degrade existing recreational resources (Evaluated in this section)

The physical degradation of existing resources could occur if the WSIP were to:

- Remove or damage existing recreational resources directly
- Cause environmental impacts (such as air quality or noise effects) that would indirectly result in deterioration in the quality of the recreational experience
- Disrupt access to existing recreation facilities (which would divide a community from some of the established amenities used by its members)

Impacts on parks are discussed in this section. Impacts on other public facilities are addressed in Section 4.3, Land Use and Visual Quality; Section 4.8, Traffic, Transportation, and Circulation; and Section 4.11, Public Services and Utilities.

Approach to Analysis

Local planning documents and maps (including topographic maps, local street maps, and maps available electronically via the internet) were reviewed to identify the recreational resources in the study area that, because of their proximity, could be directly or indirectly affected by the WSIP projects. Existing recreational plans and policy documents, as well as scoping comments received from recreational resource management agencies and other interested parties on the WSIP Draft PEIR Notice of Preparation, were also reviewed.

To determine potential direct effects of WSIP projects construction activities and/or land acquisition, project areas were compared with the locations of identified recreational resources. Potential indirect effects on recreational resources were identified through the same means, as well as by reviewing the impact findings from Section 4.3, Land Use and Visual Quality; Section 4.5, Hydrology and Water Quality; Section 4.9, Air Quality; and Section 4.10, Noise and Vibration. Indirect impacts that would typically result from other physical impacts and could adversely affect the recreational experience include the following: removal of vegetation that could alter views (Section 4.3, Land Use and Visual Quality); construction-related noise that could affect hiking or nature appreciation (Section 4.10, Noise); or impeded access to hiking trails (Section 4.8, Traffic, Transportation, and Circulation).

Impact Summary by Region

Table 4.12-1 presents a summary of potential impacts on recreational resources associated with the WSIP projects.

Construction Impacts

Impact 4.12-1: Temporary conflicts with established recreational uses during construction.

Construction activities (such as the creation of new temporary staging areas or open-trench construction of pipelines) could temporarily disrupt access to or use of recreational facilities in the WSIP study area. Construction of pipelines, tunnels, dams, and other WSIP facilities could require excavation in areas with established recreational uses or could affect access to existing parks or other recreational facilities. Construction activities that could affect recreational resources are addressed by facility type below.

Pipelines. In some of the affected jurisdictions, formal or informal linear parks or trails have been developed or are proposed for development along the SFPUC right-of-way. Other communities have designated the SFPUC right-of-way as open space. In some instances, there are recreational amenities such as private golf courses in or adjacent to the right-of-way. Since additional pipeline construction would occur along portions of this right-of-way, existing recreational facilities or uses of this area could be disrupted.

Where feasible, WSIP pipeline construction would be accomplished using standard open-cut or cut-and-cover construction methods, progressing at a rate of approximately 120 feet per day in urban areas and 160 feet per day in rural areas; where there are no obstructions or road crossings, the pipeline construction could progress at a rate of up to 300 feet per day. Staging areas would also be required for stockpiling supplies and equipment close to the construction area. Depending on the location of staging areas and the timing of pipeline construction, these activities could

TABLE 4.12-1
POTENTIAL IMPACTS AND SIGNIFICANCE – RECREATIONAL RESOURCES

Projects	Project Number	Impact 4.12-1: Temporary conflicts with established recreational uses during construction	Impact 4.12-2: Conflicts with established recreational uses due to facility siting and project operation

Recycled Water Projects	SF-3	PSM	PSM

LS = Less than Significant impact, no mitigation required
PSM= Potentially Significant impact, can be mitigated to less than significant
N/A = Not Applicable

cause adverse (although temporary) impacts on recreational resources, including the temporary loss of facility access, temporary removal of facilities, or the longer term loss of lawns or landscaped areas, which could take time to be restored after construction is completed.

Tunnels. Unlike pipeline construction, tunneling would not affect parks, open space, or recreational areas, except in the vicinity of the entry and exit portal locations, which would also serve as construction staging areas. Recreational resources could be adversely affected if the portals were located on or near existing parks and recreational facilities, or if access to these areas were disrupted by construction traffic or construction activities. Similarly, the noise and dust generated by tunneling and associated equipment could reduce the quality of the recreational experience at nearby facilities, depending on where the portals are sited in relation to established recreational uses.

Vaults, Valve Lots, and Crossover Facilities. These facilities would be constructed at isolated locations near existing SFPUC facilities along the regional system. Design would vary by location, but facilities would typically occupy approximately 4,000 square feet and would be partially or completely buried. Control buildings might be constructed to house associated electrical facilities, and crossover structures could require permanent discharge or drainage piping for maintenance or emergency repairs. Construction activities would generally be confined to the immediate site vicinity. If these facilities were located in or near areas of established recreational use, they could temporarily disrupt recreational resources (during construction).

Pump Stations. The WSIP includes construction of new pump stations and upgrades to existing pump stations along the regional system. Upgrading existing pump stations, which would involve removing existing equipment and replacing it with new equipment, is not likely to adversely affect recreational resources. New pump stations could adversely affect resources if they are located in areas with established recreational uses.

Treatment Facilities. The WSIP includes upgrades and expansion of existing treatment facilities at two treatment plants as well as the system's primary disinfection facility, and construction of a new secondary disinfection facility. Proposed upgrades at existing treatment plants would occur within the existing property boundaries and are not likely to affect offsite recreational resources. Impacts associated with new facility construction would depend on the site location in relation to established recreational uses in the area.

Storage Facilities. The WSIP calls for improvements to water storage facilities, including water reservoirs and dams. Some storage facility sites are open to the public, and projects located in these areas could affect recreational access. Other storage facilities are closed to the public, and projects located in these areas would not likely affect recreational facilities.

As mentioned above, a criterion for impacts on recreational resources is the disruption of access to existing recreation facilities. For this analysis, if access to a recreational site would be closed during construction, the impact would be potentially significant, even with SFPUC construction measures such as those requiring neighborhood notice and traffic plans. However, if a WSIP project would temporarily close one access route to a recreational site but another access route remained opened to the public, the impact would be less than significant.

If a WSIP project would construct facilities through or adjacent to a recreational facility and disrupt access to part or all of the recreational facility, the impact, although temporary, would be potentially significant.

If there is not enough detail about a WSIP project to assess its impacts on recreational resources, a conservation determination of potentially significant is made in this analysis.

In general, potentially significant impacts could be reduced to a less-than-significant level through coordination with golf course and other recreational facility managers (Measure 4.12-1) and implementation of various mitigation measures to address traffic, air quality, and noise issues. Recreational resources in the vicinity of the WSIP projects are identified by region below and summarized in **Table 4.12-2**.

San Joaquin Region

Impact 4.12-1: Temporary conflicts with established recreational uses during construction		
Advanced Disinfection	SJ-1	N/A
Lawrence Livermore	SJ-2	N/A
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	N/A

Of the five WSIP projects in the San Joaquin Region, the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects could affect recreational resources during construction.

The SJPL System (SJ-3) would construct valve houses at Oakdale and Tesla Portals, two crossover facilities, and approximately 16 to 22 miles of pipeline (a minimum of 6 miles of pipeline west of Oakdale Portal in Tuolumne and Stanislaus Counties, and 10 miles of pipeline east of Tesla Portal in Stanislaus and San Joaquin Counties, including in the vicinity of Tracy Golf and Country Club). Construction would take place over approximately three years. Most construction would occur within the existing SFPUC right-of-way, but additional right-of-way could be required. Additional land could also be acquired for power supply facilities associated with crossovers, depending on the final locations selected.

Temporary, but *potentially significant* impacts associated with the SJPL System and SJPL Rehabilitation projects could be reduced to a less-than-significant level through implementation of SFPUC Construction Measures #1, #3, #5, #6, and #10 (neighborhood notice, air quality, traffic, noise, and site restoration), mitigation measures identified in Chapter 6 (under 4.8, Traffic, Transportation, and Circulation; 4.9, Air Quality; and 4.10, Noise and Vibration), as well as coordination with golf course managers/recreational facility managers and provision of temporary access (Measure 4.12-1). These measures would provide park and recreation facility managers with an opportunity to notify recreationists of any anticipated disruption of resource access or use. Separate, project-level CEQA review would be conducted on these projects to determine if potential recreation impacts would occur and, if appropriate, to refine mitigation measures to address site-specific conditions.

The Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) projects would install disinfection facilities at the SFPUC's existing Tesla Portal, which is currently used for water system purposes, so these projects would not affect recreational resources. New water filtration facilities for the Lawrence Livermore project (SJ-2) would be constructed at the SFPUC's existing Thomas Shaft property in San Joaquin County and would not affect existing recreational uses. Therefore, this impact would *not apply* to these projects.

TABLE 4.12-2
PUBLIC PARKS AND RECREATIONAL FACILITIES IN THE PROJECT VICINITY

Projects	Potentially Affected Recreational Resources
SJ-1: Advanced Disinfection	None
SJ-2: Lawrence Livermore Supply Improvements	None
SJ-3: San Joaquin Pipeline System	Tracy Golf and Country Club
SJ-4: Rehabilitation of Existing San Joaquin Pipelines	Tracy Golf and Country Club; Hetch Hetchy Trail Linear Park; Wesson Ranch Park and Chrysler 99 Park (in Modesto); San Joaquin National Wildlife Refuge
SJ-5: Tesla Portal Disinfection Station	None
SV-1: Alameda Creek Fishery Enhancement	Alameda Creek
SV-2: Calaveras Dam Replacement	Sunol Regional Wilderness
SV-3: Additional 40-mgd Treated Water Supply	None
SV-4: New Irvington Tunnel	Mission Peak Regional Park
SV-5: SVWTP – Treated Water Reservoirs	None
SV-6: San Antonio Backup Pipeline	None
BD-1: Bay Division Pipeline Reliability Upgrade	Don Edwards San Francisco Bay Regional Wildlife Refuge; Ravenswood Open Space Preserve; San Francisco Bay Trail; local parks in Fremont, Newark, San Mateo County, and Redwood City; numerous school properties in East Palo Alto, Fremont, Menlo Park, Newark, and Redwood City
BD-2: BDPL Nos. 3 and 4 Crossovers	Guadalupe River trails in Ulistac Natural Area; Gunn High School
BD-3: Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault	None
PN-1: Baden and San Pedro Valve Lots Improvements	None
PN-2: Crystal Springs/San Andreas Transmission Upgrade	Crystal Springs Golf Course Sawyer Camp Trail
PN-3: HTWTP Long-Term Improvements	None
PN-4: Lower Crystal Springs Dam Improvements	Trails and passive uses along Canada Road; site-seeing from the San Mateo County Bridge
PN-5: Pulgas Balancing Reservoir Rehabilitation	Pulgas Water Temple
SF-1: San Andreas Pipeline No. 3 Installation	Direct impacts on the San Francisco Golf Club; indirect impacts on Lake Merced Golf & Country Club and Daly City Skatepark
SF-2: Groundwater Projects	South Sunset Playground; West Sunset Playground; and Francis Scott Key School playground; Golden Gate Park; Lake Merced (and Harding Park Golf Course); San Francisco Zoo; and Pine Lake/Stern Grove (all in San Francisco)
SF-3: Recycled Water Projects	San Francisco Zoo; Lincoln Park

Sunol Valley Region

Impact 4.12-1: Temporary conflicts with established recreational uses during construction		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	N/A
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	N/A
SABUP	SV-6	N/A

Within the Sunol Valley Region, construction of three of the proposed WSIP projects could affect recreational resources or the quality of the recreational experience in the Sunol Regional Wilderness, which lies between Calaveras and San Antonio Reservoirs. The remaining Sunol Valley Region projects would involve construction or upgrades on existing SFPUC property or at existing facilities, minimizing the potential for impacts on nearby recreational resources.

The Alameda Creek Fishery project (SV-1) would involve construction of facilities to recapture water that is released for fishery enhancement in Alameda Creek. Construction in the vicinity of Alameda Creek could temporarily disrupt access to the creek for dispersed recreational activities such as fishing or picnicking; however, since this disruption would be temporary and alternative locations for these activities are available, this impact would be *less than significant*.

The Calaveras Dam project (SV-2) is a major construction project that would replace the existing Calaveras Dam and restore the capacity of Calaveras Reservoir. Calaveras Road, designated as a scenic route by Alameda and Santa Clara Counties, would be closed to the public during an estimated three-year construction period, blocking access to the Sunol Regional Wilderness from the south during that time. Access to the Sunol Regional Wilderness from the north would remain open during project construction. Because this disruption to recreational access would be temporary and an alternate route into the wilderness area would be available, this impact would constitute a *less than significant*, indirect effect on established recreational uses. Implementation of SFPUC Construction Measures #1, #3, #5, and #6 (neighborhood notice, air quality, traffic, and noise) would also help ensure that potential impacts on this resource are less than significant.

Construction of New Irvington Tunnel (SV-4) would take place over approximately three to four years. The project would require construction of two new tunnel portals and associated construction staging areas. The new east portal would be about 75 feet south of the Alameda West Portal, and the new west portal would be about 175 feet south of the existing Irvington Portal. The project would tunnel below a portion of Mission Peak Regional Park, but is not expected to affect surface facilities. This project would end east of Mission Boulevard and would not directly affect schools in the vicinity of Mission Boulevard in Fremont. However, there could be *potentially significant*, indirect impacts on these schools associated with construction-related traffic on local roadways, air pollutant emissions, and increased noise. Implementation of the SFPUC Construction Measures #1, #3, #5, and #6 (neighborhood notice, air quality, traffic, and noise), as well as mitigation measures identified in Chapter 6 (under 4.8, Traffic, Transportation, and Circulation; 4.9, Air Quality; and 4.10, Noise and Vibration) would help to reduce potential impacts to a less-than-significant level. Two projects in this region (40-mgd Treated Water, SV-3, and Treated Water Reservoirs, SV-5) would construct new facilities or upgrade existing equipment within the fenceline of SFPUC properties. The SABUP project (SV-6) would not affect any public parks or recreational facilities. Therefore, this impact would *not apply* to these three projects.

Bay Division Region

Impact 4.12-1: Temporary conflicts with established recreational uses during construction		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	PSM
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	N/A

Of the WSIP projects proposed for construction in the Bay Division Region, the BDPL Reliability Upgrade project (BD-1) would have the greatest potential impact on recreational facilities in the area. The preferred pipeline alignment for the new Bay Division Pipeline (No. 5) would pass beneath the Don Edwards San Francisco Bay Regional Wildlife Refuge, with an approximately five-mile tunnel segment installed beneath marshlands and San Francisco Bay. The two cut-and-cover sections of pipeline (approximately seven miles from the Irvington Tunnel Portal to the Newark Valve House and nine miles from the Ravenswood Valve House to the Pulgas Tunnel Portal) would be located within the existing SFPUC right-of-way. The Ravenswood Open Space Preserve and San Francisco Bay Trail are also located in the vicinity of the Ravenswood Valve House.

Recreational amenities in the vicinity of the pipeline alignment for the BDPL Reliability Upgrade project (BD-1) include Agua Caliente Creek, Central Park, Azeveda Park, Noll Park, and Mission San Jose in Fremont; Flood Park in Menlo Park; Ash Park and Birch Grove Park in Newark; Edgewood Park, Fleishman Park, Hawes Park, and Red Morton Park in Redwood City; and local parks in San Mateo County. Recreational facilities may also be present at numerous school properties, including Chadbourne School, Durham School, Fremont School, Irvington School, Mission San Jose School, Joseph Azeveda Elementary School, and Walters Junior High School in Fremont; Cesar Chavez Academy and Costano School in East Palo Alto; Bell Haven Elementary School and James Flood Magnet School in Menlo Park; Bunker Elementary School in Newark; and Fair Oaks School, Hawes School, Gill School, and West Bay Christian Academy in Redwood City. While none of these recreational resources would be directly affected, indirect (temporary, construction-related) impacts would be *potentially significant*. Implementation of SFPUC Construction Measures #1, #3, #5, and #6 (neighborhood notice, air quality, traffic, and noise), as well as coordination with golf course/recreational facility managers (Measure 4.12-1) would reduce this impact to a less-than-significant level.

The BDPL 3 and 4 Crossovers project (BD-2) would involve construction of pipeline crossovers at three separate locations along a 32-mile stretch of the existing Bay Division Pipeline. One of these crossover locations is adjacent to the Guadalupe River in San Jose, in the recently restored Ulistac Natural Area (formerly the Fairway Glen Golf Course) across from Lick Mill Park. Another is located near Barron Creek, adjacent to the running track and sports fields at Gunn High School in Palo Alto. These track and field facilities can be used by the public when not being used for school purposes (Jacoubowsky, 2006). The third crossover would be located at Bear Gulch Reservoir in Atherton, which is not accessible to the public. All crossovers would be constructed within existing SFPUC right-of-way (with the possible exception of outfall facilities), so direct impacts on recreational facilities are not expected. However, because construction could temporarily disrupt the enjoyment of nearby recreational resources, impacts would be *potentially* *significant*. Implementation of SFPUC Construction Measures #1, #3, #5, and #6 (neighborhood notice, air quality, traffic, and noise), mitigation measures identified in Chapter 6 (under 4.8, Traffic, Transportation, and Circulation; 4.9, Air Quality; and 4.10, Noise and Vibration), as well as coordination with golf course managers/recreational facility managers (Measure 4.12-1) would help to reduce potential impacts to a less-than-significant level. These conditions and measures would provide park and recreation facility managers with an opportunity to notify recreationists of any anticipated disruption of resource access or use.

The BDPL 3 and 4 Seismic Upgrade at Hayward Fault project (BD-3) would not affect established recreational uses in the vicinity, so this impact would *not apply* to this project.

Peninsula Region

Impact 4.12-1: Temporary conflicts with established recreational uses during construction		
Baden and San Pedro Valve Lots	PN-1	N/A
CS/SA Transmission	PN-2	PSM
HTWTP Long-Term	PN-3	N/A
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS

Two of the proposed Peninsula Region projects would be located on SFPUC facility sites that are not accessible to the public. However, three of the WSIP projects in this region are located on or close to existing recreational facilities and thus have the potential to disrupt (directly or indirectly) established recreational uses.

The CS/SA Transmission project (PN-2) would replace approximately 1,350 feet of pipeline and renew the remaining pipeline (through lining, coating, new manholes and valves, etc.) that conveys water from Crystal Springs Reservoir to the Harry Tracy Water Treatment Plant (WTP) through San Andrea Reservoir. If the pipeline is replaced, all work would occur within SFPUC Peninsula watershed lands; however, the alignment could pass through Crystal Springs Golf Course, roughly paralleling Sawyer Camp Trail, with portions of the pipeline alignment touching the trail alignment. Construction traffic and staging areas could also affect access to and/or enjoyment of Sawyer Camp Trail and Crystal Springs Golf Course, resulting in *potentially significant* impacts. Implementation of SFPUC Construction Measures #1, #3, #5, and #6 (neighborhood notice, air quality, traffic, and noise), and coordination with golf course and other recreational facility managers to ensure facility managers notify recreationists of anticipated access or use disruptions (Measure 4.12-1) would reduce this impact to a less-than-significant level.

The Lower Crystal Springs Dam project (PN-4) would make dam safety improvements to Lower Crystal Springs Dam, including raising the dam parapet wall and lengthening the spillway crest. The areas where the improvements are proposed are not accessible to the public. The project would be coordinated with San Mateo County's replacement of the County Bridge (which is built on the crest of the dam and provides sightseeing opportunities) as well as a nearby parking lot and vista point overlooking the reservoir. Indirect impacts related to the recreational enjoyment of the area would be *less than significant*. Implementation of SFPUC Construction Measures #1, #3, #5, and #6 (neighborhood notice, air quality, traffic, and noise) would also help ensure that potential impacts related to recreational enjoyment are less than significant.

The Pulgas Balancing Reservoir project (PN-5) would replace the Pulgas Channel with an enlarged channel and replace the roof of the existing Pulgas Balancing Reservoir and associated equipment. The reservoir is located on SFPUC watershed land west of I-280 and east of Cañada Road in unincorporated San Mateo County, southeast of Pulgas Water Temple. Pulgas Channel crosses under Cañada Road and extends southwestward, near the south side of the parking lot for the water temple. Construction activities would occur over a total of four years and would be confined to the vicinity of the existing reservoir structure. Replacement of the Pulgas Channel is not expected to directly affect recreational uses in the water temple area, unless recreational parking is reduced during construction. However, if access to the temple's parking lot is restricted during channel construction, the impact on this recreational use could be *less than significant*. Implementation of SFPUC Construction Measures #1, #3, #5, and #6 (neighborhood notice, air quality, traffic, and noise) would also help ensure that potential impacts related to the recreational enjoyment of this area are less than significant.

The Baden and San Pedro Valve Lots project (PN-1) would involve seismic upgrades or repairs at valve lot locations and other facility locations (within SFPUC fencelines) that would not disrupt nearby recreational uses. The HTWTP Long-Term project (PN-3) would involve modifications at the Harry Tracy WTP and would not affect established recreational uses of the area. Therefore, this impact would *not apply* to these projects.

San Francisco Region

Impact 4.12-1: Temporary conflicts with established recreational uses during construction		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	PSM
Recycled Water Projects	SF-3	PSM

All WSIP projects in the San Francisco Region would potentially affect parks and recreational resources.

The SAPL 3 Installation project (SF-1) would replace the Baden-Merced Pipeline in Daly City by extending San Andreas Pipeline No. 3 from the San Pedro Valve Lot to Merced Manor Reservoir in San Francisco. Following the alignment of the existing Baden-Merced Pipeline, the project would pass in the vicinity of numerous parks and recreational facilities. Project construction would occur for almost two years and would disrupt two major recreational resources, the Lake Merced Golf & Country Club and the San Francisco Golf Club. Construction would disrupt use of the San Francisco Golf Club during the construction period, since the alignment would pass directly through the course, and time would be needed to restore the greens and fairways to a usable condition after construction is completed. The pipeline alignment runs parallel to the edge of the Lake Merced Golf & Country Club and could indirectly affect use of that golf club, including parking. These impacts would be *potentially significant*; however, they would be temporary in duration and the golf courses would be restored once the pipeline is buried. Implementation of SFPUC Construction Measures #1, #3, #5, and #6 (neighborhood notice, air quality, traffic, and noise), mitigation measures identified in Chapter 6 (under 4.8, Traffic, Transportation, and Circulation; 4.9, Air Quality; and 4.10, Noise and Vibration), and coordination with golf course/recreational facility managers and provision of temporary access if applicable (Measure 4.12-1) would reduce these potential impacts to a less-than-significant level.

The Groundwater Projects (SF-2) would construct new groundwater extraction wells on properties owned by the CCSF, including the South Sunset and West Sunset Playgrounds, and the playground at Francis Scott Key School. This project would also upgrade wells at a number of city locations, including two sites in Golden Gate Park as well at Lake Merced (Harding Park Golf Course), the San Francisco Zoo, and Pine Lake at Stern Grove. These upgrades would occur intermittently over a three-year timeframe (from 2009 to 2011) and could disrupt adjacent recreational uses during this period. The Groundwater Projects would also develop approximately 7 million gallons per day (mgd) of potable groundwater in San Mateo County as part of a regional conjunctive-use project, at locations that have not yet been identified. One of the recreational sites that could be affected is the Daly City Skatepark. In the absence of more detailed project information, these potential impacts are assumed to be *potentially significant*. Implementation of SFPUC Construction Measures #1, #3, #5, and #6 (neighborhood notice, air quality, traffic, and noise), mitigation measures identified in Chapter 6 (under 4.8, Traffic, Transportation, and Circulation; 4.9, Air Quality; and 4.10, Noise and Vibration), as well as coordination with golf course/recreational facility managers (Measure 4.12-1) would reduce these potential impacts to a less-than-significant level.

The Recycled Water Projects (SF-3) would diversify San Francisco's water supply by providing 4 mgd of annual average production of recycled water. The recycled water would be stored at an existing reservoir in Golden Gate Park, and an additional storage facility could be built in the vicinity of Lincoln Park. In the absence of more detailed project information, these potential impacts are assumed to be *potentially significant*. Implementation of SFPUC Construction Measures #1, #3, #5, and #6 (neighborhood notice, air quality, traffic, and noise), mitigation measures identified in Chapter 6 (under 4.8, Traffic, Transportation, and Circulation; 4.9, Air Quality; and 4.10, Noise and Vibration), as well as coordination with golf course facility managers and provision of temporary access if applicable (Measure 4.12-1) would reduce these potential impacts to a less-than-significant level.

Operations, Siting, and Design Impacts

Long-Term Conflicts with Established Recreational Uses

Impact 4.12-2: Conflicts with established recreational uses due to facility siting and project operation.

If a WSIP project would conflict with established recreational uses by siting a permanent facility or changing a facility's operation, the impact would be potentially significant.

San Joaquin, Sunol Valley, Bay Division, and Peninsula Regions

None of the WSIP projects in the San Joaquin, Sunol Valley, Bay Division, or Peninsula Regions would cause long-term conflicts with established recreational uses, because there would be no change in permanent access to recreational facilities, and access would be restored following project construction. Therefore, this impact would *not apply* to the projects in these regions.

San Francisco Region

Impact 4.12-2: Conflicts with established recreational uses due to facility siting and project operation		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	PSM
Recycled Water Projects	SF-3	PSM

In the San Francisco Region, new facilities could be constructed in a number of City-owned parks and recreational facilities. The SAPL 3 Installation project (SF-1) would involve construction of a pipeline and various facilities, including two new structures (up to 8 feet high). The proposed pipeline alignment would traverse the San Francisco Golf Club and would be adjacent to the Lake Merced Golf & Country Club. The Groundwater Projects (SF-2) would construct new groundwater extraction wells at South Sunset Playground and West Sunset Playground. The Recycled Water Projects (SF-3) would store recycled water at an existing reservoir in Golden Gate Park (resulting in no new impact), and possibly at a new storage facility to be constructed at Lincoln Park. The impacts from these projects would be *potentially significant*. Implementation of architectural design, landscaping, and tree removal measures to reduce visual impacts (Measures 4.3-4a, 4.3-4b, 4.3-4c, and 4.3-4d), as well as appropriate siting of proposed facilities to minimize the direct loss of recreational access (Measure 4.12-2) would reduce these potential impacts to a less-than-significant level.

4.13 Agricultural Resources

4.13 Agricultural Resources

4.13.1 Setting

Regional Overview

California is the nation's leading agricultural producer, responsible for approximately one-eighth of the country's agricultural output. The Central Valley (comprised of the Sacramento and San Joaquin Valleys) is the most productive agricultural area of the state; all eight counties in the San Joaquin Valley are among the top 15 most productive counties in the state (Legislative Analyst's Office, 2002; Umbach, 1997).

The WSIP study area stretches from Tuolumne County in the Sierra Nevada mountains, through two counties—San Joaquin and Stanislaus—that are part of the agriculturally productive San Joaquin Valley, then through four other counties that are part of the urbanized San Francisco Bay Area. Most agricultural production occurs in the San Joaquin Region, where there are large tracts of fertile farmland. Agricultural production is much more limited in the central and western portions of the study area for a variety of reasons, including less appropriate soil types, subdivision of land into smaller parcel sizes, higher production costs, and the predominance of urban development.

San Joaquin and Stanislaus Counties are ranked among the top 10 California counties in terms of the total value of annual agricultural production, while the remaining five counties in the WSIP study area have much lower rankings, as show on **Table 4.13-1**.

TABLE 4.13-1
VALUE OF AGRICULTURAL PRODUCTION IN WSIP STUDY AREA COUNTIES, 2003

County	Value of Agricultural Production ($1,000s)	2003 Ranking
San Joaquin	1,494,693	6
Stanislaus	1,454,928	7
Santa Clara	241,043	28
San Mateo	178,039	31
Alameda	37,342	44

Farmland Mapping

The California Department of Conservation, Division of Land Resource Protection, maps important farmlands throughout California. Important farmlands are divided into the following five categories based on their suitability for agriculture:

- *Prime Farmland* is land that has the best combination of physical and chemical characteristics for crop production. It has the soil quality, growing season, and moisture supply needed to produce sustained high yields of crops when treated and managed.
- *Farmland of Statewide Importance* is land other than Prime Farmland that has a good combination of physical and chemical characteristics for crop production.
- *Unique Farmland* does not meet the criteria for Prime Farmland or Farmland of Statewide Importance but has been used for the production of specific high-economic-value crops.
- *Farmland of Local Importance* is either currently producing crops or has the capability of production, but does not meet the criteria of the categories above.
- *Grazing Land* is land on which the vegetation is suited to the grazing of livestock.

Table 4.13-2 shows the quantities of these types of agricultural lands that are currently mapped in each of the WSIP study area counties. As this table indicates, San Joaquin and Stanislaus Counties have the highest acreages of prime, unique, and important farmlands.

TABLE 4.13-2
IMPORTANT FARMLAND ACREAGE IN WSIP STUDY AREA COUNTIES, 2002

County	Prime Farmland (acres)	Farmland of Statewide Importance (acres)	Unique Farmland (acres)	Farmland of Local Importance (acres)	Grazing Land (acres)
Tuolumne	N/A	N/A	N/A	N/A	N/A
Stanislaus	260,730	30,069	61,205	29,519	374,898
San Joaquin	415,527	92,521	61,849	56,507	148,710
Alameda	6,328	1,485	2,100	0	245,728
Santa Clara	28,816	4,244	1,404	7,711	388,696
San Mateo	2,503	178	2,800	3,744	45,829
San Francisco	N/A	N/A	N/A	N/A	N/A

NOTE: Tuolumne County is not part of the California Department of Conservation's Farmland Mapping and Monitoring Program; San Francisco County is urbanized and has virtually no agricultural lands.

SOURCE: California Department of Conservation, Division of Land Resource Protection, 2002.

Description of Agricultural Resources by County in the Study Area

Tuolumne County

In 2003, Tuolumne County ranked 49th (out of 58 counties) in California for the value of its agricultural production, which was almost $22 million. The county's leading commodities include cattle, irrigated and range pasture, firewood, and apiary products. In 2004, the gross agricultural output was $28 million. Field crops in 2004 included hay (600 acres), irrigated pasture (1,200 acres), and rangeland (200,000 acres) (California Department of Finance, 2003; Tuolumne County Agricultural Commissioner, 2004).

While Tuolumne County covers the largest geographic area (1,415,781 acres) of the affected counties, it does not meet the minimum agricultural acreage requirement for inclusion of lands in the California Department of Conservation's Farmland Mapping and Monitoring Program. A total of 118,422 acres of land were enrolled in the Williamson Act in Tuolumne County in 2003 (California Department of Conservation, 2004).[1]

The WSIP projects in Tuolumne County pertain to the easternmost pipeline segment of the San Joaquin Pipeline—the SJPL System (SJ-3) and SJPL Rehabilitation (SF-4) projects. These projects are located in an area identified mainly as Grazing Land.

Stanislaus County

In 2003, Stanislaus County ranked seventh in California for the value of its agricultural production, which was almost $1.5 billion. The county's leading commodities are milk, almonds, chickens, nursery products (fruit, vine, and nut), and walnuts. In 2004, Stanislaus County had a gross agricultural income of $1.9 billion, showing a 36 percent increase from the previous year. The sectors showing the most significant gains were fruit and nut crops (approximately 43 percent) and livestock and poultry (approximately 68 percent) (California Department of Finance, 2003).

Grazing Land (38.6 percent) makes up a large portion of the county's total land area (970,169 acres). Almost 27 percent of the county (26,195 acres) is designated as Prime Farmland. The remaining important farmland is designated as Unique Farmland (6.3 percent), Farmland of Statewide Importance (3.1 percent), and Farmland of Local Importance (3.0 percent) (California Department of Conservation, 2003).

Stanislaus County had 286,957 acres of Prime Farmland and 405,546 acres of nonprime farmland enrolled in Williamson Act contracts in 2003, for a total of 692,503 acres (California Department of Conservation, 2004). However, the county has been experiencing rapid population growth and associated pressure to convert farmland to urban land uses. The county general plan anticipates an 83 percent increase in population between 1988 and 2010, requiring another 36,358 acres of urban land to accommodate this growth. As a result, it is likely that the competition between urban and agricultural land uses will increase, although County policy is to direct urban growth away from the most productive agricultural land (Stanislaus County, 1992).

There are two WSIP projects located in Stanislaus County. The SJPL System (SJ-3) would involve two pipeline segments—one at the eastern end of the county (west of Oakdale Portal) and a short segment at the western side of the county, south of the community of Vernalis. The SJPL Rehabilitation (SJ-4) project would involve the entire length of pipeline within this county, including the cities of Vernalis and Modesto.

---

[1] Under a Williamson Act (Land Conservation Act of 1965) contract, the landowner agrees to limit the use of the land to agriculture and compatible uses for a period of at least 10 years. In return, the land is taxed at a rate based on the agricultural production of the land, rather than its real estate market value.

Stanislaus County attributes the success of its agricultural sector to the availability of affordable, high-quality irrigation water, much of which is taken from the Tuolumne River to irrigate farms in the Modesto-Turlock area (Stanislaus County, 1992). Irrigation water is provided through the Turlock and Modesto Irrigation Districts. These two districts, which were formed in 1887 to become the first publicly owned irrigation districts in California, are described below.

Turlock Irrigation District

Turlock Irrigation District (TID) operates about 250 miles of canals and laterals in a service area that encompasses 307 square miles. TID currently supplies irrigation water from the Tuolumne River to 5,800 growers and approximately 150,000 acres of land. TID also supplies electricity to 88,000 customers in a 662-square-mile service area.

In 1893, through its partnership with neighboring Modesto Irrigation District (MID), TID built La Grange Dam, a water diversion dam on the Tuolumne River. In 1923, the districts jointly built the original dam and powerhouse at Don Pedro Reservoir (a new Don Pedro Dam was built and the reservoir expanded substantially in 1970, in cooperation with both TID and the City and County of San Francisco [CCSF]). TID and MID share the costs and benefits of maintaining the dam and reservoir based on the areas they serve; TID receives about two-thirds of the irrigation water and power output from jointly managed facilities, and MID receives about one-third (Turlock Irrigation District, 2007).

Modesto Irrigation District

MID operates 208 miles of canals and pipelines to supply irrigation water to over 3,000 growers farming approximately 60,000 acres of land in Stanislaus County. MID also supplies electricity to about 100,000 customers in a 160-mile service area that includes the greater Modesto area, Waterford, Salida, Mountain House, and parts of Ripon, Escalon, Oakdale, and Riverbank (Modesto Irrigation District, 2007a).

For the past decade, MID has provided about half the drinking water for the city of Modesto. In 2004, MID and the City of Modesto reached an agreement that will eventually double the capacity of the Modesto Regional Water Treatment Plant. This increased capacity could allow MID to supply more water for urban uses, particularly during drought conditions, although city wells will continue to provide a substantial amount of Modesto's drinking water (Modesto Irrigation District, 2007b).

San Joaquin County

San Joaquin County has the most Prime Farmland and the highest agricultural production of any county in the study area. In 2003, it ranked sixth in California for the value of its agricultural production, which was almost $1.5 billion. The county's leading commodities include milk, grapes, almonds, tomatoes and cherries. In 2004, despite a 5 percent drop in the harvested acreage, the total production value increased 9 percent, bringing the gross agricultural production to $1.6 billion (California Department of Finance, 2003).

More than 45 percent of San Joaquin County's total land area (912,601 acres) consists of Prime Farmland. There are also substantial amounts of Farmland of Statewide Importance (10.1 percent), Unique Farmland (6.8 percent), Farmland of Local Importance (6.2 percent), and Grazing Land (16.3 percent). Almost 85 percent of the county is mapped as some type of important farmland (California Department of Conservation, 2005b).

In 2002, 812,629 acres of land were in farms, the total cropland was 574,752 acres, and the irrigated cropland comprised 520,172 acres. There were over 4,000 farms, with an average size of 202 acres. In 2003, San Joaquin County had 334,762 acres of Prime Farmland and 146,680 acres of nonprime farmland participating in the Williamson Act (California Department of Conservation, 2004). The remaining 60,131 acres of the total 541,573 acres enrolled were designated as Farmland Security Zones.[2]

Bay Area housing prices have lead to the construction of "bedroom" suburbs in outlying areas of San Joaquin County, increasing the pressure to convert farmland to urban uses. The County General Plan encourages the preservation of farmland and discourages incompatible uses in agricultural areas (San Joaquin County, 1992).

WSIP project components that are located in San Joaquin County include the westernmost portion of the proposed SJPL System project (SJ-3), which would cross Prime Farmland and the Delta-Mendota Canal before terminating at Tesla Portal, and the proposed Lawrence Livermore facility (SJ-2), located on grazing lands in the southernmost section of the county. The Advanced Disinfection (SJ-1), SJPL Rehabilitation (SJ-4), and Tesla Portal Disinfection (SJ-5) projects are also located in this county.

Alameda County

In 2003, Alameda County ranked 49th in California for the value of its agricultural production, which was approximately $37 million. Its leading commodities include nursery products, wine grapes, cattle, range pasture, alfalfa, and hay. The gross agricultural output for 2004 was $40 million, a 7.6 percent increase from 2003 (California Department of Finance, 2003).

While only about 1 percent of Alameda County's total land area (525,338 acres) is classified as Prime Farmland, almost 47 percent is devoted to Grazing Land. Farmland of Statewide Importance (0.3 percent) and Unique Farmland (0.4 percent) comprise the remainder of the important farmland in the county (California Department of Conservation, 2005a). In 2003, Alameda County enrolled a total of 134,332 acres of farmland in the Williamson Act—9,968 acres of Prime Farmland and 124,364 acres of nonprime farmland (California Department of Conservation, 2004).

[2] A Farmland Security Zone is a contract between a private landowner and a County that restricts land to agricultural or open space uses for a minimum initial term of 20 years. Like a Williamson Act contract, Farmland Security Zone contracts self-renew for an additional year annually; unless either party files a notice of nonrenewal, the contract is automatically renewed each year for the 20-year term.

All of the Sunol Valley Region projects (SV-1 through SV-6) in addition to the BDPL Reliability Upgrade project (BD-1) are located in Alameda County. The Sunol Valley Region projects are located on SFPUC watershed lands that are classified as Grazing Lands, although some areas of Unique Farmland are mapped along Alameda Creek between San Antonio Creek and the Sunol Valley Water Treatment Plant (WTP). The Bay Division Region projects lie in urbanized areas and the salt evaporators and marshlands adjacent to San Francisco Bay.

Local jurisdictions within Alameda County that are potentially affected by these WSIP project components include Fremont, and Newark. Agricultural resources in these local jurisdictions are briefly described below.

City of Fremont

The Baylands District in Fremont is planned for open space and agricultural uses, with the exception of a possible future waste facility. Salt production is considered an agricultural use, and salt ponds cover approximately 8,800 acres in Fremont. In addition, the Northern Plain Planning Area has 400 acres of privately owned farmland, including Patterson Ranch, as well as the 200-acre Ardenwood Regional Preserve, a working historic farm owned by the City and managed by the East Bay Regional Park District. The Land Use Plan for this area indicates a 150-acre open space easement for agricultural purposes; however, the City is studying potential future urban development in this area. Fremont's General Plan also states that some agricultural lands are targeted for incorporation by the National Wildlife Refuge. The Hills Area of Fremont includes lands owned by the CCSF, as well as the unincorporated Vargas Plateau East, which Fremont plans to incorporate. This area, which is designated for agricultural use by Alameda County, has productive agricultural land used for grazing, over half of which is under Williamson Act contracts (City of Fremont, 1991).

City of Newark

Although Newark is historically an agricultural area, only a small area of prime agricultural lands remains cultivated today. Over 3,000 acres of lands in the western and southwestern parts of Newark are designated as Open Spaces of Statewide Significance, and most are currently under Williamson Act contract. The Draft EIR for the general plan update (March 1992) indicates that portions of both Prime Farmland and Open Spaces of Statewide Significance will be converted to urban use at some point in the future; however, the existence of the Williamson Act contracts will hinder rapid conversion. The general plan update envisions that salt ponds will remain as resource preservation lands in the future (City of Newark, 1992).

Santa Clara County

In 2003, Santa Clara County ranked 28th in California for the value of its agricultural production, which was about $241 million. Its leading commodities were nursery crops, mushrooms, peppers, cut flowers, and cattle. In 2004, Santa Clara experienced a 7 percent increase in its agricultural production value, bringing the total to $258 million (California Department of Finance, 2003).

Just over half (51.6 percent) of Santa Clara County's 835,226 acres is mapped as important farmland. The majority (46.5 percent of all county land) is designated as Grazing Land. Prime Farmland constitutes 3.5 percent of the county's total area, followed by Farmland of Local Importance (0.9 percent), Farmland of Statewide Importance (0.5 percent), and Unique Farmland (0.2 percent). The majority of the Prime Farmland is located along the Highway 101 corridor between San Jose and Gilroy, at the southern end of the county (California Department of Conservation, 2005d). In 2003, Santa Clara County had a total of 330,769 acres under Williamson Act contracts. Of these, 11,396 acres were considered Prime Farmland, and 319,374 acres were nonprime (California Department of Conservation, 2004).

WSIP projects that lie within Santa Clara County include portions of the Bay Division Pipeline improvement projects (BDPL Reliability Upgrade, BD-1; BDPL 3 and 4 Crossovers, BD-2; and BDPL 3 and 4 Seismic Upgrade at Hayward Fault, BD-3) and the Calaveras Dam project (SV-2). The cities in Santa Clara County that could be affected by WSIP components include Milpitas, San Jose, Mountain View, Santa Clara, Sunnyvale, Los Altos, and Palo Alto. Sunnyvale, Los Altos, Palo Alto, and Santa Clara are urbanized, with few remaining agricultural lands. Agricultural resources in the other cities are briefly described below.

City of Milpitas

In Milpitas, along Coyote Creek, an area of land is used for growing a variety of truck and berry field crops, including peppers, lettuce, squash, melons, and corn (City of Milpitas, 2002).

City of San Jose

The City of San Jose, in conjunction with Santa Clara County, has policies in place to preserve its remaining agricultural land uses, including grazing, dairying, livestock raising, feedlots, orchards, row crops, nursery stock, flower growing, ancillary residential uses, ancillary commercial uses, and the processing of agricultural products. The Coyote Valley Urban Reserve allows only agricultural and rural residential land uses, and these are the predominate uses in the area (City of San Jose, 2005).

City of Mountain View

Agricultural resources in Mountain View include a community garden as well as Deer Hollow Farm, a 10-acre working farm. According to the Mountain View General Plan, the City has adopted an agricultural district to preserve land for agricultural use. Two properties (45 acres and 135 acres) in Mountain View are designated as prime agricultural lands, and seven other sites totaling 55.1 acres are designated for agricultural purposes (City of Mountain View, 1992).

San Mateo County

In 2003, San Mateo County ranked 31st in California for the value of its agricultural production, which was approximately $178 million. The county's leading commodities include nursery plants, mushrooms, cut flowers, and Brussels sprouts. The county's gross agricultural output in 2004 was $181.5 million (California Department of Finance, 2003).

Grazing Land constitutes 13 percent of San Mateo County's total land area (353,449 acres)—the majority of the important farmland mapped in the county. Farmland of Local Importance (1.1 percent), Unique Farmland (0.8 percent), Prime Farmland (0.7 percent), and Farmland of State Importance (0.1 percent) make up the remaining acreage of important farmland in the county. San Mateo County's Prime and Unique Farmland and Farmland of Statewide Importance are concentrated along the Pacific coast and coastal valleys (California Department of Conservation, 2005c). In 2003, San Mateo County enrolled 3,070 acres of Prime Farmland and 43,988 acres of nonprime farmland in the Williamson Act, for a total of 47,058 acres (California Department of Conservation, 2004).

WSIP project components that fall within San Mateo County include portions of two Bay Division Region projects (BDPL Reliability Upgrade, BD-1, and BDPL 3 and 4 Crossovers, BD-2) and all of the Peninsula Region projects (PN-1 through PN-5). Portions of the SAPL 3 Installation project (SF-1) are also located in San Mateo County.

The cities in San Mateo County that could be affected by WSIP project components include East Palo Alto, Menlo Park, Atherton, Redwood City, Woodside, San Carlos, San Mateo, Hillsborough, Burlingame, Millbrae, San Bruno, South San Francisco, Colma, Brisbane, and Daly City. Agricultural uses, where they remain in these cities, are described below.

City of East Palo Alto

Agriculture was an important part of East Palo Alto's history, and the general plan includes policies to preserve open space lands that are of economic use, in particular the Weeks and Gardens/Gateway III neighborhoods. Examples of uses on these lands are nurseries, horticulture, and community gardens. The plan states that the City will allow the establishment and continuation of these open space activities, while ensuring that the surrounding planned land uses are compatible (City of East Palo Alto, 1999).

Town of Colma

Colma contains approximately 113 acres of agricultural lands, dedicated mainly to nurseries, greenhouse operations, open field flowers, and vegetable plots. All of the agricultural land is privately maintained open space (Town of Colma, 2000).

City of Daly City

Daly City contains three neighborhoods that have agricultural lands: the Bayshore (5.50 acres), Original Daly City (0.55 acres), and Hillside (4.02 acres) neighborhoods. Included in the agricultural designation are greenhouses, row crops, cut flowers, and livestock grazing (City of Daly City, 1987).

San Francisco County

In 2003, San Francisco County ranked 57th (out of 58 counties) in California for the value of its agricultural production, which was less than $2 million. The county's leading commodities were vegetables and cut flowers (California Department of Finance, 2003). The CCSF does not participate in the Williamson Act and does not have the minimum amount of farmland required to participate in the Farmland Mapping and Monitoring Program.

Regulatory Framework

Farmland in California is protected mainly by federal and state legislation, although local policies and ordinances are also in place at the county or city level to control uses on or adjacent to farmland. The main federal legislation protecting agriculture is the Farmland Protection and Policy Act, which requires an evaluation of the relative value of farmland potentially affected by decisions sponsored in whole or part by the federal government. The Farmland Protection and Policy Act would not apply to the proposed program, however, since the WSIP is not a federal government action or program. The state and local regulatory setting for agricultural resources in the study area is described below.

California State Legislation

The California Land Conservation Act of 1965—commonly referred to as the Williamson Act—enables local governments to enter into contracts with private landowners to ensure that specific parcels are kept in agricultural or open space use as “agricultural preserves.” In return, landowners receive lower property tax assessments than they would otherwise receive. Williamson Act contracts are typically renewed annually for a term of 10 additional years.

“Agricultural preserve” is defined broadly in the Williamson Act to include areas devoted to either agricultural, recreational, or open space use, or any combination of these uses. Open space use is defined in the act as “the use or maintenance of land in a manner that preserves its natural characteristics, beauty, or openness for the benefit and enjoyment of the public, to provide essential habitat for wildlife, or for the solar evaporation of seawater in the course of salt production for commercial purposes.” The act states that contracted land in open space use must be within a scenic highway corridor, a wildlife habitat area, a salt pond, a managed wetland area, or a submerged area. Changes in the terms of a specific Williamson Act contract must go through the planning and zoning department approval process of the appropriate local jurisdiction before they can be enacted.

Williamson Act contracts may be cancelled only with the approval of a local board or council. Cancellation of the contract may occur if it is determined to be in the public interest (i.e., other public concerns outweigh the objectives of having the land under contract, and there is no other suitable land available for the proposed alternative use), or if all of the following conditions are met: (1) a notice of nonrenewal has been served; (2) the cancellation is not likely to result in the removal of adjacent lands from agricultural use; (3) the cancellation is for an alternative use that is consistent with the relevant city or county general plan; (4) cancellation will not result in discontinuous patterns of urban development; and (5) there is no suitable uncontracted land available nearby for the proposed alternative purpose. The property owner generally pays a fee of 12.5 percent of the “cancellation” value of the property once cancellation of the contract has been authorized.

Local Plans and Policies

Refer to Section 4.2, Plans and Policies, regarding the application of local land use plans and policies to implementation of the WSIP.

4.13.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to agricultural resources, but generally considers that implementation of the proposed program would have a agricultural resource impact if it were to:

- Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance, as shown on the maps prepared pursuant to the Farmland Mapping and Monitoring Program of the California Department of Conservation, to a non-agricultural use[3] (Evaluated in this section)
- Conflict with existing zoning for agricultural use, or a Williamson Act contract (Evaluated in this section)
- Involve other changes in the existing environment which, due to their location or nature, could result in the conversion of Farmland of Statewide Importance to non-agricultural use (Evaluated in this section)

CEQA Guidelines Section 15206 states that a project would cause a significant impact if it resulted in the cancellation of a Williamson Act contract for parcels of 100 acres or more. No comparable threshold is available in state or city guidance for the loss or conversion of Prime Farmland.

Approach to Analysis

For the purpose of this analysis, each program element was considered in relation to farmland in the immediate site vicinity to identify any potential disruption that might be caused temporarily (during project construction) or permanently (due to project siting or operations on land that is currently in agricultural use). In addition, each project component was examined for its potential to affect land under Williamson Act contract.

Impact Summary by Region

Table 4.13-3 presents a summary of potential impacts on agricultural resources associated with the WSIP projects.

[3] Based on the definition of agricultural use contained in the Williamson Act, conversion to "non-agricultural use" would mean that land previously used for producing an agricultural commodity for commercial purposes is no longer capable of serving this purpose.

TABLE 4.13-3
POTENTIAL IMPACTS AND SIGNIFICANCE – AGRICULTURAL RESOURCES

Projects	Project Number	Impact 4.13-1: Temporary conflicts with established agricultural resources	Impact 4.13-2: Conversion of farmlands to non-agricultural uses
San Joaquin Region			
Advanced Disinfection	SJ-1	N/A	N/A

LS = Less than Significant impact, no mitigation required
PSM= Potentially Significant impact, can be mitigated to less than significant
N/A = Not Applicable

Construction Impacts

Impact 4.13-1: Temporary conflicts with established agricultural resources.

Various elements of the WSIP have the potential to affect agricultural resources in different ways. For example, open-trench construction of pipelines could temporarily disrupt production of field crops or orchards. Other construction activities could affect agricultural resources if they disrupted access to actively farmed parcels. In some areas, the loss of even a small amount of

Prime or Unique Farmland could contribute to significant cumulative impacts on agricultural resources if other projects have removed or will remove substantial amounts of important farmland from the area. These types of potential impacts on agricultural resources associated with the WSIP projects are identified by region below.

Construction of pipelines, tunnels, dams, and other WSIP facilities could disrupt agricultural activities in the study area by excavating in areas used for agricultural purposes, by affecting access to agricultural lands, or by disrupting utilities that serve agricultural uses. This analysis considers a project's impact to be significant if it would be incompatible with existing zoning for agricultural uses in the project vicinity. Temporary environmental impacts that would occur during construction (e.g., noise, dust, traffic) or conflicts with local adopted policies are used as indicators of incompatibility. Construction activities that could affect agricultural resources are described by facility type below.

Pipelines. Depending upon the location of staging areas and the seasonal timing of pipeline construction, cut and cover construction has the potential to cause adverse (but temporary) impacts on agricultural activities, including the potential loss of seasonal crops grown within and around the right-of-way. In addition, road and utility crossings could temporarily affect access to or provision of power or water to actively farmed land. These impacts would be relatively minor (i.e., confined to a linear strip the width of pipeline right-of-way or to a temporary construction easement area) and brief (less than one growing season) and could be reduced to a less-than-significant level with appropriate mitigation measures.

Tunnels. Unlike pipeline construction, tunneling would not affect sensitive agricultural resources at the surface, except in the vicinity of entry and exit portal locations, which would serve as construction staging areas. Agricultural resources could be adversely affected if the portals were located on important farmlands, or if access to nearby farmland were disrupted by construction traffic or grading for new construction access roads. These impacts would be temporary and less than significant after implementation of normal construction mitigation measures, unless portal siting would convert important farmland or lands under Williamson Act contract to non-agricultural use.

Vaults, Valve Lots, and Crossover Facilities. These facilities would be constructed at isolated locations near existing SFPUC facilities along the regional system. Unless they occurred on important farmland or on land zoned for agricultural use or under Williamson Act contract, these facilities are unlikely to affect agricultural resources, and any impacts would be less than significant.

Pump Stations. Upgrading existing pump stations, which would involve removing equipment and replacing it with new equipment, would not affect agricultural resources. New pump stations could affect agricultural resources if they were located on important farmland or on land zoned for agricultural use or under Williamson Act contract, in which case the impacts could be potentially significant.

Treatment Facilities. The proposed upgrades at existing treatment plants would occur within the property boundaries and would not affect agricultural resources. Impacts associated with a new facility would depend on the site location in relation to important farmlands and lands under Williamson Act contracts.

Storage Facilities. The WSIP improvements to water storage facilities could temporarily disrupt agricultural activities in the area (e.g., if grazing lands are located in the vicinity of the construction project) or significantly affect agricultural resources (e.g., if the project would entail flooding important farmland, land zoned for agricultural use, or land under Williamson Act contract).

San Joaquin Region

Impact 4.13-1:	**Temporary conflicts with established agricultural resources**	
Advanced Disinfection	SJ-1	N/A
Lawrence Livermore	SJ-2	N/A
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	N/A

Of the five WSIP projects within the San Joaquin Region, most construction activities would be associated with the San Joaquin Pipeline projects (SJPL System, SJ-3, and SJPL Rehabilitation, SJ-4). Pipeline and crossover construction and associated staging areas for the SJPL System project would temporarily disrupt agricultural activities in the vicinity of the two proposed pipeline segments. Construction would take place over three years. Most construction would occur within the existing SFPUC right-of-way, but up to an additional 200-foot width of temporary or additional right-of-way could be required north of the existing right-of-way. (Additional land might also be needed for crossover facilities and associated power supply facilities, depending on the final locations of these facilities. This impact is discussed under Impact 4.13-2.)

These construction activities could temporarily disrupt the production of field crops on important farmland within and adjacent to the right-of-way easement and staging areas, or cause temporary access conflicts for agricultural operators in the vicinity. Without mitigation, these temporary impacts could be *potentially significant* in some areas, especially the Prime Farmland east of Tesla Portal in the southern portions of Stanislaus and San Joaquin Counties. With implementation of SFPUC Construction Measures #1, #3, #5, and #6 (neighborhood notice, traffic, air quality, and noise); construction mitigation measures for traffic, noise, and air quality (described in Section 4.8, Transportation, Traffic, and Circulation; Section 4.9, Air Quality; and Section 4.10, Noise and Vibration); as well as supplemental noticing and soil stockpiling measures (Measure 4.13-1a), it is expected that potentially significant temporary construction impacts could be reduced to a less-than-significant level. The SJPL Rehabilitation project (SJ-4) could require pipeline rehabilitation at any location along the entire 48-mile San Joaquin Pipeline right-of-way, which extends through areas of important farmland in Stanislaus and San Joaquin Counties. Similar to the SJPL System project (SJ-3), depending on the location of construction work in relation to agricultural lands and activities, impacts could be *potentially significant*, but would likely be reduced to a less-than-significant level with implementation of SFPUC Construction Measures #1, #3, #5, and #6 (neighborhood notice, traffic, air quality, and noise); construction mitigation measures for traffic, noise, and air quality (described in Section 4.8, Transportation, Traffic, and Circulation;

Section 4.9, Air Quality; and Section 4.10, Noise and Vibration), and supplemental noticing and soil stockpiling measures (Measure 4.13-1a).

Two projects (Advanced Disinfection, SJ-1, and Tesla Portal Disinfection, SJ-5) would involve installing disinfection facilities at existing SFPUC facility sites that are currently used for water system purposes, and thus would not affect agricultural resources. The Lawrence Livermore project (SJ-2) would construct new water filtration facilities for the Lawrence Livermore Laboratory (at Thomas Shaft) in San Joaquin County and would not affect any existing agricultural uses or important farmlands. Therefore, this impact would *not apply* to these projects.

Sunol Valley Region

Impact 4.13-1:	**Temporary conflicts with established agricultural resources**	
Alameda Creek Fishery	SV-1	PSM
Calaveras Dam	SV-2	PSM
40-mgd Treated Water	SV-3	PSM
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	N/A
SABUP	SV-6	PSM

Construction of the 40-mgd Treated Water (SV-3) and SABUP (SV-6) projects would include new pipelines from the Sunol Valley WTP to the Alameda Siphons or new Irvington Tunnel and from San Antonio Reservoir to the San Antonio Pump Station. Construction of these pipelines could disrupt the sensitive area of agricultural soils mapped as Unique Farmland in the bottomlands adjacent to Alameda Creek in this area (California Department of Conservation, 2002), a *potentially significant* impact. Construction of the New Irvington Tunnel project (SV-4) could also affect identified agricultural soils in the Alameda Creek vicinity, depending on the ultimate location of staging areas and access roads. In addition, depending on the design of the Alameda Creek Fishery project (SV-1), construction of facilities such as a pipeline, associated staging areas, and pump stations could also disrupt these identified agricultural soils. Such disruption would be temporary, lasting for the duration of the construction period only. Similarly, depending on design and location of staging areas, the Calaveras Dam project (SV-2) could disrupt areas used for grazing. Potential impacts of the Alameda Creek Fishery, Calaveras Dam, and New Irvington Tunnel projects on agricultural resources (including consistency with any affected Williamson Act contracts) would be evaluated in more detail as part of separate, project-level CEQA review. It is expected that these *potentially significant* impacts could be mitigated to a less-than-significant level with implementation of avoidance or soil stockpiling measures, unless other actions are required as a result of contracts affecting use of the property or under specific agreements with individual landowners (Measure 4.13-1b).

Construction of the Treated Water Reservoirs project (SV-5) would not affect identified agricultural resources in the Sunol Valley. Construction activities associated with this project (where applicable) would occur entirely within the fenceline at the existing CCSF-owned Sunol Valley WTP site, which is used for water system purposes. Therefore, this impact would *not apply* to this project.

Bay Division Region

Impact 4.13-1: Temporary conflicts with established agricultural resources		
BDPL Reliability Upgrade	BD-1	N/A
BDPL 3 and 4 Crossovers	BD-2	N/A
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	N/A

The BDPL Reliability Upgrade project (BD-1) would be located in areas that are not mapped as important farmland. The open-trench sections of the pipeline would be constructed within the existing SFPUC right-of-way through urbanized areas. Similarly, none of the proposed locations for the BDPL 3 and 4 Crossovers project (BD-2) would affect agricultural resources, and the BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) would not disturb important farmlands or existing agricultural activities. Therefore, this impact would *not apply* to the projects in this region.

Peninsula Region

Impact 4.13-1: Temporary conflicts with established agricultural resources		
Baden and San Pedro Valve Lots	PN-1	N/A
CS/SA Transmission	PN-2	N/A
HTWTP Long-Term	PN-3	N/A
Lower Crystal Springs Dam	PN-4	N/A
Pulgas Balancing Reservoir	PN-5	N/A

All of the Peninsula Region projects (PN-1 through PN-5) would occur on CCSF-owned sites that are not used for agricultural activities. New controls and valves would be installed at existing SFPUC facilities in urbanized locations, which are not important farmlands. The CS/SA Transmission project (PN-2) could entail construction of a new parallel pipeline on undeveloped land within the Peninsula watershed, but would not affect important farmland or disrupt existing agricultural uses. Therefore, this impact would *not apply* to the projects in this region.

San Francisco Region

Impact 4.13-1: Temporary conflicts with established agricultural resources		
SAPL 3 Installation	SF-1	N/A
Groundwater Projects	SF-2	N/A
Recycled Water Projects	SF-3	N/A

No agricultural activities would be affected by any of the program components in the urbanized San Francisco Region. Therefore, this impact would *not apply* to the projects in this region.

Operations, Siting, and Design Impacts

Impact 4.13-2: Conversion of farmlands to non-agricultural uses.

This section addresses potential impacts on agricultural resources associated with the siting and permanent operation of WSIP facilities in each region. In some areas, the loss of Prime or Unique Farmland could contribute to significant cumulative impacts on agricultural resources if other projects in the area have removed or would remove substantial amounts of important farmland.

These types of potential impacts on agricultural resources associated with the WSIP projects are identified by region below.

San Joaquin Region

Impact 4.13-2: Conversion of farmlands to non-agricultural uses		
Advanced Disinfection	SJ-1	N/A
Lawrence Livermore	SJ-2	N/A
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	N/A
Tesla Portal Disinfection	SJ-5	N/A

Additional land might be acquired to site the SJPL System project (SJ-3) crossover facilities and associated power supply facilities. Depending on the final locations selected, the siting of these facilities could adversely affect important farmland and result in its conversion to non-agricultural use, a *potentially significant* impact. Such impacts could be reduced to a less-than-significant level by siting facilities to avoid these lands or adopting a permanent set-aside for an equivalent acreage of similarly valued farmland in the area (Measure 4.13-2). The additional land required for these facilities might be under a Williamson Act contract, but would be less than 100 acres; therefore, acquisition of these lands would not cause a significant impact as defined by CEQA.

None of the other WSIP projects in the San Joaquin Region (Advanced Disinfection, SJ-1; Lawrence Livermore, SJ-2; SJPL Rehabilitation, SJ-4; and Tesla Portal Disinfection, SJ-5) would result in the permanent conversion of important agricultural land, land zoned for agricultural use, or land under Williamson Act contract to non-agricultural use. Therefore, this impact would *not apply* to these projects.

Sunol Valley Region

Impact 4.13-2: Conversion of farmlands to non-agricultural uses		
Alameda Creek Fishery	SV-1	N/A
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	PSM
New Irvington Tunnel	SV-4	N/A
Treated Water Reservoirs	SV-5	PSM
SABUP	SV-6	N/A

The Sunol Valley contains important farmland and established agricultural uses that could be affected by WSIP components in Alameda County. The Calaveras Dam project (SV-2) has the potential to submerge approximately 100 acres of grasslands, portions of which may be potential Grazing Land within the SFPUC watershed. Extensive earthmoving activities would also occur within this area, since it has been designated as a borrow area. Because this area is not currently used for agricultural activities and the soils are not prime, unique, or of statewide importance and because the land is not under a Williamson Act contract, this impact would be *less than significant*.

Under the 40-mgd Treated Water (SV-3) and Treated Water Reservoirs (SV-5) projects, proposed basins or reservoirs could require the use of approximately two acres of land adjacent to the existing Sunol Valley WTP. Depending on their design, these facilities could convert potential agricultural land, including soils mapped as Unique Farmland, to non-agricultural uses or disrupt existing agricultural uses. It is expected that avoiding the siting of facilities on these lands or adopting a permanent set-aside for an equivalent acreage of similarly valued farmland in the area (Measure 4.13-2) would reduce this *potentially significant* impact to a less-than-significant level.

The siting and operation of the remaining projects in the Sunol Valley Region (Alameda Creek Fishery, SV-1; New Irvington Tunnel, SV-4; and SABUP, SV-6) would have no effect on agricultural resources, as they would all take place within the boundaries of the existing SFPUC water system (or, in the case of pipelines, disruption would be temporary, and long-term agricultural uses would not be affected). Therefore, this impact would *not apply* to these projects.

Bay Division, Peninsula, and San Francisco Regions

Impact 4.13-2: Conversion of farmlands to non-agricultural uses		
BDPL Reliability Upgrade	BD-1	N/A
BDPL 3 and 4 Crossovers	BD-2	N/A
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	N/A
Baden and San Pedro Valve Lots	PN-1	N/A
CS/SA Transmission	PN-2	N/A
HTWTP Long-Term	PN-3	N/A
Lower Crystal Springs Dam	PN-4	N/A
Pulgas Balancing Reservoir	PN-5	N/A
SAPL 3 Installation	SF-1	N/A
Groundwater Projects	SF-2	N/A
Recycled Water Projects	SF-3	N/A

None of the proposed WSIP projects in these regions would result in the conversion of Prime or Unique Farmland or Farmland of Statewide Importance to non-agricultural uses, nor would they conflict with agricultural zoning or Williamson Act contracts. Therefore, this impact would *not apply* to the projects in these regions.

4.14 Hazards

4.14 Hazards

If released to the soil, groundwater, or air, hazardous materials and wastes can result in public health hazards. Hazardous materials, defined in Section 25501(h) of the California Health and Safety Code, are materials that, because of their quantity, concentration, or physical or chemical characteristics, pose a substantial present or potential hazard to human health and safety or to the environment if released to the workplace or environment. Hazardous materials have been and are commonly used in commercial, agricultural, and industrial applications as well as in residential areas to a limited extent. A waste is any material that is relinquished, recycled, or inherently waste-like. In accordance with Title 22 of the California Code of Regulations, Division 4.5, Chapter 11, a waste is considered a hazardous waste if it is toxic (causes adverse human health effects), ignitable (has the ability to burn), corrosive (causes severe burns or damage to materials), or reactive (causes explosions or generates toxic gases) in accordance with the criteria established in Article 3. Article 4 lists specific hazardous wastes and Article 5 identifies specific waste categories, including Resource Conservation and Recovery Act (RCRA) hazardous wastes, non-RCRA hazardous wastes, extremely hazardous wastes, and special wastes.

Environmental screening analyses or environmental database reviews have been performed for several WSIP projects; and the results of these analyses are described below as an indicator of the potential to encounter hazardous materials in the soil and groundwater. The types of sites identified in the environmental databases include permitted hazardous materials uses,[1] environmental cases,[2] and spill sites.[3] For projects where an environmental screening analysis or environmental database review has not been performed, general land uses are described.

4.14.1 Setting

San Joaquin Region

The San Joaquin Pipeline spans previous and current agricultural areas, where the application of pesticides and herbicides may have resulted in soil or shallow groundwater contamination. Underground fuel tanks, including heating oil or fuel tanks at individual farms, adjacent to or near the existing and proposed pipeline alignment may also have affected shallow soil or groundwater quality within the alignment.

The SJPL Rehabilitation project (SJ-4) could include assessment and rehabilitation along any section of the 48-mile San Joaquin Pipeline system. The environmental database review performed for this pipeline system in 2004 (EDR, 2004a) identified a number of permitted hazardous materials uses within 1/4 mile of the pipeline system, primarily concentrated in

1 Permitted hazardous materials uses are facilities that use hazardous materials or handle hazardous wastes but comply with current hazardous materials and hazardous waste regulations.

2 Environmental cases are sites suspected of releasing hazardous substances or that have had cause for hazardous materials investigations and are identified on regulatory agency lists. These are sites where soil and/or groundwater contamination is known or suspected to have occurred.

3 Spill sites are locations where a spill has been reported to the state or federal regulatory agencies. Such spills do not always involve a release of hazardous materials.

Modesto and to the west toward Shackelford Road. The uses considered to have the greatest potential to affect soil and groundwater quality within the pipeline right-of-way are the U.S. Army River Bank Ammunitions Plant site, located near Riverbank, and 43 historical underground storage tank sites.

The U.S. Army River Bank Ammunition Plant site, a government-owned and contractor-operated ammunitions manufacturing plant, is partially located within the San Joaquin Pipeline right-of-way. There are four unlined evaporation ponds, located approximately 1.5 miles north of the plant site and used since 1952 for the disposal of treated effluent. Cyanide, potliner wastes, and other wastes and debris were generated and reportedly disposed of in a landfill in the northeastern portion of the main plant area. Other wastes historically produced at the plant include corrosive wastes (phosphoric acid, sulfuric acid, caustic cleaners), solvents, spent pickle liquids, wastewater containing metals, and nitrates. Hexavalent chromium and cyanide have been identified in groundwater beneath the plant site and beyond the property boundaries, at maximum concentrations of 2,000 micrograms per liter (µg/L) and 9,300 µg/L, respectively. As a result, the U.S. Army Corps of Engineers has been required to permanently connect nearby residential areas relying on groundwater as the principal water source to a potable water source. This facility is a Superfund site undergoing corrective action under RCRA. A Record of Decision mandating a permanent remedy has been developed for this site. Other environmental cases identified within the pipeline corridor include six leaking underground storage tank sites, five of which are located within Modesto.

The SJPL System project (SJ-3) would include construction of a 6.4-mile-long pipeline extending from the Oakdale Portal to the west (eastern segment) and 10-mile-long pipeline extending from Tesla Portal to the east (western segment), although this latter segment could be as long as 16.3 miles. Both pipeline segments would be constructed within the existing right-of-way. The database review identified two historical underground storage tank sites within 1/4 mile of the western segment. No permitted hazardous materials uses, environmental cases, or spill sites were identified within 1/4 mile of the eastern segment.

Tesla Portal, where the Advanced Disinfection facility (SJ-1) and Tesla Portal Disinfection project (SJ-5) would be located, is in a rural area; there were no permitted hazardous materials uses, environmental cases, or spill sites identified within one mile of Tesla Portal (Vista Information Solutions, 1999a). No environmental database reviews have been conducted for the Thomas Shaft, where the Lawrence Livermore project (SJ-2) would be constructed. This site is also located in a rural area.

Gas Fields

The western segment of the San Joaquin Pipeline (SJPL System, SJ-3, and SJPL Rehabilitation, SJ-4) passes between the Vernalis and Southwest Vernalis Gas Fields. The alignment is near several plugged and abandoned gas wells in the Southwest Vernalis Field. Active gas wells in the Vernalis Field are more than one mile north of the alignment, although plugged and abandoned dry oil exploration holes are located about 1/2 mile from the alignment.

Sunol Valley Region

Most of the projects in this region would be located within Sunol Valley, which is mostly developed with water facilities, commercial nurseries, and quarries. The environmental database review conducted in 2003 for the New Irvington Tunnel project (SV-4) identified one environmental case within 1/4 mile of the Alameda West Portal (EDR, 2003a). This site had a confirmed release of hazardous materials and was also identified as a leaking underground storage tank site.

The Calaveras Test Site at the end of Marsh Road is located at the south end of Calaveras Reservoir where the Calaveras Dam project (SV-2) would be constructed. The SFPUC leased this 3.2-acre site to various operators between 1948 and 1993; during this time, the site was used for the testing and manufacturing of propellants and explosives (URS, 2004). A number of soil and groundwater investigations at this site have identified solvents, including trichloroethylene, in the groundwater. The Regional Water Quality Control Board (RWQCB) has approved monitored natural attenuation as the preferred remedial approach for the groundwater. In 1996, the plume of trichloroethene identified in the groundwater at this site extended about 730 feet to the northwest of where it originated, but by 2003 the length of the plume decreased to 570 feet. In 2006, the concentration of trichloroethene detected in groundwater was up to 11 µg/L, twice the cleanup level of 5 µg/L (Conestoga-Rovers & Associates, 2006). Solvents and semivolatile organic compounds have not been detected in Calaveras Creek or a nearby water supply well, and volatile organic compounds have not been detected in surface water samples collected from Calaveras Reservoir. Although trichloroethene concentrations have not reached cleanup levels, the RWQCB is preparing to recommend closure of the groundwater contamination case at this site (Johnson, 2007).

No hazardous materials assessments have been prepared for the Alameda Creek Fishery (SV-1), 40-mgd Treated Water (SV-3), Treated Water Reservoirs (SV-5), and SABUP (SV-6) projects, but hazardous materials are used at the Sunol Valley Water Treatment Plant (WTP), where the two treated water projects (SV-3 and SV-5) would be constructed.

Bay Division Region

The WSIP projects proposed in this region are generally located along the existing Bay Division Pipelines Nos. 1 and 2 (northern) alignment or Bay Division Pipelines Nos. 3 and 4 (southern) alignment; these pipelines span geographically different areas and are discussed separately below.

Northern Alignment

The proposed alignment for the BDPL Reliability Upgrade project (BD-1) generally follows the alignment of Bay Division Pipelines Nos. 1 and 2 and passes through residential, commercial, and industrial areas on both sides of San Francisco Bay. The environmental database review conducted for the project in 2003 identified a number of environmental cases, permitted hazardous materials uses, and spill sites within 1/4 mile of the alignment (EDR, 2003a, 2003b). On the east side of the bay, the majority of environmental cases were located in the vicinity of Cherry Street and Central

Avenue and within one mile of the proposed east tunnel portal at the Newark Valve House. Groundwater contamination by dissolved petroleum products or solvents was identified at six environmental cases located within 1/2 mile of the proposed east tunnel portal.

On the west side of the bay, the proposed west tunnel portal and Ravenswood Valve House are located at the site of the former Peninsula Sportsmen's Club. Soil at this site and sediment in the adjacent Cargill Salt Pond and levee have been contaminated by lead shot and clay pigeon debris from former skeet-shooting activities at the gun club. Although the City did not cause the contamination, as the landowner it is responsible for the cleanup in accordance with RWQCB Order No. 01-095 (RWQCB, 2001). Remediation of the site is ongoing, and complete cleanup is expected before 2009.

There are a number of leaking underground storage tank sites as well as sites with documented groundwater contamination within 1/4 mile of the remainder of the alignment on the east side of the bay. These sites are generally concentrated near Willow Road, Marsh Road, El Camino Real, and Canyon Road.

Southern Alignment

The Bay Division Pipelines Nos. 3 and No. 4 traverse the south end of the bay. WSIP projects along this alignment include the BDPL 3 and 4 Crossovers (BD-2) and BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3).

BDPL 3 and 4 Crossovers (BD-2) includes the construction of crossovers at the Guadalupe River, Bear Gulch Reservoir, and Barron Creek sites. Based on the 2003 environmental database review, all identified permitted hazardous materials uses were located approximately 1/4 mile from the crossover locations at Guadalupe River, and there were no identified environmental cases or spill sites within 1/4 mile (EDR, 2003a). There were two permitted hazardous materials uses within 1/4 mile of the Bear Gulch site, but no environmental cases or spill sites in this area. The Barron Creek site is near the Hillview-Porter regional groundwater plume, in which solvents have been identified. There were also two leaking underground storage tank sites and one case under the jurisdiction of the RWQCB within 1/4 mile of this site.

As part of a screening analysis, a database search was conducted to identify high- and medium-priority environmental cases[4] along Bay Division Pipelines Nos. 3 and 4, including the BDPL 3

[4] High-priority environmental cases are those sites identified as undergoing remediation or enforcement actions under the federal Superfund or RCRA regulations. These are sites identified on the National Priorities List (NPL), RCRA Corrective Action Sites, and RCRA Administrative Action Tracking System. A Record of Decision (ROD), which mandates a permanent remedy, has been developed for each of the NPL sites, and these sites are also tracked in the ROD database. Medium-priority environmental cases are those sites where a confirmed or potential release of hazardous materials has occurred and there is the potential to encounter hazardous materials during construction, but the contamination is not severe enough to warrant action under federal regulations. These include sites undergoing enforcement actions under the jurisdiction of state regulatory agencies, including the San Francisco Bay RWQCB and the California Department of Toxic Substances Control, as well as those sites tracked in the federal Comprehensive Environmental Response, Compensation, and Liability Information System as potential NPL sites. Toxic pit sites, waste management units, and sites with a reported release that could threaten a drinking water source are also included in this category.

and 4 Seismic Upgrade at Hayward Fault (BD-3) project location (EDR, 2003a). There were no high- or medium-priority environmental cases within 1/4 mile of the BD-3 improvements. Additional permitted hazardous materials uses, environmental cases, and spill sites may be located within 1/4 mile of these proposed improvements, but the existing environmental assessment only identified specific high-priority environmental cases.

Peninsula Region

The Peninsula Region includes open space lands of the Peninsula watershed as well as developed urban areas. The environmental database review conducted in 1999 for the Harry Tracy WTP, where the HTWTP Long-Term project (PN-3) would be constructed, reported a 1993 leak of motor vehicle fuel from an underground storage tank at the treatment plant (Vista Information Solutions, 1999c). The case was reported to affect soil only and was closed in 1995 after excavation and disposal of the contaminated soil. The Harry Tracy WTP site was not identified as a RCRA-permitted facility. The database review identified one leaking underground storage tank site within a one-mile radius of the site.

The Pulgas Balancing Reservoir site (PN-5) is located in a rural area. The environmental database review conducted in 1999 did not identify this site as an environmental case or a permitted hazardous materials use (Vista Information Solutions, 1999b). No environmental cases were identified within a one-mile radius of the site.

An environmental database review has not been conducted for the Baden and San Pedro Valve Lots (PN-1), CS/SA Transmission (PN-2), or Lower Crystal Springs Dam (PN-4) projects. There is a low potential to encounter soil or groundwater contamination during construction of the CS/SA Transmission and Lower Crystal Springs Dam projects because they are located on watershed land. However, there is the potential to encounter soil and groundwater contamination during the construction of the Baden and San Pedro Valve Lots project, which is partially located in urban areas.

San Francisco Region

The San Francisco Region projects are primarily located in San Francisco, although the SAPL 3 Installation (SF-1) extends to Highway 82 in Daly City, and the Regional Groundwater Projects (SF-2) are located outside of the San Francisco, in San Mateo County.

An environmental database review has been conducted for the SAPL 3 Installation project (SF-1). Environmental database reviews have not been conducted specifically for the Groundwater Projects (SF-2) or Recycled Water Projects (SF-3), although there is documented soil contamination at the Pacific Rod and Gun Club near Lake Merced, which is part of the Local Groundwater Projects. The environmental database review and Pacific Rod and Gun Club are discussed below.

San Andreas Pipeline No. 3 Installation Vicinity

Mixed residential and commercial land uses surround the southern end of the SAPL 3 Installation (SF-1) pipeline alignment for approximately 1,000 feet. The remainder of the alignment north to Sunset Reservoir traverses residential or golf course uses. The environmental database review conducted for the SAPL 3 Installation project identified leaking underground storage tank sites and additional environmental cases within 1/4 mile of the pipeline alignments under consideration (EDR, 2004b).

Pacific Rod and Gun Club

The Pacific Rod and Gun Club, located on 14 acres of property along the shores of Lake Merced (South Lake) off of John Muir Drive, has been used for skeet and trap shooting since 1928. Although the use of lead shot was discontinued in 1994 and biodegradable targets have been used since 2000, soil and sediment quality have been affected by the historical use of lead shot and clay pigeons at this facility; the primary constituents of concern are lead, arsenic, copper, and polynuclear aromatic hydrocarbons (URS, 2005).

Regulatory Framework

Hazardous materials and hazardous wastes are subject to numerous federal, state, and local laws and regulations intended to protect health and safety and the environment. The major federal, state, and regional agencies enforcing these regulations include the U.S. Environmental Protection Agency (U.S. EPA, federal); the DTSC and the RWQCB of the California Environmental Protection Agency (state); and the Bay Area Air Quality Management District (BAAQMD, regional). The state and federal regulatory framework is described in Appendix G.

In accordance Chapter 6.11 of the Health and Safety Code (Section 25404, et seq.), local regulatory agencies enforce many federal and state regulatory programs through the Certified Unified Program Agency (CUPA) program, including:

- Hazardous materials business plans (Chapter 6.95 of the Health and Safety Code, Section 25501 et seq.)
- The California accidental release prevention program for acutely hazardous materials (Chapter 6.95 of the Health and Safety Code, Section 25531 et seq.)
- State Uniform Fire Code requirements (Section 80.103 of the Uniform Fire Code as adopted by the state fire marshall pursuant to Health and Safety Code, Section 13143.9)
- Underground storage tanks (Chapter 6.7 of the Health and Safety Code, Section 25280 et seq.)
- Aboveground storage tanks (Health and Safety Code Section 25270.5[c])
- Hazardous waste generator requirements (Chapter 6.5 of the Health and Safety Code, Section 25100 et seq.)

Several county and city agencies within the WSIP study area are CUPA agencies. The environmental health departments in Tuolumne, Stanislaus, San Joaquin, Alameda, Santa Clara, and San Mateo Counties are the CUPA agencies in these counties. Local fire departments are the CUPA agencies in Newark, Fremont, and Santa Clara. Some local fire departments (Santa Clara County and Palo Alto) are participating agencies that support the CUPA agencies. The San Francisco Department of Public Health is the responsible CUPA agency in San Francisco.

Use and Storage of Hazardous Materials and Fuels

Hazardous Materials Business Plans

Businesses that handle specified quantities of chemicals are required to submit a hazardous materials business plan (HMBP) in accordance with community right-to-know laws. This plan allows local agencies to plan appropriately for a chemical release, fire, or other incident. The HMBP must include the following:

- An inventory of hazardous materials with specific quantity data, storage or containment descriptions, ingredients of mixtures, and physical and health hazard information
- Site and facility layouts that must be coded for chemical storage areas and other facility safety information
- Emergency response procedures for a release or threatened release of hazardous materials
- Procedures for immediate notification of releases to the administering agency
- Evacuation plans and procedures for the facility
- Descriptions of employee training in evacuation and safety procedures in the event of a release or threatened release of hazardous materials consistent with employee responsibilities, and proof of implementing such training on an annual basis
- Identification of local emergency medical assistance appropriate for potential hazardous materials incidents

The HMBP is filed with and administered by the CUPA agency, which ensures review by and distribution to other potentially affected agencies. The SFPUC has prepared and implemented HMBPs for its facilities that use hazardous materials above threshold limits.

California Accidental Release Program

The California Accidental Release Program (CalARP) includes regulatory requirements for facilities that handle regulated substances.[5] Ammonia and propane are regulated substances under state and federal risk management regulations. In accordance with CalARP regulations, preparation of a risk management plan (RMP) is required for the storage of regulated substances above threshold quantities. The RMP includes a hazard assessment to evaluate the potential

[5] CalARP incorporates the requirements of the Federal Risk Management Program, but is more stringent with respect to the threshold quantities of chemicals requiring risk management plans.

effects of an accidental release, a program for preventing an accidental release, and a program for responding to an accidental release. The RMP is filed with and administered by the CUPA agency, which ensures review by and distribution to other potentially affected agencies. The SFPUC has prepared and implemented RMPs for the storage of ammonia at the Harry Tracy WTP and Sunol Valley Chloramination Facility.

Aboveground Storage of Petroleum Products

The Aboveground Petroleum Storage Act of 1990 requires facilities storing petroleum products in a single tank greater than 1,320 gallons or facilities storing petroleum in aboveground tanks or containers with a cumulative storage capacity of greater than 1,320 gallons to file a storage statement with the State Water Resources Control Board (SWRCB) and prepare a spill prevention, control, and countermeasure plan. The plan must identify appropriate spill containment or equipment for diverting spills from sensitive areas, and discuss facility-specific requirements for the storage system, inspections, record keeping, security, and personnel training.

The SWRCB requires registration of an aboveground fuel storage tank at a construction site only if the tank is 20,000 gallons or larger, or if the aggregate volume of aboveground petroleum storage is over 100,000 gallons. For smaller temporary tanks used during construction, methods for controlling a release and measures to clean up an accidental release and prevent degradation of water quality are addressed in the construction stormwater pollution prevention plan prepared for the project, as described in Section 4.5, Hydrology and Water Quality.

Hazardous Materials Worker Safety Requirements

The federal Occupational Safety and Health Administration (Fed-OSHA) and the California Occupational Safety and Health Administration (Cal-OSHA) are the agencies responsible for assuring worker safety in the handling and use of chemicals in the workplace. The federal regulations pertaining to worker safety are contained in Title 29 of the Code of Federal Regulations, as authorized in the Occupational Safety and Health Act of 1970. They provide standards for safe workplaces and work practices, including standards relating to hazardous materials handling. In California, Cal-OSHA assumes primary responsibility for developing and enforcing workplace safety regulations; Cal-OSHA standards are generally more stringent than federal regulations.

The state regulations concerning the use of hazardous materials in the workplace are included in Title 8 of the California Code of Regulations, which contain requirements for safety training, availability of safety equipment, accident and illness prevention programs, hazardous substance exposure warnings, and emergency action and fire prevention plan preparation. Cal-OSHA also enforces hazard communication program regulations, which contain worker safety training and hazard information requirements, such as procedures for identifying and labeling hazardous substances, communicating hazard information relating to hazardous substances and their handling, and preparation of health and safety plans to protect workers and employees.

Control of Asbestos During Construction

The California Air Resources Board (CARB) has adopted an asbestos Airborne Toxic Control Measure (ATCM) for construction, grading, quarrying, and surface mining operations (CARB, 2002). The ATCM requires the use of best available dust mitigation measures to prevent offsite migration of asbestos-containing dust from road construction and maintenance activities, construction and grading operations, and quarrying and surface mining operations in areas of ultramafic rock,[6] serpentine,[7] or asbestos.[8] The BAAQMD implements the regulation, which became effective on July 22, 2002.

For construction projects within areas where ultramafic rock (primarily serpentinite) is mapped that disturb one acre or less of land, the ATCM requires the site operator to implement standard dust mitigation measures before construction begins, and to maintain each measure throughout the duration of the construction project. Construction activities disturbing more than one acre of asbestos-containing materials are required to prepare an asbestos dust mitigation plan specifying measures that would be taken to ensure that no visible dust crosses the property boundary. The asbestos dust mitigation plan must be submitted to and approved by the BAAQMD prior to the beginning of construction, and the site operator must ensure the implementation of all measures throughout the construction project. In addition, the BAAQMD may require air monitoring for offsite migration of asbestos dust during construction activities and may change the plan on the basis of the air monitoring results.

In the program area, naturally occurring asbestos would most likely be encountered in Franciscan ultramafic rock (primarily serpentinite) or mélange.[9] The asbestos ATCM could apply to the Calaveras Dam (SV-2), BDPL Reliability Upgrade (BD-1), CS/SA Transmission (PN-2), and Lower Crystal Springs Dam (PN-4) projects, because at least part of these projects would be located in areas where these bedrock units have been identified, as discussed in Section 4.4, Geology, Soils, and Seismicity. San Francisco Region projects could be subject to the ATCM if they would require disturbance of one of these bedrock units or would be located in areas that have been filled with materials excavated from bedrock containing serpentinite. Additional projects could be subject to the asbestos ATCM if naturally occurring asbestos were identified during construction.

---

6 Ultramafic rocks are formed in high-temperature environments well below the surface of the earth.

7 Serpentine is a naturally occurring group of minerals that can be formed when ultramafic rocks are metamorphosed during uplift to the earth's surface. Serpentinite is a rock consisting of one or more serpentine minerals. This rock type is commonly associated with ultramatic rock along earthquake faults. Small amounts of chrysotile asbestos, a fibrous form of serpentine minerals, are common in serpentinite.

8 Asbestos is a term used for several types of naturally occurring fibrous materials found in many parts of California.

9 Mélange is a mixture of rock materials of differing sizes and types typically contained within a sheared matrix.

Wildland Fire

The California Public Resources Code, beginning with Section 4427, includes fire safety regulations that: restrict the use of equipment that may produce a spark, flame, or fire; require the use of spark arrestors[10] on construction equipment that use an internal combustion engine; specify requirements for the safe use of gasoline-powered tools in fire hazard areas; and specify fire suppression equipment that must be provided onsite for various types of work in fireprone areas. The Public Resources Code requirements would apply to construction activities at the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) east segment near the Oakdale Portal and west segment near Tesla Portal; projects at the Tesla Portal (Advanced Disinfection, SJ-1, and Tesla Portal Disinfection, SJ-5); the Lawrence Livermore project (SJ-2); all of the Sunol Valley Region projects; the BDPL Reliability Upgrade project (BD-1); and the Peninsula Region projects within the Peninsula watershed (Baden and San Pedro Valve Lots, PN-1; CS/SA Transmission, PN-2; Lower Crystal Springs Reservoir, PN-4; and Pulgas Balancing Reservoir, PN-5), because these sites are in or near areas designated by the California Department of Forestry and Fire Protection (CDF) as a “Wildland Area That May Contain Substantial Forest Fire Risks and Hazards” (CDF, various dates).

Any additional requirements of the local fire agencies would also apply to projects located within a “Very High Fire Hazard Severity Zone.” The fire protection agencies may also designate new areas in their jurisdictions as “Very High Fire Severity Zones,” which could result in more WSIP projects being located in such zones and subject to local requirements for construction in these zones.

In addition, the City and County of San Francisco has identified areas of Urban-Wildland Interface in Golden Gate Park, where some Groundwater Projects (SF-2) or Recycled Water Projects (SF-3) could be located (CCSF, 2005). While not a major threat, there is the potential for an urban-wildland fire in this area.

Tunnel Classification and Safety

The California Tunnel Safety Orders (California Code of Regulations, Title 8, Subchapter 20, Article 8) require the Division of Industrial Safety to classify all tunnels or portions of tunnels into one of the following classifications before a public works project can be put out to bid:

- Nongassy, the classification assigned when there is little likelihood of encountering gas during the construction of the tunnel.
- Potentially gassy, the classification assigned when there is a possibility that flammable gas or hydrocarbons will be encountered during construction of the tunnel.
- Gassy, the classification assigned when it is likely gas will be encountered, or if monitoring indicates the presence of hazardous gases at a concentration greater than 5 percent of the lower explosive limit.

---

[10] A spark arrestor is a device that prohibits exhaust gases from an internal combustion engine from passing through the impeller blades where they could cause a spark. A carbon trap is commonly used to retain carbon particles from the exhaust.

- Extra hazardous, the classification assigned to tunnels when the Division finds that there is a serious danger to the safety of employees, flammable gas or petroleum vapors emanating from the strata have been ignited in the tunnel, or monitoring indicates the presence of hazardous gases at a concentration greater than 20 percent of the lower explosive limit.

In accordance with the Tunnel Safety Orders, a tunnel is defined as an underground passageway, 30 inches in diameter or greater, that is excavated by employees working below the ground surface. Therefore, the orders would apply to tunnels proposed as part of the WSIP as well as jack-and-bore excavations that are 30 inches or more in diameter where employees work underground. A classification has not been assigned to the tunnels that would be constructed under the New Irvington Tunnel (SV-4) and BDPL Reliability Upgrade (BD-1) projects, although the New Irvington Tunnel is considered potentially gassy. Classification of these tunnels and other applicable bore excavations would be made by the Division of Industrial Safety on the basis of geologic assessments and recommendations of the SFPUC in accordance with the Tunnel Safety Orders.

The Tunnel Safety Orders require an emergency plan for all tunnel operations that includes maps, ventilation controls, firefighting equipment, rescue procedures, evacuation plans, and communications. The Tunnel Safety Orders specify ventilation requirements for all tunnels. For potentially gassy tunnels, the orders specify monitoring requirements during construction. If threshold levels of gases are exceeded, work must halt and may not resume until the Division of Industrial Safety has authorized reentry in writing. For gassy tunnels, the Tunnel Safety Orders specify monitoring requirements for explosive gases; actions to be taken in the event that explosive vapors are identified; additional requirements for ventilation; restrictions on the use of equipment with internal combustion engines and spark-producing work activities such as welding or cutting; restrictions on smoking and possession of personal sources of ignition such as lighters or matches; requirements for a “kill” button to cut off electrical equipment in the event that sufficient vapors accumulate; and provision of a refuge chamber or escape route for employee safety.

Emergency Response Procedures

The HMBPs and RMPs for the SFPUC facilities that store chemicals specify response procedures to be implemented in the event of a chemical emergency, in accordance with the applicable local regulations. These procedures include notification requirements in the event of a spill; measures to be taken to control and cleanup a spill; procedures for coordination of emergency response personnel; and procedures to be followed should emergency evacuation be required. Plant personnel maintain a comprehensive inventory of emergency response equipment at the facility, and emergency response equipment is regularly inspected and maintained. In accordance with community right-to-know laws, a copy of the HMBP or RMP is on file with the local fire department to assist them in responding to chemical emergencies at the SFPUC chemical storage facilities.

Hazardous Building Materials

Hazardous building materials are included in this discussion because some WSIP projects would involve demolition or renovation of structures that may contain such materials. Some building materials commonly used in older buildings could present a public health risk if disturbed during an accident or during demolition or renovation. Hazardous building materials include asbestos, electrical equipment such as transformers and fluorescent light ballasts that contain polychlorinated biphenyls (PCBs) or di (2 ethylhexyl) phthalate (DEHP), fluorescent lights containing mercury vapors, and lead-based paints. Asbestos and lead-based paint may also present a health risk to building occupants if the materials are in a deteriorated condition. If removed during demolition of a building, these materials would require special disposal procedures.

Asbestos is a common name for a group of naturally occurring fibrous silicate minerals that are made up of thin but strong, durable fibers. Because of its physical properties, asbestos was commonly used until the 1970s as a building material, including use as insulation material, shingles and siding, roofing felt, floor tiles, acoustical ceiling material, and automotive brakes and clutches. Asbestos is a known carcinogen and presents a public health hazard if it is present in the friable (easily crumbled) form. Long-term, chronic inhalation of high levels of asbestos can cause lung diseases such as asbestosis, mesolethioma, and lung cancer.

PCBs are mixtures of synthetic organic chemicals with physical properties ranging from oily liquids to waxy solids. Due to their nonflammability, chemical stability, high boiling point, and electrical insulating properties, PCBs were used in hundreds of industrial and commercial applications, including use in electrical, heat transfer, and hydraulic equipment; as plasticizers in paints, plastic, and rubber compounds; in pigments, dyes, and carbonless copy paper; and many others. More than 1.5 billion pounds of PCBs were manufactured in the United States before production ceased in 1977 (U.S. EPA, 2005). PCBs are a known human carcinogen; they are highly toxic substances that remain persistent in the environment, accumulate in biological systems, interfere with the reproductive system, and act as an immunosuppressant. Under Section 6(e) of the Toxic Substances Control Act, Congress began regulating the use and manufacturing of PCBs in 1976, legislating “cradle to grave” (i.e., from manufacture to disposal) management of PCBs in the United States. Because PCBs were historically used in the WSIP study area, the potential exists for leaks to have occurred.

Most fluorescent light ballasts manufactured before 1978 contain approximately 0.5 ounces of PCBs in a small capacitor, although the quantity can be up to 2 ounces. In 1978, the U.S. EPA estimated that approximately 850 million of these capacitors were in use in the United States. Ballasts manufactured after January 1, 1978 do not contain PCBs and should be labeled as such on the ballast. Between 1979 and the early 1990s, DEHP was used in place of PCBs as a dielectric fluid in some fluorescent light ballasts and other electrical equipment (Green Lights Recycling, 2007). DEHP is classified as a probable human carcinogen by the U.S. Department of Health and Human Services and as a hazardous substance by the U.S. EPA. Because of this classification, ballasts containing DEHP must be legally disposed of; ballast incineration or a combination of ballast recycling and incineration are recommended for complete destruction of DEHP.

Spent fluorescent light tubes commonly contain mercury vapors. In February 2004, regulations took effect in California that classified all fluorescent lamps and tubes as a hazardous waste. When these lamps or tubes are broken, mercury is released to the environment; mercury can also be absorbed through the lungs into the bloodstream and can be washed by rain into waterways. The mercury in urban stormwater sediment results in part from improperly discarded fluorescent lamps and tubes (CIWMB, 2007). In 2000, approximately 370 pounds of mercury were released in California due to the breakage of electric lamps and tubes during storage and transportation. It is estimated that nearly 75 million waste fluorescent lamps and tubes are generated annually in California, and these lamps and tubes contain more than half a ton of mercury.

Lead-based paint is paint that contains lead, a heavy metal historically added to paint as pigment and to speed drying, increase durability, retain a fresh appearance, and resist moisture (which causes corrosion). Because of its toxicity, paint containing more than 0.06 percent lead was banned for residential use in 1978 by the U.S. Consumer Product Safety Commission. Lead is toxic to humans, particularly young children, and can cause a range of human health effects depending on the level of exposure. When adhered to the surface of a material, lead-based paint poses little health risk. Where the paint is delaminated or chipping, it can cause a potential threat to the health of young children or other building occupants who may ingest the paint. Lead dust also presents public health risks during the demolition of structures that contain lead-based paint. Lead-based paint that has separated from a structure may also contaminate nearby soil.

4.14.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to hazards, but generally considers that implementation of the proposed program would have a significant impact if it were to:

- Create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials (Evaluated in this section)
- Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment (Evaluated in this section)
- Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within 1/4 mile of an existing or proposed school (Evaluated in this section)
- Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would create a significant hazard to the public or the environment (Evaluated in this section)
- For a project located within an area covered by an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, result in a safety hazard for people residing or working in the project area (Not evaluated in this section, see Appendix B)

- For a project within the vicinity of a private airstrip, result in a safety hazard for people residing or working in the project area (Not evaluated in this section, see Appendix B)

- Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan (Not evaluated in this section, see Appendix B and Section 4.8, Traffic, Transportation, and Circulation)

- Expose people or structures to a significant risk of loss, injury, or death involving fires (Evaluated in this section)

Approach to Analysis

The program-level assessment focuses on the following issues:

- The potential for encountering hazardous substances in soil and groundwater during construction at the WSIP sites, based on land uses and regulatory database searches to identify permitted hazardous materials uses and environmental cases in the vicinity of ground-disturbing activities

- The potential for encountering naturally occurring asbestos during construction of the WSIP projects

- Potential wildland fire hazards associated with project construction

- Safety risks associated with potentially gassy conditions in the proposed tunnels

- Hazardous building materials that could be encountered during demolition or renovation required for the WSIP projects

- New uses of chemicals and changes in the use of chemicals at the WSIP project sites

The level of analysis used in this program-level assessment allows for the identification of potential impacts related to each project. However, these program-level reviews would be further refined as part of separate, project-level CEQA review of individual WSIP projects, which could result in a change in significance determination.

Impact Summary by Region

Table 4.14-1 provides a summary of the hazards impacts associated with implementation of the WSIP.

TABLE 4.14-1
POTENTIAL IMPACTS AND SIGNIFICANCE – HAZARDS

Projects	Project Number	Impact 4.14-1: Potential to encounter hazardous materials in soil groundwater	Impact 4.14-2: Exposure to naturally occurring asbestos	Impact 4.14-3: Risk of fires during construction	Impact 4.14-4: Gassy conditions in tunnels	Impact 4.14-5: Exposure to hazardous building materials	Impact 4.14-6: Accidental hazardous materials release from construction equipment	Impact 4.14-7: Increased use of hazardous materials during operation	Impact 4.14-8: Emission or use of hazardous materials within 1/4 mile of a school

LS = Less than Significant impact, no mitigation required
PSM= Potentially Significant impact, can be mitigated to less than significant
N/A = Not Applicable

Construction Impacts

Impact 4.14-1: Potential to encounter hazardous materials in soil and groundwater.

All Facilities. If hazardous materials are present in excavated soil, groundwater, or tunnel muck, a release to the environment could occur, and construction workers and the public could be exposed to the hazardous materials in the soil and groundwater and to chemical vapors during construction. Depending on the nature and extent of any contamination encountered, adverse health effects and nuisance vapors could result if proper precautions are not taken. Contaminated soil, groundwater, or tunnel muck could also require disposal as a restricted or hazardous waste; tunnel muck could contain petroleum hydrocarbons, metals, or cement slurry, in which case it would not be suitable for disposal at unregulated local fill sites. The greatest potential for encountering contaminated soil and groundwater during construction is in areas where past or current land uses may have resulted in leaking fuel or chemical storage tanks or other releases of hazardous materials have occurred. Land uses that typically involve the handling of hazardous materials include commercial or industrial areas as well as agricultural areas, where soils may contain pesticides and herbicides. Areas with known contamination are referred to as "environmental cases."

This impact analysis evaluates the potential to encounter hazardous materials in soil, groundwater, and tunnel muck based on previous land uses and, where available, environmental database reviews conducted for specific projects. The potential to encounter hazardous materials in the soil and groundwater would be low for projects located in areas with no known historical uses of hazardous materials, or for which the environmental database review did not identify known environmental cases; in such cases, impacts related to exposure to hazardous materials in soil and groundwater would be less than significant with implementation of SFPUC Construction Measure #7 (hazardous materials). This measure would require conduct of a site assessment to evaluate the potential for soil or groundwater contamination at each site prior to construction to ensure that contaminated materials are handled in accordance with applicable laws and regulations, as well as preparation of a contingency plan specifying measures to be taken should unanticipated contamination be identified during construction. The site assessment conducted under Construction Measure #7 would analyze site-specific information, which would either confirm the program-level determination of less than significant or provide a basis to revise this determination.

Impacts related to exposure to hazardous materials in soil, groundwater, or tunnel muck would be potentially significant if a proposed project would be located in an area where past or current land uses may have resulted in leaking fuel or chemical storage tanks or other releases of hazardous materials and if, based on project information presented in Appendix C, the project could disturb contaminated soil or groundwater. In such cases, implementation of mitigation measures to control exposure to contaminants and ensure proper handling of contaminated soil would be required to reduce this impact to a less-than-significant level. These measures include preparation of a site health and safety plan (Measure 4.14-1a) and materials disposal plan (Measure 4.14-1b). If groundwater dewatering is required, impacts related to the discharge of contaminated water would be less than significant with preparation of a dewatering plan in accordance with SFPUC

Construction Measure #4 (groundwater). The site assessment conducted under Construction Measure #7 would analyze site-specific information, which would either confirm the program-level significance determination or provide a basis to revise this determination.

Pipelines, Tunnels, Reservoirs, and Lakes. In addition to the potential hazardous materials impacts identified above, construction of pipelines or tunnels at or through existing environmental cases could interfere with activities at sites that have undergone or are undergoing remediation. At environmental cases that have undergone remediation or have received regulatory closure, the regulatory agencies may have approved engineering controls (such as a cap or landscaping) to prevent unacceptable exposure to hazardous materials in the soil and groundwater, or health-based cleanup levels that are based on current land uses. Where pipeline or tunnel alignments cross these sites, construction could disturb engineering controls or expose construction workers to unsafe levels of hazardous materials.

Dewatering at tunnel portal locations or along pipeline alignments as well as increased water levels in existing reservoirs could alter groundwater flow patterns and contaminant plume migration, and potentially interfere with ongoing groundwater remediations. In addition, the higher water levels in reservoirs or lakes could cause existing environmental cases to be inundated.

Impacts related to the potential to interfere with site remediations or to inundate a known environmental case would be reduced to a less-than-significant level through coordination with the property owner (or responsible SFPUC agency) and regulatory agencies (as specified under Measure 4.14-1c, which requires the SFPUC to assess the potential to encounter unacceptable levels of hazardous materials at known environmental cases; the potential for construction activities to cause groundwater plume migration or interfere with ongoing remediations at known environmental cases; and the potential for increased water levels in reservoirs or lakes to inundate known environmental cases). If the review indicates that the project could encounter unacceptable levels of hazardous materials or interfere with a remediation, or that adverse effects such as water quality degradation could occur from inundation of an environmental case, the SFPUC would contact the site owner (or responsible SFPUC department for the Peninsula Sportsmen's Club and Pacific Rod and Gun Club) and the responsible regulatory agency to determine appropriate construction modifications or remediation measures to avoid adverse effects. The site assessment conducted under SFPUC Construction Measure #7 would analyze site-specific information, which would either confirm the program-level significance determination or provide a basis to revise this determination.

San Joaquin Region

Impact 4.14-1: Potential to encounter hazardous materials in soil and groundwater		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	LS

Based on existing land uses in the vicinity of the Advanced Disinfection (SJ-1), Lawrence Livermore (SJ-2), and Tesla Portal Disinfection (SJ-5) projects, and previous database reviews conducted for Tesla Portal, there is a low potential to encounter hazardous materials in the soil or groundwater during construction of facilities at these locations. With implementation of SFPUC Construction Measure #7 (hazardous materials), this impact would be *less than significant* for these projects. SFPUC Construction Measure #7 requires preparation of a site assessment to evaluate the potential for soil or groundwater contamination at each site prior to construction to ensure that contaminated materials are handled in accordance with applicable laws and regulations, as well as preparation of a contingency plan identifying measures to be taken should unanticipated contamination be identified during construction.

Although there are seven historical underground storage tank sites located within 1/4 mile of the western pipeline alignment for the SJPL System project (SJ-3), there is a low potential to encounter hazardous materials in the soil and groundwater from known environmental cases because there are no documented releases of hazardous materials from these sites. Similarly, there is a low potential to encounter hazardous materials in the soil and groundwater along the eastern pipeline alignment because there are no documented hazardous materials uses or environmental cases within 1/4 mile of this alignment. Based on previous and current agricultural land uses along the pipeline, there is the potential to encounter pesticides and herbicides in the soil; however, this potential would be further evaluated in the site assessment conducted in accordance with SFPUC Construction Measure #7 (hazardous materials). Therefore, with implementation of this construction measure, it is expected that this impact would be *less than significant* for this project.

Pipeline rehabilitation could occur along any portion of the existing San Joaquin Pipeline as part of the SJPL Rehabilitation project (SJ-4). Depending on the location, hazardous materials could be encountered in the soil and groundwater, particularly in Modesto and near the U.S. Army Riverbank Ammunitions Plant. Therefore impacts related to the potential to encounter hazardous materials in the soil and groundwater are considered *potentially significant* for this project, but would be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #7 (hazardous materials), as well as preparation of a site health and safety plan (Measure 4.14-1a) and materials disposal plan (Measure 4.14-1b) if contamination is identified during the site assessment conducted in accordance with SFPUC Construction Measure #7.

Pipeline rehabilitation in the vicinity of the U.S. Army Riverbank Ammunitions Plant could also interfere with ongoing remediation activities at this site, and dewatering along the pipeline alignment could enhance groundwater plume migration or interfere with remediations in Modesto and at the ammunitions plant, resulting in a *potentially significant* impact. However, this impact would be reduced to a less-than-significant level through coordination with the property owner and regulatory agencies (Measure 4.14-1c).

The western portion of the San Joaquin Pipeline alignment (SJPL System, SJ-3, and SJPL Rehabilitation, SJ-4) is near the Vernalis and Southwest Vernalis Gas Fields; during construction, potentially explosive gases could accumulate in the trench excavation. However, in compliance with the State of California Construction Safety Orders (Title 8 of the California Code of Regulations, Chapter 4, Subchapter 4), the construction contractor would be required to take adequate precautions to prevent the accumulation of unacceptable levels of explosive gases in the excavation. Compliance with these regulations would ensure potential impacts related to the accumulation of natural gas in the pipeline excavation would be less than significant.

If groundwater dewatering is required for any WSIP projects in the San Joaquin Region, impacts related to the discharge of contaminated water would be less than significant with compliance with the discharge regulations discussed in Section 4.5, Hydrology and Water Quality, and implementation of a dewatering plan in accordance with SFPUC Construction Measure #4 (groundwater).

Sunol Valley Region

Impact 4.14-1: Potential to encounter hazardous materials in soil and groundwater		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	LS
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	LS

The Alameda Creek Fishery (SV-1), 40-mgd Treated Water (SV-3), New Irvington Tunnel (SV-4), Treated Water Reservoirs (SV-5), and SABUP (SV-6) projects include construction of facilities, pipelines, or tunnels. There is a low potential to encounter hazardous materials in the soil or groundwater during construction of these projects, based on existing land uses and environmental database reviews conducted for the New Irvington Tunnel project (SV-4). As described in the Setting, contaminants have been identified in the soil at the Calaveras Test Site, near the Calaveras Dam. However, excavation for the Calaveras Dam project (SV-2) would not take place within the areas of identified contamination. Therefore, with implementation of SFPUC Construction Measure #7 (hazardous materials), impacts related to the potential to encounter hazardous materials in the soil, groundwater, and tunnel muck would be *less than significant* for each of these projects.

As discussed in the Setting, a plume of trichloroethene has been identified at the Calaveras Test Site, adjacent to the Calaveras Reservoir. Raising the water level in the reservoir under the Calaveras Dam project would restore the reservoir to pre-2001 conditions and would likely result in a flatter groundwater gradient than exists under current conditions, thereby slowing the migration of trichloroethene in the groundwater and reducing risks to water quality in Calaveras Reservoir. Furthermore, groundwater quality monitoring would continue until the RWQCB grants regulatory closure of the groundwater contamination case. Therefore, impacts related to the potential to interfere with an ongoing remediation and to degrade water quality in Calaveras Reservoir would be *less than significant* for this project.

If groundwater dewatering is required for any of the Sunol Valley Region projects, impacts related to the discharge of contaminated water would be less than significant with compliance with the discharge regulations discussed in Section 4.5, Hydrology and Water Quality, and implementation of a dewatering plan in accordance with SFPUC Construction Measure #4 (groundwater).

Bay Division Region

Impact 4.14-1: Potential to encounter hazardous materials in soil and groundwater		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	PSM
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSM

Based on the environmental database review conducted for the Bay Division Pipelines, there is a high potential to encounter hazardous materials during construction of the BDPL Reliability Upgrade project (BD-1), particularly at the east tunnel portal (where groundwater contamination has been identified at six sites within 1/2 mile in Newark) and at the west tunnel portal (which is located on the site of a former gun club undergoing remediation by the SFPUC). Therefore, impacts related to the potential to encounter hazardous materials in soil, groundwater, and tunnel muck are considered *potentially significant*, but would be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #7 (hazardous materials) as well as preparation of a site health and safety plan (Measure 4.14-1a) and materials disposal plan (Measure 4.14-1b).

Dewatering at the tunnel portal locations for the BDPL Reliability Upgrade project (BD-1) could enhance the migration of groundwater contaminant plumes or interfere with ongoing remediations at the east tunnel portal location, where there are six cases of known groundwater contamination within 1/2 mile. These effects could also occur at additional locations along the pipeline alignment where dewatering is conducted. Furthermore, although remediation of the former Peninsula Sportsmen's Club at the west tunnel portal location should be completed before construction of the BDPL Reliability Upgrade project, construction activities for this project could interfere with remediation activities if the remediation is delayed, or could encounter unacceptable levels of hazardous materials in the soil, depending on the cleanup level achieved during remediation. Therefore, impacts related to the potential to enhance groundwater plume migration or interfere with site remediations are considered *potentially significant* for this project, but would be reduced to a less-than-significant level with coordination with the property owner (or responsible SFPUC department) and regulatory agencies (Measure 4.14-1c).

The BDPL 3 and 4 Crossovers (BD-2) and BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) projects would include pipeline installation, pipeline improvements, or construction of crossover facilities on the existing Bay Division Pipelines Nos. 3 and 4. A database review has not been conducted specifically for these projects. However, there is a potential to encounter hazardous materials in the soil and groundwater during construction of these projects because they are all located at least partially within commercial or industrial areas. Therefore, impacts related to the potential to encounter hazardous materials in the soil and groundwater are considered *potentially significant* for these projects, but would be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #7 (hazardous materials), as well as preparation of a site health and safety plan (Measure 4.14-1a) and materials disposal plan (Measure 4.14-1b) if contamination is identified during the site assessment conducted in accordance with Construction Measure #7.

If groundwater dewatering is required for any Bay Division Region project, impacts related to the discharge of contaminated groundwater would be less than significant with compliance with the discharge regulations discussed in Section 4.5, Hydrology and Water Quality, and implementation of a dewatering plan in accordance with SFPUC Construction Measure #4 (groundwater).

Peninsula Region

Impact 4.14-1: Potential to encounter hazardous materials in soil and groundwater		
Baden and San Pedro Valve Lots	PN-1	PSM
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS

No database reviews have been conducted for the Baden and San Pedro Valve Lots project (PN-1), but because these valve lots are located in an urbanized area, the potential exists to encounter hazardous materials in the soil at these sites. Therefore, impacts related to the potential to encounter hazardous materials in the soil and groundwater are considered *potentially significant*, but would be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #7 (hazardous materials), as well as preparation of a site health and safety plan (Measure 4.14-1a) and materials disposal plan (Measure 4.14-1b) if contamination is identified by the site assessment conducted in accordance with Construction Measure #7.

The HTWTP Long-Term (PN-3), Lower Crystal Springs Dam (PN-4), and Pulgas Balancing Reservoir (PN-5) projects would each include construction of facilities, while the CS/SA Transmission (PN-2) project would include construction of pipelines as well. These projects are located in undeveloped watershed land or residential areas. Based on their locations as well as previous database reviews for the Harry Tracy WTP and Pulgas Balancing Reservoir, there is a low potential to encounter hazardous materials in the soil or groundwater. Therefore, with implementation of SFPUC Construction Measure #7 (hazardous materials), it is expected that impacts related to the potential to encounter hazardous materials in the soil and groundwater would be *less than significant*. This measure would require the conduct of a site assessment to evaluate the potential for soil or groundwater contamination at each site prior to construction to ensure that contaminated materials are handled in accordance with applicable laws and regulations, as well as preparation of a contingency plan identifying measures to be taken should unanticipated contamination be identified during construction.

If groundwater dewatering is required for any Peninsula Region project, impacts related to the potential to discharge contaminated groundwater would be less than significant with compliance with the discharge regulations discussed in Section 4.5, Hydrology and Water Quality, and implementation of a dewatering plan in accordance with SFPUC Construction Measure #4 (groundwater).

San Francisco Region

Impact 4.14-1: Potential to encounter hazardous materials in soil and groundwater		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	PSM
Recycled Water Projects	SF-3	PSM

No database reviews have been conducted specifically for the Groundwater Projects (SF-2) and Recycled Water Projects (SF-3). Since these projects are located in urbanized areas, impacts related to the potential to encounter hazardous materials in soil and groundwater are considered *potentially significant* for these projects, but would be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #7 (hazardous materials), as well as preparation of site health and safety plan (Measure 4.14-1a) and materials disposal plan (Measure 4.14-1b) if contamination is identified by the site assessment conducted in accordance with Construction Measure #7.

A database review conducted for the SAPL 3 Installation project (SF-1) indicated the presence of documented environmental cases along the pipeline alignment. Therefore, impacts related to the potential to encounter hazardous materials in the soil and groundwater are considered *potentially significan*t, but would be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #7 (hazardous materials) as well as preparation of a site health and safety plan (Measure 4.14-1a) and materials disposal plan (Measure 4.14-1b).

According to a voluntary study performed on behalf of the SFPUC in 2004, raising the water level in Lake Merced under the Local Groundwater Projects (SF-2) would inundate a portion of the Pacific Rod and Gun Club property and could result in lead and arsenic concentrations that exceed drinking water standards, cause adverse effects on fish and other aquatic organisms, or cause adverse effects on sediment-dwelling species that would occupy the newly inundated area (URS, 2005). The results of the study suggest that before inundating the shoreline it may be necessary to perform remedial action or further assess the potential for releases of lead and arsenic into Lake Merced. Therefore, impacts related to the potential to cause adverse effects from inundation of a known environmental case are considered *potentially significant* for this project, but would be reduced to a less-than-significant level with coordination with regulatory agencies and implementation of appropriate measures to avoid adverse effects on water quality and aquatic organisms (Measure 4.14-1c).

If groundwater dewatering is required for any San Francisco Region projects, impacts related to the potential to discharge contaminated groundwater would be less than significant with compliance with the discharge regulations discussed in Section 4.5, Hydrology and Water Quality, and implementation of a dewatering plan in accordance with SFPUC Construction Measure #4 (groundwater).

Impact 4.14-2: Exposure to naturally occurring asbestos.

As discussed in the Setting, some of the pipeline, tunnel, and dam excavations traverse mapped areas of Franciscan Complex serpentinite and mélange, which commonly contain naturally occurring chrysotile asbestos (a fibrous mineral that can be a human health hazard if it becomes airborne). If serpentinite or mélange is encountered during construction, onsite workers and the surrounding population could be exposed to asbestos in airborne dust and tunnel emissions unless appropriate control measures are implemented.

Pipelines and Other Excavation Activities. Excavation in soil containing naturally occurring asbestos could produce airborne (or "fugitive") dust. However, the SFPUC would be required to comply with the asbestos ATCM (CARB's Airborne Toxic Control Measure for Construction, Grading, Quarrying, and Surface Mining Operations; see the Setting for more discussion) to prevent fugitive dust containing asbestos from migrating beyond property boundaries during excavation.

In accordance with the asbestos ATCM, for surface construction activities in the WSIP study area that would disturb rock containing naturally occurring asbestos (serpentinite and mélange) within an area of less than one acre, contractors are required to comply with the following dust mitigation measures before construction begins and to maintain each measure throughout the duration of the construction project:

- Limit construction vehicle speed at the worksite to 15 miles per hour
- Sufficiently wet all ground surfaces prior to disturbance to prevent visible dust emissions from crossing the property line
- Keep all graded and excavated areas adequately wetted during construction to prevent visible dust emissions from crossing the property line
- Adequately wet all storage piles, treat with chemical dust suppressants, or cover piles when material is not being added to or removed from the pile
- Wash down all equipment before moving from the property onto a paved public road
- Clean all visible track-out from the paved public road by street sweeping or using a vacuum equipped with a high-efficiency particulate air (HEPA) filter within 24 hours

For construction activities in the WSIP study area that would disturb more than one acre of rock containing naturally occurring asbestos (serpentinite and mélange), construction contractors are required to submit the appropriate notification forms, although an application for exemption may be filed if a registered geologist determines that there is no ultramafic rock or serpentine in the construction area. For projects of this size where ultramafic rock or serpentinite are present, contractors must prepare an asbestos dust mitigation plan specifying measures that would be taken to ensure that no visible dust crosses the property boundary during construction. The plan must specify the following measures:

- Prevent and control visible track-out from the property

- Ensure adequate wetting or covering of active storage piles
- Control disturbed surface areas and storage piles that would remain inactive for seven days
- Control traffic on onsite unpaved roads, parking lots, and staging areas, including a maximum vehicle speed of 15 miles per hour
- Control earthmoving activities
- Control offsite transport of dust emissions that contain naturally occurring asbestos-containing materials
- Stabilize disturbed areas following construction

The asbestos dust mitigation plan must be submitted to and approved by the BAAQMD prior to the beginning of construction, and the site operator must ensure the implementation of all specified dust mitigation measures throughout the construction project. In addition, the BAAQMD may require air monitoring for offsite migration of asbestos dust during construction activities and may change the plan on the basis of the air monitoring results.

For WSIP construction projects of all sizes, notification of the BAAQMD and compliance with the asbestos ATCM are required if rock containing naturally occurring asbestos (serpentinite or mélange) is identified during construction.

Tunnels. Similar to construction of pipelines and facilities, excavation of the portal areas and handling of tunnel muck outside of the tunnels could produce fugitive dust emissions. Wet conditions within the tunnels during construction would likely prevent asbestos from becoming airborne. However, in the absence of proper controls, asbestos could become airborne in emissions from the tunnel ventilation system and could expose nearby receptors to unacceptable levels of asbestos.

San Joaquin Region

Impact 4.14-2: Exposure to naturally occurring asbestos		
Advanced Disinfection	SJ-1	N/A
Lawrence Livermore	SJ-2	N/A
SJPL System	SJ-3	N/A
SJPL Rehabilitation	SJ-4	N/A
Tesla Portal Disinfection	SJ-5	N/A

None of the proposed WSIP facilities in the San Joaquin Region are expected to encounter Franciscan Complex serpentinite or mélange. Therefore, the potential for naturally occurring asbestos to become airborne during construction in these regions is considered *not applicable*. However, if naturally occurring asbestos is identified during construction, these projects would have to comply with the asbestos ATCM requirements.

Sunol Valley Region

Impact 4.14-2: Exposure to naturally occurring asbestos		
Alameda Creek Fishery	SV-1	N/A
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	N/A
New Irvington Tunnel	SV-4	N/A
Treated Water Reservoirs	SV-5	N/A
SABUP	SV-6	N/A

Under the Calaveras Dam project (SV-2), construction of the new dam and haul roads would disturb Franciscan Complex serpentinite and mélange. In addition, the existing dam (which would be removed) includes materials obtained from serpentinite and mélange. However, as discussed above, compliance with the asbestos ATCM requirements would ensure that impacts related to exposure to naturally occurring asbestos would be *less than significant* for this project.

No Franciscan Complex serpentinite or mélange is mapped near the remaining projects in this region (Alameda Creek Fishery, SV-1; 40-mgd Treated Water, SV-3; New Irvington Tunnel, SV-4; Treated Water Reservoirs, SV-5; and SABUP, SV-6), so this impact would *not apply* to these projects. However, if naturally occurring asbestos is identified during construction, these projects would have to comply with the asbestos ATCM requirements.

Bay Division Region

Impact 4.14-2: Exposure to naturally occurring asbestos		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	N/A
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	N/A

The BDPL 3 and 4 Crossovers (BD-2) and BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) projects are not located in areas of mapped Franciscan Complex serpentinite or mélange, so this impact would *not apply* to these projects. However, if naturally occurring asbestos is identified during construction, these projects would have to comply with the asbestos ATCM requirements.

The BDPL Reliability Upgrade project (BD-1) could encounter several hundred feet of highly weathered and intensely fractured serpentinite, sandstone, and shale of the Franciscan Complex in the tunnel approximately 1,000 feet west of the Newark Valve Lot. Construction of the tunnel portion of this project would have to comply with the asbestos ATCM for the handling of materials containing naturally occurring asbestos, including tunnel muck. In addition, operation of the tunnel ventilation system could emit airborne asbestos fibers. This *potentially significant* impact would be reduced to a less-than-significant level with implementation of a health risk screening assessment and preparation of an airborne-asbestos monitoring plan (Measure 4.14-2).

Peninsula Region

Impact 4.14-2: Exposure to naturally occurring asbestos		
Baden and San Pedro Valve Lots	PN-1	N/A
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	N/A
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	N/A

Two Peninsula Region projects located near Crystal Springs Reservoir and San Andreas Reservoir (CS/SA Transmission, PN-2, and Lower Crystal Springs Dam, PN-4) could encounter Franciscan Complex serpentinite or mélange. However, as discussed above, compliance with the asbestos ATCM would ensure that impacts related to exposure to naturally occurring asbestos are *less than significant* for these projects.

The other Peninsula Region projects are not located in Franciscan Complex serpentinite or mélange (Baden and San Pedro Valve Lots, PN-1; HTWTP Long-Term, PN-3; and Pulgas Balancing Reservoir, PN-5), so this impact would *not apply* to these projects. However, if naturally occurring asbestos is identified during construction, these projects would have to comply with the asbestos ATCM requirements.

San Francisco Region

Impact 4.14-2: Exposure to naturally occurring asbestos		
SAPL 3 Installation	SF-1	LS
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	LS

The three San Francisco Region projects (SAPL 3 Installation, SF-1; Groundwater Projects, SF-2; and Recycled Water Projects, SF-3) are not likely to encounter Franciscan Complex serpentinite or mélange, although naturally occurring asbestos could be encountered in fill materials within San Francisco. However, as discussed above, compliance with the asbestos ATCM would ensure that impacts related to exposure to naturally occurring asbestos would be *less than significant* for each project.

Impact 4.14-3: Risk of fires during construction.

The use of construction equipment and temporary onsite storage of diesel fuel could pose a wildland fire risk in areas classified by the CDF as a “Wildland Area That May Contain Substantial Forest Fire Risks and Hazards” or a “Very High Fire Hazard Severity Zone” or in areas identified as an Urban-Wildland Interface in the city of San Francisco. The time of the greatest fire danger is during the clearing phase, when people and machines are working among vegetative fuels that can be highly flammable; if piled onsite, the cleared vegetative materials could also become a fire fuel. Potential sources of ignition include equipment with internal combustion engines, gasoline-powered tools, and equipment or tools that produce a spark, fire, or flame. Such sources include sparks from blades or other metal parts scraping against rock, overheated brakes on wheeled equipment, friction from worn or unaligned belts and drive chains, and burned-out bearings or bushings. Sparking as a result of scraping against rock is difficult to prevent. The other hazards result primarily from poor maintenance of the equipment. Smoking by onsite construction personnel is also a potential source of ignition during construction.

Regulations governing the use of construction equipment in fireprone areas are designed to minimize the risk of wildland fires during construction activity. In accordance with the Public Resources Code, the construction contractor would be required to comply with the following legal requirements during construction activities at sites located in areas classified as a "Wildland Area That May Contain Substantial Forest Fire Risks and Hazards" or a "Very High Fire Hazard Severity Zone":

- Earthmoving and portable equipment with internal combustion engines would be equipped with a spark arrestor to reduce the potential for igniting a wildland fire (PRC Section 4442).
- Appropriate fire suppression equipment would be maintained during the highest fire danger period – from April 1 to December 1 (PRC Section 4428).
- On days when a burning permit is required, flammable materials would be removed to a distance of 10 feet from any equipment that could produce a spark, fire, or flame, and the construction contractor would maintain the appropriate fire suppression equipment (PRC Section 4427).
- On days when a burning permit is required, portable tools powered by gasoline-fueled internal combustion engines would not be used within 25 feet of any flammable materials (PRC Section 4431).

In addition, projects in the Sunol Valley Region and Peninsula Region located within the Peninsula watershed would be required to comply with fire-related policies and actions contained in the SFPUC's Alameda and Peninsula Watershed Management Plans (WMPs). The WMPs are described in Section 4.2, Plans and Policies. Action fir1 of the WMPs, which requires compliance with CDF fire prevention regulations for SFPUC vehicles and equipment as well as certification by the CDF of non-SFPUC equipment, must be implemented for these projects.

San Joaquin Region

Impact 4.14-3: Risk of fires during construction		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	LS
Tesla Portal Disinfection	SJ-5	LS

The Advanced Disinfection (SJ-1), Lawrence Livermore (SJ-2), and Tesla Portal Disinfection (SJ-5) projects as well as the easternmost and westernmost pipeline segments of the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects are located in areas classified as a "Wildland Area That May Contain Substantial Forest Fire Risks and Hazards." However, mandatory compliance with the Public Resources Code, impacts related to wildland fires would be *less than significant* for each project.

Sunol Valley Region

Impact 4.14-3: Risk of fires during construction		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	LS
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	LS

All of the Sunol Valley Region projects (Alameda Creek Fishery, SV-1; Calaveras Dam, SV-2; 40-mgd Treated Water, SV-3, New Irvington Tunnel, SV-4; Treated Water Reservoirs, SV-5; and SABUP, SV-6) are located in areas classified as a "Wildland Area That May Contain Substantial Forest Fire Risks and Hazards." However, with compliance with the Public Resources Code and Alameda WMP Action fir1 (described above), impacts related to wildland fires would be *less than significant* for each project.

Bay Division Region

Impact 4.14-3: Risk of fires during construction		
BDPL Reliability Upgrade	BD-1	LS
BDPL 3 and 4 Crossovers	BD-2	N/A
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	N/A

The Irvington Tunnel and Pulgas Portal, located at either end of the BDPL Reliability Upgrade project (BD-1), may be located in an area classified as a "Wildland Area That May Contain Substantial Forest Fire Risks and Hazards." However, with compliance with the Public Resources Code, impacts related to wildland fires would be *less than significant* for this project.

The BDPL 3 and 4 Crossovers (BD-2) and BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) projects are not located in mapped areas of high wildland fire risk; therefore, this impact would *not apply* to these projects.

Peninsula Region

Impact 4.14-3: Risk of fires during construction		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	N/A
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS

The Baden and San Pedro Valve Lots project (PN-1) would include construction at the Pulgas Pump Station, Pulgas Gate Shaft, and Pulgas Air Shaft, which are each located in an area classified as a "Wildland Area That May Contain Substantial Forest Fire Risks and Hazards." In addition, the CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4), and Pulgas Balancing Reservoir (PN-5) projects are located in areas classified as a "Wildland Area That May Contain Substantial Forest Fire Risks and Hazards." However, with compliance with the Public Resources Code and the Peninsula WMP Action fir1 (described above), impacts related to wildland fires would be *less than significant* for these projects.

The HTWTP Long-Term project (PN-3) is not located in mapped areas of high wildland fire risk, so this impact would *not apply* to this project.

San Francisco Region

Impact 4.14-3: Risk of fires during construction		
SAPL 3 Installation	SF-1	N/A
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	LS

Depending on the specific locations selected for components of the Groundwater Projects (SF-2), some components of this project could be located within high fire hazard zones within or outside of San Francisco, and some Recycled Water Projects (SF-3) could be located within an Urban-Wildland Interface at Golden Gate Park. However, with compliance with the Public Resources Code, impacts related to wildland fires would be *less than significant* for these projects.

The SAPL 3 Replacement project (SF-1) is not located within a mapped area of high wildland fire risk within or outside of San Francisco. Therefore, this impact would *not apply* to this project.

Impact 4.14-4: Gassy conditions in tunnels.

Gassy conditions in tunnels could increase the risk of an explosion, which would endanger construction workers and the public.

Tunnels and Pipelines. Accumulated natural gases in a tunnel, including jack-and-bore excavations that are 30 inches in diameter or larger, could cause an explosion during construction. A classification has not yet been assigned to the tunnels that would be constructed under the WSIP; however, prior to the project being put out to bid, the SFPUC would be required to file an application for gas classification with the Division of Industrial Safety in accordance with the Tunnel Safety Orders (described in the Setting). This application would be required for all tunnels and jack-and-bore excavations that are 30 inches in diameter or larger where workers would work underground. The application would be based on a detailed geotechnical characterization that would be performed for final design of the proposed tunneling project. If the tunnel is classified as potentially gassy or gassy, project construction would be performed in compliance with the Tunnel Safety Orders, which specify requirements for the monitoring of explosive vapors, ventilation, and the restriction of potential ignition sources in tunnels. The Division of Industrial Safety could require additional measures if conditions warrant and could shut down the tunneling operation if unsafe conditions were identified. Resumption of tunneling operations would not be allowed until the Division of Industrial Safety inspected the tunnel conditions and cleared the tunnel for reentry.

San Joaquin Region

Impact 4.14-4: Gassy conditions in tunnels		
Advanced Disinfection	SJ-1	N/A
Lawrence Livermore	SJ-2	N/A
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	LS
Tesla Portal Disinfection	SJ-5	N/A

The SJPL System project (SJ-3) includes the installation of approximately 16 to 22 miles of pipeline and the SJPL Rehabilitation project (SJ-4) could include rehabilitation along any portion of the San Joaquin pipeline system. These projects could require tunneling using jack-and-bore construction at stream or roadway crossings. In accordance with the Tunnel Safety Orders, an assignment would be made for these tunnels prior to construction if employees would work underground. Compliance with the tunnel safety orders and any additional requirements of the Department of Industrial Safety would ensure that impacts related to a potential explosion are *less than significant* for these projects. None of the other San Joaquin Region projects (Advanced Disinfection, SJ-1; Lawrence Livermore, SJ-2; and Tesla Portal Disinfection, SJ-5) would involve tunneling, so this impact would *not apply* to these projects.

Sunol Valley Region

Impact 4.14-4: Gassy conditions in tunnels		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	N/A
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	LS
Treated Water Reservoirs	SV-5	N/A
SABUP	SV-6	LS

The New Irvington Tunnel project **(**SV-4) includes construction of a new 18,200-foot-long tunnel in an area considered to be potentially gassy. Tunneling using jack-and-bore construction to install pipelines beneath streams or roadways could also be required for the Alameda Creek Fishery (SV-1), 40-mgd Treated Water (SV-3), and SABUP (SV-6) projects. In accordance with the Tunnel Safety Orders, an assignment would be made for these tunnels prior to construction if employees would work underground. Compliance with the Tunnel Safety Orders and any additional requirements of the Department of Industrial Safety would ensure that impacts related to a potential explosion are *less than significant* for these projects. The other Sunol Valley Region projects (Calaveras Dam, SV-2, and Treated Water Reservoirs, SV-5) would not involve tunneling, so this impact would *not apply* to these projects.

Bay Division Region

Impact 4.14-4: Gassy conditions in tunnels		
BDPL Reliability Upgrade	BD-1	LS
BDPL 3 and 4 Crossovers	BD-2	N/A
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	LS

The BDPL Reliability Upgrade project (BD-1) includes construction of a new five-mile-long tunnel beneath San Francisco Bay. Pipelines would also be installed for this project and for the BDPL 3 and 4 Seismic Upgrade at Hayward Fault project (BD-3), which could require tunneling using jack-and-bore construction at stream and road crossings. In accordance with the Tunnel Safety Orders, an assignment would be made for these tunnels prior to construction if employees would work underground. Compliance with the Tunnel Safety Orders and any additional requirements of the Department of Industrial Safety would ensure that impacts related to a potential explosion are *less than significant* for these projects. The BDPL 3 and 4 Crossovers project (BD-2) would not involve tunneling, so this impact would *not apply* to this project.

Peninsula Region

Impact 4.14-4: Gassy conditions in tunnels		
Baden and San Pedro Valve Lots	PN-1	N/A
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	N/A
Lower Crystal Springs Dam	PN-4	N/A
Pulgas Balancing Reservoir	PN-5	N/A

Tunneling using jack-and-bore construction beneath streams and roadways could be required to install pipelines under the CS/SA Transmission project (PN-2). In accordance with the Tunnel Safety Orders, an assignment would be made for these tunnels prior to construction if employees would work underground. Compliance with the Tunnel Safety Orders and any additional requirements of the Department of Industrial Safety would ensure that impacts related to a potential explosion are *less than significant* for this project. None of the other Peninsula Region projects (Baden and San Pedro Valve Lots, PN-1; HTWTP Long-Term, PN-3; Lower Crystal Springs Dam, PN-4; and Pulgas Balancing Reservoir, PN-5) would involve tunneling, including the, so this impact would *not apply* to these projects.

San Francisco Region

Impact 4.14-4: Gassy conditions in tunnels		
SAPL 3 Installation	SF-1	LS
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	LS

The SAPL 3 Installation (SF-1), Groundwater Projects (SF-2), and Recycled Water Projects (SF-3) include pipeline construction and could require tunneling using jack-and-bore construction at stream or roadway crossings. In accordance with the Tunnel Safety Orders, an assignment would be made for these tunnels prior to construction if employees would work underground. Compliance with the Tunnel Safety Orders and any additional requirements of the Department of Industrial Safety would ensure that impacts related to a potential explosion are *less than significant*.

Impact 4.14-5: Exposure to hazardous building materials.

Demolition or modification of existing facilities could result in exposure to hazardous building materials. In the absence of proper abatement procedures, demolition or renovation of a structure that contains hazardous building materials can expose workers and the public to hazardous materials. The types of hazardous building materials that could be encountered during building demolition include asbestos, lead-based paint, electrical equipment containing PCBs, fluorescent tubes containing mercury vapors, and fluorescent light ballasts containing DEHP.

If friable or nonfriable asbestos is present, disturbance of the asbestos-containing materials could result in the exposure of the public or construction workers to airborne asbestos fibers, unless proper asbestos abatement precautions are taken. Similarly, if lead-based paint or other hazardous materials are present and have delaminated or chipped from the surface of the building materials, there is a potential for the release of airborne particulates unless proper abatement procedures are followed. If PCBs are present in the buildings to be demolished, leakage could expose workers to unacceptable levels of PCBs. Removal of fluorescent tubes could result in exposure to mercury vapors if the lights are broken, or to DEHP in the light ballasts.

Well-established regulatory requirements for asbestos abatement are provided in the California Health and Safety Code, Section 19827.5, and Title 8 of the California Code of Regulations, Sections 341.6 through 341.14 and 1529. The BAAQMD and San Joaquin Valley Air Pollution Control District requirements would also apply to the abatement of asbestos-containing materials. Requirements for lead-based paint abatement in residential and public use buildings are specified in Title 17 of the California Code of Regulations, Sections 35001 through 3600. However, existing state and local regulations do not address the abatement of lead-based paint in nonresidential or nonpublic buildings and other structures.[11] Because surveys have not been conducted to identify hazardous building materials in the structures that would be demolished, existing regulations do not address abatement of lead-based paint in nonresidential or public use buildings, and other hazardous building materials such as PCB- or DEHP-containing equipment and fluorescent light tubes could require disposal, this impact is considered potentially significant for projects where demolition or modifications of a structure would be required but for which hazardous building material surveys have not been completed. Additional information analyzed as part of subsequent, project-specific CEQA review for each project would either confirm the program-level determination of potentially significant or provide a basis to revise this determination.

Pump Stations, Treatment Facilities, Tunnels, and Standby Power. Construction of these permanent facilities could first require demolition of existing structures. If demolition is required, the hazardous building materials discussed above could be encountered (e.g., existing storage tanks may be painted with lead-based paint).

Reservoirs. For dam improvements, the structures that would be demolished or modified could contain lead-based paint, PCBs, or other hazardous building materials. For existing reservoirs, there may be hazardous building materials in the liner materials, roof, or piping systems.

Pipelines. The regional water system pipelines are largely constructed of steel or concrete. These pipelines have been constructed over the years using a variety of lining, coating, and joint-sealant materials, including coal tar and lead as well as other substances. While these substances do not present a hazard under current conditions, they could become hazardous if mishandled during construction. In addition, in some locations the right-of-way may have been encroached upon by structures that would need to be demolished prior to project construction, and these structures could include the hazardous building materials described above.

Valves, Vaults, and Crossover Facilities. Construction of valves, vaults, and crossover facilities would not be expected to encounter hazardous building materials.

---

[11] Senate Bill 460 added text to the California Health and Safety Code specifying that lead-based paint above certain quantities cannot be disturbed without providing containment, but does not address specific requirements for abatement or containment of lead-based paint. The requirements of this bill are not enforceable through permit conditions. Title 17 of the California Code of Regulations does include requirements for the abatement of lead-based paint, but these requirements apply only to residential and public use buildings.

San Joaquin Region

Impact 4.14-5: Exposure to hazardous building materials		
Advanced Disinfection	SJ-1	N/A
Lawrence Livermore	SJ-2	N/A
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	PSM

The SJPL System project (SJ-3) would require excavation along approximately 16 miles of existing right-of-way and the SJPL Rehabilitation project (SJ-4) could require access to the pipeline anywhere along the entire length. While unlikely, in some locations the right-of-way may have been encroached upon by structures that would need to be demolished. Depending on their age, these structures may contain hazardous building materials. In addition, the Tesla Portal Disinfection project (SJ-5) would include renovation of the existing chlorination system, including possible demolition of existing structures. Because no surveys have been conducted to identify hazardous building materials in these structures and the extent of demolition is currently unknown, this impact is conservatively considered to be *potentially significant* for these projects; however, if demolition does occur, this impact would be reduced to a less-than-significant level with implementation of hazardous materials building surveys and abatement (Measure 4.14-5). The other San Joaquin Region projects (Advanced Disinfection, SJ-1, and Lawrence Livermore, SJ-2) are not expected to require demolition or renovation of structures, so this impact would *not apply* to these projects.

Sunol Valley Region

Impact 4.14-5: Exposure to hazardous building materials		
Alameda Creek Fishery	SV-1	N/A
Calaveras Dam	SV-2	PSM
40-mgd Treated Water	SV-3	N/A
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	N/A
SABUP	SV-6	N/A

The Calaveras Dam project (SV-2) would require demolition of the cofferdam, chemical treatment building, valve vaults, existing spillway, and portions of the outlet tower. Demolition of the existing Irvington Portal structure would also be required for the New Irvington Tunnel project (SV-4). Depending on their age, the structures that would be demolished could contain hazardous building materials. Because no surveys have been conducted to identify hazardous building materials in these structures, this impact is considered *potentially significant* for these projects, but would be reduced to a less-than-significant level with implementation of hazardous materials building surveys and abatement (Measure 4.14-5). None of the other projects in the Sunol Valley Region (Alameda Creek Fishery, SV-1; 40-mgd Treated Water, SV-3; Treated Water Reservoirs, SV-5; and SABUP, SV-6) are expected to require demolition or renovation of structures, so this impact would *not apply* to these projects.

Bay Division Region

Impact 4.14-5: Exposure to hazardous building materials		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	N/A
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	N/A

The BDPL Reliability Upgrade project (BD-1) would remove 1.4 miles of pipeline between the Edgewood Valve Lot and Pulgas Valve Lot and decommission the aboveground and submarine sections of the Bay Division Pipelines Nos. 1 and 2. In addition, pipeline installation would require excavation along approximately 16 miles of existing right-of-way and, in some locations, the right-of-way may have been encroached upon by structures that would need to be demolished. Depending on their age, these structures could contain hazardous building materials. Because no surveys have been conducted to identify hazardous building materials in these structures or pipelines, this impact is considered *potentially significant* for this project, but would be reduced to a less-than-significant level with implementation of hazardous materials building surveys and abatement (Measure 4.14-5). The BDPL 3 and 4 Crossovers (BD-2) and BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) projects are not expected to require demolition or renovation of structures, so this impact would *not apply* to these projects.

Peninsula Region

Impact 4.14-5: Exposure to hazardous building materials		
Baden and San Pedro Valve Lots	PN-1	PSM
CS/SA Transmission	PN-2	PSM
HTWTP Long-Term	PN-3	PSM
Lower Crystal Springs Dam	PN-4	PSM
Pulgas Balancing Reservoir	PN-5	PSM

Removal of existing pipelines within the vaults could be required for the Baden and San Pedro Valve Lots project (PN-1). In addition, the CS/SA Transmission project (PN-2) could involve upgrades to or demolition of the Crystal Springs Pump Station, and the HTWTP Long-Term project (PN-3) could require the demolition or upgrade of structures at the Harry Tracy WTP. The Lower Crystal Springs Dam project (PN-4) would modify the spillway, parapet walls and stilling basin, and the Pulgas Balancing Reservoir project (PN-5) would modify the inlet/outlet piping and sediment catchment basin. Hazardous building materials could be present in the structures to be demolished or modified, depending on their age. Because no surveys have been conducted to identify hazardous building materials in these structures, this impact is considered *potentially significant* for these projects, but would be reduced to a less-than-significant level with implementation of hazardous materials building surveys and abatement (Measure 4.14-5).

San Francisco Region

Impact 4.14-5: Exposure to hazardous building materials		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	PSM
Recycled Water Projects	SF-3	PSM

The SAPL 3 Installation project (SF-1) would involve construction of approximately four miles of new pipeline and removal of some existing pipeline. The Recycled Water Projects (SF-3) could require demolition of existing structures, depending on the actual location of project facilities. The need for demolition under the Groundwater Projects (SF-2) has not been determined. Because the need for demolition is uncertain and no surveys have been conducted to identify hazardous building materials in the structures that could be demolished, this impact is considered *potentially significant* for all San Francisco Region projects, but would be reduced to a less-than-significant level with implementation of hazardous materials building surveys and abatement (Measure 4.14-5).

Impact 4.14-6: Accidental hazardous materials release from construction equipment.

Recycled Water Projects	SF-3	LS

Storage and use of hazardous materials at construction sites could result in the accidental release of hazardous materials such as oil, grease, or fuel, which could enter an adjacent watercourse and degrade water quality. Many of the WSIP projects are located near creeks or storm systems that discharge to a surface water body. If accidentally released, such hazardous materials could degrade surface water quality. However, as discussed in Impact 4.5-1 in Section 4.5, Hydrology and Water Quality, impacts related to a potential release would be *less than significant* with implementation of SFPUC Construction Measure #3 (onsite air and water quality measures during construction), which requires the implementation of erosion control measures, including preparation and implementation of a stormwater pollution prevention plan (SWPPP) if required by the RWQCB. A SWPPP would be required for all projects outside of San Francisco that disturb more than one acre of land. The SWPPP would include protection measures for the temporary onsite storage of diesel fuels used during construction, including requirements for secondary containment and berming of the diesel storage area (or any chemical storage areas) to contain a potential release and to prevent any such release from reaching an adjacent waterway or stormwater collection system. The erosion control plan prepared for San Francisco projects in compliance with Article 4.1 of the San Francisco Public Works Code and for other projects in accordance with SFPUC Construction Measure #3 would also include measures to prevent a release of hazardous materials from reaching an adjacent waterway.

Furthermore, projects located within the Alameda and Peninsula watersheds would be required to implement the following watershed management plan actions pertaining to potential spills from construction equipment. (In the actions listed below, the first number is for the Alameda WMP and the second number is for the Peninsula WMP.)

- *Action haz4/haz5*: Conduct regular servicing for the SFPUC vehicle fleet and equipment so that leaks/drips/spills of contaminants are minimized. Guidelines include:
    a. Immediately report accidental spills of hazardous materials into surface waters to the Water Quality Bureau and the appropriate state agencies.
    b. Require that buckets and absorbent materials be carried in all SFPUC vehicles in case of an accident or breakdown in which vehicle-related fluids are released.
    c. Follow appropriate BMPs [best management practices] in C-6 to minimize leaching of vehicle-related contaminants into the soil or groundwater from facilities.
    d. For fire protection purposes, ensure that all vehicles and equipment are equipped with spark arrestors and each vehicle carries fire suppression equipment.
- *Action haz6/haz8*: Identify high-risk spill potential areas and implement measures (e.g., fines, barricades, etc.) to reduce the risk of hazardous spills.
- *Action haz7/haz10*: Develop spill response and containment measures for SFPUC vehicles on the watershed. These measures should be coordinated with the overall Emergency Response Plan developed in Action saf7.

Operations, Siting, and Design Impacts

Impact 4.14-7: Increased use of hazardous materials during operation.

The proposed WSIP projects would result in an increase in the quantities of chemicals stored at some of the facilities or would introduce a new use of hazardous materials. If accidentally released, these chemicals could cause human health effects to plant personnel and surrounding populations and could cause adverse environmental effects if released to the environment.

Treatment Facilities. Treatment facilities use a variety of hazardous materials for disinfection, typically ammonia and sodium hypochlorite which are incompatible materials that could pose a public health or water quality risk if mixed. Other hazardous materials such as liquid oxygen might also be used, depending on the water treatment method.

The Uniform Fire Code, Article 80, includes specific requirements for the safe storage and handling of hazardous materials. These requirements reduce the potential for a release of hazardous materials and for mixing of incompatible chemicals. Design of chemical storage facilities at the WSIP project sites would comply with the current Uniform Fire Code requirements and other applicable federal, state, and local regulations, including the following specific design features that would reduce the potential for a release of hazardous materials that could affect public health or the environment:

- Separation of incompatible materials with a noncombustible partition.
- Spill control in all storage, handling, and dispensing areas.
- Separate secondary containment for each chemical storage system. The secondary containment would hold the entire contents of the tank, plus the volume of water needed to supply the fire suppression system for a period of 20 minutes in the event of a catastrophic spill.

Liquid oxygen is an oxidizing cryogenic liquid[12] that is not toxic or flammable. However, if released, ignition of combustible materials can occur more easily in the oxygen-enriched atmosphere. National Fire Protection Association (NFPA) 50, Standard for Bulk Oxygen at Consumer Sites, specifies standards to ensure the safe storage of liquid oxygen and provide adequate separation between the storage facilities and combustibles. NFPA 50 also specifies minimum distances from nonambulatory patients, places of public assembly, public sidewalks or parked cars, and property lines for the protection of public safety. Additional standards for liquid oxygen systems are provided in Article 75 of the California Fire Code and Standard 80-2 of the Uniform Fire Code.

Incorporation of these legally required design features would reduce the potential for spills resulting from the storage and handling of hazardous materials at the treatment facilities. In addition, the SFPUC would be required by the local CUPA agency to prepare an HMBP for new facilities or update the HMBP for existing facilities to reflect the changes in hazardous materials storage.

Ammonia is a regulated substance, and subject to more stringent regulatory requirements. At the federal level, only solutions with an ammonia concentration greater than 20 percent are regulated. However, CalARP regulations apply to all ammonia solutions. The federal and state threshold quantities for ammonia are 20,000 and 500 pounds, respectively. For facilities that would use ammonia in excess of these quantities, the SFPUC would be required by the local CUPA agency to prepare an RMP for new facilities or update the RMP for existing facilities to reflect the changes in storage.

In addition, projects located in the Alameda and Peninsula watersheds would be required to comply with actions outlined in the watershed management plan pertaining to safe hazardous materials storage, as described below. Compliance with legal requirements and implementation of the actions specified in the Alameda and Peninsula WMPs would ensure that potential impacts related to a release of chemicals from WSIP facilities are less than significant.

[12] An oxidizing cryogenic liquid is one that has a normal boiling point below -150 degrees Fahrenheit and readily reacts to promote or initiate combustion of combustible materials.

Standby Power. WSIP implementation would include provision of standby power (propane-, battery-, or diesel-fueled emergency generators) at a number of facilities to keep facilities operating during power outages. Safe use of diesel, propane, and batteries would be addressed through preparation and implementation of the legally required HMBP and compliance with the Aboveground Petroleum Storage Act, discussed in the Setting. In addition to compliance with these legal requirements, projects located in the Alameda and Peninsula watersheds would be required to comply with actions outlined in the watershed management plans pertaining to aboveground storage tanks. Although propane is a federally regulated flammable substance, the quantities that would be stored are well below the federal threshold planning quantity of 10,000 pounds. Therefore, an RMP would not be required for this substance.

San Joaquin Region

Impact 4.14-7: Increased use of hazardous materials during operation		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	N/A
Tesla Portal Disinfection	SJ-5	LS

Hazardous materials required for the disinfection facilities for the Advanced Disinfection project (SJ-1) would depend on the treatment methods selected to achieve compliance with water quality regulations. The Tesla Portal Disinfection project (SJ-5) could require the use of new water treatment chemicals, and the Lawrence Livermore project (SJ-2) would also likely require the use of disinfection chemicals. Construction of standby power facilities for the Advanced Disinfection (SJ-1), Lawrence Livermore (SJ-2), SJPL System (SJ-3), and Tesla Portal Disinfection (SJ-5) projects would introduce the use of propane or diesel. However, impacts related to a potential release of hazardous materials would be *less than significant* for these projects with preparation and implementation of a legally required HMBP for the new uses at Thomas Shaft (under Lawrence Livermore) and revision of the existing HMBP for Tesla Portal (under Advanced Disinfection, SJPL System, and Tesla Portal Disinfection). There would be no new use of hazardous materials under the SJPL Rehabilitation project (SJ-4), so this impact would *not apply* to this project.

Sunol Valley Region

Impact 4.14-7: Increased use of hazardous materials during operation		
Alameda Creek Fishery	SV-1	N/A
Calaveras Dam	SV-2	N/A
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	N/A
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	N/A

Increased water treatment capacity under the 40-mgd Treated Water (SV-3) and Treated Water Reservoirs (SV-5) projects would increase the use of sodium hypochlorite and introduce the use of ammonia and fluoride at the Sunol Valley WTP. Construction of standby power facilities under the Treated Water Reservoirs project (SV-5) could also require the use of diesel. However, impacts related to a potential release of hazardous materials would be *less than significant* with revision of the existing HMBP for the Sunol Valley WTP to account for changes in the storage of hazardous materials, and preparation of an RMP for new use of ammonia. Furthermore, chemical storage at the Sunol Valley Chloramination Facility would be reduced by the same amounts, and the HMBP and RMP for this facility would be revised to reflect this change in chemical storage.

In addition, the 40-mgd Treated Water (SV-3) and Treated Water Reservoirs (SV-5) projects would be required to implement actions of the Alameda WMP regarding the use of hazardous materials in the watershed. Action haz1 requires development of hazardous chemical management procedures addressing the type, use, storage, transport, and disposal of hazardous chemicals and pesticides used in watershed activities. Action haz2 requires the SFPUC to inventory and annually monitor all above- and below-ground fuel storage tanks, refueling stations, and vehicle maintenance yards within the watershed with respect to the control of vehicle-related contaminants as well as for compliance with applicable underground storage tank requirements and hazardous materials storage and handling requirements.

None of the other Sunol Valley Region projects (Alameda Creek Fishery, SV-1; Calaveras Dam, SV-2; New Irvington Tunnel, SV-4; and SABUP, SV-6) would involve a new use or change in use of hazardous materials, so this impact would *not apply* to these projects.

Bay Division Region

Impact 4.14-7: Increased use of hazardous materials during operation		
BDPL Reliability Upgrade	BD-1	LS
BDPL 3 and 4 Crossovers	BD-2	LS
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	N/A

The BDPL Reliability Upgrade project **(**BD-1) would require the storage of propane and a battery to fuel the emergency generators at the vaults and backup generators using propane or diesel could also be required for the BDPL 3 and 4 Crossovers project (BD-2). However, impacts related to a potential release from project facilities would be *less than significant* with preparation and implementation of a legally required HMBP.

The BDPL 3 and 4 Seismic Upgrade at Hayward Fault project (BD-3) would involve installation of or modifications to transmission pipelines and would not involve the use of hazardous materials during operation; therefore, this impact would *not apply* to this project.

Peninsula Region

Impact 4.14-7: Increased use of hazardous materials during operation		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	N/A
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	N/A

The Baden and San Pedro Valve Lots project (PN-1) would add a propane tank to provide backup power for the water quality building at the Baden Valve Lot. In addition, the treatment capacity of the Harry Tracy WTP would be increased under the HTWTP Long-Term project (PN-3), potentially resulting in an increase in the use of treatment chemicals, including sodium hypochlorite and ammonia. The possible construction of standby power facilities under the HTWTP Long-Term (PN-3) and Lower Crystal Springs Dam (PN-4) projects could also require the use of diesel. However, impacts related to a potential release of hazardous materials would be *less than significant* with preparation of an HMBP or revision of the existing HMBPs as well as revision of the Harry Tracy WTP RMP to account for changes in the use of hazardous materials and regulated substances (ammonia). The Lower Crystal Springs Dam project is located in the Peninsula watershed, and the actions specified in the Peninsula WMP would apply. Action haz1 requires development of hazardous chemical management procedures addressing the type, use, storage, transport, and disposal of hazardous chemicals and pesticides used in watershed activities. Action haz2 requires the SFPUC to inventory and annually monitor all above- and below-ground fuel storage tanks, refueling stations, and vehicle maintenance yards within the watershed with respect to the control of vehicle-related contaminants, as well as for compliance with applicable underground storage tank requirements and hazardous materials storage and handling requirements.

The CS/SA Transmission (PN-2) and Pulgas Balancing Reservoir (PN-5) projects would not include a new use or change in use of hazardous materials, so this impact would *not apply* to these projects.

San Francisco Region

Impact 4.14-7: Increased use of hazardous materials during operation		
SAPL 3 Installation	SF-1	N/A
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	LS

Implementation of the Groundwater Projects (SF-2) and Recycled Water Projects (SF-3) could require the use of chlorination or chloramination treatment chemicals, such as sodium hypochlorite or ammonia, and other water treatment chemicals, as well as propane or diesel for backup power at the well or other locations. However, impacts related to a potential release of hazardous materials would be *less than significant* with preparation and implementation of a legally required HMBP or RMP for new uses of hazardous materials, and revision of the existing HMBP for changes in hazardous materials uses at existing facilities.

The SAPL 3 Installation project (SF-1) would not include a new use or change in use of hazardous materials, so this impact would *not apply* to this project.

Impact 4.14-8: Emission or use of hazardous materials within 1/4 mile of a school.

As discussed in Impact 4.14-7, the proposed WSIP projects would increase the quantities of chemicals stored at some of the facilities or would introduce a new use of hazardous materials. If emitted or accidentally released near a school, these chemicals could cause health effects for children.

San Joaquin Region

Impact 4.14-8: Emission or use of hazardous materials within 1/4 mile of a school		
Advanced Disinfection	SJ-1	N/A
Lawrence Livermore	SJ-2	N/A
SJPL System	SJ-3	N/A
SJPL Rehabilitation	SJ-4	N/A
Tesla Portal Disinfection	SJ-5	N/A

The Advanced Disinfection (SJ-1) and Telsa Portal Disinfection (SJ-5) projects at Tesla Portal and the Lawrence Livermore project at Thomas Shaft (SJ-2) would likely involve an increase in the use of disinfection and other water treatment chemicals. In addition, the Advanced Disinfection (SJ-1), Lawrence Livermore (SJ-2), SJPL System (SJ-3), and Tesla Portal Disinfection (SJ-5) projects would introduce the use of hazardous materials for backup power systems. However, these projects are not located within 1/4 mile of a school, so this impact would *not apply* to these projects.

There would be no change in the hazardous materials used under the SJPL Rehabilitation project (SJ-4). Therefore, this impact would *not apply* to this project.

Sunol Valley Region

Impact 4.14-8: Emission or use of hazardous materials within 1/4 mile of a school		
Alameda Creek Fishery	SV-1	N/A
Calaveras Dam	SV-2	N/A
40-mgd Treated Water	SV-3	N/A
New Irvington Tunnel	SV-4	N/A
Treated Water Reservoirs	SV-5	N/A
SABUP	SV-6	N/A

An increase in the use of water treatment chemicals would occur at the Sunol Valley WTP under the 40-mgd Treated Water (SV-3) and Treated Water Reservoir (SV-5) projects and standby power facilities would be constructed at the WTP under the Treated Water Reservoir project. However, the Sunol Valley WTP is not located within 1/4 mile of a school, so this impact would *not apply* to these projects.

There would be no change in the hazardous materials used under the other Sunol Valley Region projects (Alameda Creek Fishery, SV-1; Calaveras Dam, SV-2; New Irvington Tunnel, SV-4; and SABUP, SV-6). Therefore, this impact would *not apply* to these projects.

Bay Division Region

Impact 4.14-8: Emission or use of hazardous materials within 1/4 mile of a school		
BDPL Reliability Upgrade	BD-1	LS
BDPL 3 and 4 Crossovers	BD-2	LS
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	N/A

The Bay Division Reliability project (BD-1) would use propane or a battery for backup power supplies within approximately 1/4 mile of Mission San Jose High School, J. Haley Durham Elementary School, St. Leonard Santa Paula School, and Saint Matthias School. The BDPL 3 and 4 Crossovers project (BD-2) might also use these materials within 1/4 mile of a school. However, propane storage and battery use would be safely managed to protect public health, in accordance with the existing and future regulatory-approved HMBP. Therefore, this impact would be *less than significant* for these projects with compliance with current regulations.

There would be no change in the hazardous materials used under the BDPL 3 and 4 Seismic Upgrade at Hayward Fault project (BD-3). Therefore, this impact would *not apply* to this project.

Peninsula Region

Impact 4.14-8: Emission or use of hazardous materials within 1/4 mile of a school		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	N/A
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	N/A
Pulgas Balancing Reservoir	PN-5	N/A

The Baden and San Pedro Valve Lots project (PN-1) would use propane as a backup power supply for the water building at the Baden Valve Lot, within approximately 1/4 mile of Los Cerritos School, Southwood School, and South San Francisco High School. The Harry Tracy WTP is located within approximately 1/4 mile of Meadows Elementary School, and there would likely be an increase in the use of water treatment chemicals associated with the increased capacity of this treatment plant and construction of standby power facilities under the HTWTP Long-Term project (PN-3). However, hazardous materials used at these facilities would be safely managed to protect public health, in accordance with the existing and future regulatory-approved HMBPs and RMP. Therefore this impact would be *less than significant* with compliance with current regulations.

Although the Lower Crystal Springs Dam project (PN-4) could use diesel for a backup power supply, this project is not located within 1/4 mile of a school. There would be no change in the hazardous materials used under the CS/SA Transmission (PN-2) or Pulgas Balancing Reservoir (PN-5) projects. Therefore, this impact would *not apply* to these projects.

San Francisco Region

Impact 4.14-8: Emission or use of hazardous materials within 1/4 mile of a school		
SAPL 3 Installation	SF-1	N/A
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	LS

Both the Groundwater Projects (SF-2) and Recycled Water Projects (SF-3) could increase the use of water treatment chemicals such as sodium hypochlorite or ammonia, or require propane or diesel for backup power at the well or other locations. Specific sites for these project facilities have not been determined. However, even if located within 1/4 mile of a school, these hazardous materials would be safely managed to protect public health, in accordance with the future regulatory-approved HMBPs and RMPs. Therefore, this impact would be *less than significant* with compliance with current regulations.

The SAPL 3 Installation project (SF-1) would not include a new use or change in use of hazardous materials, so this impact would *not apply* to this project.

4.15 Energy Resources

4.15 Energy Resources

4.15.1 Setting

Electrical Utility Providers

SFPUC Power Enterprise

SFPUC Power Enterprise (formerly part of Hetch Hetchy Water and Power Enterprise) would provide electrical power service for the WSIP facilities, primarily from power generated by the SFPUC's hydroelectric facilities in the Hetch Hetchy system. As discussed in Chapter 2, the Hetch Hetchy Project comprises 400 megawatts of hydroelectric power generation plants on the Tuolumne River and 150 miles of high-voltage transmission lines linking Hetch Hetchy power to California's electricity grid at Newark. Energy production varies by season and by year depending on hydrologic conditions. The long-term annual average production is approximately 1.7 billion kilowatt-hours (kWh); historical production has ranged from a low of 1.2 billion kWh per year to a high of 2.2 billion kWh per year (SFPUC, 2002). The total energy usage of existing facilities within the WSIP regions is nearly 44 million kWh, less than 4 percent of the historical low production rate of the Hetch Hetchy Project and less than 3 percent of the long-term annual average production rate.

SFPUC Power Enterprise provides electricity to all City and County of San Francisco (CCSF) facilities (including tenants) and to San Francisco International Airport and its tenants. SFPUC Power Enterprise also sells electricity to Norris Industries (a federal facility), provides electricity for the municipal and agricultural pumping loads of the Modesto and Turlock Irrigation Districts, and sells electricity to other public agency wholesalers. While the quantity of power produced exceeds San Francisco's municipal power needs on an annual basis, the CCSF must supplement its power sources to meet municipal demand and its contractual obligations during the summer and fall months, at which time power generation is reduced so that water can be stored.

Pacific Gas and Electric Company

Pacific Gas and Electric Company (PG&E) provides natural gas and electricity to most of Northern California. It provides SFPUC Power Enterprise with transmission and distribution services from Newark to the west, pursuant to an Interconnection Agreement regulated by the Federal Energy Regulatory Commission. Under this agreement, PG&E transmits and distributes electricity to SFPUC Power Enterprise customers, which would include the WSIP facilities.

California's Electricity Supply

California's electricity is supplied by a number of sources, including natural gas (41 percent), coal (21 percent), large hydroelectric plants (15 percent), and nuclear (13 percent) (CEC, 2005). The remaining 10 percent is supplied from geothermal, biomass, small hydroelectric, wind, and solar sources. Despite California policies aimed at diversifying the state's electrical supply, dependence on natural gas is continuing to grow, from 30 percent in 1999 to 36 percent in 2002 to 41 percent in 2004. Electricity generation accounted for 50 percent of the natural gas usage in 2004. In 2002, California imposed a requirement that electrical corporations increase procurement of eligible renewable energy resources by at least 1 percent per year so that 20 percent of its retail sales are procured from renewable resources by 2017 (Public Utilities Code, Section 399.15), and publicly owned utilities have been asked to consider establishing a similar target.

Current Energy Use

Electricity

While per capita electricity consumption in the United States has increased by nearly 50 percent over the past 30 years, per capita California energy use during this period has been approximately flat (CEC, 2005). This achievement is the result of continued progress in cost-effective building and appliance standards and ongoing enhancements in efficiency programs. These combined efforts have reduced peak capacity needs by more than 12,000 megawatts and continue to save about 40,000 gigawatt-hours (GWh) per year of electricity.

Even though California's increases in energy use are small relative to the rest of the country, electricity consumption in California grew from 250,241 GWh in 2001 to 270,927 GWh in 2004. Electricity use is forecast to grow between 1.2 and 1.5 percent annually, from 270,927 GWh in 2004 to between 310,716 and 323,372 GWh by the end of the 2016. Overall, electricity demand in California increases most dramatically in the summer, driven by high air-conditioning usage. The generation system must be able to accommodate these high summer peaks in addition to demand swings caused by weather variability and the economy. Although peak demand periods total only 50 to 100 hours per year, they impose huge burdens on the electrical system. The state's dependence on natural gas to generate electricity is escalating, as is the demand for natural gas in the residential and commercial sectors, with California's natural gas consumption second only to that of Texas.

Despite improvements in power plant licensing, energy efficiency programs, and continued technological advances, development of new energy supplies is not keeping pace with the state's increasing demand (CEC, 2005). Construction of new power plants has lagged, and the number of new plant permit applications has decreased. Transmission lines are frequently running at capacity, forcing system operators to reduce generation to avoid overloading the system, and transmission line outages sometimes result in rolling blackouts. In addition, the development of new renewable resources has been slower than anticipated, due in part to the state's complex and cumbersome approval process. Additional actions are still needed for California to achieve its full energy efficiency potential.

In September 2004, the California Public Utilities Commission (CPUC) adopted the nation's most aggressive energy savings goals for both electricity and natural gas. In achieving these targets, the state will save an additional 5,000 megawatts and 23,000 GWh per year of electricity and 450 million therms per year of natural gas by 2013.

As stated above, the Hetch Hetchy Project provides 400 megawatts of hydroelectric power that is not dependent on natural gas. SFPUC Power Enterprise customer base and generation base are distinguishable from other power supplies, and its load profile is relatively flat (i.e., not dramatically higher in the summer) because it is not driven by air-conditioning usage.

Energy Use Associated with Water Infrastructure Projects

Industrywide, California's water infrastructure uses large amounts of energy to collect and treat water; to dispose of wastewater; and to power the large pumps that move water throughout the state. However, SFPUC Water Enterprise electricity consumption is less intensive than many water providers in California because the regional water system relies on gravity, as opposed to pumping, to bring water from the Sierra Nevada to local storage facilities. Industrywide energy usage for water infrastructure accounts for nearly 20 percent of the state's electricity consumption, one-third of non-power-plant natural gas consumption, and about 88 million gallons of diesel fuel consumption (CEC, 2005). The California Energy Commission (CEC) states that, if not coordinated and properly managed on a statewide basis, water-related electricity demand could ultimately affect the reliability of the electrical system during peak demand periods when reserves are low.

Water and wastewater agencies would similarly be unable to meet the needs of their customers without adequate electricity supplies. More efficient water usage, coupled with energy efficiency improvements in the water infrastructure itself, could reduce electricity demand in this sector. The CEC recommends that the CEC, the California Department of Water Resources, the CPUC, local water agencies, and other stakeholders explore and pursue cost-effective water efficiency opportunities that would save energy and decrease the intensity of energy use in the water sector.

According to the CEC, industry experts estimate that untapped energy efficiency opportunities in water and wastewater treatment range from 5 to 30 percent. In the mid-1990s, the Electric Power Research Institute and HDR, Inc. conducted an audit of the energy savings potential of water and wastewater facilities in California. The audit indicated that over 880 GWh could be saved through implementation of a variety of measures, including load shifting and installation of high-efficiency motors and pumps. The National Resources Defense Council (NRDC) and Pacific Institute further evaluated energy usage by water and wastewater systems, assessing the intensity of energy usage for components of the water supply and treatment system and identifying areas where energy efficiency could be achieved (NRDC and Pacific Institute, 2004). The results of this study are further discussed below under Impact 4.15-2.

Regulatory Framework

National Energy Policy

The National Energy Policy, established in 2001 by the National Energy Policy Development Group, is designed to help the private sector and state and local governments promote dependable, affordable, and environmentally sound production and distribution of energy for the future (NEPDG, 2001). Key issues addressed by the energy policy are energy conservation, repair and expansion of energy infrastructure, and ways of increasing energy supplies while protecting the environment.

2005 California Energy Action Plan II

The *Energy Action Plan II* is the state's principal energy planning and policy document (CPUC and CEC, 2005). The plan continues the goals of the original *Energy Action Plan*, describes a coordinated implementation plan for state energy policies, and identifies specific action areas to ensure that California's energy is adequate, affordable, technologically advanced, and environmentally sound. In accordance with this plan, the first-priority actions to address California's increasing energy demands are energy efficiency and demand response (i.e., reduction of customer energy usage during peak periods in order to address system reliability and support the best use of energy infrastructure). Additional priorities include the use of renewable sources of power and distributed generation (i.e., the use of relatively small power plants near or at centers of high demand). To the extent that these actions are unable to satisfy the increasing energy and capacity needs, clean and efficient fossil-fired generation is supported.

The *Energy Action Plan II* includes the following energy efficiency action specific to water supply systems:

- Identify opportunities and support programs to reduce electricity demand related to the water supply system during peak hours, and opportunities to reduce the energy needed to operate water conveyance and treatment systems.

In 2002, California established its Renewable Portfolio Standard program,[1] with the goal of increasing the percentage of renewable energy in the state's electricity mix to 20 percent by 2017. The CPUC subsequently accelerated that goal to 2010 for electrical corporations, and the CEC further recommended that the state increase the target for all retail electricity sellers to 33 percent by 2020. Because much of electricity demand growth is expected to be met by increases in natural-gas-fired generation, reducing consumption of electricity and diversifying electricity generation resources are significant elements of plans to reduce natural gas demand.

Building Energy Efficiency Standards

The Energy Efficiency Standards for Residential and Nonresidential Buildings, as specified in Title 24, Part 6, of the California Code of Regulations, were established in 1978 in response to a legislative mandate to reduce California's energy consumption. The standards are updated periodically to allow consideration and possible incorporation of new energy efficiency technologies and methods. The current version of the standards was adopted in October 2005, and the CEC has begun development of an update, which is planned for adoption in 2008.

[1] The Renewable Portfolio Standard is a flexible, market-driven policy to ensure that the public benefits of wind, solar, biomass, and geothermal energy continue to be realized as electricity markets become more competitive. The policy ensures that a minimum amount of renewable energy is included in the portfolio of electricity resources serving a state or country. By increasing the required minimum amount over time, the Renewable Portfolio Standard puts the electricity industry on a path toward increasing sustainability.

California's building efficiency standards (along with those for energy-efficient appliances) have saved more than $56 billion in electricity and natural gas costs since 1978 (CEC, 2007). It is estimated that the standards will save an additional $23 billion by 2013.

San Francisco Plans

Sustainability Plan for San Francisco

The *Sustainability Plan for San Francisco* contains a set of general goals and specific objectives and actions for San Francisco to ensure that the city's current needs are met without sacrificing the ability of future generations to meet their own needs (SFDE, 1996). The major energy goals expressed in the plan are to reduce overall power use by maximizing energy efficiency; to maintain an energy supply based on renewable, environmentally sound resources; to eliminate climate-changing and ozone-depleting emissions and toxics associated with energy production and use; and to base energy decisions on the goal of creating a sustainable society.

The Energy, Climate Change and Ozone Depletion chapter of the Sustainability Plan encourages the use of solar energy (harvested directly as sunlight and converted to heat or electricity, or indirectly through wind, water, or vegetation and converted to fuel) as a path towards reducing reliance on nonrenewable fossil fuels. The plan also includes goals to develop energy efficiency requirements that exceed Title 24 standards by 25 percent; provide every building with a renewable energy provider; retrofit mechanically cooled buildings with passive cooling; provide a reliable energy supply system even in times of natural or economic disaster; and install alternative fuels for backup of electrical systems in critical buildings. Specific actions that may be related to the WSIP projects include conducting an energy efficiency audit of public facilities and developing a plan to improve energy efficiency; creating an incentive-based program for managers of city agencies to save energy; establishing city policy that requires staff in municipal facilities to turn off lights and computers when not in use; encouraging building construction that utilizes passive solar technology; and initiating demonstration projects that use solar, wind, ocean, and/or biogas energy sources.

Electricity Resource Plan

The *Electricity Resource Plan* for San Francisco presents an action plan to meet the growth in demand for electricity, as well as allow the shutdown of the Hunters Point power plant and replacement of the aging power plants at Potrero (SFDE and SFPUC, 2002). The main components of the plan include demand reduction through energy efficiency and load management; use of renewable energy resources such as solar, wind, and water; construction of medium-sized generation plants using the most efficient gas-fired generators and cogeneration plants;[2] construction of small-scale distributed generation such as fuel cells, package cogeneration plants, and micro-turbines; and improved power transmission from the Peninsula. The plan calls for a renewed commitment and an accelerated pace to achieving the goals of the 1997 Sustainability Plan, including the elimination of all fossil-fuel power; an energy supply

2 Cogeneration is the production and use of electricity and heat from the same installation.

based on renewable, environmentally sound resources; and maximum energy efficiency. Specific energy savings and production goals for each component of the *Electricity Resource Plan* are identified.

Climate Action Plan

In February 2002, the San Francisco Board of Supervisors passed the *Greenhouse Gas Emissions Reduction Resolution* (Number 158-02) committing the City and County of San Francisco to a greenhouse gas (GHG) emissions reductions goal of 20 percent below 1990 levels by the year 2012. The resolution also directs the San Francisco Department of the Environment, the SFPUC, and other appropriate City agencies to complete and coordinate an analysis and planning of a local action plan targeting GHG emission reduction activities. In September 2004, the San Francisco Department of the Environment and the SFPUC published the *Climate Action Plan for San Francisco: Local Actions to Reduce Greenhouse Emissions* (Plan) (SFDE and SFPUC, 2004). Although the San Francisco Board of Supervisors has not formally committed the City to perform the actions addressed in the Plan, and many of the actions require further development and commitment of resources, it serves as a blueprint for GHG emission reductions, and several actions are now in progress. The climate Action Plan is further discussed in Section 4.9, Air Quality.

4.15.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to energy resources, but generally considers that implementation of the proposed program would have a significant energy resource impact if it were to:

- Encourage activities that resulted in the use of large amounts of fuel, water, or energy, or use these in a wasteful manner (Evaluated in this section)

Approach to Analysis

This analysis evaluates proposed WSIP projects in terms of energy demand during construction and operation and assesses the potential for long-term increases in energy demand and/or the wasteful use of energy. For energy used during construction, the analysis discusses how construction operations would be conducted to minimize the use of fuels and ensure that they are not used in a wasteful manner. For energy used during operation, the analysis identifies WSIP projects for which increases in energy demand would occur. For these projects, energy efficiency measures, consistent with the *Energy Action Plan II*, would be evaluated as part of subsequent, project-level CEQA review. Although any increase in energy demand would be considered potentially significant, implementation of measures to increase energy efficiency, to be determined on a project-by-project basis, would ensure that energy is not used in a wasteful manner and would reduce potential impacts on the state's limited energy supply and aging energy infrastructure.

Impact Summary by Region

Table 4.15-1 presents a summary of potential impacts on energy associated with the WSIP projects. For each impact, the summary presents the expected level of significance of each potential impact for each WSIP project.

TABLE 4.15-1
POTENTIAL IMPACTS AND SIGNIFICANCE – ENERGY

Projects	Project Number	4.15-1: Construction-related energy use	4.15-2: Long-term energy use during operation
San Joaquin Region			
Advanced Disinfection	SJ-1	PSM	PSM
Lawrence Livermore Supply Improvements	SJ-2	PSM	PSM
San Joaquin Pipeline System	SJ-3	PSM	PSM
Rehabilitation of Existing San Joaquin Pipelines	SJ-4	PSM	LS
Tesla Portal Disinfection Station	SJ-5	PSM	PSM
Sunol Valley Region			
Alameda Creek Fishery Enhancement	SV-1	PSM	PSM
Calaveras Dam Replacement	SV-2	PSM	N/A
Additional 40-mgd Treated Water Supply	SV-3	PSM	PSM
New Irvington Tunnel	SV-4	PSM	N/A
SVWTP – Treated Water Reservoirs	SV-5	PSM	PSM
San Antonio Backup Pipeline	SV-6	PSM	N/A
Bay Division Region			
Bay Division Pipeline Reliability Upgrade	BD-1	PSM	PSM
BDPL Nos. 3 and 4 Crossovers	BD-2	PSM	PSM
Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault	BD-3	PSM	PSM
Peninsula Region			
Baden and San Pedro Valve Lots Improvements	PN-1	PSM	N/A
Crystal Springs/San Andreas Transmission Upgrade	PN-2	PSM	PSM
HTWTP Long-Term Improvements	PN-3	PSM	PSM
Lower Crystal Springs Dam Improvements	PN-4	PSM	N/A
Pulgas Balancing Reservoir Rehabilitation	PN-5	PSM	N/A
San Francisco Region			
San Andreas Pipeline No. 3 Installation	SF-1	PSM	PSM
Groundwater Projects	SF-2	PSM	PSM
Recycled Water Projects	SF-3	PSM	PSM

LS = Less than Significant impact, no mitigation required
PSM= Potentially Significant impact, can be mitigated to less than significant
N/A = Not Applicable

Construction Impacts

Impact 4.15-1: Construction-related energy use.

Construction of the WSIP projects would require the use of fuels (primarily gas, diesel, and motor oil) for a variety of construction activities, including excavation, grading, demolition, and vehicle travel. During these activities, fuel use for construction worker commute trips would be minor compared to the fuel use by construction equipment. Although the fuels would only be used during construction of the WSIP projects, excessive idling and other inefficient site operations could result in the wasteful use of fuels. Therefore, impacts related to the wasteful use of fuels during construction would be *potentially significant* for all WSIP projects. However, certain exhaust control measures specified in Section 4.9, Air Quality, such as limiting idling time and performing low-emissions tune-ups (Measures 4.9-1b and 4.9-1d), would ensure that fuels are not used in a wasteful manner and would therefore reduce this impact to a less-than-significant level.

Operational Impacts

Impact 4.15-2: Long-term energy use during operation.

Operation of WSIP project facilities could increase the long-term consumption of energy. As stated above in the Setting, California's water infrastructure accounts for nearly 20 percent of the state's electricity consumption, one-third of non-power-plant natural gas consumption, and about 88 million gallons of diesel fuel consumption. Electricity consumption also contributes to greenhouse gas emissions and associated climate change effects (see Section 4.9, Air Quality, Impact 4.9-6, for more discussion). Furthermore, many of the peak demands for water and much the energy required to treat and transport the water coincide with peak seasonal demands experienced by electrical utilities, and can contribute to the need for rolling blackouts. Thus, reducing the energy required to move, use, and treat water would help relieve stresses on California's energy infrastructure and help California to meet its energy savings goals, while shifting loads from peak demand periods would also help relieve stresses on the system. To address these issues, SFPUC Power Enterprise is developing energy efficiency design guidelines for use by WSIP project staff in designing energy-efficient pump stations and buildings, and the SFPUC already participates in demand-shifting programs to shift more water and wastewater energy usage to off-peak hours, therefore decreasing the use of energy during peak demand periods and reducing the potential for rolling blackouts.

In their analysis of water system energy requirements, the NRDC and Pacific Institute divided the water supply/use/disposal chain into five stages: providing a source of water and conveying it to the point of use, water treatment, distribution, end use, and wastewater treatment (NRDC, 2004). Based on a San Diego case study, the NRDC concluded that end uses of water (especially clothes washing and taking showers) consume more energy than any other part of the urban water conveyance and treatment cycle (56 percent of the total energy usage in San Diego). Of the total usage, providing source water and conveyance of the water accounted for 30 percent, wastewater treatment accounted for 8 percent, distribution accounted for 5 percent, and water treatment accounted for 1 percent.

Water conservation, planned as part of the WSIP and incorporated in the estimated 2030 water demand, would save substantial amounts of energy, not only by reducing the amount of energy consumed by end-users, but also by reducing the amount of water requiring conveyance and treatment as well as the volume of wastewater requiring treatment. These measures include implementation of plumbing code changes for more efficient water use, continuation of existing conservation practices, and varying levels of additional conservation measures, depending on the system customer. In addition, the WSIP preferred water supply option includes about 4 mgd of additional water conservation measures in San Francisco not already included in the 2030 demand projection, as described in Chapter 3 of this PEIR.

The following analysis focuses on the general energy efficiency approach used by the SFPUC as well as energy consumption required for conveyance and treatment of water under the WSIP. Energy uses by end-users and for wastewater treatment are not evaluated, because the WSIP does not address these components of the water supply/use/disposal chain.

General Energy Usage and Energy Efficiency Approach. Operation of the WSIP projects would increase power consumption relative to existing conditions. Although the Hetch Hetchy Project produces far greater power than is currently used by SFPUC projects in the WSIP regions, the proposed increase in power use by the WSIP facilities could result in a higher reliance on nonrenewable energy resources; this is because less hydroelectric power would be available, particularly during the fall and summer months when power generation under the Hetch Hetchy Project is reduced and power supplies are supplemented by PG&E. However, SFPUC Water Enterprise is developing energy efficiency design guidelines and also participates in energy savings programs, such as the demand-shifting program mentioned above. Participation in demand-shifting programs along with implementation of project-specific energy efficiency measures, consistent with the *Energy Action Plan II*, would ensure that energy under the WSIP is not used in a wasteful manner.

Pump Stations. Much of the energy involved in municipal water systems is used for pumping. SFPUC Power Enterprise is working with WSIP staff to identify energy efficiency opportunities in two areas: pumping energy optimization and efficient pump station design. Pumping energy optimization, or demand shifting, is aimed at designing pumping systems that reduce on-peak energy requirements for water pumping operations. With optimized pumping, pumping operations would shift to the off-peak and part-peak periods of each day (within system constraints) to reduce on-peak energy consumption, while at the same time maintaining uninterrupted water delivery to end users. This measure is projected to reduce on-peak electricity demand by 6 megawatts.

Efficient pump station design is being addressed by incorporating efficient motors, pumps, lighting, and ventilation systems. Energy savings resulting from this measure would be determined based on the energy efficiency guidelines of SFPUC Power Enterprise. Pumping facilities (including CS/SA Transmission, PN-2; HTWTP Long-Term, PN-3; and Recycled Water Projects, SF-3) would be designed in accordance with these energy efficiency guidelines.

Water Treatment Plants. Water treatment facilities use energy to pump and process water. The amount of energy required for treatment depends on source-water quality, treatment methods used, and pumping requirements for the treated water. Energy requirements for treatment have typically been small, with the bulk of the energy used to pump raw water. Energy savings can be achieved by reducing the volume of raw water pumped (through water conservation), using energy-efficient treatment and pumping equipment, using effective instrumentation and controls, managing pumping operations, and implementing consistent repairs and maintenance of facilities to minimize power use. Other than approximately 2 percent for backwash, treated water is not pumped in the water treatment plants.

Many water suppliers are moving in the direction of using more energy-intensive treatment methods for disinfection, such as ozonation, which is currently used at one SFPUC water treatment plant. The energy required for water treatment is expected to increase over the next decade as treatment capacity expands, new water quality standards are put in place, and new treatments are developed to improve drinking water taste and color. The implementation of the Advanced Disinfection project (SJ-1), for instance, would lead to an increase in energy needs for water treatment.

Groundwater Production. The production of groundwater requires electricity to pump the groundwater from the wells and convey it to a water treatment system. The amount of energy required depends on the efficiency of the pumping equipment, the depth to groundwater, and the distance to the treatment facility. Some of this energy use could be offset, however, because less energy could be required to treat the generally high-quality groundwater. Conjunctive groundwater use, included as part of the drought supply for the WSIP preferred water supply option, would increase energy demands associated with the retrieval of accumulated water in the Westside Basin.

Recycled Water Facilities. The energy costs for water recycling include the incremental costs to treat the wastewater to the standard necessary for its intended use, and the cost of energy required to convey the water to its intended users. The amount of energy required would depend on the equipment used, the degree of treatment required, and the proximity of the treatment plant to the location where the recycled water would be used.

Pipelines and Tunnels. For the most part, WSIP pipelines and tunnels would be gravity driven and would not require power to operate. Where the pipeline would operate under pressure, a pumping plant would be required; power consumption for pumping plants is addressed above. Valve lots constructed for the pipeline systems could result in a small increase in energy demand during their operation. Valves constructed along the pipelines would require a power source for operation, typically connected to the power grid.

Backup power would typically be provided by propane, diesel, or an uninterruptible power supply, all of which are nonrenewable energy sources. However, backup power would only be used in the event of a disruption in power service. One standby power facility constructed for the BDPL Reliability Upgrade project (BD-1) would use a battery and require operation of an air conditioner to maintain an acceptable temperature for battery operation, but energy requirements for this use would be minimal. Therefore, impacts related to the use of large amounts of energy would be less than significant for the standby power facilities used on pipelines.

Crossover Facilities. Crossover facilities would use energy to switch service from one pipeline to another for maintenance or in the event that a pipeline is damaged in a natural disaster. While this use could result in a small increase in energy demand, energy efficiency measures could be employed to reduce the amount of energy required, or an alternative power supply could be utilized. Some crossovers could be hydraulically activated and would not require a power source.

San Joaquin Region

Impact 4.15-2: Long-term energy use during operation		
Advanced Disinfection	SJ-1	PSM
Lawrence Livermore	SJ-2	PSM
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	LS
Tesla Portal Disinfection	SJ-5	PSM

SFPUC Power Enterprise provides power in the San Joaquin Region, where existing power usage is 199,574 kWh. As summarized in **Table 4.15-2**, operation of new disinfection facilities at Tesla Portal under the Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) projects could substantially increase energy consumption at this site, depending on the disinfection methods used and pumping requirements of the treatment facility. Energy usage could be as high as 28,280,000 kWh for the Advanced Disinfection project and 128,000 kWh for the Tesla Portal Disinfection project. Operation of disinfection facilities at Thomas Shaft under the Lawrence Livermore project (SJ-2) and crossover facilities for the SJPL System project (SJ-3) would also result in a small increase in energy usage (40,000 kWh for SJ-2 and 60,000 kWh for SJ-3). Implementation of these projects would increase energy usage in the San Joaquin Region by more than 100-fold over existing conditions, primarily due to the large energy consumption required for the Advanced Disinfection project. Therefore, impacts related to the use of large amounts of energy are *potentially significant* for each of these projects, particularly for the Advanced Disinfection project. However, incorporation of energy efficiency measures (Measure 4.15-2) would reduce this impact to a less-than significant-level. Energy efficiency measures would be evaluated in more detail as part of subsequent, project-level CEQA review for each project.

Although the SJPL Rehabilitation project (SJ-4) would require some electricity for the operation of valves and associated instruments, this power load would be temporary and would not be continuous, and any increase in energy demand would thus be negligible. Therefore, this impact would be *less than significant* for this project.

TABLE 4.15-2
ESTIMATED ANNUAL OPERATIONAL ENERGY DEMAND, 2030

No.	Project Name	Existing Power Supply (2005)	Estimated Increase in Annual Operational Energy Consumption, 2030		
			New or Additional Power Needed	Expected Provider	Electricity Requirement (kWh)
SJ-1	Advanced Disinfection	SFPUC	Yes	SFPUC	26,280,000
SJ-2	Lawrence Livermore Supply Improvements	SFPUC	Yes	SFPUC	40,000
SJ-3	San Joaquin Pipeline System	SFPUC	Yes	SFPUC	60,000
SJ-4	Rehabilitation of Existing San Joaquin Pipelines	SFPUC	No[a]	N/A	N/A
SJ-5	Tesla Portal Disinfection Facility	SFPUC	Yes	SFPUC	128,000
SV-1	Alameda Creek Fishery Enhancement	SFPUC	Yes	SFPUC	55,000
SV-2	Calaveras Dam Replacement	SFPUC	No	N/A	N/A
SV-3	Additional 40-mgd Treated Water Supply	SFPUC	Yes	SFPUC	TBD
SV-4	New Irvington Tunnel	SFPUC	No	N/A	N/A
SV-5	SVWTP – Treated Water Reservoirs	SFPUC	Yes	SFPUC	TBD
SV-6	San Antonio Backup Pipeline	SFPUC	No	N/A	N/A
BD-1	Bay Division Pipeline Reliability Upgrade	SFPUC	Yes	SFPUC	70,000
BD-2	BDPL Nos. 3 and 4 Crossovers	SFPUC	Yes	SFPUC	TBD
BD-3	Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault	SFPUC	Yes	SFPUC	TBD
PN-1	Baden and San Pedro Valve Lots Improvements	SFPUC	No	N/A	N/A
PN-2	Crystal Springs/San Andreas Transmission Upgrade	SFPUC	Yes	SFPUC	TBD
PN-3	HTWTP Long-Term Improvements	SFPUC	Yes	SFPUC	TBD
PN-4	Lower Crystal Springs Dam Improvements	SFPUC	No	N/A	N/A
PN-5	Pulgas Balancing Reservoir Rehabilitation	SFPUC	No	N/A	N/A
SF-1	San Andreas Pipeline No. 3 Installation	SFPUC	Yes	SFPUC	8,760
SF-2	Groundwater Projects	SFPUC	Yes	SFPUC	5,100,000
SF-3	Recycled Water Projects	SFPUC	Yes	SFPUC	6,500,000 to 7,000,000

NOTES: SFPUC = SFPUC Power Enterprise; N/A = not applicable

[a] Although the SJPL Rehabilitation project (SJ-4) would require some electricity for the operation of valves and associated instruments, this power load would be temporary and would not be continuous.

Sunol Valley Region

Impact 4.15-2: Long-term energy use during operation		
Alameda Creek Fishery	SV-1	PSM
Calaveras Dam	SV-2	N/A
40-mgd Treated Water	SV-3	PSM
New Irvington Tunnel	SV-4	N/A
Treated Water Reservoirs	SV-5	PSM
SABUP	SV-6	N/A

SFPUC Power Enterprise provides power in the Sunol Valley Region, where existing power usage is 5,076,996.5 kWh. The Alameda Creek Fishery project (SV-1) would likely include a pumping plant to transport recaptured water via a pipeline to a reservoir or treatment plant; as summarized in Table 4.15-2, increased energy required for this project may be 55,000 kWh. Implementation of this project would increase energy usage in the Sunol Valley Region by approximately 1 percent over existing conditions. Although, the 40-mgd Treated Water (SV-3) and Treated Water Reservoirs (SV-5) projects would also result in increased energy use for pumping and treating water at the Sunol Valley WTP, the amount of this increase has not been determined. The increase in energy use for all three projects would be small, but because there would be an increase, impacts related to the use of energy would be *potentially significant* for each of these projects. However, incorporation of energy efficiency measures (Measure 4.15-2) and continued participation in demand-shifting programs would reduce this impact to a less-than-significant level. Incorporation of energy efficiency measures would be evaluated in the project-level CEQA documentation for each project.

There would be no increase in operational energy use for the Calaveras Dam (SV-2), New Irvington Tunnel (SV-4), and SABUP (SV-6) projects. Therefore, this impact would *not apply* to these projects.

Bay Division Region

Impact 4.15-2: Long-term energy use during operation		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	PSM
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSM

SFPUC Power Enterprise (through connections with PG&E) provides power in the Bay Division Region, where existing power usage is 191,438.5 kWh. The BDPL Reliability Upgrade project (BD-1) would require an estimated increase of 70,000 kWh for the operation of valving and actuators, as indicated in Table 4.15-2. The BDPL 3 and 4 Crossovers (BD-2) and BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) projects would also involve an increase in energy use to operate valves and actuators, but the actual increase has not been determined. Although these facilities would only be operated during pipeline outages for planned maintenance, emergencies, or other unusual circumstances, impacts related to the use of energy would be *potentially significant* for each of these projects. However, incorporation of energy efficiency measures (Measure 4.15-2) would reduce this impact to a less-than-significant level. Potential energy demand associated with each of these projects and energy efficiency measures would be evaluated in more detail as part of the project-level CEQA review for each project.

Peninsula Region

Impact 4.15-2: Long-term energy use during operation		
Baden and San Pedro Valve Lots	PN-1	N/A
CS/SA Transmission	PN-2	PSM
HTWTP Long-Term	PN-3	PSM
Lower Crystal Springs Dam	PN-4	N/A
Pulgas Balancing Reservoir	PN-5	N/A

SFPUC Power Enterprise (through connections with PG&E) provides power in the Peninsula Region, where existing power usage is 24,423,491.5 kWh. As summarized in Table 4.15-2, the CS/SA Transmission (PN-2) and HTWTP Long-Term (PN-3) projects, both of which include construction or improvements to a pumping plant, would require an increase in operational energy use, but the amount has not been determined. Because there would be an increase in energy use, impacts related to the use of energy would be *potentially significant* for each of these projects. However, incorporation of energy efficiency measures (Measure 4.15-2) and continued participation in demand-shifting programs would reduce this impact to a less-than-significant level. Energy efficiency measures would be evaluated in the project-level CEQA documentation for each project.

There would be no increase in the use of energy during operation of the Baden and San Pedro Valve Lots (PN-1), Lower Crystal Springs Dam (PN-4), or Pulgas Balancing Reservoir (PN-5) projects. Therefore, this impact would *not apply* to these projects.

San Francisco Region

Impact 4.15-2: Long-term energy use during operation		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	PSM
Recycled Water Projects	SF-3	PSM

SFPUC Power Enterprise (through connections with PG&E) provides power in the San Francisco Region, where existing power usage is 13,882,397 kWh. As summarized in Table 4.15-2, the SAPL 3 Installation project (SF-1) would require 8,760 kWh of energy to operate valving and monitoring stations. The Groundwater Projects (SF-2) would require up to 5,100,000 kWh to convey water for restoration of Lake Merced water levels, pump groundwater, and convey groundwater to a treatment plant; the Recycled Water Projects (SF-3) would require up to 7,000,000 kWh of electricity to operate the recycled water facility and convey the water to storage facilities and end-users.

Implementation of these projects would result in an approximately 87 percent increase in energy use in the San Francisco Region over existing conditions. Therefore, impacts related to the use of large amounts of energy are *potentially significant* for each of these projects. However, incorporation of energy efficiency measures (Measure 4.15-2) would reduce this impact to a less-than-significant level. Energy efficiency measures would be evaluated as part of project-level CEQA documentation for each project.

4.16 Collective Impacts Related to WSIP Facilities

4.16 Collective Impacts Related to WSIP Facilities

4.16.1 Introduction and Approach

This analysis evaluates the potential for multiple WSIP projects to generate *collective* impacts in multiple WSIP regions or within the same WSIP region, which are the combined impacts resulting from implementation of multiple WSIP facility improvement projects. The collective impact sections presented below are organized by the same environmental resource topics analyzed in the preceding sections of Chapter 4. The analyses assume that the SFPUC would implement the measures identified to reduce the impacts of individual WSIP projects, including SFPUC standard construction measures, mitigation measures described in Chapter 6 (Measures 4.3-1 through 4.15-2), regulatory requirements of other agencies with jurisdiction over environmental resources, and, where applicable, policies of the Alameda and Peninsula Watershed Management Plans (WMPs). The overall approach to the Chapter 4 facilities impact assessment is described in Section 4.1.

Additionally, this section assesses the program-wide impacts that could result from collective WSIP facility impacts (i.e., the residual effects that are still significant after mitigation) combined with relevant residual impacts associated with the proposed water supply and system operations (as analyzed in Chapter 5, and which relate only to water quality, biological resources, recreation, and visual quality). Since there are undetermined aspects of many of the WSIP projects at this stage of program planning, this PEIR errs on the conservative side in its determination of impact of significance and assumes that separate, project-level CEQA review would confirm the existing conditions and degree of impact.

Mitigation measures that address potentially significant collective impacts are presented in Chapter 6, Mitigation Measures. These measures are numbered to correspond to the collective impact number (4.16-X) to differentiate them from program-level mitigation measures for facilities impacts, which are numbered 4.3-X through 4.15-X. In some cases, a collective mitigation measure repeats a program-level measure that was required for a specific project in Sections 4.3 through 4.15, but applies the same measure to more projects (e.g., all projects in the region or in a specific area) in order to reduce the collective impact.

4.16.2 Potential Overlap of WSIP Facility Locations and Schedules

This section compares WSIP project locations and schedules and identifies any overlap. The geographic scope of some impacts (e.g., air pollutant emissions) could extend beyond the boundary of a given WSIP region (referred to as multi-regional collective impacts). Other collective impacts (e.g., traffic) would be confined to specific areas within a particular WSIP region, where the locations and schedules of WSIP projects could overlap (referred to as localized collective impacts). The analysis evaluates the potential for residual impacts from each WSIP project (i.e., impacts after mitigation) to contribute to collective or combined effects; identifies the severity or significance of such impacts; and indicates whether mitigation is available to reduce these effects to a less-than-significant level.

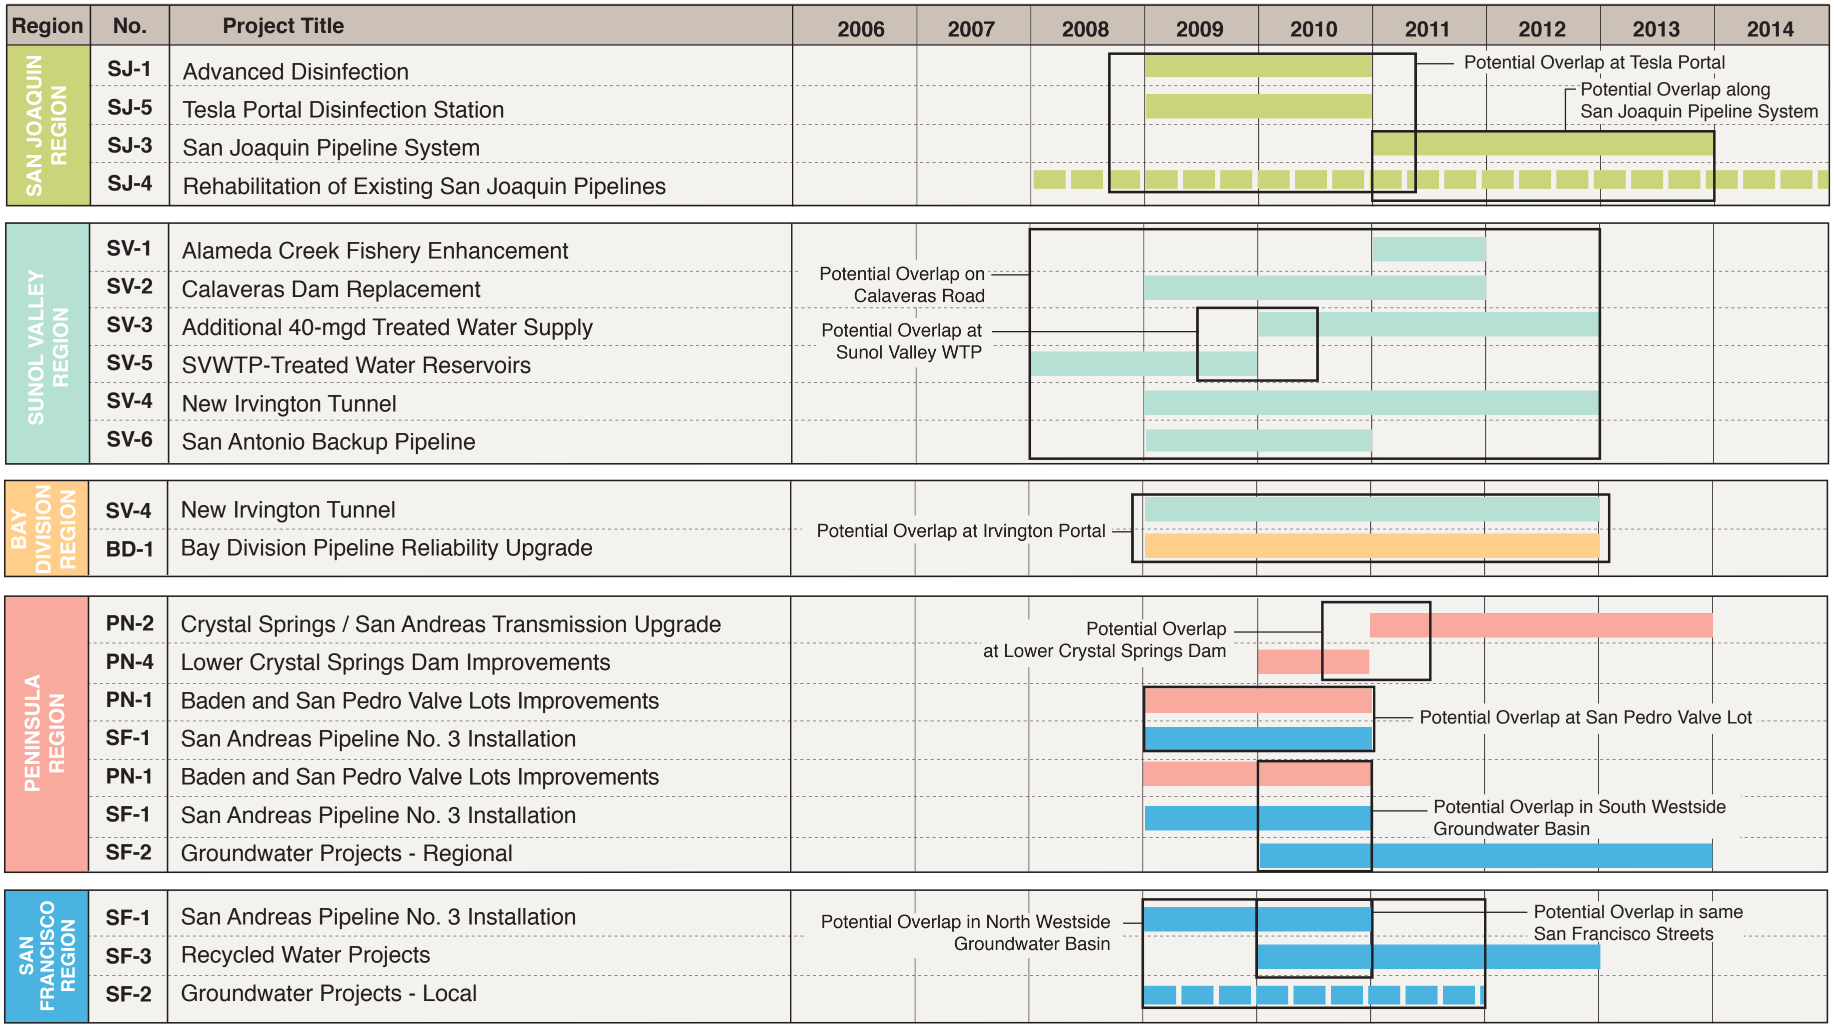
Implementation of the proposed program would result in simultaneous construction and operation of multiple WSIP projects and could cause collective impacts that are greater (more severe, more frequent, and/or longer in duration) than individual project impacts. Two types of collective impacts are evaluated in this section:

- *Multi-regional Collective Impacts*. Impacts in different WSIP regions that would occur at the same time. These impacts would not necessarily overlap geographically. Since project-related activities would occur over many regions, the multi-regional impacts represent those impacts that would span more than one region. Multi-regional impacts would only pertain to the following resource areas: hydrology and water quality (regional water bodies), biological resources (sensitive biological habitats that occur regionally), and air quality (regional air basins). There could also be multi-regional traffic impacts for drivers who commute daily through more than one region, since these motorists could encounter traffic delays from WSIP construction projects in multiple regions.

- *Localized Collective Impacts*. Projects would be considered to have a potential collective impact if they overlapped geographically (in terms of affecting the same resources) in one WSIP region, and construction would occur during the same time period. The locations of each WSIP project (see Chapter 3, Figure 3.5) and preliminary construction schedules (Figure 3.6) were compared to identify where simultaneous construction activities could occur. **Figure 4.16-1** shows the geographic areas and time periods of potential overlaps; specific overlapping projects are listed in **Table 4.16-1**.

  Geographic overlap for construction activities would occur if projects were constructed in the same location, shared the same access/haul/delivery routes, or drained to the same waterway. Schedule overlap, for the purpose of this PEIR, is defined as an overlap in the preliminary construction schedules, or preliminary construction schedules that are separated by one year or less (and could therefore overlap if construction schedules shifted by up to a year). It should be noted that this analysis would still be representative of the types of program-level impacts that could occur if construction schedules shifted by more than one year. For example, if both geographic and schedule overlap for multiple projects were to occur, a combined increase in truck traffic and other temporary construction impacts (such as noise and dust) could result. However, in all cases, the likelihood and extent of overlapping construction activities from two or more WSIP projects would vary depending on the SFPUC's ongoing and future planning (preliminary construction schedules could change over time), coordination, individual project construction phasing, and/or the intermittent nature of construction activities for some projects. In addition, the area affected by construction would shift over time for the linear WSIP projects (e.g., pipelines and aqueducts).

Specific areas of potential overlap are discussed below by region.



Note: Only WSIP projects with potential overlap are shown. See Figure 3.6 for complete construction schedule

NOTE: *Italicized* text indicates projects with sequential start and end dates. Although there is no overlap between the date one project ends and another project starts, sequential project schedules have some potential for overlap, since construction delays could alter schedules.

San Joaquin Region

The following potential overlaps have been identified:

- *Tesla Portal*. Up to four WSIP projects with potentially overlapping construction schedules could be built at this location. The Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) facilities might both be built at Tesla Portal, and the construction schedules overlap in 2009 and 2010. The SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects would also include construction at Tesla Portal. The SJPL Rehabilitation project could overlap with the Advanced Disinfection and Tesla Portal Disinfection projects at the Tesla Portal in 2009 and 2010. The SJPL System project could also overlap with the Advanced Disinfection and Tesla Portal Disinfection projects at the Tesla Portal because the construction of the SJPL System project is scheduled to start when construction of these projects ends in 2011.

- *San Joaquin Pipeline System*. Both the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects would occur along the existing San Joaquin Pipeline alignment and could overlap with each other between 2011 and 2014. However, the nature of potential overlap with construction activities under the SJPL Rehabilitation project is unknown, since the rehabilitation work would not be defined until the conditions assessment is completed.

Sunol Valley Region

The following potential overlaps have been identified:

- *Use of Calaveras Road During Construction of Multiple Projects*. Five of the Sunol Valley Region projects could be under construction between 2009 and 2010, with construction of Calaveras Dam (SV-2) extending to the end of 2011 and two projects (40-mgd Treated Water, SV-3, and New Irvington Tunnel, SV-4) extending to the end of 2012. If the construction schedule changed, the Alameda Creek Fishery project (SV-1), scheduled for 2011, could also be under construction during this time period. Four projects could be simultaneously under construction between 2011 and 2012. The actual overlap of the New Irvington Tunnel would depend on the phasing of this project, because much of the construction activity would take place in the Sunol Valley near the Alameda West Portal.

- *Sunol Valley WTP*. The 40-mgd Treated Water (SV-3) and Treated Water Reservoirs (SV-5) projects are both proposed at the Sunol Valley WTP; although the Treated Water Reservoirs project is scheduled for completion by the end of 2009, prior to the 40-mgd Treated Water project, some overlap could occur if there were construction delays. As shown in Figure 4.16-1, construction activities at the Sunol Valley WTP would be continuous for five years, from 2008 through the end of 2012.

Bay Division Region

In the Bay Division Region, the BDPL Reliability Upgrade (BD-1) and New Irvington Tunnel (SV-4) projects involve work at the Irvington Portal vicinity in Fremont, and the two project schedules overlap from 2009 through 2012. Most of the construction activity for the New Irvington Tunnel project would occur in the Sunol Valley. Under the BDPL Reliability Upgrade project, the pipeline would be constructed using cut-and-cover methods along much of the pipeline alignment, while construction activities associated with tunnel construction would occur primarily at the east tunnel portal in Newark (approximately seven miles west of the Irvington Portal) and the west tunnel portal in East Palo Alto, across San Francisco Bay. However, since the west end of the New Irvington Tunnel would connect to the east end of the BDPL Reliability Upgrade, there would necessarily be coordination and overlap in the design and construction of both projects.

Peninsula Region

The following specific overlaps have been identified:

- *Lower Crystal Springs Reservoir Area*. The CS/SA Transmission (PN-2) and Lower Crystal Springs Dam (PN-4) projects involve construction at or near Lower Crystal Springs Dam. These projects have sequential start and end dates at the end of 2010 and could overlap if construction schedules were to change, depending on the phasing of the CS/SA Transmission project.

- *San Pedro Valve Lot*. Construction at the San Pedro Valve Lot could occur under both the Baden and San Pedro Valve Lots (PN-1) and SAPL 3 Installation (SF-1) projects. Their schedules overlap for the entire two-year construction duration in 2009 and 2010. Actual overlap of these projects would depend on the phasing of the SAPL 3 Installation construction, which would take place over the entire pipeline length.

- *South Westside Groundwater Basin, San Mateo County*. The Baden and San Pedro Valve Lots project (PN-1) is in the South Westside Groundwater Basin, where the Regional Groundwater Projects (SF-2) would be constructed. Construction could overlap for one year in 2010. The actual overlap would depend on the specific locations selected for the Regional Groundwater Projects.

San Francisco Region

Specific project overlaps include:

- *San Francisco North Westside Groundwater Basin*. In San Francisco, a portion of the SAPL 3 Installation (SF-1) pipeline alignment and the Recycled Water Projects (SF-3) are located within the North Westside Groundwater Basin, where the Local Groundwater Projects (SF-2) would be constructed, and some of the facilities are within one mile of each other. The construction schedules for the SAPL 3 Installation project and the Local Groundwater Projects overlap in 2009 and 2010. The construction schedules for the Recycled Water Projects and Local Groundwater Projects overlap for two years in 2010 and 2011. The actual overlap for all projects would depend on the specific locations selected for the Local Groundwater Projects and the phasing of the SAPL 3 Installation project. In addition, construction activities under the Local Groundwater Projects would be intermittent, and there would not be continual overlap for the duration of the construction period.

- *South Westside Groundwater Basin, San Mateo County*. A portion of the SAPL 3 Installation (SF-1) pipeline alignment is located in San Mateo County within the South Westside Groundwater Basin, where the Regional Groundwater Projects (SF-2) would be constructed, and these projects could overlap for one year in 2010. The actual overlap would depend on the specific locations selected for the Regional Groundwater Projects and the phasing of the SAPL 3 Installation project.

- *San Francisco Streets*. In some San Francisco locations, the installation of recycled water pipelines under the Recycled Water Projects (SF-3) could occur in the same street alignments as pipelines for the SAPL 3 Installation project (SF-1), and construction activities could coincide in 2010.[1]

4.16.3 Collective Facility Impacts

Significance Criteria

The City and County of San Francisco (CCSF) has not formally adopted significance standards for impacts related to the combined or collective effects of a program such as the WSIP. Sections 4.3 through 4.15 present the criteria used to determine the significance of individual facility impacts under the various environmental resource topics. This assessment of collective impacts applies the same significance criteria to the same resource topics to identify the residual impacts that would remain following implementation of mitigation measures identified in Sections 4.3 through 4.15 (described in Chapter 6).

Impact Summary

Collective impacts are discussed below, and impact significance determinations by region and environmental topic are summarized in **Table 4.16-2**.

Land Use and Visual Quality

Impact 4.16-1a: Collective temporary and permanent impacts on existing land uses in the vicinity of proposed facility sites.

Multi-regional Collective Impacts

As described in Section 4.3, implementation of the WSIP could result in temporary adverse impacts on existing land uses located adjacent to proposed WSIP facility sites by causing temporary incompatibility problems or conflicts between existing uses and construction activities (e.g., disrupting use of a school or park) (Impact 4.3-1). Although temporary disruptions could occur where facility sites would be in separate discrete locations, there would be no multi-regional collective temporary disruption or division of land uses (*not applicable*).

Implementation of the WSIP could require the acquisition of easements or land, and such acquisition could result in permanent displacement of existing land uses at discrete locations adjacent to or near specific project facility sites (Impact 4.3-2). For sites that are separate from other WSIP sites, no multi-regional collective or additive permanent displacement of existing land uses would occur (*not applicable*).

[1] Note that pipelines for the Recycled Water Projects (SF-3) would carry recycled water, while pipelines for the SAPL 3 Installation project (SF-1) would carry potable water; if both types of pipes were to be installed in the same streets, the pipeline placement would require review for compliance with regulations regarding the separation of potable and recycled water pipelines.

TABLE 4.16-2
POTENTIAL COLLECTIVE IMPACTS AND SIGNIFICANCE – BY REGION

Impact Number and Topic	Multi-regional Collective Impact[a]	Localized Collective Impacts in Overlapping Areas				
		San Joaquin Region	Sunol Valley Region	Bay Division Region	Peninsula Region	San Francisco Region
4.16-1a: Land Use	N/A	N/A	N/A	PSU	LSM	N/A
4.16-1b: Visual Quality	N/A	LSM	LS	LSM	LSM	LSM
4.16-2: Geology, Soils, and Seismicity	B	N/A	N/A	N/A	N/A	N/A
4.16-3: Hydrology and Water Quality	LSM	LSM	LSM	LSM	LSM	LSM
4.16-4: Biological Resources	PSM	PSM	PSU	PSM	PSU	N/A
4.16-5: Cultural Resources	LSM	LSM	PSU	LSM	PSU	N/A
4.16-6: Traffic, Transportation, and Circulation	PSU	PSM	PSM	PSM	PSM	PSM
4.16-7: Air Quality	PSU	PSM	PSM	LSM	LS	LS
4.16-8: Noise and Vibration	N/A	PSU	PSM	PSU	PSU	PSU
4.16-9: Public Services and Utilities	LSM	N/A	N/A	N/A	N/A	N/A
4.16-10: Recreational Resources	LS	LSM	LSM	LSM	LSM	LSM
4.16-11: Agricultural Resources	LSM	N/A	N/A	N/A	N/A	N/A
4.16-12: Hazards	LS	LSM	LSM	LSM	LSM	LSM
4.16-13: Energy Resources	LSM	LSM	LSM	LSM	LSM	LSM

NOTE: The significance determinations presented in this table assume implementation of all SFPUC construction measures, regulations, and mitigation measures identified in Chapter 6.

B = Beneficial impact
N/A = Not applicable, because there is no collective or combined effect
LS = Less than Significant impact, no mitigation required
LSM = Less than Significant with program-level mitigation (Measures 4.3-1 through 4.15-2)
PSM= Potentially Significant impact, can be mitigated to a less-than-significant level with collective mitigation (Measures 4.16-1 through 4.16-9b)
PSU = Potentially Significant Unavoidable impact

[a] For Energy Resources, the significance determination includes systemwide (area encompassing the entire water system) impacts as well as impacts within the WSIP study area (area between San Francisco and Oakdale Portal)

Localized Collective Impacts

WSIP projects with overlapping sites, staging areas, and/or haul routes could exacerbate temporary community disruption impacts (e.g., traffic congestion and access constraints, dust, and noise) or collectively alter existing land use patterns. Temporary direct collective impacts would occur in overlapping areas if construction activities or staging associated with multiple WSIP projects affected the same or adjacent uses. Indirect collective impacts from overlapping projects, such as construction-related traffic conflicts on common haul routes, combined construction air pollutant emissions, and construction-related noise increases, are discussed below under the traffic, air quality, and noise discussions. Permanent collective impacts could occur in overlapping areas if multiple WSIP projects adversely affected the same land uses, especially if the same or adjacent lands or easements were required for access to more than one project.

As stated in Section 4.3, the potential for temporary land use disruption or conflicts would be low during construction of most WSIP projects, since they generally involve improvements to existing SFPUC facilities that occur within existing facility sites and SFPUC rights-of-way, or are located in areas isolated from other development. However, some project facilities would involve construction outside of CCSF-owned lands and thus would be more likely to affect existing land uses on or adjacent to lands to be acquired. When the projects identified as requiring land acquisition or staging areas (see Table C.1 in Appendix C) are considered together and then evaluated in the context of overlapping schedules (Figure 4.16-1), the potential for direct temporary or permanent collective impacts in each region would be as follows:

- *San Joaquin Region*. Two projects in this region (SJPL System, SJ-3, and Tesla Portal Disinfection, SJ-5) would require temporary land acquisition for staging areas, but there would be no permanent change in land use at Tesla Portal, which is already developed with water facilities. Since the construction schedules of these two projects would not overlap (Figure 4.16-1), no collective impacts would result from temporary changes in land use associated with each project's construction staging. Therefore, this impact would *not apply*.

- *Sunol Valley Region*. Three projects in this region (Calaveras Dam, SV-2; 40-mgd Treated Water, SV-3; and Treated Water Reservoirs, SV-5) would require temporary acquisition of land or easements for construction staging or access, and portions of their construction schedules would overlap. However, since the acquired land would not overlap geographically, no temporary or permanent collective impacts would occur in this region. Therefore, this impact would *not apply*.

- *Bay Division Region – Irvington Portal in Fremont*. Staging and access areas for both the new Irvington Tunnel portal (SV-4) and easternmost segment of the BDPL Reliability Upgrade project (BD-1) would overlap in the area east of Mission Boulevard and in the vicinity of existing homes. Since the construction schedules for these projects overlap for their entire four-year durations (2009 to 2013), it is not known whether or how long the construction activities would overlap. Both of these projects would introduce temporary staging and construction activities into a currently undeveloped area adjacent to a residential neighborhood. Such construction-related impacts would be a potentially significant collective impact. Implementation of a collective mitigation measure to coordinate staging and construction of these two projects in the Irvington Tunnel portal vicinity (Measure 4.16-1a) could reduce this collective impact; however, since the feasibility of such coordination cannot be determined at this stage of project planning, temporary impacts on residences near the Irvington Tunnel portal would be *potentially significant and unavoidable.*

  The WSIP would also develop new permanent water facilities and an access road in an undeveloped area adjacent to a residential neighborhood. Implementation of program-level measures, such as conducting siting studies to minimize permanent impacts on existing land uses and using buffer zones and visual screens (Measures 4.3-2a and 4.3-2b), would help minimize each project's impact such that the residual collective land use impact would be less than significant.

- *Peninsula Region – Lower Crystal Springs Dam Vicinity*. Construction of the CS/SA Transmission (PN-2) and Lower Crystal Springs Dam (PN-4) projects could overlap briefly between 2010 and 2011 if construction schedules were changed or delayed. Even if the schedules do not overlap, staging areas for each project or prolonged use of the same staging area in the dam vicinity for both projects could affect recreational uses if access or parking were disrupted. Implementation of measures to accommodate the displaced public parking supply for recreational visitors (Measure 4.8-4) would help minimize each project's impact such that the potential residual collective land use impact would be *less than significant with mitigation*.

- San Francisco Region. Only one project in this region (Groundwater Projects, SF-2) would require the acquisition of land or easements for staging. With only one project, there would be no overlap with any other WSIP projects in this region, and this impact would *not apply*.

Impact 4.16-1b: Collective temporary and permanent impacts on the visual character of the surrounding area.

Section 4.3 also addresses the aesthetic and visual quality impacts associated with implementation of the WSIP (Impact 4.3-3).

Multi-regional Collective Impacts

Potential visual impacts of the WSIP (e.g., temporary visual effects during construction or permanent visual effects due to proposed aboveground facilities) would be confined to specific sites and corridors within the WSIP study area. In addition, as discussed in Chapter 5, the proposed water supply and system operations would have the potential to affect visual resources associated with changes in stream flow or water levels in affected water bodies in the Tuolumne, Alameda, and Peninsula watersheds. However, these effects would also be confined to specific sites and corridors within the WSIP program area. Therefore, no multi-regional degradation of visual resources would occur (*not applicable*).

Localized Collective Impacts

Temporary and permanent collective impacts could occur where more than one WSIP project with aboveground facilities would adversely affect the same visual resource (e.g., views of natural areas, such as ridgelines and riparian corridors, from a designated scenic route), thus creating a collective visual change. When projects identified as having aboveground elements (see Table C.1, Appendix C) are considered together and then evaluated in the context of overlapping schedules (see Figure 4.16-1), the potential for collective visual impacts in each region would be as follows:

- *San Joaquin Region – Tesla Portal*. Distant views of the Tesla Portal facility are visible from I-580, a designated scenic route. The Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) projects would collectively expand the cluster of buildings that already exists at the Tesla Portal facility. Implementation of measures pertaining to architectural siting and design (Measure 4.3-4a), revegetation and site restoration (Measure 4.3-4b), and tree care (Measure 4.3-4c) would reduce each project's impact such that the residual collective visual impact would be *less than significant with mitigation*.

- *Sunol Valley Region – Sunol Valley WTP*. There are two projects involving new aboveground facilities at the Sunol Valley WTP: 40-mgd Treated Water (SV-3) and

Treated Water Reservoirs (SV-5). Since the WTP is not visible from Calaveras Road (due to trees in the Alameda riparian corridor that block the view), proposed facilities would also not be visible from this road. In addition, the proposed water supply and system operations could affect the visual character of creeks and reservoirs in the Sunol Valley Region (see Chapter 5, Section 5.4.7); however, due to the separate viewsheds for the WTP and the creeks/reservoirs as well as the difference in impact type (i.e., the appearance of proposed structures vs. changes in stream flow and water levels), there would be no additive effects on the visual character of the area. Therefore, the collective visual impact would be *less than significant*, particularly with implementation of the SFPUC's Alameda WMP design guidelines.

- *Bay Division Region – Irvington Portal in Fremont*. The New Irvington Tunnel (SV-4) and BDPL Reliability Upgrade (BD-1) projects would overlap geographically in the vicinity of Irvington Portal (east of Mission Boulevard) in Fremont, and their schedules would coincide. The BDPL Reliability Upgrade project would have two vaults (Irvington Portal Vault and Mission Boulevard Venturi Meter Vault) in the vicinity of the new Irvington Tunnel portal. Implementation of measures for architectural siting and design (Measure 4.3-4a), revegetation and site restoration (Measure 4.3-4b), and tree care (Measure 4.3-4c) would reduce each project's impact such that the residual collective impact would be *less than significant with mitigation*.

- *Peninsula Region – Lower Crystal Springs Dam Vicinity*. Aboveground facilities associated with the CS/SA Transmission (PN-2) and Lower Crystal Springs Dam (PN-4) projects would overlap in the area below the dam and could collectively alter views from Highway 35 (Skyline Road Bridge over Lower Crystal Springs Dam) or Crystal Springs Road, both designated scenic routes. However, these views would be limited somewhat by elevational differences and intervening vegetation; furthermore, implementation of the SFPUC's Peninsula WMP design guidelines for structures and roads within the watershed plan area, in addition to mitigation measures for architectural siting and design (Measure 4.3-4a), revegetation and site restoration (Measure 4.3-4b), and tree care (Measure 4.3-4c) would reduce each project's impact such that the potential residual collective visual impact would be *less than significant with mitigation*. In addition, the proposed water supply and system operations could affect the visual character of creeks and reservoirs in the Peninsula Region (see Chapter 5, Section 5.5.7); however, due to the limited views and difference in impact type (i.e., the appearance of proposed structures vs. changes in stream flow and water levels), there would be no additive effects on the visual character of the area.

- *San Francisco Region*. Although the locations for all 16 single-story structures associated with the Groundwater Projects (SF-2) have not been determined, one of these aboveground structures could overlap with one of four new aboveground structures for the Recycled Water Projects (SF-3) in the vicinity of the San Francisco Zoo, Golden Gate Park, or other locations. Implementation of measures for architectural siting and design (Measure 4.3-4a), revegetation and site restoration (Measure 4.3-4b), and tree care (Measure 4.3-4c) would reduce each project's impact such that the residual potential collective visual impact would be *less than significant with mitigation*.

Geology, Soils, and Seismicity

Impact 4.16-2: Collective exposure of people or structures to geologic and seismic hazards.

Multi-regional Collective Impacts

One of the primary objectives of the WSIP is to ensure that sufficient water is available to customers served by the SFPUC following an earthquake on one of the regional faults. To meet this objective, the program consists of projects to strengthen and improve water system components that could be subject to seismic hazards, and to provide redundancy in the system should substantial damage and/or a failure of part of the system occur. Therefore, implementation of the WSIP would collectively result in *beneficial* effects related to the seismic safety of the regional water system.

Localized Collective Impacts

Section 4.4 presents the potential geologic and seismic impacts associated with implementation of the WSIP, which include slope instability, erosion, various seismic hazards, expansive or corrosive soils, and squeezing ground (Impacts 4.4-1 through 4.4-9). These potential impacts would be site-specific (i.e., dependent on local geologic and soil conditions) and would not be additive or collective. Therefore, the WSIP projects would not have any localized collective impacts related to geology, soils, and seismicity (*not applicable* in overlapping areas).

Hydrology and Water Quality

Impact 4.16-3: Collective WSIP impacts related to the degradation of surface waters and flooding hazards.

Multi-regional and Localized Collective Impacts

The WSIP projects would have multi-regional and localized collective impacts on hydrology or water quality if they would cause adverse impacts on the same water body or watershed or cause degradation of San Francisco Bay, which ultimately receives drainage from all of the WSIP regions. However, all discharges to surface water occurring under the WSIP would be conducted under a National Pollutant Discharge Elimination System (NPDES) permit(s) issued by the Regional Water Quality Control Board (RWQCB). These permits require compliance with water quality regulations as well as with the plans, policies, and water quality objectives and criteria of the relevant Basin Plan, including the total maximum daily load (TMDL) requirements for impaired water bodies. Compliance with permit conditions and implementation of control measures specified in the permit would ensure the protection of water quality consistent with regional goals and objectives.

Permit conditions and control measures typically include: stormwater controls or treatment of discharges to achieve the stated water quality goals (described in plans subject to RWQCB approval); self-monitoring and reporting to demonstrate compliance with these criteria; and implementation of corrective actions should permit limitations be exceeded. Furthermore, the RWQCB can amend, revoke, and reissue an NPDES permit if investigations demonstrate that the discharge could potentially cause or contribute to adverse effects on water quality and/or beneficial uses of the receiving waters. The permit can also be amended if water quality objectives change or additional pollutants could exceed water quality objectives, or to incorporate waste load allocations determined during the TMDL process. The RWQCB may also revoke the permit if the discharger fails to meet the requirements of the permit, or if the RWQCB finds that the permitted discharge endangers human health or the environment.

Therefore, with adherence to the control measures specified in NPDES permit(s), implementation of SFPUC Construction Measures #3 and #10 (onsite water quality and project site measures) and Measures 4.5-4a through 4.5-6 (described in Chapter 6), and compliance with the water quality requirements of regulatory agencies, impacts related to discharges from the WSIP projects would be reduced such that the residual contributions to multi-regional and localized collective impacts on surface waters would be *less than significant with mitigation*, as described below.

- *Construction-Phase Water Quality Impacts*. Potential water quality impacts during construction include increased erosion and sedimentation, the discharge of groundwater produced during dewatering, or the discharge of treated water (Impacts 4.5-1, 4.5-3a, and 4.5-3b). All WSIP projects would be required to implement SFPUC Construction Measure #3 (onsite air and water quality measures during construction) and to comply with applicable water quality regulations, including Article 4.1 of the San Francisco Public Works Code for projects in San Francisco and NPDES construction stormwater permitting requirements for other projects, as discussed in Section 4.5 (including implementation of stormwater pollution prevention plans and best management practices for erosion control). Such compliance is designed to achieve consistency with regional water quality objectives and criteria of the appropriate Basin Plan, which contains water quality objectives deemed protective of water quality by the State of California.

- *Flood Flow Impacts*. Construction activities in a flood zone could divert flood flows or contribute sediment or contaminants to flood flows (Impact 4.5-4); however, the WSIP projects would not be located in the same flood zones (except for possibly the Alameda Creek Fishery, SV-1, and SABUP, SV-6, projects in the Sunol Valley Region as well as the SJPL System, SJ-3, and SJPL Rehabilitation, SJ-4, projects in the San Joaquin Region), and no collective effect would occur. Where construction would occur in the same flood zone, incorporation of flood flow protection measures (Measure 4.5-4a) would reduce each project's impact such that the residual collective impact on affected flood zones would be less than significant with mitigation.

  As discussed under Impact 4.5-4, the diversion dam or concrete weir and small earthen dam that might be constructed under the Alameda Creek Fishery project (SV-1) could alter the drainage of surface flows in Alameda Creek and potentially exacerbate flooding or siltation. With implementation of a site-specific flooding analysis (Measure 4.5-4b), these potential impacts would be reduced to a less-than-significant level. There would be no collective flooding impacts associated with the 40-mgd Treated Water (SV-3) and Treated Water Reservoirs (SV-5) projects, since both projects would involve only intermittent, small-magnitude discharges to Alameda Creek and San Antonio Creek. Discharges to these two creeks under the SABUP project (SV-6) would be a continuation of an existing discharge, and no new discharges under this project would occur. Therefore, collective increases in the potential for flooding along Alameda Creek due to these projects would be less than significant with mitigation.

- *Operations-Phase Discharges from Multiple Sites to the Same Water Bodies*. The WSIP projects could contribute to multi-regional or localized collective water quality, erosion, or flooding impacts related to discharges of treated water during operation (Impact 4.5-5) as well as alteration of drainage patterns or increased impervious surfaces (Impact 4.6-6). However, any new discharges of treated water during operation would not contribute to flooding and would not degrade water quality because the discharges would be intermittent (for maintenance purposes only) and would be dechlorinated prior to discharge in compliance with NPDES permit requirements and any other applicable permitting requirements of the California Department of Fish and Game (CDFG) and U.S. Army Corps of Engineers. Implementation of these permitting requirements would ensure that the quality and beneficial uses of all receiving waters are protected such that any residual collective impacts would be less than significant.

None of the WSIP sites would collectively contribute to water quality degradation (including offsite erosion and flooding as a result of increased impervious surfaces) for the following reasons:

- Projects in the San Joaquin Region would incorporate post-construction stormwater controls, as specified in the stormwater management plan required under NPDES regulations or Measure 4.5-6.

- Projects in the Sunol Valley, Bay Division, and Peninsula Regions would comply with municipal stormwater requirements (see Section 4.5), which specify numeric design standards for sizing stormwater treatment controls; limits on increases in peak stormwater discharges from new or redevelopment sites that could increase erosion in creeks; requirements for the operation and maintenance of stormwater controls; and requirements for site design and source control measures.

- Construction of WSIP projects in the San Francisco Region would not collectively contribute to an increase in impervious surfaces. The pipelines constructed under each of the projects would be installed in existing streets, and some facilities associated with the Recycled Water Projects (SF-3) would be constructed in areas that are currently paved; therefore, no new impervious surfaces would be created. If the Groundwater Projects (SF-2) or Recycled Water Projects (SF-3) created any new impervious surfaces, the extent would be minimal and would not be expected to measurably affect the volume or frequency of combined sewer discharges.

None of the projects would collectively alter drainage patterns in such a way that would result in collective offsite flooding, erosion or sedimentation effects because all WSIP projects would be required to: (1) implement SFPUC Construction Measure #10 (project site), which would return all sites to the general condition that existed prior to construction; (2) implement erosion control measures in accordance with SFPUC Construction Measure #3 (onsite air and water quality measures during construction); and (3) comply with applicable water quality regulations, including Article 4.1 of the San Francisco Public Works Code for projects in San Francisco and NPDES construction stormwater permitting requirements for other projects, as discussed in

Section 4.5. Implementation of SFPUC Construction Measures #10 and #3 and regulatory permitting requirements would ensure that the quality and beneficial uses of all receiving waters are protected such that any residual collective impacts in the San Joaquin, Sunol Valley, Bay Division, or Peninsula Regions would be less than significant.

As described in Chapter 5, the WSIP water supply and system operations would have the potential to affect water quality and hydrology in the Tuolumne, Alameda, and Peninsula watersheds. The only potential for overlapping, collective effects due to long-term facilities impacts combined with water supply impacts would be for water bodies in the Alameda and Peninsula watersheds. However, no collective or combined impacts on water quality and hydrology would occur, since there would be no substantive overlap between affected water quality or hydrological parameters. Water quality and hydrological effects related to long-term facilities impacts (for both project-specific and collective impacts) would be associated with operations-phase discharges. On the other hand, the proposed water supply and system operations would alter stream flow and reservoir water levels, with the potential for related water quality effects on temperature, dissolved oxygen, and possibly nutrients; however, these effects would be distinct from effects related to discharges from facilities, and mitigation measures identified for the individual effects would reduce these impacts to a less-than-significant level. Therefore, multi-regional and collective impacts on water quality and hydrology would be *less than significant with mitigation.*

Biological Resources

Impact 4.16-4: Collective loss of sensitive biological resources.

Multi-regional Collective Impacts

Section 4.6 presents the potential impacts of each WSIP project on biological resources, including wetlands, sensitive habitats (as defined by the CDFG), as well as heritage trees, special-status plant and wildlife species, and riparian habitat potentially subject to state and federal protection (Impacts 4.6-1 through 4.6-3). As indicated in Section 4.6, Table 4.6-3, WSIP facility projects would affect approximately 2,000 acres considering project footprints, borrow and fill areas, spoil piles, temporary laydown areas for construction, and indirect impacts such as inundation and fugitive dust. Multi-regional collective biological impacts could occur when projects are constructed simultaneously or in close sequence, such as:

- Impacts on wildlife movement due to temporary habitat fragmentation and reduction in areas for cover or escape
- Compounded impacts on functional units of habitat as WSIP projects simplify vegetation structure and increase “edge” (the boundary between two different habitats)
- Increased habitat impacts due to the spread of weedy, non-native plant species

When these multi-regional collective facilities impacts are considered in combination with the water supply and system operation impacts on biological resources in the Alameda and Peninsula watersheds (as discussed in Chapter 5, Sections 5.4.6 and 5.5.6), there would be several instances of combined effects on reservoir and riparian vegetation. For some species, especially riparian-dependent species, construction of a WSIP facility could displace animals to habitat along streams or reservoir edges that could be of reduced quality due to WSIP-related reductions in stream flow, flooding, or channel-forming events (as described in Chapter 5). Since the PEIR's significance determination errs on the conservative side (and assumes that separate, project-level CEQA review would confirm the existing condition and effects), this impact is considered to be *potentially significant*.

Implementation of habitat compensation measures, implemented either on a project by project basis or through a coordinated program such as proposed in the SFPUC's Habitat Reserve Program (HRP) (Measure 4.16-4a) would help reduce this combined collective impact. Effective mitigation through habitat conservation could occur on SFPUC property or could require the acquisition of conservation easements and conservation lands. Although the SFPUC could provide mitigation within the watershed, this conservative analysis considers the availability of suitable land in the Bay Area for such mitigation efforts. Of an estimated 4.5 million acres of Bay Area land, 720,000 acres (16 percent) are developed and 1.1 million acres (24 percent) are in protected open space (GreenInfo Network, 2007). Although it may appear that property for land conservation is not available, competition for open lands is on a more level playing field than one might first assume. Successful conservation programs in Southern California (where regional biodiversity planning has proceeded at a faster rate than in the Bay Area) are one indicator of potential feasibility.[2] Where conservation easement or land acquisition is not feasible, another way to achieve habitat compensation goals and mitigation requirements would be to assist land trusts and other stewards in more effectively managing their lands.

Thus, even if the WSIP were to mitigate its impact at a typical replacement ratio and mitigation within SFPUC property was insufficient, such acreage could be accommodated within the regional area, thereby reducing the WSIP's potentially significant collective biological impacts to a less-than-significant level.

Localized Collective Impacts

Figure 4.16-1 indicates where projects would overlap geographically and project schedules would coincide. When overlapping areas in this figure are considered in the context of areas of known biological sensitivity, the potential for combined or collective biological impacts would be greatest in the Sunol Valley and Peninsula Regions. However, these collective impacts could

[2] In San Diego's conservation plan, for example, the reserve design included 22,083 acres of land already conserved and targeted an additional 30,884 acres for conservation. By 2001, 83 percent of that additional amount had been conserved or obligated for conservation through a combination of state, federal, and local purchases as well as exactions (Pollak, 2001). What has made the programs in Southern California viable is the private-sector economic reality that places the value of land conservation on an equal footing with development interests. Undeveloped land is likely to be sold at or above market rates to either a conservation planning entity or a private developer without prejudice. Furthermore, conservation easements present a unique opportunity for sellers who wish to preserve some use rights to properties or pass them along to heirs. A wildlife habitat easement might prohibit development, for example, but allow continued farming. There is also substantial social consensus on this aspect of implementing a program like the HRP. In August 2006, Congress approved a substantial expansion of the federal conservation tax incentive for conservation easement donations, and President Bush signed it into law.

occur in any of the regions where construction associated with overlapping projects would increase the extent of traffic, noise, and temporary habitat loss (e.g., if multiple staging areas were needed). These potential impacts are as follows:

- San Joaquin Region. The construction schedules associated with the Advanced Disinfection (SJ-1), SJPL Rehabilitation (SJ-4), and Tesla Portal Disinfection (SJ-5) projects would overlap for a brief time, and it is possible that these projects could affect the Tesla Portal vicinity at the same time (2009 and 2010). Potentially affected biological resources include grassland and wetland habitats with associated special-status species. It is also possible that construction of the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects could overlap if the projects affected the same pipeline segment (2011 through 2013). Potentially affected biological resources include grassland, oak woodland, riparian, vernal pool, and wetland habitats with associated special-status species. Collective increases in haul truck traffic and noise along with increased surface disturbance for staging areas would result in *potentially significant* collective impacts if such overlaps occurred near identified sensitive biological resources. Implementation of SFPUC Construction Measure #8 (biological screening survey for each individual project) and mitigation measures for general impacts (Measures 4.6-1 through 4.6-3, including Table 4.6-4) would reduce each project's contribution to collective impacts on biological resources. These measures combined with consolidation of construction staging and access (Measure 4.16-4b) would reduce this collective impact. Because of the limited extent of project overlap in this region, the mitigation measures identified could reduce this impact to less than significant.

- Sunol Valley Region. The construction schedules for all projects in this region would overlap at various times between 2008 and 2012. Some of these projects would have the potential to contribute to collective impacts on sensitive biological resources in the Sunol Valley, while increased truck traffic on Calaveras Road, the haul route for all projects in this region, could adversely affect sensitive biological resources adjacent to Calaveras Road. Collective increases in haul truck traffic and noise along with increased surface disturbance for facility construction and staging areas would result in potentially significant collective impacts if project overlaps occurred near identified sensitive biological resources. Implementation of SFPUC Construction Measure #8 (biological screening survey for each individual project) and mitigation measures for general impacts (Measures 4.6-1 through 4.6-3, including Table 4.6-4) would reduce each project's contribution to collective impacts on biological resources. These measures combined with consolidation of construction staging and access (Measure 4.16-4b) would reduce this collective impact, but some sensitive biological resources would remain at risk. For example, a recent sighting of a San Joaquin kit fox on another SFPUC project site near Sunol suggests a small population may be reestablishing itself in the area. Such populations are more vulnerable to disturbance.[3]

  For purposes of this program-level evaluation, the collective impact of multiple WSIP project construction activities in Sunol Valley on sensitive biological resources such as listed species is considered *potentially significant and unavoidable* because of the number of WSIP projects to be implemented in this region and the extent of overlap in terms of construction activity timing and location. Further site-specific analysis for each WSIP project to be conducted as part of project-level CEQA review for each project may determine that this potentially significant collective impact can be mitigated to less than

3 A single individual was observed during nighttime surveys associated with the SFPUC Sunol / Niles Dam Removal Project in 2006. The species is not otherwise considered present in the Sunol Valley Region.

significant based on more detailed information about the project site location, schedule and construction methods.

- *Bay Division Region – Irvington Portal in Fremont*. Staging and access areas for both the new Irvington Tunnel portal (SV-4) and easternmost segment of the BDPL Reliability Upgrade project (BD-1) would overlap in the area east of Mission Boulevard and existing homes. This area is currently undeveloped, and these two projects would result in the removal of annual grassland to accommodate temporary staging areas as well as new permanent water facilities and an access road. The significance of this impact would depend on the presence of sensitive biological resources, which is not likely given the low quality of the habitat present. Implementation of SFPUC Construction Measure #8 (biological screening survey for each individual project) and mitigation measures for general impacts (Measures 4.6-1 through 4.6-3, including Table 4.6-4) would reduce each project's contribution to collective impacts on biological resources. Given the limited extent of WSIP project overlap in this region, these measures combined with coordination of construction staging and access (Measure 4.16-4b) would reduce this *potentially significant* collective impact to less than significant.

- *Peninsula Region – Lower Crystal Springs Dam Vicinity*. Staging areas for the CS/SA Transmission (PN-2) and Lower Crystal Springs Dam (PN-4) projects could overlap or affect the same areas for a longer duration. Increased traffic and the inadvertent use of road shoulders when vehicles pass could have a potentially significant collective impact on the endangered San Mateo woolly sunflower. Implementation of SFPUC Construction Measure #8 (biological screening survey for each individual project) and mitigation measures for general impacts (Measures 4.6-1 through 4.6-3, including Table 4.6-4) would reduce each project's contribution to collective impacts on biological resources. These measures combined with consolidation of construction staging and access (Measure 4.16-4b) would reduce this collective impact; however, protection of San Mateo woolly sunflower individuals would be problematic, since incidental disturbance of plants along the road shoulder would be difficult to completely avoid. Therefore, the collective impact in the Peninsula Region would be *potentially significant and unavoidable*.

- *San Francisco Region*. As indicated in Figure 4.16-1, construction of WSIP projects in this region would have the potential to overlap in San Francisco streets. Collective impacts on sensitive biological resources would not be expected (*not applicable*).

Cultural Resources

Impact 4.16-5: Collective increase in impacts related to archaeological, paleontological, and historical resources.

Section 4.7 describes potential impacts of the WSIP on paleontological and archaeological resources (Impacts 4.7-1 and 4.7-2); it also evaluates the effects of new construction on historical resources, including historic districts or contributors to historic districts (Impact 4.7-3), on individual facilities within the system (Impact 4.7-4); and on adjacent historical resources (Impact 4.7-5).

Multi-regional Collective Impacts

Multi-regional collective WSIP impacts on cultural resources are not expected to occur because the site-specific impacts of the various WSIP facility projects on individual paleontological, archaeological, or historical resources were not found to be additive. As described under Impact 4.7-4, select WSIP facility improvement projects could result in significant impacts on an individual historic facility, but the combined impacts from these projects do not represent a collective impact on historical resources. For example, the potentially significant impact on the potentially historic Irvington Portal as part of the New Irvington Tunnel project (SV–4) is distinct from the potentially significant impact on the potentially historic Crystal Springs Pump Station (PN–2); impacts on these two different historic facilities within the SFPUC regional water system do not, in combination, represent a larger, multiregional collective impact. WSIP project effects on potential paleontological and archaeological resources are similarly site-specific and considered to have a system-wide or region-wide collective effect. This impact is not applicable with respect to effects on individual resources.

Impact 4.7-3 addresses the issue of potential effects of one or more WSIP projects on the historical significance of historic districts or resources that would be contributors to a historic district. That analysis concludes that removal and replacement of the historic Calaveras Dam (SV–2) could, for example, represent a potentially significant, unavoidable impact on a historic district, if one were determined to be present. This impact would be distinct from the potentially significant impact on historic districts due to implementation of the CS/SA Transmission project (PN-2) in the vicinity of Crystal Springs Reservoir on the Peninsula.

Elsewhere, potential historic districts may have boundaries that extend beyond the WSIP regional boundaries identified in this PEIR. Such districts would be identified based on an appropriate historical context and significance, which may not correspond with the SFPUC water system regions. Implementation of SFPUC Construction Measure #9 (cultural resources) and various measures to document and protect historical resources (Measures 4.7-4a, through 4.7-4f) would reduce each project's impact on any historic districts that may be located in more than one region. Mitigation measures identified during project-level CEQA review are expected to reduce the potential collective effect of these projects to a level that is *less than significant*.

Localized Collective Impacts

In general, potential impacts on paleontological and archaeological resources (Impacts 4.7-1 and 4.7-2) would be site-specific (dependent on local conditions) and would not be additive or collective. Therefore, the WSIP projects would not have any localized collective impacts on these resources. Section 4.7 also analyzes the WSIP's potential for impacts on the historical significance of potential historic districts (Impact 4.7-3), individual facilities (Impact 4.7-4), and adjacent historical resources (Impact 4.7-5). As with impacts on paleontological and archaeological resources, impacts on historical resources are typically not additive, and thus the potential for collective impacts is generally low.

Localized collective impacts on historical resources could occur, however, when (1) multiple WSIP projects are proposed in the same general area and could each affect the same individual historic facility/resource, or (2) when multiple WSIP projects could each affect one or more facilities/resources that are part of an historic district. Figure 4.16-1 identifies where WSIP projects overlap geographically. The potential for such localized collective impacts on historical resources is discussed below by region:

- San Joaquin Region. Four of the five WSIP projects in this region (Advanced Disinfection, SJ-1; SJPL System, SJ-3; SJPL Rehabilitation, SJ-4; and Tesla Portal Disinfection, SJ-5) would overlap at or near the Tesla Portal. These projects could affect potential historical resources that could be contributors to a potential historic district associated with the implementation of John R. Freeman's plan for the development of the Hetch Hetchy system, such as the San Joaquin Pipelines, Tesla Portal, and the caretaker's residence adjacent to the proposed facilities. Implementation of SFPUC Construction Measure #9 (cultural resources) and various measures to document and protect resources (Measures 4.7-4a through 4.7-4f) would reduce each project's impact such that these projects would not have a significant, localized collective. This impact would be *less than significant.*

- Sunol Valley Region. Three projects in the region (Calaveras Dam, SV-2; New Irvington Tunnel, SV-4; and SABUP, SV-6) could result in a significant impact on the historical significance of individual facilities (Impact 4.7-4) and on adjacent historic resources (Impact 4.7-5). Implementation of SFPUC Construction Measure #9 (cultural resources) and various measures to document and protect resources (Measures 4.7-4a through 4.7-4f) would reduce each project's impact such that the residual collective impact on individual facilities would be less than significant.

  Given the concentration of water system facilities in the Sunol Valley Region that are more than 45 years old, some of which were previously identified as historical resources for the purposes of CEQA, it is possible that one or more historic districts could be present in this region. More detailed assessment to identify historic districts and potential impacts of the WSIP projects on any historic districts, if present, will occur during project-level environmental review. Because it has not been determined whether the Sunol Valley Region or a portion of this region meets the National Register criteria or California Register criteria as a historic district (or districts), or whether the WSIP projects in the Sunol Valley Region could cause a substantial adverse change to such a district(s), this PEIR conservatively considers the collective effect of the six WSIP projects in this region on historic districts to be *potentially significant and unavoidable*. Measures 4.7-4a through 4.7-4f could reduce the significance of this impact but the impact is still considered significant at the programmatic level; until project-level environmental review will further define the impact and identify additional measures to reduce this potential effect to a less-than-significant level.

- Bay Division Region – Irvington Portal in Fremont. The three WSIP projects in this region (BDPL Reliability Upgrade, BD-1; BDPL 3 and 4 Crossover, BD-2; and BDPL 3 and 4 Seismic Upgrade at Hayward Fault, BD-3) could have potentially significant impacts on the historical significance of a historic district (Impact 4.7-3), individual facilities (Impact 4.7-4), or adjacent facilities (Impact 4.7-5). These projects would be located near or adjacent to the Bay Division Pipelines and the existing Irvington Portal, both of which are potential historic facilities. One or more of the Bay Division Pipelines could be a contributor to a potential historic district related to the implementation of John R. Freeman's plan for the development of the Hetch Hetchy system. There could also be individual resources in this program that are historically significant. Implementation of SFPUC Construction Measure #9 (cultural resources) and various measures to document and protect resources (Measures 4.7-4a through 4.7-4f) would reduce each project's impact such that the potential collective effect of these projects would be *less than significant*, particularly on the Bay Division Pipeline because portions of the existing pipelines would remain following construction.

- *Peninsula Region – Lower Crystal Springs Dam Vicinity*. Potential alteration of the potentially historic Crystal Springs Pump Station (CS/SA Transmission, PN-2) and the historic Lower Crystal Springs Dam (PN-4) could have potentially significant impacts on the historical significance of the individual facilities (Impact 4.7-4) and adjacent facilities (Impact 4.7-5). Implementation of SFPUC Construction Measure #9 (cultural resources) and various measures to document and protect resources (Measures 4.7-4a through 4.7-4f) would reduce each project's impact such that the residual collective impact on individual facilities would be less than significant.

  Given the concentration of water system facilities in the Peninsula Region that are more than 45 years old, some of which were previously identified as historical resources, it is possible that a historic district, or multiple historic districts, could be present in the Peninsula Region. More detailed assessment to identify historic districts and potential impacts of the WSIP project on any historic districts, if present, will occur during project-level environmental review. Because it has not been determined whether the Peninsula Region or a portion of this region meets the National Register criteria or California Register criteria as a historic district (or districts), or whether the WSIP projects in the Peninsula Region could cause a substantial adverse change to such a district(s), this PEIR conservatively considers the collective effect of the five WSIP projects in this region on historic districts to be *potentially significant and unavoidable*. Measures 4.7-4a through 4.7-4f could reduce the significance of this impact, but the impact is still considered significant at the programmatic level; project-level environmental review will further define the impact and identify additional measures to reduce this potential effect to a less-than-significant level.

  San Francisco Region. Two of the WSIP projects in this region (SAPL 3 Installation, SF-1, and Recycled Water Projects, SF-3) could have potentially significant impacts on historical resources. The SAPL 3 Installation project could effect a historic district (Impact 4.7-3), individual facilities (Impact 4.7-4), or adjacent facilities (Impact 4.7-5). These potential resources include the Baden-Merced Pipeline. The Recycled Water projects (SF-5) has the potential to cause a substantial adverse change to an adjacent facility (Impact 4.7-5) – that is, the historic Fleishhacker Bath House, which was built in 1925, which could be indirectly affected under some project scenarios. The collective impact on historical resources is *not applicable*, however, because there would be no overlapping or collective impact in this region.

Traffic, Transportation, and Circulation

Impact 4.16-6: Collective traffic increases on local and regional roads.

As described in Section 4.8, implementation of the WSIP could cause traffic delays as a result of construction activities and construction vehicles. Construction activities would comply with the encroachment permit requirements (from Caltrans, county agencies, and/or local jurisdictions) for construction affecting public rights-of-way (Impacts 4.8-1 and 4.8-2). Implementation of traffic control plans (Measure 4.8-1) would reduce each project's individual local impacts to a less-than-significant level. However, even with mitigation, the WSIP projects together could significantly increase traffic delays *across* and *within* the five regions due to construction in public roadways and construction vehicles traveling to and from project sites.

WSIP construction activities would take place between 2007 and 2014; however, most projects would occur between 2009 and 2012, and the greatest number of projects would be under construction between 2009 and 2010 (see Table 4.16-1). Many of these projects involve construction within or across public roadways, which would temporarily reduce the available capacity and result in increased traffic delays. In addition, under many of the WSIP projects, construction vehicles would travel to and from material suppliers and excavation disposal or reuse sites. These vehicles would use the same regional freeways (e.g., Highway 101, I-5, I-580, I-680), resulting in increased truck traffic on segments where construction trucks from multiple projects overlap, and such increases could, at times, lower travel speeds on these roadways.

As described below, implementation of additional measures (appointing a traffic coordinator and preparing combined traffic control plans for the San Joaquin and Sunol Valley Regions) would reduce collective impacts within specific regions, but might not reduce multi-regional collective traffic impacts to a less-than-significant level. Traffic impacts of the individual projects would be evaluated in more detail during separate, project-level CEQA review, at which time the potential for combined or collective impacts of multiple projects would be reassessed.

Multi-regional Collective Impacts

Multi-regional collective impacts would occur when the travel routes of individual drivers cross multiple roadways affected by WSIP construction activities within one or more regions, and/or when construction vehicles use regional roadways. Multi-regional collective impacts would include increased travel times; however, the extent and duration of delays would vary depending on individual driver origins and destinations, time of travel, and use of alternate routes. Implementation of Measure 4.16-6a (identifying a program construction coordinator to coordinate project specific traffic control plans to minimize multi-regional impacts) would serve to offset the potential multi-regional collective traffic impacts, but might not reduce impacts to a less-than-significant level. Therefore, the multi-regional collective traffic impacts are considered *potentially significant and unavoidable*.

Localized Collective Impacts

Implementation of the WSIP would result in potential impacts on traffic and circulation, including increased construction vehicles and traffic delays, loss of parking, traffic safety issues, access disruption, and increased operational traffic (Impacts 4.8-1 and 4.8-3 through 4.8-6). These impacts could be collective where the construction schedules of multiple WSIP projects overlap (see Table 4.16-1).

For each WSIP project, truck trips generated by overlapping projects would be dispersed throughout the day, and construction workers for the projects would commute to and from the worksites primarily before or after peak traffic hours. The percent increase in traffic volumes caused by project-generated construction traffic on the arterials and freeways serving the WSIP project sites would not be substantial, while the project-generated trips on local serving roadways would represent a higher (more noticeable) percent increase in daily traffic volumes. Project traffic would not significantly disrupt daily traffic flow on these roadways. However, drivers would experience intermittent delays if they were traveling behind a construction truck.

Collective traffic impacts could occur if there were overlapping construction schedules in areas with limited construction access, since construction vehicles would have to share the same access route(s). The total number of vehicle trips added to the common route(s) due to concurrent construction of multiple WSIP projects could be collectively higher than the maximum number of daily and hourly vehicle trips used to determine impacts of a single WSIP project. However, because the timeframe of maximum trip generation would vary among the WSIP projects, the maximum traffic flows on the common route(s) would not necessarily be the sum of the maximum trips generated by the overlapping projects.

When overlapping areas in Figure 4.16-1 are considered in conjunction with traffic volumes on construction access roads identified in Table C.5 (Appendix C), the potential for collective traffic impacts would be as follows:

- San Joaquin Region – Tesla Portal. Construction of the SJPL System project (SJ-3) could overlap with construction of the Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) projects. Implementation of traffic control plans for each project (Measure 4.8-1) and coordination of individual traffic control plans for projects in the Tesla Portal vicinity (Measure 4.16-6b) would reduce this *potentially significant* collective impact to a less-than-significant level.

  Construction traffic for the Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) projects would use I-580, Chrisman Road, and Vernalis Road for site access. The number of daily truck trips associated with construction of the Advanced Disinfection project has not yet been determined, but would likely be similar to the number of truck trips generated by the Tesla Portal Disinfection project (i.e., an average of about 15 truck trips per day and a maximum of 40 truck trips per day). Although the construction schedules of these two projects could overlap, the increase in the number of daily construction vehicle trips could likely be accommodated within the existing capacity of the access routes, and the Advanced Disinfection and Tesla Portal Disinfection projects would not result in significant collective traffic impacts. With implementation of a traffic control plan for each these projects (Measure 4.8-1) and coordination of individual traffic control plans for projects in the Tesla Portal vicinity (Measure 4.16-6b), collective construction-related traffic impacts associated with these two projects would be reduced to a less-than-significant level.

- *Sunol Valley Region – Calaveras Road*. To varying degrees, the six projects in this region would utilize Calaveras Road, I-580, and I-680 for haul and delivery routes as well as site access. Current schedule projections estimate that these projects could overlap for up to two years. Accordingly, there could be significant increases in truck traffic along Calaveras Road and I-680. The volume of construction traffic would vary depending on the particular construction phase of each project. However, during a two-year period (2009 and 2010), four or five projects could overlap (different combination of projects each year; see Table C.5, Appendix C and Table F-3, Appendix F for estimated traffic volumes), resulting in periods with up to approximately 1,200 daily construction-generated vehicle trips (including inbound and outbound construction worker and construction truck trips) on Calaveras Road. It should be noted that the number of truck trips associated with the Calaveras Dam project (SV-2) might be reduced if fill materials could be found or processed in the dam vicinity.

  Increased construction vehicles on Calaveras Road between Geary Road and I-680, as well as on I-680, would increase delays due to the slower speeds and larger turning radii of trucks. The increase in truck traffic resulting from multiple projects would be considerable in relation to the capacity of Calaveras Road (one travel lane in each direction) and would result in *potentially significant* collective traffic impacts. Although I-680 has additional capacity in the vicinity of Calaveras Road, an increase in the number of trucks accessing the freeway on an uphill grade and merging with through-traffic could interfere with freeway operations.

  The entire length of Calaveras Road between I-680 and Calaveras Dam would be subject to damage due to the combined truck traffic associated with the six WSIP projects in this region. Trucks carrying sand and gravel from Sunol Valley to the dam could affect access to Sunol Regional Park.

  Implementation of traffic control plans for each project (Measure 4.8-1) along with a coordinated Sunol Valley traffic control plan (Measure 4.16-6c) would reduce this collective impact to a less-than-significant level.

- *Bay Division Region – Irvington Portal in Fremont*. The haul/delivery/site access route for the New Irvington Tunnel (SV-4) exit portal would include a new access road constructed through a residential neighborhood to connect the portal with Mission Boulevard (Highway 238) and the I-680 freeway. Due to the possible overlap in the construction schedules of the New Irvington Tunnel and BDPL Reliability Upgrade (BD-1) projects, there could be substantial increases in haul and delivery truck traffic in this area; these traffic increases could substantially affect the capacity of Mission Boulevard, a *potentially significant* collective impact. Implementation of traffic control plans for each project (Measure 4.8-1) and coordination of individual traffic control plans (Measure 4.16-6a) would reduce potential collective traffic impacts to a less-than-significant level.

- *Peninsula Region – Lower Crystal Springs Dam Vicinity*. Although construction of the CS/SA Transmission (PN-2) and Lower Crystal Springs Dam (PN-4) projects would not overlap (one project is scheduled to end just as the other begins), there is some potential for short-term combined increases in construction traffic on Crystal Springs Road near Lower Crystal Springs Reservoir. The number of daily truck trips associated with these two projects has not yet been determined, but it is expected that the number of truck trips would be similar to that generated by the Calaveras Dam project (SV-2) (i.e., up to 40 truck trips per day for each project, for a total of 80 truck trips per day). Construction vehicles associated with the HTWTP Long-Term project (PN-3) would also use Crystal Springs Road and Skyline Boulevard, although the construction schedules for all three projects are not expected to overlap. Implementing a traffic control plan for these projects (Measure 4.8-1) and coordinating individual traffic control plans (Measure 4.16-6a) would reduce any *potential significant* collective traffic impacts to a less-than-significant level.

- *San Francisco Region*. Pipeline construction associated with the SAPL 3 Installation (SF-1) and Recycled Water Projects (SF-3) could overlap in the same San Francisco streets. There could also be an overlap in vicinity of the San Francisco Zoo, which is identified as a possible site for facilities under the Groundwater Projects (SF-2) and Recycled Water Projects. The volume of overlapping construction traffic would vary depending on the location of each project (some project locations have not yet been determined) and particular construction phase of each project. However, each project is projected to result in about 20 truck trips per day. Implementing a traffic control plan for these projects (Measure 4.8-1) and coordinating individual traffic control plans (Measure 4.16-6a) would reduce any *potential significant* collective traffic impacts to a less-than-significant level. In addition, each project's construction activities would be coordinated by the San Francisco Department of Public Work's Street Construction Coordination Center (which coordinates utility excavation activities).

Air Quality

Impact 4.16-7: Collective increases in construction and/or operational emissions in the region.

Section 4.9 evaluates the air quality impacts associated with implementation of the WSIP. Potential air quality impacts include increases in dust and equipment emissions during construction, exposure to diesel particulate matter (DPM), tunnel-related emissions, operational emissions, odors, secondary emissions from power generation and conflicts with regional and statewide air quality planning (Impacts 4.9-1 through 4.9-7). Tunnel-related emissions would be site-specific and would not have a collective impact (Impact 4.9-3).

Multi-regional Collective Impacts

Criteria Pollutants

As summarized in Table 4.9-5, construction of the WSIP would result in potentially significant multi-regional collective increases in air pollutant emissions in the San Joaquin Valley Air Basin and the San Francisco Bay Area Air Basin. Table 4.9-5 indicates that onsite construction-related air pollutant emissions would exceed the applicable BAAQMD and SJVAPCD thresholds within the San Joaquin, Sunol Valley, and Bay Division regions, but not within the Peninsula and San Francisco regions. However, when emissions from all regions are considered together, construction-related emissions would be collectively significant. Implementation of the mitigation measure requiring dust and exhaust controls, but modified so it applies to all WSIP projects (Measure 4.16-7a), would be required to address the WSIP's collective impact on criteria air pollutants. Although these measures would reduce each project's impact incrementally, there would still be a residual contribution from each project to the region's nonattainment status for ozone and particulate matter (PM_{10} and $PM_{2.5}$) in both the San Francisco Bay Area and San Joaquin Valley Air Basins. Given the region's nonattainment status for ozone and particulate matter, the residual multi-regional collective impact associated construction of the WSIP as a whole is considered *potentially significant and unavoidable*.

Non-GHG air quality emissions during operation of the WSIP facility improvement projects would be required to comply with the air quality regulations of the Bay Area Air Quality Management District (BAAQMD) and San Joaquin Valley Air Pollution Control District (SJVAPCD), which would ensure consistency with regional air quality planning efforts (Impacts 4.9-4 and 4.9-5). Therefore, multi-regional collective air pollutant emissions from priority pollutants associated with operation of the WSIP as a whole would be *less than significant*.

GHG Emissions

Sources of GHGs from WSIP projects include those associated with construction equipment and increases in vehicle traffic and use of refrigerants during facility operations. However, as documented in Section 4.9 (Impact 4.9-7) increases in GHGs from construction sources associated with WSIP projects would be minimal.

The WSIP would also result in secondary operational increases in GHG emissions as a result of electricity generated to meet the WSIP's increase in energy demand (Impact 4.9-7). Although electricity for the WSIP projects would be derived primarily from hydroelectric sources, power would need to be purchased by current customers of the SFPUC Power Enterprise from the grid when less hydroelectric power is available, particularly during the summer and fall months. The WSIP's incremental increase in power demand during project operations (the portion that is not from hydroelectric or alternative energy sources) would indirectly serve to sustain rather than reduce current GHG emissions from these emission sources. The WSIP projects at completion would create approximately 14,260 metric tons of CO_2-equivalent emissions by consuming hydroelectric power that is no longer available to current users. Compared to the current annual inventory of 427,000,000 metric tons in California (California Energy Commission, 2006), this represents 0.0033 percent of that inventory. Planned increases in water distribution and treatment system efficiencies will offset a limited portion of the increased power demand, but not enough to eliminate the increase in GHG emissions that would result from WSIP-diverted electrical power. Nevertheless, the total increased power demand associated with the operation of the WSIP projects is a small fraction of total state demand.

As the CARB's Early Action Measures and CEC's greenhouse gases emission performance standard for local, public-owned electric utilities become effective (see discussion under Regulatory Framework, Greenhouse Gas Emissions Limits), the SFPUC will implement them as required to reduce GHG emissions from the WSIP project operations. Given the minimal contribution of GHG emissions from the WSIP, continuing implementation of GHG reduction actions by the CCSF and SFPUC and additional GHG reduction actions that SFPUC will take as part of the WSIP project (see above under "Existing Setting"), the WSIP projects would not conflict with the State's goals of reducing GHG emissions to 1990 levels by 2020. Therefore, residual multi-regional collective GHG emissions associated with construction and operation of the WSIP as a whole would be less than significant.

As part of implementation of the WSIP, the SFPUC will also be required to implement mitigation measures related to exhaust control (see Measures 4.9-1b, 4.9-1d, and 4.16-7a), waste reduction measures (Measure 4.11-2), and feasible energy efficiency measures in applicable WSIP projects, consistent with the *Energy Action Plan II* priorities for reducing energy usage (as specified in Measure 4.15-2). Implementation of these measures would also achieve reductions that would help minimize overall GHG emission increases. In addition, as CARB's Early Action Measures become effective, the SFPUC will implement them as required to reduce GHG emissions from the WSIP-related activities.

Localized Collective Impacts

During construction of the WSIP projects, worker vehicles and diesel haul/delivery trucks would generate offsite emissions. Localized short-term collective increases in emissions of DPM (the particulates of greatest concern) could occur in overlapping areas if construction activities associated with multiple WSIP projects affected the same access routes. As outlined in Impact 4.9-2, a cancer risk between 1 and 10 in a million is conservatively considered to be potentially significant for purposes of this PEIR (20,000 truckloads or 40,000 trips = 1 in a million; 200,000 loads or 400,000 trips = 10 in a million). Conducting a health risk screening or using soot filters on haul trucks (Measure 4.9-2a) and vacating the two SFPUC Land Managers' residences (Measure 4.9-2b) are identified in Section 4.9 for certain projects. As described below, when overlapping areas in Figure 4.16-1 are considered in conjunction with traffic volumes and construction access roads identified in Table C.5 (Appendix C), the potential for collective air quality impacts in overlapping areas could necessitate implementation of this measure for additional projects, as follows:

- <u>San Joaquin Region</u>. The haul routes for up to four WSIP projects could affect the same residents near Tesla Portal (i.e., along Chrisman and Vernalis Roads, the access route between Tesla Portal and I-580). Residents living along this route could be exposed to increases in DPM from haul truck and delivery traffic during construction of the western segments of the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects, in addition to the Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) projects if construction schedules overlapped in the Tesla Portal vicinity. Together, these four projects are not expected to generate over 40,000 truck trips on Chrisman or Vernalis Roads over the entire period of construction, but peak truck volumes could depending on the extent of excavation spoils that are hauled offsite. Most residences along these roads are set back

250 to 300 feet, reducing the potential for exposure to DPM health risks. However, if combined truck trips were to exceed 40,000 on Chrisman or Vernalis Roads, the combined or collective impacts would be *potentially significant,* and implementation of the mitigation measure requiring a health risk screening or use of soot filters on haul trucks, but modified so it applies to all projects in this region (Measure 4.16-7b), would reduce this collective impact to a less-than-significant level.

- *Sunol Valley Region*. Due to the overlap in construction schedules for proposed WSIP projects within this region, there could be significant combined or collective increases in haul and delivery truck traffic along Calaveras Road in the Sunol Valley. As indicated in Table 4.9-6, truck trips could exceed the significant "10 in a million" threshold or the potentially significant "1 in a million" threshold, depending on the proportion of excavation spoils that would be hauled offsite. Therefore, the combined or collective DPM impact would be *potentially significant* for all projects in the Sunol Valley Region. However, exposure of sensitive receptors to elevated DPM levels would be limited to occupants of the two SFPUC Land Managers' residences. Implementation of the mitigation measure requiring the two SFPUC Land Managers' residences be vacated, but modified so it applies to all projects in this region (Measure 4.16-7c), would reduce this collective impact to a less-than-significant level.

- *Bay Division Region – Irvington Portal in Fremont*. Outside of the Sunol Valley, the haul route for the New Irvington Tunnel (SV-4) exit portal would be a new access road constructed through a residential neighborhood to connect the portal with Mission Boulevard (Highway 238) and I-680. Due to the possible overlap in construction schedules for the New Irvington Tunnel and BDPL Reliability Upgrade (BD-1) projects, this neighborhood could be subject to combined DPM increases if there were any overlap in haul and delivery truck traffic for these two projects. Potential combined increases in construction traffic would be evaluated in more detail as part of separate, project-level CEQA review for these two projects. If combined truck trips were to exceed 40,000 on this access road over the entire construction period, the combined or collective impacts would be potentially significant. However, completion of a health risk screening or use of soot filters on haul trucks would be required for the BDPL Reliability Upgrade project under Measure 4.9-2a as well as at the exit portal for the New Irvington Tunnel project (SV-4) under Measure 4.16-7c (above). Therefore, implementation of this measure would reduce each project's impact such that the residual collective impact would be *less than significant with mitigation*.

- *Peninsula Region – Lower Crystal Springs Dam Vicinity*. Given the limited amounts of surface disturbance and facility construction associated with these three projects, it is expected that the combined DPM levels for this region would be *less than significant* (excess cancer risk would be less than 1 in a million, or 40,000 total truck trips).

- *San Francisco Region*. The combined increase in DPM levels associated with all three WSIP projects in this region would be *less than significant* (combined excess cancer risk would be less than 1 in a million); however, this conclusion would need to be confirmed at the project level due to the potential proximity of construction activities to sensitive receptors.

Noise and Vibration

Impact 4.16-8: Collective increases in construction-related and operational noise.

Multi-regional Collective Impacts

Section 4.10 identifies potential noise and vibration impacts associated with construction and operation of WSIP facilities. As described in Impacts 4.10-1, 4.10-3, and 4.10-4, there could be potentially significant noise and vibration impacts at most project sites. However, these potential impacts would be site-specific and would not be additive or collective. Therefore, the WSIP projects would not have a multi-regional collective impact on noise (*not applicable*). Since most construction noise impacts would be specific to each facility site, collective or overlapping noise impacts could only occur at adjoining construction sites or along common haul/delivery routes where overlapping schedules for two or more facilities with a shared haul/delivery route could result in combined noise increases. This localized issue is discussed below.

Localized Collective Impacts

Localized collective increases in noise could occur in overlapping areas if construction activities associated with multiple WSIP projects affected the same adjacent sensitive receptors or if haul/delivery trucks for multiple projects used the same access routes. When overlapping areas in Figure 4.16-1 are considered in conjunction with traffic volumes and construction access roads identified in Table C.5 (Appendix C), the potential for collective noise impacts in overlapping areas would be as follows:

- *San Joaquin Region – Tesla Portal*. Haul and delivery trucks would use Chrisman and Vernalis Roads to access Tesla Portal from I-580, and residential receptors along this route could be subject to traffic noise increases. Collective noise increases along this route could occur from overlapping construction schedules for the Advanced Disinfection and Tesla Portal Disinfection projects (SJ-1 and SJ-5). If construction of the SJPL Rehabilitation project (SJ-4) were to occur in the Tesla Portal vicinity at the same time, truck traffic on these roads could increase further. Construction of the SJPL System project (SJ-3) in the Tesla Portal vicinity would prolong the duration that construction-related truck traffic would use these two roads, but this project would not overlap with the Advanced Disinfection and Tesla Portal Disinfection projects. It is possible that implementation of the mitigation measures limiting hourly truck volumes and restricting truck operations at night (Measures 4.10-2a and 4.10-2b), but modified so they apply to all projects in this region (Measure 4.16-8a), could reduce this collective impact to a less-than-significant level. However, since truck volumes and hours of truck operations are undetermined for these projects, potential collective noise impacts on residential receptors located along this route are conservatively considered to be *potentially significant and unavoidable.*

  Collective noise impacts associated with adjoining construction sites for the Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) projects at Tesla Portal could result in combined or prolonged construction-related noise impacts. Any construction activities associated with either the SJPL System (SJ-3) or SJPL Rehabilitation (SJ-4) projects in the Tesla Portal vicinity also could add to combined or prolonged construction-related noise impacts. Although there are no private residences near Tesla Portal (the closest residence is approximately 3,500 feet away), there is an SFPUC caretaker's residence at Tesla Portal.

Collective increases in daytime construction noise would be potentially significant for occupants of the caretaker's residence, but less than significant for private residences located to the south. While there could be potentially significant collective noise impacts on occupants of both the SFPUC caretaker's residence and private residences from any nighttime construction noise at Tesla Portal, given the distance to the nearest receptors, it is possible that this impact could be reduced to a less-than-significant level with implementation of noise controls (Measure 4.10-1a) and vacating the caretaker's residence (Measure 4.10-1b). However, since construction activities associated with any of these projects could extend beyond the typical daytime hours (during the evening or nighttime hours on weekends as well as weekdays), it is also possible that collective noise impacts could occur at both the SFPUC caretaker's residence and private residences. Therefore, the PEIR errs on the conservative side and has determined that *potentially significant and unavoidable* collective noise impacts could occur at these receptors if the hours of construction associated with these projects extended beyond the hours specified in local noise ordinances and local noise limits specified for nighttime hours cannot be met.

- *Sunol Valley Region – Calaveras Road*. Due to the overlap in construction schedules of proposed WSIP projects in this region, there could be significant collective increases in haul and delivery truck traffic along Calaveras Road in the Sunol Valley and on I-680. Collective hourly truck traffic increases (averaging 60 to 70 trucks per hour, inbound and outbound, see Table F-2, Appendix F) from these projects would not collectively cause an exceedance of the 70-dBA speech interference criterion adjacent to this road (approximately 80 trucks per hour would cause an exceedance of this criterion). However, if truck operations occurred during the nighttime hours, such collective hourly volumes would exceed the sleep interference criterion. There is one private residence 2,000 feet from Calaveras Road; at this distance, the residence would not be adversely affected by noise from daytime or nighttime collective truck traffic increases (speech or sleep interference criteria would not be exceeded and noise ordinance noise limits could feasibly be met). However, occupants of the SFPUC Land Manager's residence adjacent to Alameda East Portal could be significantly affected by collective nighttime truck noise along Calaveras Road, a *potentially significant* collective noise impact. Vacating this residence during construction of all projects in this region (Measure 4.16-8b) would reduce this potential collective noise impact to a less-than-significant level.

- *Bay Division Region – Irvington Portal in Fremont*. The haul route for the New Irvington Tunnel (SV-4) exit portal would be a new access road constructed through a residential neighborhood to connect the portal with Mission Boulevard (Highway 238) and I-680. Due to the possible overlap in construction schedules for the New Irvington Tunnel and BDPL Reliability Upgrade (BD-1) projects, there could be significant collective increases in haul and delivery truck traffic in this neighborhood. It is possible that limiting hourly truck volumes during the day (Measure 4.10-2a) and restricting nighttime truck operations (Measure 4.10-2b), but modified so they apply to both the New Irvington Tunnel and BDPL Reliability Upgrade projects (Measure 4.16-8a), could reduce this impact to a less-than-significant level. However, since haul routes, truck volumes, and hours of truck operations are undetermined for these projects, potential noise impacts on residential receptors in this area are conservatively considered to be *potentially significant and unavoidable*. The potential for such a collective noise impact would be evaluated in more detail as part of separate, project-level CEQA review for the New Irvington Tunnel and BDPL Reliability Upgrade projects.

Collective noise impacts associated with adjoining construction sites for the New Irvington Tunnel (SV-4) and BDPL Reliability Upgrade (BD-1) projects at Irvington Portal could result in combined or prolonged construction-related noise impacts. Due to the proximity of residential receptors (setbacks of less than 75 feet), *potentially significant and unavoidable* noise impacts could occur in this neighborhood if construction were prolonged (longer than two weeks), any simultaneous construction activities generated combined noise levels that exceeded the 70-dBA speech interference or 50-dBA sleep interference criteria, or construction activities extended beyond the ordinance time limits and could not meet local noise limits specified for nighttime hours.

- *Peninsula Region – Crystal Springs Road in the Lower Crystal Springs Dam Vicinity*. If construction activities associated with the CS/SA Transmission (PN-2) and Lower Crystal Springs Dam (PN-4) projects overlapped in the vicinity of Lower Crystal Springs Reservoir, there could be collective increases in haul or delivery truck traffic on Crystal Springs Road. Since truck traffic is expected to travel on I-280, collective truck traffic increases would occur primarily on the west end of this road between the pump station access road and I-280. It is possible that limiting hourly truck volumes during the day (Measure 4.10-2a) and restricting nighttime truck operations (Measure 4.10-2b), but modified so they apply to both CS/SA Transmission and Lower Crystal Springs Dam projects (Measure 4.16-8a), could reduce this impact to a less-than-significant level since the closest residential receptors are approximately 225 feet north of Crystal Springs Road. However, since haul routes, truck volumes, and hours of truck operations are undetermined for these projects, potential noise impacts on residential receptors in this area are conservatively considered to be *potentially significant and unavoidable*.

  Collective noise impacts associated with adjoining construction sites for the CS/SA Transmission (PN-2) and Lower Crystal Springs Dam (PN-4) projects in the Lower Crystal Springs Dam vicinity could result in combined or prolonged construction-related noise impacts. Since the closest residential receptors are approximately 500 feet from the Crystal Springs Pump Station, any collective increases in daytime construction noise would be less than significant. While there could be potentially significant collective noise impacts on the closest receptors from any nighttime construction noise in the Crystal Springs Pump Station vicinity, implementation of noise controls (Measure 4.10-1a) would reduce each project's impact such that the potential residual collective nighttime noise impact would be less than significant. However, since construction activities associated with these projects could extend beyond the typical daytime hours (during the evening or nighttime hours on weekends as well as weekdays), the PEIR errs on the conservative side and has determined that *potentially significant and unavoidable* collective noise impacts could occur at these receptors if the hours of construction associated with these projects extended beyond the hours specified in local noise ordinances and local noise limits specified for nighttime hours cannot be met.

- *San Francisco Region – Various Streets*. Pipeline construction associated with the SAPL 3 Installation (SF-1) and Recycled Water Projects (SF-2) could overlap in the same San Francisco streets. Such overlap could prolong the duration of construction-related noise increases (longer than two weeks) at affected sensitive receptors; however, any collective construction-related noise increases associated with these projects cannot be determined at this time and would be evaluated as part of separate, project-level CEQA review.

  There could also be a collective increase in haul/delivery trucks and associated noise if the same haul routes are used. These collective noise impacts would only occur if the construction schedules overlapped on the same streets. Since each project is projected to generate about 20 truck trips per day, collective increases from the overlap of these projects, either on San Francisco streets or near the zoo, are not expected to exceed the 70-dBA speech interference criterion in adjacent areas. However, if truck operations extended beyond the daytime and evening hours (between 10 p.m. and 7 a.m.), any collective truck traffic increases could exceed the 50-dBA sleep interference criterion, a potentially significant impact. Implementation of the mitigation measures limiting hourly truck volumes and restricting truck operations at night (Measures 4.10-2a and 4.10-2b), but modified so they apply to all projects in this region (Measure 4.16-8a), would reduce this collective impact to a less-than-significant level. However, since haul routes, truck volumes, and hours of truck operations are undetermined for these projects, potential noise impacts on residential receptors where haul routes overlap are conservatively considered to be *potentially significant and unavoidable*.

Public Services and Utilities

Impact 4.16-9: Collective impacts on utilities and landfill capacity.

Multi-regional Collective Impacts

Section 4.11 evaluates the WSIP's impact on regional landfill disposal capacity (Impact 4.11-2). Construction of WSIP projects could collectively generate approximately 2 million cubic yards of excavated materials requiring offsite disposal. When compared to the approximately 400 million cubic yards of remaining capacity in existing landfills across the WSIP study area (see Table 4.11-3), the WSIP's potential disposal requirements represent approximately 1/2 percent of the total remaining capacity. Implementation of waste reduction measures for design and construction (Measures 4.11-2a and 4.11-2b) would reduce each project's offsite disposal requirements such that the residual contributions to this collective impact would be *less than significant with mitigation*.

Localized Collective Impacts

Section 4.11 evaluates potential construction-related impacts on public utilities, including disruption of existing utilities (Impact 4.11-1) or required relocation of existing utilities (Impact 4.11-3). These potential impacts would be site-specific and would not be additive. Therefore, the WSIP projects would not result in localized collective impacts on existing public utilities (*not applicable*).

Recreational Resources

Impact 4.16-10: Collective effects on recreational resources during construction.

Multi-regional and Localized Collective Impacts

As described in Section 4.12, construction activities associated with some WSIP facilities could temporarily disrupt access to or use of recreational facilities. While implementation of the WSIP could result in the temporary closure or disruption of several recreational opportunities (displacing demand to other facilities and therefore potentially collectively increasing demand at some other regional facilities), the effects on recreational resources within the WSIP study area would be distributed over a relatively large area. Further, given the availability and diversity of recreational opportunities in the vicinity of the WSIP projects in each region as well as in the WSIP study area as a whole, the diversion of recreation users would not likely result in overcrowding or associated deterioration of recreational resources. Therefore, multi-regional collective impacts on recreational resources would be *less than significant*. Coordination with golf course and park planning staff (Measures 4.12-1 and 4.12-2) would also reduce each project's impact such that the residual contributions to localized collective impacts on recreational resources within each region would be *less than significant with mitigation*.

The WSIP water supply and system operations would have no impact on water-related recreational facilities or activities in the Alameda or Peninsula watersheds, as described in Sections 5.4.7 and 5.5.7. It would, however, affect recreational resources within the Tuolumne River watershed, as described in Section 5.3.8. Since facility impacts on recreational resources (described in Section 4.12) would not affect access to or use of the recreational resources in Yosemite National Park and the Tuolumne River watershed, no combined or collective multi-regional impacts on recreational resources in this area are expected to occur.

Agricultural Resources

Impact 4.16-11: Collective conversion of farmland to nonagricultural uses.

Multi-regional and Localized Collective Impacts

Section 4.13 identifies potential temporary and permanent impacts on agricultural resources associated with implementation of the WSIP. The permanent conversion of farmland would be site-specific and not additive or collective within the WSIP study area, since there is only one project in the San Joaquin Region and one project in the Sunol Valley Region (*not applicable* for localized overlapping impacts) that could affect agricultural resources. The SJPL System (SJ-3) and 40-mgd Treated Water (SV-3) projects could convert important farmland to nonagricultural use; since these projects are in two different regions, multi-regional collective impacts on agricultural resources could occur. Siting both of these facilities to avoid prime agricultural lands or offsetting its loss (Measure 4.13-2) would reduce each project's impact such that the residual contributions to this multi-regional collective impact would be *less than significant with mitigation*.

Hazards

Impact 4.16-12: Collective effects related to hazardous conditions and exposure to or release of hazardous materials.

Multi-regional Collective Impacts

Construction impacts associated with the potential to encounter hazardous materials or hazardous conditions, or to release hazardous materials during construction (Impacts 4.14-1, 4.14-2, and 4.14-4 through 4.14-6) would, for the most part, be site-specific and would not be additive or collective. Similarly, the potential for accidental releases of chemicals stored at the water treatment plants (Impacts 4.14-7 and 4.14-8) would also be site-specific and would not be additive or collective.

For many of the projects, soil excavated during construction could be classified as a hazardous waste, potentially requiring disposal at any of the three hazardous waste disposal facilities in California (Impact 4.14-1). With implementation of SFPUC Construction Measure #7 (hazardous materials) and preparation of a materials disposal plan (Measure 4.14-1b), project-level impacts related to disposal of hazardous wastes would be less than significant. As discussed above in Section 4.16-9, construction of the WSIP projects could collectively generate approximately 2 million cubic yards of excavated materials requiring offsite disposal. However, only a portion of that material would potentially be classified as a hazardous waste. Although project-level estimates have not been made to determine the quantity of soil that could be classified as a hazardous waste, it can be assumed based on historical land uses that the soil generated from the Peninsula and Alameda Creek watersheds would not be considered hazardous. Assuming, as a worst case, that 25 to 70 percent of the soil requiring offsite disposal from the Bay Division and San Francisco Region projects and 10 percent of the soil requiring offsite disposal from the SJPL System project (SJ-3) in the San Joaquin Region would be classified as hazardous, the total volume of soil requiring disposal as a hazardous waste could be up to 270,000 cubic yards.

The existing capacity of the three in-state hazardous waste disposal facilities is 18.8 million cubic yards, including 7.3 million cubic yards[4] at the Kettleman Hills Hazardous Waste Facility (Yarbrough, 2007), 9 million cubic yards at Buttonwillow (Buoni, 2006a), and 2.5 million cubic yards at Westmorland (Buoni, 2006b). In addition, Kettleman Hills is in the process of permitting another 15-million-cubic-yard waste disposal unit to be constructed by 2013, when the current disposal unit is scheduled for closure. Based on worst-case estimates, the WSIP's potential hazardous waste disposal requirements would represent approximately 1.5 percent of the total existing hazardous waste disposal capacity in the region, and less than 1 percent of the disposal volume expected to be available by 2013. Therefore, the WSIP's contribution to this multi-regional collective impact on hazardous waste disposal capacity would be *less than significant*.

[4] The total capacity of the Kettlemen Hills Hazardous Waste Facility includes a 5-million-cubic-yard expansion that will be constructed prior to 2013.

Localized Collective Impacts

Impact 4.14-3 describes the potential for an increased risk of wildland fires during construction in high fire hazard areas. Potential impacts at individual WSIP sites would be mitigated to a less-than-significant level through compliance with the Public Resources Code provisions governing the use of construction equipment in fire-prone areas. Because some WSIP project sites are near each other and would share access and haul/delivery routes, there could be a collective increase in fire hazards in the following overlapping areas, especially if construction were to overlap during the season of highest fire danger:

- *San Joaquin Region – Tesla and Oakdale Portals*. Potential overlap in high fire danger areas identified as "Wildland Area That May Contain Substantial Forest Fire Risks and Hazards" could occur in the San Joaquin Region at both the Tesla and Oakdale Portals. Both the Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) projects would be constructed at Tesla Portal in 2009 and 2010, and additional construction could occur at this portal during the same timeframe as part of the SJPL Rehabilitation project (SJ-4). Both the SJPL System (SJ-3) and SJPL Rehabilitation projects could also include construction at Oakdale Portal and, depending on the phasing of both projects, could overlap at this portal for some period of time between 2011 and the end of 2013.

- *Sunol Valley Region – Sunol Valley*. All six WSIP projects in this region are located in high fire danger areas and could be under construction between 2009 and 2010, with multiple projects under construction through 2012.

- *Bay Division Region – Irvington Portal in Fremont*. The BDPL Reliability Upgrade (BD-1) and New Irvington Tunnel (SV-4) projects could overlap at the Irvington Portal for some period of time between 2009 and the end of 2012.

- *Peninsula Region – Lower Crystal Springs Dam Vicinity*. If schedules change, both the CS/SA Transmission (PN-2) and Lower Crystal Springs Dam (PN-4) projects could be under construction in 2010 and 2011 in the Peninsula Region, and construction activities for both projects would be conducted in the vicinity of the Lower Crystal Springs Dam.

The potential collective increase in wildland fire risk could place an additional burden on the local fire service provider, particularly if access for emergency vehicles were impeded. The extent of this impact would depend on the actual timing and phasing of these WSIP projects. Notification of fire departments, as required under Measure 4.8-1 as part of each project's traffic control plan, would reduce each project's impact such that all residual contributions to this collective impact in all regions would be *less than significant with mitigation*.

Energy Resources

Impact 4.16-13: Collective increases in the use of nonrenewable energy resources.

Section 4.15 describes the potential for increased electricity demand associated with construction and operation of the WSIP projects. SFPUC Power Enterprise provides the energy required to operate the SFPUC regional water system, primarily from power generated by the SFPUC's hydroelectric facilities in the Hetch Hetchy system. Within the WSIP study area, annual average energy consumption for water system operation totals approximately 44 million kilowatt-hours (kWh). Implementation of the WSIP would increase annual operational energy consumption in the WSIP study area by approximately 39 million kWh, or approximately 89 percent over existing conditions. The increase would be highest in the San Joaquin Region due to the Advanced Disinfection project (SJ-1), which could use as much as 26.5 million kWh of electricity to provide disinfection of the Hetch Hetchy water supply to meet the requirements of the Long-Term 2 Enhanced Water Treatment Rule.[5]

As discussed in Chapter 5, Section 5.3.9, changes in water releases from WSIP system operations would increase SFPUC Power Enterprise's power production from an average of 1,618 million kWh in 2005 to an average of 1,641 million kWh in 2030. With this 23 million kWh increase in power production, the net increase in energy demand for the regional system under the WSIP would be approximately 16 million kWh, which represents less than 1 percent of SFPUC Power Enterprise's 2005 average production. In addition, changes in water supply and system operations under the WSIP would affect hydroelectric power generation downstream on the Tuolumne River at the Don Pedro Power Plant, which is operated by the Turlock Irrigation District (TID) and Modesto Irrigation District (MID). The WSIP system operations would result in a decrease in hydroelectric generation from the Don Pedro Power Plant of 14 million kWh (see Impact 5.3.9-1). Combined with the 16 million kWh increase in energy demand from the WSIP, the net loss in available hydroelectric energy attributable to the WSIP would be 30 million kWh, which is less than 0.1 percent of the estimated total energy usage in the counties within the WSIP study area.[6]

Although this increased energy consumption under the WSIP is small, the WSIP would utilize more hydroelectric power generated by SFPUC Power Enterprise, making slightly less hydroelectric power available to other users during times when there is an excess of hydroelectric power, and slightly increasing demands on other energy sources during the summer and fall months when SFPUC Power Enterprise does not generate enough power to meet its municipal demand and contractual obligations. In addition, the decrease in hydroelectric generation by the Don Pedro Power Plant would require the TID and MID to rely more on other sources of energy, possibly derived from fossil fuels. Electricity generation from nonrenewable sources contributes to greenhouse gas emissions and associated global warming effects (see Air Quality Impact 4.16-7 above for more discussion).

In accordance with Appendix F of the CEQA Guidelines, a project would have an adverse environmental effect if it were to use energy in an unnecessary, wasteful, or inefficient manner. Section 15126.4(a)(1) of the CEQA Guidelines further requires that an EIR describe feasible measures to minimize the inefficient and unnecessary consumption of energy where relevant.

---

5 The WSIP's collective energy impacts would be program-wide (multi-regional) rather than localized, since all WSIP projects affect the same power sources. Therefore, the WSIP projects would not result in localized collective impacts on energy (*not applicable*).

6 Total energy usage in Alameda, San Francisco, San Joaquin, San Mateo, Santa Clara, and Tuolumne Counties was 45,072 million kWh in 2000 (CEC, 2006). Assuming a 1.2 percent annual increase in energy consumption, the total usage in 2005 would have been 47,842 million kWh.

Implementation of the WSIP and the associated increase in energy demand is necessary to provide a reliable water supply of sufficient quality to meet future water quality regulations, including the Long-Term 2 Enhanced Water Treatment Rule. Furthermore, implementation of energy efficiency measures, which would be evaluated in more detail as part of project-level CEQA review for each WSIP project (Measure 4.15-2), and continued participation in demand-shifting programs, as described in Section 4.15, would ensure that energy would not be used in a wasteful or inefficient manner, and could reduce the projected increase in energy demand. The WSIP's multi-regional (program-wide) collective increase in operational energy demand would be *less than significant with mitigation*, because the increase in energy demand would be less than 1 percent of SFPUC Power Enterprise's existing average production; the increase in energy use and decrease in Don Pedro Power Plant hydroelectric production would be necessary to provide a reliable water source; and the energy would not be used in a wasteful or inefficient manner.

Construction activities associated with each WSIP project in all regions would require the use of fuels to operate construction equipment and transport employees and materials. Each project's impacts related to the wasteful use of fuels during construction would be reduced by certain exhaust control measures (limiting idling time and performing low-emissions tune-ups, as specified Measures 4.9-1b and 4.9-1d) such that the collective increase in construction-related energy consumption would be *less than significant with mitigation*.

4.17 Cumulative Effects

4.17 Cumulative Effects

4.17.1 Introduction and Approach

As defined in Section 15355 (CEQA Guidelines), a cumulative impact is the impact that results from implementing the proposed project together with other projects causing related impacts. The CEQA Guidelines require that EIRs discuss the cumulative impacts of a project when the project's incremental effect is "cumulatively considerable," meaning that the project's incremental effects are significant when viewed in connection with the effects of past, present, and reasonably foreseeable (i.e., probable) future projects. The discussion of cumulative impacts should include:

- Either: (1) a list of past, present, and probable future projects producing related or cumulative impacts; or (2) a summary of projections contained in an adopted general plan or similar document, or in an adopted or certified environmental document, that described or evaluated conditions contributing to a cumulative impact
- A discussion of the geographic scope of the area affected by the cumulative impact
- A summary of expected environmental effects to be produced by these projects
- Reasonable, feasible options for mitigating or avoiding the project's contribution to any significant cumulative effects

This analysis addresses the cumulative impacts associated with construction and operation of the WSIP facility improvement projects. Section 5.7 (in Chapter 5) presents the cumulative impacts associated with the WSIP's water supply and system operations. Chapter 7 discusses the cumulative effects associated with growth inducement and secondary effects of growth based on projections from adopted general plans and related environmental documents. The overall approach to the facilities impact assessment in Chapter 4 is described in Section 4.1.

This section presents an analysis of the *cumulative* impacts of the WSIP as a whole (i.e., the WSIP impacts identified in Sections 4.3 through 4.16 prior to mitigation, with the effects of mitigation measures considered in determining the significance of the WSIP's contribution of residual effects after mitigation to overall cumulative impacts) in combination with other proposed, planned, and approved projects from the past, present, and reasonably foreseeable future, including: (a) other SFPUC projects or activities in the WSIP study area, and (b) non-SFPUC projects or activities in the WSIP study area under the jurisdiction of other local agencies. The projects are listed by WSIP region in Tables 4.17-1 through 4.17-6 and are either: (1) planned, proposed, or approved but not yet constructed, or (2) recently completed or under construction (all as of July 2006).[1]

[1] Construction schedules for non-SFPUC projects were estimated based on information obtained in project-related documents such as initial studies and environmental impact reports; city, county, and regional agency websites; and interviews with representatives from local jurisdictions or regional agencies. In some cases, project schedules could not be estimated from these sources, but the projects were in sufficient stages of planning to be considered likely to start or complete construction before 2014, the planning horizon for construction of WSIP facilities. The schedules for these projects are listed as "Unknown." The estimated schedules are based on the most current information available during preparation of this PEIR (as of July 2006). However, as with all proposed development projects, estimated construction schedules are subject to revisions and delays and therefore could vary from the time periods indicated.

4.17.2 Projects Considered in Cumulative Analysis

Section 4.16 describes the collective impacts associated with construction and operation of the WSIP facilities based on the geographic scope of the affected environmental resource and the proposed project schedule. This section describes other "cumulative" projects, including past projects, projects currently under construction, and probable future projects that have or could potentially result in similar impacts as those resulting from the construction and/or operation of WSIP facility improvement projects. Cumulative projects identified by local and regional agencies as well as other projects planned or proposed by the SFPUC (including SFPUC projects funded with WSIP bond funds that are not analyzed in the PEIR for the reasons explained in Chapter 3, Section 3.1) are listed by region in **Tables 4.17-1** through **4.17-6**. The tables present the planning jurisdiction, a brief description, and the estimated construction schedule associated with each cumulative project. The tables also identify WSIP projects that could, in conjunction with the cumulative projects, contribute to cumulative effects and potential cumulative impact topics are identified.

The potential for cumulative impacts would depend on both the geographic locations and the construction schedules of the other projects. **Figure 4.17-1** shows the approximate locations of the cumulative projects listed in these tables. **Table 4.17-7** lists the potential schedule overlap between cumulative projects and WSIP projects. However, for future projects, construction schedules are often broadly estimated and may be subject to change. In addition, the construction schedules were unavailable for numerous projects listed in Tables 4.17-1 through 4.17-6; therefore, the estimated construction schedules for the projects were grouped into roughly five-year periods to determine the potential for schedule overlap with the WSIP projects.

Project information listed in Tables 4.17-1 through 4.17-6 is based on consultations with local jurisdictions within the San Joaquin, Sunol Valley, Bay Division, Peninsula, and San Francisco Regions (the local planning, community development, and public works/engineering departments of these agencies) as well as review of EIRs and information posted on agency websites. The tables include the following:

- Projects proposed by PG&E, AT&T, and other service providers
- Projects proposed by Caltrans, BART, Caltrain, and county transportation agencies
- Projects proposed by the SFPUC (including other planned water, wastewater, and power projects that are not part of the WSIP, or projects funded with WSIP bond funds that are not analyzed in the PEIR for the reasons explained in Chapter 3, Section 3.1), many of which are repair and rehabilitation projects[2]

[2] Projects listed in these tables do not necessarily represent all SFPUC repair and rehabilitation projects.

TABLE 4.17-1
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE SAN JOAQUIN REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Areas	Estimated Construction Schedule[b]
Other Non-SFPUC Planned or Approved Projects in the San Joaquin Region (Public and Private Developments)						
SJC-1	City of Waterford	Waterford Government Center	Construction of new East County Sheriff's Substation, an expanded County Branch Library and City of Waterford administrative offices (Stanislaus County, 2007).	SJPL System (SJ-3), SJPL Rehabilitation (SJ-4)	Impacts on sensitive habitats and species; increased surface runoff and water quality impacts; traffic impacts on regional roads (e.g., Highways 132 and 99) and associated air quality and noise impacts	2007–2009
SJC-2	City of Waterford	Reconstruction of Western Avenue	Reconstruction of Western Avenue from Kadota Avenue south to Highway 132 (City of Waterford, 2007).	SJPL System (SJ-3), SJPL Rehabilitation (SJ-4)	Traffic impacts along the southern reconstructed segment of the roadway near Highway 132 and associated air quality and noise impacts	2007–2008
SJC-3	Stanislaus County	Grizzly Ranch	Construction of 142 estate homes, interspersed among almond grove ranches on 2,843 acres, over a 10-year buildout period (City of Waterford, 2007; Borchard, 2006).	SJPL System (SJ-3), SJPL Rehabilitation (SJ-4)	Impacts on sensitive habitats and species; increased surface runoff and water quality impacts; traffic impacts on regional roads (e.g., Highways 132 and 99) and associated air quality and noise impacts; encroachment of nonagricultural uses onto farm orchards	2007–2017
SJC-4	City of Modesto	Beard Industrial Tract	Development of ongoing medium and heavy industrial infill projects (Kachel, 2006).	SJPL System (SJ-3), SJPL Rehabilitation (SJ-4)	Impacts on sensitive habitats and species; increased surface runoff and water quality impacts; traffic impacts on regional roads (e.g., Highways 132 and 99) and associated air quality and noise impacts; conversion of farmland to nonagricultural uses	Ongoing
SJC-5	City of Oakdale	Residential Subdivision	Phased construction of 200 units west of Central Avenue (Huey, 2006).	SJPL System (SJ-3), SJPL Rehabilitation (SJ-4)	Impacts on sensitive habitats and species; increased surface runoff and water quality impacts; traffic impacts on regional roads (e.g., Highways 132 and 99) and associated air quality and noise impacts	2007–2010
SJC-6	City of Riverbank	North Corridor Expressway – Local Improvements	Extension and widening of roads (Crane Road, Sterns Avenue, and Warnerville Road) for future connections to Highway 99 as part of this countywide project (Hightower, 2006).	SJPL System (SJ-3), SJPL Rehabilitation (SJ-4)	Impacts on sensitive habitats and species; increased surface runoff and water quality impacts; traffic impacts on regional roads (e.g., Highways 132 and 99) and associated air quality and noise impacts	2009–2013

TABLE 4.17-1 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE SAN JOAQUIN REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Areas	Estimated Construction Schedule[b]
Other Non-SFPUC Planned or Approved Projects in the San Joaquin Region (Public and Private Developments) (cont.)						
SJC-7	Stanislaus County	Kaiser Modesto Medical Center	Development of a full-service hospital facility with nursing towers, three medical office buildings, three parking garages (2,185 spaces), and a central utility plant in three phases, which began in 2004 and will be completed in 2025. Project includes replacement of the existing hospital, built to meet state seismic safety standards (City of Modesto, 2004).	SJPL System (SJ-3), SJPL Rehabilitation (SJ-4)	Impacts on sensitive habitats and species; increased surface runoff and water quality impacts; traffic impacts on regional roads (e.g., Highways 132 and 99) and associated air quality and noise impacts; and improved seismic safety and reliability of critical public facilities	Phase A: 2004–2008 Phase B: 2010–2013 Phase C: 2018–2025
SJC-8	Stanislaus County	Cornerstone Business Park	Construction of a 400,000-gross-square-foot business park with professional and medical office space adjacent to, and concurrent with, Phase A of Kaiser Medical Center (City of Modesto, 2004).	SJPL System (SJ-3), SJPL Rehabilitation (SJ-4)	Impacts on sensitive habitats and species; increased surface runoff and water quality impacts; traffic impacts on regional roads (e.g., Highways 132 and 99) and associated air quality and noise impacts	2004–2011
SJC-9	Stanislaus County/City of Modesto	Pelendale/ McHenry Specific Plan	Proposed specific plan to develop up to 386 residential units at Pelandale and McHenry Avenues on an 84.4-acre site currently occupied by commercial businesses, 15 mobile homes, and a public storage facility. The SPLJ System (SJ-3) and SJPL Rehabilitation (SJ-4) projects traverse the site from northeast to northwest. The SFPUC right-of-way is proposed for open space. Project approvals include a general plan amendment, annexation to the City of Modesto, and a permit from the SFPUC to develop within its right-of-way (City of Modesto, 2006).	SJPL System (SJ-3), SJPL Rehabilitation (SJ-4)	Increased surface runoff and water quality impacts; traffic impacts on regional roads (e.g., Highways 99 and 132) and associated air quality and noise impacts	2010–2014+
SJC-10	City of Modesto	Salida Boulevard/ Pelandale Avenue Interchange	Reconstruction of the Pelandale Avenue/Salida Boulevard Interchange (City of Salida, 2007).	SJPL System (SJ-3), SJPL Rehabilitation (SJ-4)	Construction-related traffic impacts on regional roads (e.g., Highways 132 and 99) and construction-related air quality and noise impacts	2007–2009
SJC-11	Stanislaus County	Highway 99/ Whitmore Avenue Interchange	Reconstruction of the Highway 99/Whitmore Avenue Interchange (Stanislaus County, 2007).	SJPL System (SJ-3), SJPL Rehabilitation (SJ-4)	Construction-related traffic impacts on regional roads (e.g., Highways 132 and 99) and construction-related air quality and noise impacts	TBD
SJC-12	Stanislaus County	Salida Hulling Almond Hulling Facility	Construction of relocated and expanded almond hulling and shelling facility on a 50.4-acre site (Stanislaus County, 2006).	SJPL System (SJ-3), SJPL Rehabilitation (SJ-4)	Impacts on sensitive habitats and species; increased surface runoff and water quality impacts; traffic impacts on regional roads (e.g., Highway 132) and associated air quality and noise impacts	2007–2009

TABLE 4.17-1 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE SAN JOAQUIN REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Areas	Estimated Construction Schedule[b]
Other Non-SFPUC Planned or Approved Projects in the San Joaquin Region (Public and Private Developments) (cont.)						
SJC-13	City of Modesto	Highway 132/ Highway 99 to Morse, Nebraska, or Dakota Avenue	Construction of a portion of the Modesto Freeway on a new alignment (Stanislaus County, 2007).	SJPL System (SJ-3), SJPL Rehabilitation (SJ-4)	Impacts on sensitive habitats and species; water quality impacts; construction-related traffic impacts on regional roads (e.g., Highways 132 and 99) and associated air quality and noise impacts	TBD
SJC-14	Stanislaus County	Highway 132/ Highway 33 Widening	Widening of Highway 132/Highway 33 to the San Joaquin River to four lanes (Stanislaus County, 2007).	Advanced Disinfection (SJ-1), SJPL System (SJ-3), SJPL Rehabilitation (SJ-4), Tesla Portal Disinfection (SJ-5)	Impacts on sensitive habitats and species; increased surface runoff and water quality impacts; construction-related traffic impacts on regional roads (e.g., Highway 132) and associated air quality and noise impacts	TBD
SJC-15	Stanislaus County	West Patterson Business Park	Phased development of flex, light industrial, and distribution warehouse uses on 832 acres. The current proposal is for 2.5 million square feet on a 224-acre site within a park between I-5, the Mendota Delta, Rodgers Road, and Sperry Avenue; remaining future development unknown (City of Patterson, 2003; Simpson, 2006).	SJPL System (SJ-3), SJPL Rehabilitation (SJ-4)	Impacts on sensitive habitats and species; increased surface runoff and water quality impacts; traffic impacts on regional roads (e.g., I-5) and associated air quality and noise impacts; construction-related water quality impacts	2006–2013+
SJC-16	Stanislaus County	Patterson Gardens	Phased construction of 940 single-family units, a 47-unit senior residential neighborhood, and 300,000 square feet of commercial office and recreational uses, including a 16-acre lake on a 305-acre site partly in agricultural use. The first phase was completed and the second phase is under construction (City of Patterson, 2003; Simpson, 2006).	SJPL System (SJ-3), SJPL Rehabilitation (SJ-4)	Impacts on sensitive habitats and species; increased surface runoff and water quality impacts; traffic impacts on regional roads (e.g., I-5) and associated air quality and noise impacts; conversion of farmland to nonagricultural uses	2006–2009
SJC-17	San Joaquin County/ Stanislaus County	RMC Pacific Vernalis Quarry Mining and Reclamation Project	Proposed sand and gravel extraction and processing of construction aggregate on 688 acres, with permitted active mining for 26 to 60 years on a 659-acre site in San Joaquin County (590 acres) and Stanislaus County (98 acres) (RMC Pacific Vernalis, 2006).	Advanced Disinfection (SJ-1), SJPL System (SJ-3), SJPL Rehabilitation (SJ-4), Tesla Portal Disinfection (SJ-5)	Water quality impacts; potential ground water and water quality impacts; operational traffic impacts on regional roads (e.g., Highway 132); operational air quality and noise impacts; conversion of non-productive farmland to commercial uses	2008–2068
SJC-18	San Joaquin County	Bird Road/ Highway 132 Interchange	Replacement of four-way stop with interchange facility at the intersection of Bird Road and Highway 132 (San Joaquin Council of Governments, 2007).	Advanced Disinfection (SJ-1), SJPL System (SJ-3), SJPL Rehabilitation (SJ-4), Tesla Portal Disinfection (SJ-5)	Construction-related water quality impacts; traffic impacts on regional roads (e.g., Highway 132) and associated air quality and noise impacts	2008–2009

TABLE 4.17-1 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE SAN JOAQUIN REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Areas	Estimated Construction Schedule[b]
Other Non-SFPUC Planned or Approved Projects in the San Joaquin Region (Public and Private Developments) (cont.)						
SJC-19	San Joaquin County	Mountain House Specific Plan I, II, and III	Long-term development of a new community on 4,360 acres consisting of 12 neighborhoods, 10 elementary schools, new community college, business park, public services, and recreation facilities and including 16,000 dwelling units, 21,600 jobs, and 39,000 residents over a 20- to 40-year buildout period (San Joaquin County, 1994; San Joaquin County, 2005).	**Indirect:** All San Joaquin Region projects	Traffic impacts on regional roads and associated air quality and noise impacts; disruption of existing established land use patterns; continuation of conversion of crop and farmlands to nonagricultural uses in San Joaquin County	2004–2024/2048
Other SFPUC Projects at Tesla Portal						
SJP-1a	CCSF (SFPUC)	Tesla Portal Erosion Repairs	Repairs to eroded areas around the portal and pipe connection as well as the road to the chemical building. Work would occur in a developed area within a fenced compound (SFPUC, 2006).	Advanced Disinfection (SJ-1), SJPL System (SJ-3), SJPL Rehabilitation (SJ-4), Tesla Portal Disinfection (SJ-5)	Possible overlap of onsite construction activities; construction-related traffic on access roads and associated air quality and noise impacts	TBD
SJP-1b	CCSF (SFPUC)	Tesla Portal Surface Drainage	Drainage improvement in an area of portal/pipeline connections, with additional pavement around the pump house (SFPUC, 2006).	Advanced Disinfection (SJ-1), SJPL System (SJ-3), SJPL Rehabilitation (SJ-4), Tesla Portal Disinfection (SJ-5)	Possible overlap of onsite construction activities; construction-related traffic on access roads and associated air quality and noise impacts; increased surface runoff	TBD
SJP-1c	CCSF (SFPUC)	Tesla Portal Utilities Building	Modification of electrical equipment inside an existing structure; wiring and conduit work (SFPUC, 2006).	Advanced Disinfection (SJ-1), SJPL System (SJ-3), SJPL Rehabilitation (SJ-4), Tesla Portal Disinfection (SJ-5)	Possible overlap of onsite construction activities; construction-related traffic on access roads and associated air quality and noise impacts	TBD
SJP-1d	CCSF (SFPUC)	Tesla Portal/ Thomas Shaft Disinfection Project	Construction of an access road and improvements to chemical storage (SFPUC, 2006).	Advanced Disinfection (SJ-1), Lawrence Livermore (SJ-2), SJPL System (SJ-3), SJPL Rehabilitation (SJ-4), Tesla Portal Disinfection (SJ-5)	Possible construction access restrictions at Tesla Portal and Thomas Shaft	TBD

TABLE 4.17-1 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE SAN JOAQUIN REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Areas	Estimated Construction Schedule[b]
Other SFPUC Projects at Tesla Portal (cont.)						
SJP-1e	CCSF (SFPUC)	Tesla Portal Water Quality Monitoring Improvements	Addition/enhancement of water quality monitoring at the San Joaquin Valve House and Tesla Portal (SFPUC, 2006).	Advanced Disinfection (SJ-1), SJPL System (SJ-3), SJPL Rehabilitation (SJ-4), Tesla Portal Disinfection (SJ-5)	Possible overlap of onsite construction activities; construction-related traffic on access roads and associated air quality and noise impacts	TBD
Other SFPUC Projects in Thomas Shaft Vicinity						
SJP-2	CCSF (SFPUC)	Thomas Shaft SCADA Antenna Installation	Installation of Supervisory Control and Data Acquisition antenna (satellite dish) on an existing chlorine facility in a remote coastal mountain location. In-house construction, installation of antenna, minor electrical conduit, and hookup (SFPUC, 2006).	Lawrence Livermore (SJ-2)	Possible overlap of construction-related traffic on access roads to Thomas Shaft	TBD

a A WSIP facility that, in conjunction with the cumulative project, could contribute to a potential cumulative impact, depending on construction timing or affected resources.
b Construction schedules for non-SFPUC projects were estimated based on information obtained in project-related documents such as initial studies and EIRs; city, county, and regional agency websites; and interviews with representatives from local jurisdictions or regional agencies. In some cases, project schedules could not be estimated from these sources, but the projects were in sufficient stages of planning to be considered likely to start or complete construction before 2014, the planning horizon for construction of WSIP facilities. The schedules for these projects are listed as “TBD” (To Be Determined). The estimated schedules are based on the most current information available during preparation of this PEIR (as of July 2006). However, as with all proposed development projects, estimated construction schedules are subject to revisions and delays and therefore could vary from the time periods indicated.

TABLE 4.17-2
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE SUNOL VALLEY REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other Non-SFPUC Planned or Approved Projects in the Sunol Valley Region (Public and Private Developments)						
SVC-1	Alameda County	Route 84 Safety Project	Safety improvement project that would realign and widen a section of State Route 84 (Niles Canyon Road) between Rosewarnes Bridge and Farwell Bridge. The project would improve sight distance and vertical clearances at bridges, and install a retaining wall along a section of Alameda Creek. Niles Canyon Road provides access to Calaveras Road from the north (Caltrans, 2004).	*Indirect*: All Sunol Valley Region projects; BDPL Reliability Upgrade (BD-1)	Impacts on sensitive habitats and species; water quality impacts on Alameda Creek; construction-related traffic on regional roads (e.g., Highway 84 and Highway 84/I-680 interchange) and associated air quality and noise impacts; wildland fire hazards	2007–2009
SVC-2	Alameda County	Route 84 Expressway	Widening of Highway 84 (Isabel Avenue) from a four- to six-lane roadway from Jack London Boulevard in Livermore through the Isabel Avenue/Vallecitos Road intersection. Project would add capacity, reduce congestion, improve local circulation, and eventually tie into the Isabel Avenue/I-580 interchange project. The project designates the Vallecitos Road portion of the new route a scenic corridor (ACTIA, 2007).	*Indirect*: All Sunol Valley Region projects	Construction-related traffic on regional roads (e.g., Vallecitos/I-680 ramps); associated air quality and noise impacts; potential visual impacts	2010–2012
SVC-3	Alameda County	Chevron Pipeline Relocation/ Watershed Protection Project	Construction and operation of a new pipeline segment (approximately 7.5 miles long), generally within the existing electrical transmission line easement extending north of San Antonio Reservoir and south of Vallecitos Road (Highway 84). Pipeline to be joined to an existing petroleum products pipeline in order to reduce the risk of water supply contamination at San Antonio Reservoir in the event of a pipeline failure within the reservoir's watershed. Relocation is a condition of Chevron's right-of-way lease agreement with the SFPUC (SFPUC, 2005a).	*Indirect*: All Sunol Valley Region projects	Impacts on sensitive habitat and species; construction-related traffic on Calaveras Road and associated air quality and noise impacts; temporary disruption to commercial businesses on Calaveras Road; wildland fire hazards; potential hazardous materials spills during pipeline relocation	TBD
SVC-4	Alameda County	Mission Valley Rock Company Quarries	Continuation and expansion of three surface mining permits (SMP) in areas east of Calaveras Road, north of I-680. SMP-24 is an existing 202-acre quarry and processing operation; the permit allows increased aggregate extraction and deepening of pits from 140 feet up to 250 feet. SMP-32 allows for new quarry operations on 240 acres with materials processed at SMP-24. SMP-33 a 31-acre quarry; the permit allows deepening of pits from 140 feet to up to 200 feet, footprint expansion by 6 acres to the east for a total of 37 acres, and materials processed at SMP-24 (SFPUC, 2005a).	*Indirect*: All Sunol Valley Region projects	Impacts on sensitive habitats and species; water quality impacts on nearby creeks (e.g., Alameda Creek); potential groundwater impacts; visual impacts from Calaveras Road, a designated scenic route; traffic impacts on regional roads (e.g., I-680) and Calaveras Road and associated air quality and noise impacts; wildland fire hazards	Ongoing to 2045+

TABLE 4.17-2 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE SUNOL VALLEY REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other Non-SFPUC Planned or Approved Projects in the Sunol Valley Region (Public and Private Developments) (cont.)						
SVC-5	Alameda County	Sunol Valley Quarry	Expansion of existing 308.5-acre quarry to increase mining depth from 140 feet to approximately 225 feet, plus restoration of portions of Alameda and San Antonio Creeks and installation of slurry cutoff wall (SFPUC, 2005a).	*Indirect*: All Sunol Valley Region projects	Impacts on sensitive habitats and species; water quality impacts on nearby creeks; potential groundwater impacts; visual impacts from Calaveras Road; traffic impacts on regional roads (e.g., I-680) and Calaveras Road and associated air quality and noise impacts; wildland fire hazards	2009–2011
SVC-6	Alameda County	Apperson Ridge Quarry	Potential surface mining of an existing 680-acre mining leasehold (SMP-14) situated on the central portions of the 2,555-acre Apperson Ranch located about one mile east of Calaveras Road in the SFPUC Alameda watershed. No mining or extraction activities have been initiated or are likely in the near future. However, the existing permit extends for a period of 80 years (Alameda County, 1984; Jensen, 2007).	*Indirect*: All Sunol Valley Region projects	Impacts on sensitive habitats and species; water quality impacts on nearby creeks; potential groundwater impacts; visual impacts from Calaveras Road; traffic impacts on regional roads (e.g., I-680) and Calaveras Road and associated air quality and noise impacts; wildland fire hazards	TBD
Other SFPUC Projects in the Sunol Valley Water Treatment Plant Vicinity						
SVP-1a	CCSF (SFPUC)	SVWTP/HTWTP External UPS Study	External Uninterruptible Power Supply (UPS) Bypass/Replacement Study to either install external bypass switches or replace UPS. After the study, work would entail minor installation of electrical switches on plant equipment or replacement of power supplies on the same equipment (SFPUC, 2006).	*Direct*: 40-mgd Treated Water (SV-3), Treated Water Reservoirs (SV-5) *Indirect*: All Sunol Valley Region projects	Overlap of onsite construction activities; construction-related traffic on Calaveras Road and associated air quality and noise impacts; wildland fire hazards	TBD
SVP-1b	CCSF (SFPUC)	SVWTP Tank Replacement	In-kind replacement of three existing hypochlorite tanks and five alum tanks at the Sunol Valley Water Treatment Plant (WTP). Maintenance replacement of existing chemical tanks at filter plant (SFPUC, 2006).	*Direct*: 40-mgd Treated Water (SV-3), Treated Water Reservoirs (SV-5) *Indirect*: All Sunol Valley Region projects	Overlap of onsite construction activities; construction-related traffic on Calaveras Road and associated air quality and noise impacts; wildland fire hazards	TBD
SVP-1c	CCSF (SFPUC)	SVWTP Replace Valve V40	Replacement of valve V40 within filter plant compound at the Sunol Valley WTP. Maintenance/repair project (SFPUC, 2006).	*Direct*: 40-mgd Treated Water (SV-3), Treated Water Reservoirs (SV-5) *Indirect*: All Sunol Valley Region projects	Overlap of onsite construction activities; construction-related traffic on Calaveras Road and associated air quality and noise impacts; wildland fire hazards	2007

TABLE 4.17-2 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE SUNOL VALLEY REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other SFPUC Projects in the Sunol Valley Water Treatment Plant Vicinity (cont.)						
SVP-1d	CCSF (SFPUC)	SVWTP V40–V41 Pressure Transmitters	Minor installation of pressure transmitters on valves V40 and V41 at the Sunol Valley WTP (SFPUC, 2006).	*Direct*: 40-mgd Treated Water (SV-3), Treated Water Reservoirs (SV-5) *Indirect*: All Sunol Valley Region projects	Overlap of onsite construction activities; construction-related traffic on Calaveras Road and associated air quality and noise impacts; wildland fire hazards	TBD
Other SFPUC Projects at the Alameda Portals						
SVP-2	CCSF (SFPUC)	Alameda East Portal – Chemical Piping Modification	Replacement of small high-density polyethylene piping within existing building at the Alameda East Portal, located inside off-limits, fenced-in portal compound, and relocation of existing small pumps. Minor electrical work (SFPUC, 2006).	*Direct*: SABUP (SV-6) *Indirect*: All Sunol Valley Region projects	Overlap of onsite construction activities; construction-related traffic on Calaveras Road and associated air quality and noise impacts; wildland fire hazards	TBD
SVP-3	CCSF (SFPUC)	Alameda Portal – Alameda Siphons Flow Meter Replacement	Replacement of flow meters in Alameda Siphons with more reliable meters for 69-, 91-, and 96-inch pipes. Work involves replacing small electrical devices on pipelines within existing vaults and evaluating flow meter after field-testing (SFPUC, 2006).	*Direct*: New Irvington Tunnel (SV-4), SABUP (SV-6) *Indirect*: All Sunol Valley Region projects	Overlap of on-site construction activities; construction-related traffic on Calaveras Road and associated air quality and noise impacts; wildland fire hazards	TBD
Other SFPUC Projects at the Sunol Yard						
SVP-4a	CCSF (SFPUC)	Sunol Yard Auto – Shop Remodel	Remodeling of auto shop inside existing building within maintenance yard at the Sunol Yard (SFPUC, 2006).	*Indirect*: All Sunol Valley Region projects	Construction-related traffic on regional roads and associated air quality and noise impacts; wildland fire hazards	TBD
SVP-4b	CCSF (SFPUC)	Sunol Yard New Roll-up Door at Welding Shop	Construction of an enclosure for the welding shop with a roll-up door. Work includes modification to existing building within maintenance yard (SFPUC, 2006).	*Indirect*: All Sunol Valley Region projects	Construction-related traffic on regional roads and associated air quality and noise impacts; wildland fire hazards	TBD
SVP-4c	CCSF (SFPUC)	Sunol Yard Temporary Expansion	Construction of a series of prefabricated structures to replace run-down operations shops at the Sunol Yard (SFPUC, 2006).	*Indirect*: All Sunol Valley Region projects	Construction-related traffic on regional roads and associated air quality and noise impacts; wildland fire hazards	TBD
SVP-4d	CCSF (SFPUC)	SFPUC Pipeline Repair and Readiness Improvement	This project would provide a pipe-rolling facility in the Sunol Maintenance Yard for the purpose of supplying emergency repair pipe following a major seismic event. Seven improvement/storage sites for stockpiling materials would be used. Three of these sites are currently used for materials storage and the other four were determined to	*Indirect*: All Sunol Valley Region projects	Construction-related traffic on regional roads and associated air quality and noise impacts; wildland fire hazards	2007-2008

TABLE 4.17-2 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE SUNOL VALLEY REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other SFPUC Projects at the Sunol Yard (cont.)						
SVP-4d (cont.)			be categorically exempt from CEQA. Pipe-rolling facilities would also be installed at two other sites, but would be located within existing buildings in existing SFPUC equipment yards (SFPUC, 2005b).			
Other SFPUC Projects at the Alameda Siphons						
SVP-5a	CCSF (SFPUC)	Alameda Siphon #1 Pipeline Inspection	Alameda Siphon #1 – pipeline inspection (SFPUC, 2006).	*Direct*: New Irvington Tunnel (SV-4) *Indirect*: All Sunol Valley Region projects	Treated water discharges; construction-related traffic on Calaveras Road and associated air quality and noise impacts; wildland fire hazards	2007
SVP-5b	CCSF (SFPUC)	Alameda Siphon #3 PCCP Pipeline Inspection	Alameda Siphon #3 – PCCP (prestressed concrete cylinder pipe) pipeline inspection (SFPUC, 2006).	*Direct*: New Irvington Tunnel (SV-4) *Indirect*: All Sunol Valley Region projects	Treated water discharges; construction-related traffic on Calaveras Road and associated air quality and noise impacts; wildland fire hazards	2007
SVP-5c	CCSF (SFPUC)	Alameda Siphons Upgrade	Construction of a fourth, seismically resistant Alameda Siphon across the Sunol Valley along the same corridor as the three existing Alameda Siphons. The fourth siphon would be a redundant pipeline to the three existing siphons. The preferred project would include construction of a new siphon consisting of 3,000-foot-long, 78-inch-diameter pipeline; manifold modifications at the existing Alameda East and West Portals to allow connection of the fourth siphon; and addition of line valves on the three existing siphons or a large gate in the downstream end of the Coast Range Tunnel to allow for isolation of the fourth siphon (SFPUC, 2005b).	*Direct*: New Irvington Tunnel (SV-4) *Indirect*: All Sunol Valley Region projects	Impacts on sensitive habitats and species; treated water discharges; construction-related traffic on Calaveras Road and associated air quality and noise impacts; wildland fire hazards	2009–2011
Other SFPUC Projects in the Sunol Valley Region						
SVP-6	CCSF (SFPUC)	Turner Dam – Drainage Improvement	Improvements to alleviate local ponding at the toe of Turner Dam. Project would involve removing eroded soil and rock from dry creekbed below release valve at the base of Turner Dam and re-contouring the streambed to prevent future erosion and deposits of material (SFPUC, 2006).	*Direct*: SABUP (SV-6) *Indirect*: All Sunol Valley Region projects	Impacts on sensitive habitats and species; water quality impacts; construction-related traffic on Calaveras Road and associated air quality and noise impacts; wildland fire hazards	TBD

TABLE 4.17-2 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE SUNOL VALLEY REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other SFPUC Projects in the Sunol Valley Region (cont.)						
SVP-7	CCSF (SFPUC)	San Antonio Reservoir Piezometer Study	Flushing and retrofit of existing piezometers at San Antonio Reservoir, and preparation of a maintenance plan for the long-term maintenance of piezometers at the facility (SFPUC, 2006).	*Direct*: SABUP (SV-6) *Indirect*: All Sunol Valley Region projects	Construction-related traffic on Calaveras Road and associated air quality and noise impacts	TBD
SVP-8	CCSF (SFPUC)	Calaveras Pipeline Inspection	Calaveras pipeline inspection (SFPUC, 2006).	*Direct*: SABUP (SV-6) *Indirect*: All Sunol Valley Region projects	Treated water discharges; construction-related traffic on Calaveras Road and associated air quality and noise impacts; wildland fire hazards	2012
SVP-9	CCSF (SFPUC)	San Antonio PCCP Pipeline Inspection	San Antonio PCCP pipeline inspection (SFPUC, 2006).	*Direct*: SABUP (SV-6) *Indirect*: All Sunol Valley Region projects	Treated water discharges; construction-related traffic on Calaveras Road and associated air quality and noise impacts; wildland fire hazards	2008
SVP-10	CCSF (SFPUC)	Sunol Effluent Pipeline Inspection	Sunol effluent pipeline inspection (SFPUC, 2006).	*Direct*: 40-mgd Treated Water (SV-3), SVWTP Treated Water Reservoirs (SV-5) *Indirect*: All Sunol Valley Region projects	Treated water discharges; construction-related traffic on Calaveras Road and associated air quality and noise impacts; wildland fire hazards	2007
SVP-11	CCSF (SFPUC Water)	Sunol & Niles Dam Removal	Removal of two obsolete dams on Alameda Creek (SFPUC, 2006).	Indirect: All Sunol Valley Region projects	Water quality impacts on Alameda Creek; impacts on sensitive habitats and species; loss of historical resources; construction-related traffic on regional roads and associated air quality and noise impacts; wildland fire hazards	Completed 2006
SVP-12	CCSF (SFPUC)	Sunol Watershed – Demolition of Unsafe Structures	Removal of abandoned buildings and water transmission facilities in the Sunol Valley and Niles Canyon to eliminate potential nuisances (facilities could attract and endanger people). Most structures are small wooden buildings and/or portions of the Sunol Aqueduct, an abandoned concrete enclosed channel through off-road areas of Niles Canyon (SFPUC, 2006).	*Indirect*: All Sunol Valley Region projects	Construction-related traffic on Highway 84 and associated air quality and noise impacts; wildland fire hazards	TBD

TABLE 4.17-2 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE SUNOL VALLEY REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other SFPUC Projects in the Sunol Valley Region (cont.)						
SVP-13	CCSF (SFPUC)	San Antonio Pump Station Upgrade	Upgrade and rehabilitation of the San Antonio Pump Station, including replacement of three existing electric pumps with three new electric pumps; backup power for the three electric pumps; seismic retrofit of the main pump building to correct structural deficiencies; and construction of a 6.25-mVA backup transformer at the Calaveras Substation (SFPUC, 2005b).	*Direct*: SABUP (SV-6) *Indirect*: All Sunol Valley Region projects	Construction-related traffic on local access roads and associated air quality and noise impacts; wildland fire hazards	2009–2011
SVP-14	CCSF (SFPUC)	Standby Power Facilities	Construction of standby backup power at six critical facilities to allow these facilities to remain in operation during power outages and other emergency situations. Permanent engine generators would be provided at four locations, while hookups for portable engine generators would be provided at two locations. Project locations include the San Pedro Valve Lot, Millbrae Facility, San Antonio and Calaveras Reservoirs, Alameda West Portal, and Harry Tracy WTP (SFPUC, 2005b).	*Direct*: Calaveras Dam (SV-2) *Indirect*: All Sunol Valley Region projects, Baden and San Pedro Valve Lots (PN-1), HTWTP Long-Term (PN-3), SAPL 3 Installation (SF-1)	Construction-related traffic on local access roads and associated air quality and noise impacts; wildland fire hazards	2008–2010
SVP-15	CCSF (SFPUC)	Sunol Bridge Replacement	Replacement of existing wooden bridge in a remote area of East Bay Regional Park District lands (SFPUC, 2006).	*Indirect*: All Sunol Valley Region projects	Construction-related traffic on Calaveras Road and associated air quality and noise impacts; wildland fire hazards	TBD
SVP-16 **(not shown on figure)**	CCSF (SFPUC)	Alameda Watershed Habitat Conservation Plan	Preparation of a land use and biological planning document to provide comprehensive, long-term conservation measures for species listed as threatened or endangered under the endangered species acts, or for species that could be listed in the future. The plan would identify SFPUC watershed operations and maintenance activities to be covered, with the intent of mitigating the potential effects of these covered activities on covered species through implementation of a conservation program (SFPUC, 2007b).	*Indirect*: All Sunol Valley Region projects	Biological resources impacts; water quality impacts; construction-related traffic on local access roads	2008-2009

[a] A WSIP facility that, in conjunction with the cumulative project, could contribute to a potential cumulative impact, depending on construction timing or affected resources.
[b] Construction schedules for non-SFPUC projects were estimated based on information obtained in project-related documents such as initial studies and EIRs; city, county, and regional agency websites; and interviews with representatives from local jurisdictions or regional agencies. In some cases, project schedules could not be estimated from these sources, but the projects were in sufficient stages of planning to be considered likely to start or complete construction before 2014, the planning horizon for construction of WSIP facilities. The schedules for these projects are listed as "TBD" (To Be Determined). The estimated schedules are based on the most current information available during preparation of this PEIR (as of July 2006). However, as with all proposed development projects, estimated construction schedules are subject to revisions and delays and therefore could vary from the time periods indicated.

TABLE 4.17-3
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE BAY DIVISION REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other Non-SFPUC Planned or Approved Projects in the Bay Division Region (Public and Private Developments)						
BDC-1	City of Fremont	BART Extension to Warm Springs	A 5.4-mile extension of the BART Fremont line to the Warm Springs district of Fremont, with an optional station in the Irvington district (ACTIA, 2007).	BDPL Reliability Upgrade (BD-1), BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3)	Construction-related land use impacts; increased surface runoff and water quality impacts; traffic impacts on local roads (near Paseo Padre Parkway and other nearby major arterials) and Union Pacific railroad tracks; associated air quality and noise impacts	2005–2010
BDC-2	City of Fremont	Walnut Avenue Mixed Use Project	Construction of 159 residential units and 7,000 square feet of commercial space on a 3.89-acre vacant parcel in the Central Business District (Pullen, 2005).	BDPL Reliability Upgrade (BD-1)	Increased surface runoff and water quality impacts; construction-related traffic impacts on local roads (e.g., Mowry Boulevard and Paseo Parkway) and associated air quality and noise impacts	TBD
BDC-3	City of Fremont	Patterson Ranch	Mixed-use development on a 430-acre site in northern Fremont, west of I-880; uses not established yet; replaces portion of historic Patterson Ranch (Pullen, 2005).	BDPL Reliability Upgrade (BD-1)	Impacts on sensitive habitats and species; increased surface runoff and water quality impacts; historical and cultural resource impacts; construction-related traffic impacts on regional roads (e.g., I-880 corridor) and associated air quality and noise impacts	TBD
BDC-4	City of Newark	Home Depot Project	Construction of a new store containing 107,500 square feet on a 12.25-acre site that replaces a Kmart on Thornton, east of Cedar Boulevard (City of Newark, 2007).	BDPL Reliability Upgrade (BD-1)	Construction-related traffic impacts on regional roads (e.g., I-880, I-880/Mowry Avenue interchange, BDPL alignment crossing on Cedar Boulevard at Mowry Avenue) and associated air quality and noise impacts	2006–2008
BDC-5	City of Newark	NewPark Mall Renovation	Interior and exterior mall renovation, three new restaurant sites, and the addition of a 20-screen movie theater (New Park Mall, 2007).	BDPL Reliability Upgrade (BD-1)	Construction-related traffic impacts on regional roads (e.g., I-880, I-880/Mowry Avenue interchange) and associated air quality and noise impacts	2007–2010
BDC-6	Alameda County	I-680 Smart Lanes	Construction of improvements to provide SMART lanes along I-680 from Highway 84 in Alameda County to Santa Clara County line. SMART lanes allow carpools to travel free of charge, and low-occupancy vehicles to travel for a fee (ACTIA, 2006).	New Irvington Tunnel (SV-4), BDPL Reliability Upgrade (BD-1)	Water quality impacts; traffic impacts on regional roads (e.g., I-680 corridor in Alameda County) and associated air quality and noise impacts	2007–2010
BDC-7	City of Newark	Ohlone College Newark Center for Heal Sciences and Technology	Construction of 135,000-gross-square-foot campus with capacity for 3,500 students in four buildings on an 81-acre site on Cherry Street, southwest of the BDPL No. 1 alignment, east of Mowry Avenue (Ohlone College, 2007).	BDPL Reliability Upgrade (BD-1)	Increased surface runoff and water quality impacts; construction-related traffic impacts on regional roads (e.g., I-880, I-880/Mowry Avenue interchange) and associated air quality and noise impacts	2006–2009

TABLE 4.17-3 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE BAY DIVISION REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other Non-SFPUC Planned or Approved Projects in the Bay Division Region (Public and Private Developments) (cont.)						
BDC-8	City of Fremont	Mission Boulevard/ Warren Avenue/ I-880 Interchange Reconstruction – Phases 1b and 2	Reconstruction of interchange to improve traffic between I-880 and I-680 along Mission Boulevard. Phase 1 high-occupancy-vehicle lanes completed. Phase 1b would rebuild on-/off-ramps between Mission Boulevard and Kato Road with a landscape project. Phase 2 is a City of Fremont project to construct a grade separation at Warren Avenue for BART Warm Springs service (City of Fremont, 2007).	BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3)	Construction-related traffic impacts on regional roads (e.g., I-880 corridor) and associated air quality and noise impacts	Phase 1b: 2005–2008 Phase 2: TBD
BDC-9	City of Fremont	Cisco Field (Oakland A's Ballpark)	Preliminary proposal for a 32,000 to 35,000-seat open-air baseball facility with 9,000 parking spaces on a 140-acre parcel located west of I-880 near Auto Mall Parkway (Oakland Athletics, 2007).	Direct: BDPL Reliability Upgrade (BD-1), BDPL 3 and 4 Crossovers (BD-2) Indirect: All Bay Division Region projects	Increased surface runoff and water quality impacts; construction-related and operational (seasonal) traffic impacts on regional roads (e.g., I-880 and Highway 101, and major interchanges in vicinity) and associated air quality and noise impacts; potential nighttime lighting effects	2007–2010
BDC-10	North San Jose	N. Montague Expressway, West of 1st Street	Development of 620 single-family units on an 11-acre site (City of San Jose, 2007).	BDPL 3 and 4 Crossovers (BD-2)	Redirection of flood flows within 100-year floodplain between Guadalupe River and Coyote Creek; increased surface runoff and water quality impacts on Guadalupe River; construction-related traffic on regional roads and associated air quality and noise impacts; cultural (archaeological) impacts; impacts on Coyote Creek (alternate site)	2008–2010
BDC-11	North San Jose	BEA Systems North 1st Street/ Component Drive	Construction of 859,890-square-foot research and development office buildings on a 25.5-acre site (City of San Jose, 2007)	BDPL 3 and 4 Crossovers (BD-2)	Redirection of flood flows within 100-year floodplain between Guadalupe River and Coyote Creek; increased surface runoff and water quality impacts on Adobe Creek and Guadalupe River; construction-related traffic impacts on regional roads and associated air quality and noise impacts	2008–2011
BDC-12	North San Jose	Montague Expressway/ Trimble Road	Development of 208,000 square feet of research and development space in five buildings on a 6.8-acre site (City of San Jose, 2007).	BDPL 3 and 4 Crossovers (BD-2)	Redirection of flood flows within 100-year floodplain between Guadalupe River and Coyote Creek; increased surface runoff and water quality impacts on Adobe Creek and Guadalupe River; construction-related traffic impacts on regional roads and associated air quality and noise impacts	2009–2012

TABLE 4.17-3 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE BAY DIVISION REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other Non-SFPUC Planned or Approved Projects in the Bay Division Region (Public and Private Developments) (cont.)						
BDC-13	North San Jose	Baypointe Parkway between Zanker Road and Tasman Drive	Rezoning for development of 636 attached residences and 12,000 square feet of commercial space on a 10.2-acre site (City of San Jose, 2007).	BDPL 3 and 4 Crossovers (BD-2)	Redirection of flood flows within 100-year floodplain between Guadalupe River and Coyote Creek; increased surface runoff and water quality impacts on Guadalupe River; construction-related traffic impacts on regional roads and associated air quality and noise impacts	TBD
BDC-14	North San Jose / Alviso	Los Esteros Critical Energy Facility Expansion	Expansion to convert existing simple-cycle Los Esteros facility to a combined-cycle generation station capable of producing 320 megawatts (California Energy Commission, 2006).	BDPL 3 and 4 Crossovers (BD-2)	Construction-related traffic impacts on regional roads and associated air quality and noise impacts; operational regional air quality impacts; potential water quality impacts on Coyote Creek	2007–2009
BDC-15	City of Santa Clara	49er Stadium Complex	Construction of new 49ers' football stadium complex on 40 acres northeast of existing Paramount Great American Theme Park. Conceptual design includes 68,000+ seat stadium, three-floor garage (2,000 spaces), 7,000-seat amphitheater, two eight-story office towers with ground-floor retail, and a restaurant (Forty Niners, 2007).	Direct: BDPL 3 and 4 Crossovers (BD-2) Indirect: All Bay Division Region projects	Increased surface runoff and water quality impacts; construction-related and operational traffic impacts on regional roads (e.g., I-880 and Highway 101, and major interchanges in vicinity) and associated air quality and noise impacts; potential nighttime lighting effects	2007–2012
BDC-16	City of Palo Alto	Charleston-Arastradero Corridor Project	Trial demonstration traffic-calming project on Arastradero and Charleston between Miranda Avenue and Fabian Way. A new school-only right-turn lane for westbound vehicles was constructed at Gunn Hill High School in May 2006. Final project decision in June 2008 (City of Palo Alto, 2007).	BDPL 3 and 4 Crossovers (BD-2)	Effects on operational traffic in immediate vicinity of Barron Creek site during two-year trial period; potential for permanent right-turn lane and additional traffic-calming improvements after 2008	2006–2008+
BDC-17	Cities of Redwood City, Menlo Park, Newark, Fremont	Dumbarton Rail Corridor Project	Construction of a 20.5-mile commuter rail service corridor beginning along the Southern Pacific line in Redwood City and extending east to stations in Menlo Park, Newark, and Fremont, and terminating at the Union City BART station. Service would link Caltrain, the Altamont Commuter Express, Amtrak Capitol Corridor, and BART (San Mateo County Transit Authority, 2004).	BDPL Reliability Upgrade (BD-1)	Impacts on sensitive habitats and species; water quality and flood hazards; construction-related land use, traffic, noise/vibration, and air quality impacts near at-grade crossings in Menlo Park and East Palo Alto (Marsh Road, Chilco Street [south of Belle Haven School], University Avenue, Willow Road), Newark (Cherry Street, Cedar Street), and Fremont (Blacow Road); construction-related traffic impacts on regional roads and associated air quality and noise impacts; cultural (archaeological) impacts	2008–2010

TABLE 4.17-3 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE BAY DIVISION REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other Non-SFPUC Planned or Approved Projects in the Bay Division Region (Public and Private Developments) (cont.)						
BDC-18	City of East Palo Alto	Core Development Company	Construction of 178 condominium units on a 2.63-acre site (Banico, 2005).	BDPL Reliability Upgrade (BD-1)	Increased surface runoff and water quality impacts; construction-related traffic impacts on local roads (e.g., University Avenue, University Avenue/ Highway 101 interchange, University Avenue/Bay Expressway ramp – Highway 84) and associated air quality and noise impacts	TBD
BDC-19	City of East Palo Alto	University Palms	Construction of 183,200 square feet of office, 13,280 square feet of restaurant, and 3,280 square feet of retail space with residential units above (Banico, 2005).	BDPL Reliability Upgrade (BD-1)	Increased surface runoff and water quality impacts; construction-related traffic impacts on local/regional roads (e.g., University Avenue, University Avenue/ Highway 101 interchange, University Avenue/Bay Expressway ramp – Highway 84) and associated air quality and noise impacts	TBD
BDC-20	City of East Palo Alto	Tara Road Office Condominium	Construction of 60,000-square-foot office condominium on a 4.85-acre site, replacing salvage yards and vehicle storage area (Banico, 2005).	BDPL Reliability Upgrade (BD-1)	Increased surface runoff and water quality impacts; construction-related traffic impacts on local/regional roads (e.g., University Avenue, University Avenue/Highway 101 interchange, University Avenue/Highway 84 interchange) and associated air quality and noise impacts; hazardous materials disposal	TBD
BDC-21	City of Palo Alto	PG&E 230 kV Transmission Line	Development of 230-kilovolt transmission line extending between Highway 84 and Highway 101 in Palo Alto (Banico, 2005).	BDPL Reliability Upgrade (BD-1), BDPL 3 and 4 Crossovers (BD-2)	Impacts on sensitive habitats and species; construction-related traffic impacts on regional roads and associated air quality and noise impacts	2010–2012
BDC-22	City of Menlo Park	Independence Drive/ Constitution Drive	Development of a 514,543-square-foot office, 125-room hotel, fitness center, and restaurant facilities on two sites totaling 13.5 acres (Banico, 2005).	BDPL Reliability Upgrade (BD-1)	Increased surface runoff and water quality impacts; construction-related traffic impacts on local/regional roads (e.g., Marsh Road at crossing of BD-1 and at Highway 101/Marsh Road interchange) and associated air quality and noise impacts	2009–2012
BDC-23	City of Redwood City	Abbott Laboratories West Coast Research Center 1 Cardinal Way	Construction of a 541,077-square-foot lab and research facility on a former salt pile on Redwood City's bayfront (City of Redwood City, 2003a).	BDPL Reliability Upgrade (BD-1)	Increased surface runoff and water quality impacts; construction-related traffic impacts on local/regional roads (e.g., at Woodside Road/Highway 101 interchange) and associated air quality and noise impacts	2004–2014

TABLE 4.17-3 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE BAY DIVISION REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other Non-SFPUC Planned or Approved Projects in the Bay Division Region (Public and Private Developments) (cont.)						
BDC-24	City of Redwood City	Kaiser Hospital Master Plan	Long-range development of approximately 960,000 gsf of medical center uses, and 1.032 gsf of parking, including replacement of existing hospital to meet state seismic safety mandate (City of Redwood City, 2003b).	BDPL Reliability Upgrade (BD-1)	Increased surface runoff and water quality impacts; construction-related traffic impacts on local/regional roads (e.g., Highway 101 interchanges with Whipple Avenue and Woodside Road) with associated air quality and noise impacts; and improved seismic safety and reliability of critical public facilities	2009-2014
BDC-25	City of Redwood City	Stanford Outpatient Center Project	Renovation and conversion of four commercial buildings in the Midpoint Technology Park office and research and development campus to create a new hospital outpatient center totaling 369,500 square feet (City of Redwood City, 2006).	BDPL Reliability Upgrade (BD-1)	Increased surface runoff and water quality impacts; construction-related traffic impacts on local/regional roads (e.g., at Woodside Road/ Highway 101 interchange) and associated air quality and noise impacts	2007-2009
BDC-26	California Department of Fish and Game and U.S. Fish and Wildlife Service	South Bay Salt Pond Restoration Project	Tidal wetland restoration project that would convert 15,100 acres of commercial salt ponds at the south end of San Francisco Bay to a mix of tidal marsh, mudflat, and other wetland habitats. The state and federal governments purchased the property from Cargill Salt. The project calls for an eight-year initial stewardship phase followed by long-tem implementation. Project is currently in the initial stages of environmental review (South Bay Salt Pond Restoration Project, 2007).	*Direct*: BDPL Reliability Upgrade (BD-1) *Indirect*: All Bay Division Region projects that affect water courses discharging into South Bay	Potential impacts (both positive and negative) on sensitive habitat and species associated with San Francisco Bay; potential construction-related effects on hydrology, sensitive habitats, and bayside recreation and open space activities during tunnel construction	2006–2014+
Other SFPUC Projects on Bay Division Pipeline Nos. 1 and 2						
BDP-1	CCSF (SFPUC)	BDPL2A Pipeline Inspection (A10 to A20)	Bay Division Pipeline 2A pipeline inspection (SFPUC, 2006).	BDPL Reliability Upgrade (BD-1); New Irvington Tunnel (SV-4)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2010–2011
BDP-2	CCSF (SFPUC)	BDPL1A Pipeline Inspection (B10 to B20)	Bay Division Pipeline 1A pipeline inspection (SFPUC, 2006).	BDPL Reliability Upgrade (BD-1); New Irvington Tunnel (SV-4)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2009
BDP-3	CCSF (SFPUC)	BDPL2B Pipeline Inspection (A20 to A30)	Bay Division Pipeline 2B pipeline inspection (SFPUC, 2006).	BDPL Reliability Upgrade (BD-1)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2008

TABLE 4.17-3 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE BAY DIVISION REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other SFPUC Projects on Bay Division Pipeline Nos. 1 and 2 (cont.)						
BDP-4	CCSF (SFPUC)	BDPL1B Pipeline Inspection (B20 to B30)	Bay Division Pipeline 1B pipeline inspection (SFPUC, 2006).	BDPL Reliability Upgrade (BD-1)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2010
BDP-5	CCSF (SFPUC)	BDPL1C Pipeline Inspection (A41 to A50)	Bay Division Pipeline 1C pipeline inspection (SFPUC, 2006).	BDPL Reliability Upgrade (BD-1)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2007
BDP-6	CCSF (SFPUC)	BDPL2C Pipeline Inspection (B41 to B60)	Bay Division Pipeline 2C pipeline inspection (SFPUC, 2006).	BDPL Reliability Upgrade (BD-1)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2012
BDP-7	CCSF (SFPUC)	BDPL1D Pipeline Inspection (A50 to A60)	Bay Division Pipeline 1D pipeline inspection (SFPUC, 2006).	BDPL Reliability Upgrade (BD-1)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2007
BDP-8	CCSF (SFPUC)	BDPL1E Pipeline Inspection (A60 to A70)	Bay Division Pipeline 1E pipeline inspection (SFPUC, 2006).	BDPL Reliability Upgrade (BD-1)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2011
BDP-9	CCSF (SFPUC)	BDPL2D Pipeline Inspection (B60 to B70)	Bay Division Pipeline 2D pipeline inspection (SFPUC, 2006).	BDPL Reliability Upgrade (BD-1)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2006–2007
Other SFPUC Projects on Bay Division Pipeline Nos. 3 and 4						
BDP-10	CCSF (SFPUC)	BDPL3A Seismic Upgrade (C10 to C21)	Compressive slip joint repair to existing seismic joint on BDPL No. 3. Work would be conducted within existing vault in the vicinity of I-680 on-ramp (SFPUC, 2006).	BDPL Reliability Upgrade (BD-1); New Irvington Tunnel (SV-4)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	Completed 2006
BDP-11	CCSF (SFPUC)	BDPL4A Seismic Upgrade (D10 to D20)	Compressive slip-joint repair of an existing seismic joint on Bay Division Pipeline No. 4. Work would be conducted within existing vault in the vicinity of the I-680 on-ramp (SFPUC, 2006).	BDPL Reliability Upgrade (BD-1); New Irvington Tunnel (SV-4)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	2006
BDP-12	CCSF (SFPUC)	BDPL Nos. 3 and 4 Crossover/Isolation Valve at Hayward Fault	Planning, design, and construction of shutoff and crossover facilities on Bay Division Pipelines Nos. 3 and 4 they cross the Hayward fault (SFPUC, 2005b).	BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2006–2008

TABLE 4.17-3 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE BAY DIVISION REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other SFPUC Projects on Bay Division Pipeline Nos. 3 and 4 (cont.)						
BDP-13	CCSF (SFPUC)	BDPL3D Pipeline Inspection (C50 to C70)	Bay Division Pipeline 3D pipeline inspection (SFPUC, 2006).	BDPL 3 and 4 Crossovers (BD-2)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2008
BDP-14	CCSF (SFPUC)	BDPL4D PCCP Pipeline Inspection (D50 to D70)	Bay Division Pipeline 4D PCCP pipeline inspection (SFPUC, 2006).	BDPL 3 and 4 Crossovers (BD-2)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2008–2009
Other SFPUC Projects in the Bay Division Region						
BDP-15	CCSF (SFPUC)	Peninsula Sportsmen's Club	Environmental remediation of former gun club located in East Palo Alto (SFPUC, 2006).	BDPL Reliability Upgrade (BD-1)	Overlapping construction at project site; construction-related traffic on local access roads and associated air quality and noise impacts	2007
BDP-16 **(not shown on figure)**	CCSF (SFPUC)	New Electrical Transmission Line from Newark to San Francisco	Planning, permitting, design, and construction of 50 miles of new 115-kilovolt electrical transmission line from Newark to San Francisco, and construction of a new substation (SFPUC, 2006).	BDPL Reliability Upgrade (BD-1)	Construction-related traffic impacts on local access roads; construction air quality and noise impacts and associated air quality and noise impacts	2012–2014 (Estimated)

[a] A WSIP facility that, in conjunction with the cumulative project, could contribute to a potential cumulative impact, depending on construction timing or affected resources.
[b] Construction schedules for non-SFPUC projects were estimated based on information obtained in project-related documents such as initial studies and EIRs; city, county, and regional agency websites; and interviews with representatives from local jurisdictions or regional agencies. In some cases, project schedules could not be estimated from these sources, but the projects were in sufficient stages of planning to be considered likely to start or complete construction before 2014, the planning horizon for construction of WSIP facilities. The schedules for these projects are listed as "TBD" (To Be Determined). The estimated schedules are based on the most current information available during preparation of this PEIR (as of July 2006). However, as with all proposed development projects, estimated construction schedules are subject to revisions and delays and therefore could vary from the time periods indicated.

TABLE 4.17-4
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE PENINSULA REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Projects[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other Non-SFPUC Planned or Approved Projects in the Peninsula Region (Public and Private Developments)						
PNC-1	San Mateo County	PG&E Jefferson Martin Transmission Line	Implementation of a mitigation monitoring program including restoration of wetlands, sensitive habitats, and special-status species along the eastern portion of Crystal Springs Reservoir. Transmission line completed in April 2006 (CPUC, 2003; Masuoka, 2006).	CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4), Pulgas Balancing Reservoir (PN-5)	Effects on wetlands, sensitive habitats and species, trails and passive uses, scenic views, scenic resources, historic resources	2006–2009+
PNC-2	San Mateo County	San Mateo County Crystal Springs Road Bridge Replacement	Seismic replacement of roadbridge on Crystal Springs Road extending across the crest of the Lower Crystal Springs Dam (PN-4). The roadbridge replacement is planned during construction of the Lower Crystal Springs Dam (PN-4) project (Clarke, 2007).	CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4), Pulgas Balancing Reservoir (PN-5)	Temporary construction-related traffic impacts on Highway 92 and I-280 and associated air quality and noise impacts; scenic view impacts; biological resources	2010–2011
PNC-3	City of San Bruno	The Crossings El Camino Real at I-380	Phased project on former Navy site (prior housing and administrative uses), including construction of 185-unit apartment facility (under construction); 228 units of senior apartments (under construction); and 350 units consisting of 187 condominium and 163 apartment units (approval pending) (City of San Bruno, 2006).	Baden and San Pedro Valve Lots (PN-1)	Increased surface runoff and water quality impacts; construction-related traffic impacts on local/regional roads (e.g., at I-380/El Camino Real and I-280/San Bruno interchanges) and associated air quality and noise impacts	2005–2010+
PNC-4	City of San Bruno	San Bruno Caltrain Grade Separation Project	Construction of new Caltrain station in downtown San Bruno to improve safety. Project includes elevated tracks, four street underpasses, and pedestrian underpasses to improve pedestrian bicyclists and vehicle safety at track crossings (City of San Bruno, 2006).	Baden and San Pedro Valve Lots (PN-1)	Increased surface runoff and water quality impacts; construction-related traffic impacts on local/regional roads (e.g., at I-380/El Camino Real and I-280/San Bruno interchanges) and associated air quality and noise impacts	2007–2009
Other SFPUC Projects at the Harry Tracy Water Treatment Plant						
PNP-1a	CCSF (SFPUC)	HTWTP Programmable Logic Controller Program	Work on Programmable Logic Controller (a commercial computer that controls operations within the Harry Tracy WTP filter plant) and installation of pipes in the clarifier (a sludge or treatment residuals thickening tank to help in mixing) (SFPUC, 2006).	HTWTP Long-Term (PN-3)	Construction-related traffic impacts on access roads and associated air quality and noise impacts	TBD
PNP-1b	CCSF (SFPUC)	HTWTP Power Modifications	Electrical installation for existing water pumps 101, 102, and 103 at the Harry Tracy WTP (SFPUC, 2006).	HTWTP Long-Term (PN-3)	Construction-related traffic impacts on access roads and associated air quality and noise impacts	TBD

TABLE 4.17-4 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE PENINSULA REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Projects[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other SFPUC Projects at the Harry Tracy Water Treatment Plant (cont.)						
PNP-1c	CCSF (SFPUC)	HTWTP Water Tanks Slope Study	Study to analyze the stability of hillsides near water tanks located at the Harry Tracy WTP (SFPUC, 2006).	HTWTP Long-Term (PN-3)	Impacts on sensitive habitat and species; construction-related traffic impacts on access roads and associated air quality and noise impacts	TBD
PNP-1d	CCSF (SFPUC)	HTWTP Northern Drainage Repairs	Project would plug the northern drainage line and redirect storm water into newly constructed storm drain system. Work would include excavation of the drain line within the fenced filter plant property, which is off-limits to the public (SFPUC, 2006).	HTWTP Long-Term (PN-3)	Impacts on sensitive habitat and species; stormwater runoff impacts; construction-related traffic impacts on access roads and associated air quality and noise impacts	Completed 2006
PNP-1e	CCSF (SFPUC)	HTWTP Raw Water Pipeline #3 Inspection	Inspection of one of two pipelines supplying the Harry Tracy WTP with lake water. Small permitted discharge of lake water to creek (SFPUC, 2006).	HTWTP Long-Term (PN-3)	Treated water discharges; construction-related traffic impacts on access roads and associated air quality and noise impacts	2009
PNP-1f	CCSF (SFPUC)	HTWTP External UPS Study	Study to either install external bypass switches or replace the Uninterruptible Power Supply (UPS). After the study, work would entail minor installation of electrical switches on plant equipment or replacement of power supplies on the same equipment (SFPUC, 2006).	HTWTP Long-Term (PN-3)	Construction-related traffic impacts on access roads and associated air quality and noise impacts	TBD
PNP-1g	CCSF (SFPUC)	HTWTP – Short-Term Improvements	Replacement and upgrade of the filtration system at the Harry Tracy WTP to increase the reliability and efficiency of the treatment process during normal raw water conditions (SFPUC, 2005b).	HTWTP Long-Term (PN-3)	Construction-related traffic impacts on access roads and associated air quality and noise impacts.	2006–2010
Other SFPUC Projects in the Peninsula Region						
PNP-2	CCSF (SFPUC)	Pulgas Pump Station – Alternate Power Source	Alternatives analysis to determine best way to provide alternative power to gate valves and pressure-reducing valve in Pulgas Pump Station. Installation of electrical conduit between chemical treatment facility and pump station (SFPUC, 2006).	Pulgas Balancing Reservoir (PN-5)	Construction-related traffic impacts on access roads and associated air quality and noise impacts	TBD
PNP-3	CCSF (SFPUC)	Crystal Springs Pump Station Temperature Alarms	Construction of bearing temperature alarms, which includes minor installation of electrical sensors on existing electric pump motors in the Crystal Springs Pump Station building (SFPUC, 2006).	CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4)	Construction-related traffic impacts on access roads and associated air quality and noise impacts; wildland fire hazards	TBD

TABLE 4.17-4 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE PENINSULA REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Projects[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other SFPUC Projects in the Peninsula Region (cont.)						
PNP-4	CCSF (SFPUC Water)	Pilarcitos Pipeline Inspection	Pilarcitos pipeline inspection (SFPUC, 2006).	CS/SA Transmission (PN-2)	Treated water discharges; construction-related traffic impacts on access roads and associated air quality and noise impacts; wildland fire hazards	2015
PNP-5	CCSF (SFPUC Water)	Ingoing Road and Pilarcitos Pipeline Replacement	Replacement of the Pilarcitos Pipeline west of San Andreas Dam to Portola Comfort station (SFPUC, 2006).	CS/SA Transmission (PN-2)	Impacts on sensitive habitat and species; water quality impacts; construction-related traffic impacts on access roads and associated air quality and noise impacts; wildland fire hazards	TBD
PNP-6	CCSF (SFPUC Water)	Baden Pump Station – Pump No. 3 Starter Modifications	Minor electrical modification to existing motor control starter in existing Baden Pump Station (SFPUC, 2006).	Baden and San Pedro Valve Lots (PN-1)	Construction-related traffic impacts on access roads and associated air quality and noise impacts	TBD
PNP-7	CCSF (SFPUC Water)	San Andreas Reservoir – 28" Pilarcitos Pipeline	Replacement of a section of pipeline from Pilarcitos Reservoir within the SFPUC Peninsula watershed (SFPUC, 2006).	CS/SA Transmission (PN-2)	Impacts on sensitive habitat and species; water quality impacts; construction-related traffic impacts on access roads and associated air quality and noise impacts; wildland fire hazards	2007 -2010
PNP-8	CCSF (SFPUC Water)	San Pedro Valve Lot – Drainage Improvement	Improvement of drainage at the existing San Pedro Valve Lot; all work would take place within the valve lot fence line (SFPUC, 2006).	Baden and San Pedro Valve Lots (PN-1), SAPL 3 Installation (SF-1)	Stormwater runoff impacts; construction-related traffic impacts on access roads and associated air quality and noise impacts	2006–2007
PNP-9	CCSF (SFPUC)	Adit Leak Repair – Crystal Springs Reservoir	Repair of leakage and associated damage to existing adit structures (outlet facilities) in Lower Crystal Springs Reservoir and Calaveras Dam (SFPUC, 2005b).	*Direct*: CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4), Calaveras Dam (SV-2) *Indirect*: All Sunol Valley Region projects	Construction-related traffic impacts on access roads and associated air quality and noise impacts; wildland fire hazards	2007–2008

TABLE 4.17-4 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE PENINSULA REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Projects[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other SFPUC Projects in the Peninsula Region (cont.)						
PNP-10	CCSF (SFPUC)	New Crystal Springs Bypass Tunnel	Construction of a new tunnel to increase seismic reliability and increase delivery reliability, including construction of a new 4,200-foot-long, 8-foot-diameter tunnel; north and south access shafts approximately 15 and 30 feet in diameter, respectively; and north and south connection pipes, standby power facilities, and valve vaults (SFPUC, 2005b).	CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4)	Construction-related traffic on local access roads and associated air quality and noise impacts; wildland fire hazards; visual impacts; impacts on sensitive habitat and species	2007–2010
PNP-11	CCSF (SFPUC)	Pipeline Repair and Readiness Improvements	Purchase of materials for emergency repair and improvement of seven storage sites for stockpiling materials necessary to repair pipelines in the event of an emergency. The improvements at each of the storage sites would include grubbing, grading, surfacing, and fencing. Project locations include California Department of Forestry in Sunol (Sunol yard across the street from CDF), Cedar Court in Newark, Ravenswood in East Palo Alto (biological study complete), Donovan Quarry near Hillsborough (biological study complete), Skyline Quarry near Lower Crystal Springs Dam, and Millbrae Yard in Millbrae (SFPUC, 2005b).	BDPL Reliability Upgrade (BD-1), CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4) All Sunol Valley Region projects	Construction-related traffic on local access roads and associated air quality and noise impacts; wildland fire hazards	2006
PNP-12	CCSF (SFPUC Water)	Southern Fuel Break Replacement	Removal of bushes and potential fire fuels from watershed near the Filoli Estate (SFPUC, 2006).	Pulgas Balancing Reservoir (PN-5)	Impacts on sensitive habitat and species; construction-related traffic impacts on access roads and associated air quality and noise impacts	TBD
PNP-13	CCSF (SFPUC)	SA Branch Pipeline Inspection (N42 to M41)	San Andreas Branch pipeline inspection (SFPUC, 2006).	HTWTP Long-Term (PN-3)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2007 -2010
PNP-14	CCSF (SFPUC)	CSPL2 Pipeline Inspection (K10 to K20)	Crystal Springs Pipeline #2 pipeline inspection (SFPUC, 2006).	CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2014
PNP-15	CCSF (SFPUC)	SSPL Pipeline Inspection (M10 to M31)	Sunset Supply Pipeline pipeline inspection (SFPUC, 2006).	CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2012

TABLE 4.17-4 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE PENINSULA REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Projects[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other SFPUC Projects in the Peninsula Region (cont.)						
PNP-16	CCSF (SFPUC)	CSPL2 Replacement	Repair and replacement of 4.8 miles of the existing Crystal Springs Pipeline No. 2 to improve seismic reliability and address security concerns (SFPUC, 2005b).	Baden and San Pedro Valve Lots (PN-1), CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4)	Construction-related traffic on local access roads and associated air quality and noise impacts; wildland fire hazards	2009–2011
PNP-17	CCSF (SFPUC)	CSPL2 Pipeline Inspection (K40 to K50)	Crystal Springs Pipeline #2 pipeline inspection (SFPUC, 2006).	Baden and San Pedro Valve Lots (PN-1)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2014
PNP-18	CCSF (SFPUC)	CSPL2 Pipeline Inspection (K50 to K60)	Crystal Springs Pipeline #2 pipeline inspection (SFPUC, 2006).	Baden and San Pedro Valve Lots (PN-1)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2014
PNP-19	CCSF (SFPUC)	SSPL Pipeline Inspection (M50 to M60)	Sunset Supply Pipeline pipeline inspection (SFPUC, 2006).	Baden and San Pedro Valve Lots (PN-1), SAPL 3 Installation (SF-1)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2009
PNP-20	CCSF (SFPUC)	CS/SA Pipeline (Force Main) – Temporary Drainage and Pipe Supports Repairs	Repair of supports for pipeline between Crystal Springs Pump Station and San Andreas Reservoir (SFPUC, 2006).	CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	Completed 2005
PNP-21	CCSF (SFPUC)	CS/SAPL (Force Main) Pipeline Inspection	Crystal Springs/San Andreas Pipeline (force main) pipeline inspection (SFPUC, 2006).	CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2014
PNP-22	CCSF (SFPUC)	SSPL Pipeline Inspection (M40 to M50)	Sunset Supply Pipeline pipeline inspection (SFPUC, 2006).	Baden and San Pedro Valve Lots (PN-1)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2021

TABLE 4.17-4 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE PENINSULA REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Projects[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other SFPUC Projects in the Peninsula Region (cont.)						
PNP-23	CCSF (SFPUC)	CSPL1 Replacement	Removal of and/or mitigation for Crystal Springs/San Andreas pipes placed in Polhemus Creek when the bypass tunnel is completed (SFPUC, 2005b).	CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4)	Impacts on sensitive habitats and species; water quality; construction-related traffic impacts on local access roads and associated air quality and noise impacts	TBD
PNP-24	CCSF (SFPUC)	Baden Valve Lot and Pump Station Upgrade	Upgrade of pumps, valves, and motors; seismic upgrade of structure; construction of surge protection; construction of emergency power; and installation of perimeter improvements (SFPUC, 2007c).	Baden and San Pedro Valve Lots (PN-1)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	2002-2005 and 2007-2008
PNP-25	CCSF (SFPUC)	SAPL1 Pipeline Inspection (L40P to P48)	San Andreas Pipeline No. 1 pipeline inspection (SFPUC, 2006).	Baden and San Pedro Valve Lots (PN-1)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2007
PNP-26	CCSF (SFPUC)	SAPL2 Pipeline Inspection (R12 to R50)	San Andreas Pipeline No. 2 pipeline inspection (SFPUC, 2006).	Baden and San Pedro Valve Lots (PN-1)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	TBD
PNP-27	CCSF (SFPUC)	SAPL2 Pipeline Inspection (R50 to R60)	San Andreas Pipeline No. 2 pipeline inspection (R50 to R60) (SFPUC, 2006).	Baden and San Pedro Valve Lots (PN-1), SAPL 3 Installation (SF-1)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	TBD
PNP-28	CCSF (SFPUC)	SAPL3 Pipeline Inspection (T50 to T60)	San Andreas Pipeline No. 3 pipeline inspection (T50 to T60) (SFPUC, 2006).	Baden and San Pedro Valve Lots (PN-1), SAPL 3 Installation (SF-1)	Treated water discharges; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2010
PNP-29	CCSF (SFPUC)	Pulgas Dechloramination Sampling Station No. 5	Installation of a new prefabricated sampling station over the existing channel to test chloramines residual before discharging to Upper Crystal Springs Reservoir (SFPUC, 2006).	Baden and San Pedro Valve Lots (PN-1), Pulgas Balancing Reservoir (PN-5)	Impacts on sensitive habitats and species; water quality; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2005-2007
PNP-30	CCSF (SFPUC)	Polhemus Creek Restoration	Restoration of Polhemus Creek along Polhemus Road. Rock fill that was placed in the creek on an emergency basis in 1996 would be removed and the creekbed area would be restored (SFPUC, 2007).	CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4)	Impacts on sensitive habitats and species; water quality; construction-related traffic impacts on local access roads and associated air quality and noise impacts	2006–2007

TABLE 4.17-4 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE PENINSULA REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Projects[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other SFPUC Projects in the Peninsula Region (cont.)						
PNP-31 **(not shown on figure)**	CCSF (SFPUC)	Peninsula Watershed Habitat Conservation Plan	Preparation of a land use and biological planning document to provide comprehensive, long-term conservation measures for species listed as threatened or endangered under the endangered species acts, or for species that could be listed in the future. The plan would identify SFPUC watershed operations and maintenance activities to be covered, with the intent mitigating the potential effects on covered species resulting from these covered activities through implementation of a conservation program (under preparation).	Baden and San Pedro Valve Lots (PN-1), CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4), Pulgas Balancing Reservoir (PN-5)	Biological resources, water quality, construction-related traffic impacts on local access roads and associated air quality and noise impacts	**Implementation within 10 years after adoption of Peninsula WMP**

a A WSIP facility that, in conjunction with the cumulative project, could contribute to a potential cumulative impact, depending on construction timing or affected resources.
b Construction schedules for non-SFPUC projects were estimated based on information obtained in project-related documents such as initial studies and EIRs; city, county, and regional agency websites; and interviews with representatives from local jurisdictions or regional agencies. In some cases, project schedules could not be estimated from these sources, but the projects were in sufficient stages of planning to be considered likely to start or complete construction before 2014, the planning horizon for construction of WSIP facilities. The schedules for these projects are listed as "TBD" (To Be Determined). The estimated schedules are based on the most current information available during preparation of this PEIR (as of July 2006). However, as with all proposed development projects, estimated construction schedules are subject to revisions and delays and therefore could vary from the time periods indicated.

TABLE 4.17-5
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE SAN FRANCISCO REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other Non-SFPUC Planned or Approved Projects in the San Francisco Region (Public and Private Developments)						
SFC-1	CCSF (SFPUC)	800 Brotherhood Way	Subdivision of 8.15-acre parcel into 127 lots, including 66 single-family homes, 39 two-unit buildings, and 22 three-unit buildings (CCSF, 2007; Moitra, 2006).	SAPL 3 Installation (SF-1)	Land use effects on recreational uses (Harding Park Municipal Golf Course; construction-related traffic impacts on local streets (e.g., Brotherhood Way) and associated air quality and noise impacts	2007-2008
SFC-2	CCSF (SFPUC)	50 Thomas More Way	Addition of new classroom building and gymnasium at St. Thomas More School (CCSF, 2007; Moitra, 2006).	SAPL 3 Installation (SF-1)	Construction-related traffic impacts on local streets (e.g., Brotherhood Way) and associated air quality and noise impacts	TBD
SFC-3	CCSF (SFPUC)	Stern Grove and Pine Lake Park	Phased implementation of improvements, including redesign of concert area; restoration of historic structures, new and restored playgrounds, and activity areas; infrastructure improvements; and wildlife habitat restoration (CCSF, 2007; Moitra, 2006).	SAPL 3 Installation (SF-1)	Water quality impacts; construction-related traffic impacts on local streets (e.g., Brotherhood Way) and associated air quality and noise impacts	TBD
SFC-4	CCSF (SFPUC)	2800 Sloat Boulevard	Construction of 55-unit residential building with 48 parking spaces in underground garage, and 26,000 gross square feet of ground-floor retail (CCSF, 2007; Moitra, 2006).	SAPL 3 Installation (SF-1)	Construction-related traffic impacts on local streets and associated air quality and noise impacts	TBD
SFC-5	CCSF (SFPUC)	2750 Rivera Street	Construction of new music building with coral room, classrooms, storage, batting cages, and accessory space two blocks south of reservoir (CCSF, 2007; Moitra, 2006).	SAPL 3 Installation (SF-1), Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local streets and associated air quality and noise impacts	TBD
SFC-6	CCSF (SFPUC)	18th/19th Avenue Traffic Calming Project	Implementation of phased traffic-calming improvements on 18th and 19th Avenues, including sidewalk, intersection, median, and traffic signalization improvements (CCSF, 2007).	SAPL 3 Installation (SF-1), Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local streets (e.g., 18th and 19th Avenues) and associated air quality and noise impacts	2007-2009+
SFC-7	CCSF (SFPUC)	USF, 2130 Fulton Street	Construction of a 26,000-square-foot addition to McLaren Hall, including office, classroom, and student lounge space (CCSF, 2007; Moitra, 2006).	SAPL 3 Installation (SF-1), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local streets and associated air quality and noise impacts	Under Construction

TABLE 4.17-5 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE SAN FRANCISCO REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other SFPUC Projects near the Oceanside Water Treatment Plant						
SFP-1a	CCSF (SFPUC)	OSP HVAC Improvements	HVAC (heating, ventilation, and air conditioning) system improvements of eight process buildings, an administration building, and a parking structure (SFPUC, 2006).	SAPL 3 Installation (SF-1), Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	2005–2008
SFP-1b	CCSF (SFPUC)	OSP Digester Mixing Improvements	Modifications or upgrades to internal overflow, withdrawal lines, mixing system, gas collection, and heat exchangers (SFPUC, 2006).	SAPL 3 Installation (SF-1), Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	2008–2010
SFP-1c	CCSF (SFPUC)	SWOO Cleaning and Backflow Prevention	Engineering evaluation of saltwater and sediment intrusion and development of a methodology to clean southwest ocean outfall. Installation of backflow prevention devices to eliminate further saltwater and sediment intrusion (SFPUC, 2006).	SAPL 3 Installation (SF-1), Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	2000–2009
Other SFPUC Projects in the San Francisco Region						
SFP-2	CCSF (SFPUC)	2nd Avenue/ 4th Avenue/ 12th Avenue Sewer Replacement	Replacement of the existing sewers on 2nd Avenue from Balboa to Cabrillo Street; 4th Avenue from Geary Boulevard to Cornwall Street; 12th Avenue from Geary Boulevard to Cabrillo Street; and from Lake to California Street (SFPUC, 2006).	Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts; potential to share same pipeline alignment	2007
SFP-3	CCSF (SFPUC)	Parker Avenue/ McAllister Street/ 17th Avenue Sewer Replacement	Replacement of the existing sewers on Parker Avenue from Geary Boulevard to Euclid Avenue; McAllister Street from Parker Avenue to Stanyan Street; and 17th Avenue from Balboa to Cabrillo Street (SFPUC, 2006).	Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts; potential to share same pipeline alignment	Completed 2006
SFP-4	CCSF (SFPUC)	Alma Street/ Fulton Street/ Saturn Street/ Willard Street Sewer Replacement	Replacement of the existing sewers on Alma Street from Belvedere to Cole Street; Fulton Street from Stanyan Street to Arguello Boulevard; Saturn Street from Roosevelt Way to Temple Street; and Willard North Street from Turk Boulevard to Golden Gate Avenue (SFPUC, 2006).	Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	2006–2007

TABLE 4.17-5 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE SAN FRANCISCO REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other SFPUC Projects in the San Francisco Region (cont.)						
SFP-5	CCSF (SFPUC)	Euclid Avenue/ Pacific Avenue/ 36th Avenue Sewer Replacement	Replacement of the existing sewers on Euclid Avenue from Jordan to Palm Avenue; Pacific Avenue from Presidio to Walnut Street; and 36th Avenue from Balboa to Cabrillo Street (SFPUC, 2006).	Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts; potential to share same pipeline alignment	2007-2008
SFP-6	CCSF (SFPUC)	Kirkham Sewer Improvement	Project to alleviate flooding along Kirkham Street by increasing the capacity of the sewer system along Kirkham Street from 21st to 26th Avenue, Lawton Street from 21st to 23rd Avenue, Moraga Street from 22nd to 23rd Avenue, and 21st Avenue from Lawton to Moraga Street (SFPUC, 2006).	Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts; potential to share same pipeline alignment	2009–2010
SFP-7	CCSF (SFPUC)	Vicente Street Sewer System Improvements – Phase I	Project to alleviate flooding along Vicente Street by increasing the capacity of the sewer system along Vicente Street from 34th to Sunset Avenue, 42nd to 44th Avenue, and 44th to 45th Avenue (SFPUC, 2006).	Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts; potential to share same pipeline alignment	Completed 2005–2006
SFP-8	CCSF (SFPUC)	Vicente Street Sewer System Improvements – Phase II	Project to alleviate flooding along Vicente Street and 45th Avenue by increasing the capacity of the sewer system along Vicente Street from 26th to 32nd Avenue, Ulloa Street from 45th Avenue to the Great Highway, and at the intersection of 44th Avenue and Wawona Street (SFPUC, 2006).	Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts; potential to share same pipeline alignment	Completed 2006
SFP-9	CCSF (SFPUC)	Kirkham Street/ Vicente Street/ 30th Avenue/ 48th Avenue Sewer Replacement	Replacement of the existing sewers on Kirkham Street from 10th to 11th Avenue; Vicente Street from 47th Avenue to Lower Great Highway; 30th Avenue from Taraval to Ulloa Street; 48th Avenue from Lawton to Moraga Street; and from Noriega to Ortega Street (SFPUC, 2006).	Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts; potential to share same pipeline alignment	2007-2008
SFP-10	CCSF (SFPUC)	23rd Avenue/ 31st Avenue/ Arguello Boulevard/ Funston Avenue Sewer Replacement	Replacement of the existing sewers on 23rd Avenue from Taraval to Vicente Street; 31st Avenue from Santiago to Taraval Street; Arguello Boulevard from Carl to Hugo Street; Funston Avenue from Judah to Kirkham Street (SFPUC, 2006).	Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts; potential to share same pipeline alignment	Completed 2005 to 2006

TABLE 4.17-5 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE SAN FRANCISCO REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other SFPUC Projects in the San Francisco Region (cont.)						
SFP-11	CCSF (SFPUC)	Junipero Serra Sewer Improvement	Project to alleviate flooding along Junipero Serra by increasing the capacity of the sewer system along Junipero Serra from Lyndhurst to Eucalyptus (SFPUC, 2006).	SAPL 3 Installation (SF-1), Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts; projects could share the same pipeline alignment	2009–2010
SFP-12	CCSF (SFPUC)	Ocean Avenue Sewer Improvement	Project to alleviate flooding in the vicinity of Ocean Avenue/Faxon Street (SFPUC, 2006).	SAPL 3 Installation (SF-1), Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts; projects could share same pipeline alignment	2009–2010
SFP-13	CCSF (SFPUC)	Claremont Boulevard/ Edna Street/ Naglee Street/ Oneida Street/ Seneca Avenue Sewer Replacement	Replacement of the existing sewers on Claremont Boulevard from Granville Way to Dewey Boulevard; Edna Street from Monterey Boulevard to Joost Avenue; Naglee Street from Huron Avenue to Alemany Boulevard; Oneida Street from Cayuga Avenue to end; and Seneca Avenue from Delano to Cayuga Avenue (SFPUC, 2006).	SAPL 3 Installation (SF-1), Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts; projects could share the same pipeline alignment	2006–2007
SFP-14	CCSF (SFPUC)	Streetlighting Conversion	Replacement of part of current series loop 576, located in the Lakeshore area at the end of Ocean Avenue, west of Sunset Boulevard (SFPUC, 2006).	SAPL 3 Installation (SF-1), Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	TBD
SFP-15	CCSF (SFPUC)	Brotherhood Way Sewer Improvement	Project to alleviate flooding along Brotherhood Way and St. Charles. The project involves increasing the capacity of the sewer system along Brotherhood Way between Arch and Vernon, Head and Victoria, Ramsell and Arch, St. Charles and Junipero Serra, Vernon and St. Charles, and Victoria and Ramsell (SFPUC, 2006).	SAPL 3 Installation (SF-1), Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic on local access roads and associated air quality and noise impacts; projects could share the same pipeline alignment	2006–2007

TABLE 4.17-5 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE SAN FRANCISCO REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other SFPUC Projects in the San Francisco Region (cont.)						
SFP-16	CCSF (SFPUC)	Alemany and Sickles Sewer Improvements, Phase 1	Project to address flooding complaints in the vicinity of Alemany Boulevard near the Daly City limits (SFPUC, 2006).	SAPL 3 Installation (SF-1), Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic on local access roads and associated air quality and noise impacts; projects could share the same pipeline alignment	2009
SFP-17	CCSF (SFPUC)	Sunset Reservoir – North Basin	Seismic upgrades and rehabilitation of the existing Sunset Reservoir North Basin, including stabilizing the earth embankment around the reservoir in conformance with Division of Safety of Dams requirements to minimize the potential for movement during an earthquake (SFPUC, 2005b).	SAPL 3 Installation (SF-1), Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	2005–2008
SFP-18	CCSF (SFPUC)	Central Pump Station	Structural and seismic improvements to the Central Pump Station and new emergency generator system (SFPUC, 2007c).	SAPL 3 Installation (SF-1), Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	2004-2007
SFP-19	CCSF (SFPUC)	East-West Transmission Main	Construction of 4.5 miles of new underground pipeline from the Alemany Pump Station in the Potrero District to Junipero Serra Boulevard at Holloway Avenue. This pipeline connects the water supply on the east side of the city to the west (SFPUC, 2007c).	SAPL 3 Installation (SF-1), Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	2007-2009
SFP-20	CCSF (SFPUC)	Fulton at 6th Avenue – 30" Main Replacement	Replacement of deteriorated Richmond supply main along 6th Avenue between Lincoln Way and Fulton Street (SFPUC, 2007c).	Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	2007-2008
SFP-21	CCSF (SFPUC)	Lake Merced Pump Station Essential Upgrade	Full evaluation of pump station facilities; development of phased master plan to assist completion of future projects; assessment of San Andreas #2 supply pipeline (SFPUC, 2007c).	SAPL 3 Installation (SF-1), Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	TBD

TABLE 4.17-5 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE SAN FRANCISCO REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other SFPUC Projects in the San Francisco Region (cont.)						
SFP-22	CCSF (SFPUC)	Lincoln Park Pump Station and Tank Upgrades	The previous pump station and tank were demolished in 2005. A new pump station is being built, including four new 10-horse power pumps, a new sprinkler system, new electrical system, water quality monitoring and disinfection systems, and new hydropneumatic pumps. A new seismically reinforced 100,000-gallon water tank is also being constructed (SFPUC, 2007c).	SAPL 3 Installation (SF-1), Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	2005–2007
SFP-23	CCSF (SFPUC)	Lincoln Way Transmission Line	Installation of 2.5 miles of new 48-inch transmission line that would supply water from Sunset Reservoir to the northern and eastern zones of the city. The transmission line would be installed from Pacheco Street at the Sunset Reservoir to 29th Avenue and along 29th Avenue to Lincoln Way (SFPUC, 2007c).	SAPL 3 Installation (SF-1), Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	Completed 2006
SFP-24	CCSF (SFPUC)	Merced Manor Reservoir	Structural and seismic improvements to the Merced Manor Reservoir located on Ocean Avenue between 22nd and 23rd Avenues. Other improvements include security upgrades, replacement of the reservoir lining, inlet/outlet valve repairs, removal of sediments, and disinfection and chlorination (SFPUC, 2007c).	SAPL 3 Installation (SF-1), Groundwater Projects (SF-2), Recycled Water Projects (SF-3)	Treated water discharges, construction-related traffic impacts on local access roads and associated air quality and noise impacts	2004-2006
Other SFPUC Projects at Various Locations						
N/A	CCSF (SFPUC)	Chemical Feed System	Installation of chemical feed systems and related sewer work at various locations to mitigate odors from storage/transport facilities. Instrumentation improvements on the existing chemical feed systems (SFPUC, 2006).	Depends on specific facility locations	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	2005–2008
N/A	CCSF (SFPUC)	Major Electrical and Mechanical Equipment Reliability Improvements	Replacement of critical and aging mechanical and electrical equipment at various facilities, including pumping and treatment facilities (SFPUC, 2006).	Depends on specific facility locations	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	2005–2010

TABLE 4.17-5 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE SAN FRANCISCO REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other SFPUC Projects at Various Locations (cont.)						
N/A	CCSF (SFPUC)	Miscellaneous Odor Control Improvements	Various odor control facilities for collection system, pumping stations, and treatment facilities (SFPUC, 2006).	Depends on specific facility locations	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	2010–2020
N/A	CCSF (SFPUC)	Wastewater Facilities Equipment Replacement	Ongoing replacement program for mechanical and electrical equipment to reestablish the reliability of pumping and treatment facilities (SFPUC, 2006).	Depends on specific facility locations	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	Ongoing
N/A	CCSF (SFPUC)	Miscellaneous Improvements to Structurally Inadequate Sewers	Replacement/rehabilitation of existing structurally inadequate sewers in locations throughout San Francisco (SFPUC, 2006).	Depends on specific facility locations	Construction-related traffic impacts on local access roads and associated air quality and noise impacts; potential to share same pipeline alignment	Current to 2030
N/A	CCSF (SFPUC)	Miscellaneous Sewer Replacements	Ongoing sewer replacement to reestablish structural reliability and improve capacity (SFPUC, 2006).	Depends on specific facility locations	Construction-related traffic impacts on local access roads and associated air quality and noise impacts; projects could share the same pipeline alignment	Ongoing
N/A	CCSF (SFPUC)	SFPUC Sewer Master Plan	Development of a sewer master plan to develop a long-term vision and strategy for the management of the City's wastewater and storm water; address specific challenges facing the system; and maximize system reliability and flexibility. The plan will guide sewer system improvements over the next 30 years. Short-term problems with the system are being addressed through the Five-Year Wastewater Capital Improvement Program (SFPUC, 2007d).	Depends on specific facility locations	Construction-related traffic impacts on local access roads and associated air quality and noise impacts; potential to share same pipeline alignment	Ongoing
N/A	CCSF (SFPUC)	Wet Weather Improvements	Project to maximize and/or expand capacity of the collection system and wet-weather facilities to reduce street flooding and overflow discharges (SFPUC, 2006).	Depends on specific facility locations	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	2010–2020
N/A	CCSF (SFPUC)	Miscellaneous Improvements to Sewerage Facilities	Replacement and upgrade of mechanical components and structures within sewage treatment plants, pumping facilities, and other sewerage facilities throughout San Francisco (SFPUC, 2006).	Depends on specific facility locations	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	Current to 2030

TABLE 4.17-5 (Continued)
CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES IN THE SAN FRANCISCO REGION

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule[b]
Other SFPUC Projects at Various Locations (cont.)						
N/A	CCSF (SFPUC)	Street Lighting Replacing and Repairs	Street lighting replacement and repair in multiple areas (SFPUC, 2006).	Depends on specific facility locations	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	TBD

[a] A WSIP facility that, in conjunction with the cumulative project, could contribute to a potential cumulative impact, depending on construction timing or affected resources. Potentially cumulative projects with the Regional Groundwater Projects to be constructed under SF-2 were not identified because specific well locations have not been determined and could be anywhere in the South Westside Groundwater Basin.
[b] Construction schedules for non-SFPUC projects were estimated based on information obtained in project-related documents such as initial studies and EIRs; city, county, and regional agency websites; and interviews with representatives from local jurisdictions or regional agencies. In some cases, project schedules could not be estimated from these sources, but the projects were in sufficient stages of planning to be considered likely to start or complete construction before 2014, the planning horizon for construction of WSIP facilities. The schedules for these projects are listed as "TBD" (To Be Determined). The estimated schedules are based on the most current information available during preparation of this PEIR (as of July 2006). However, as with all proposed development projects, estimated construction schedules are subject to revisions and delays and therefore could vary from the time periods indicated.

TABLE 4.17-6
OTHER SFPUC SYSTEMWIDE CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule
CSYS-1	CCSF (SFPUC)	Installation of SCADA System – Phase 2 & System Security Upgrades	Installation of monitoring and control equipment as well as security systems at various locations throughout the regional system. The project is in the initial stages and includes preparation of a needs assessment report. The project would include installing a series of water quality and flow monitoring facilities at various locations, and developing and implementing the integration of security components at 14 critical sites in the regional system (SFPUC, 2005b).	SJPL System (SJ-3), SJPL Rehabilitation (SJ-4), BDPL Reliability Upgrade (BD-1), BDPL Nos. 3 and 4 Crossovers (BD-2), Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault (BD-3), Baden and San Pedro Valve Lots (PN-1)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	2009–2011
CSYS-2	CCSF (SFPUC)	Cross Connection Controls	Upgrade of the existing configuration for air/vacuum valves and blowoffs at approximately 30 locations along the transmission system to eliminate and prevent cross connections and backflow from unapproved sources into the water system. The project would provide compliance with California water quality regulations for cross-connections. Typical project elements would include small-diameter valve and piping reconfigurations, installation of backflow prevention devices and air gaps at blowoffs and air valves, and other site-specific system modifications as necessary (SFPUC, 2005b).	BDPL Reliability Upgrade (BD-1), BDPL Nos. 3 and 4 Crossovers (BD-2), Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault (BD-3), Baden and San Pedro Valve Lots (PN-1)	Construction-related traffic impacts on local access roads and associated air quality and noise impacts	2008
CSYS-3	CCSF (SFPUC)	Habitat Reserve Program (HRP)	The HRP is a program to develop wetland and other habitat mitigation credits required to implement WSIP projects through early habitat creation or enhancement at select mitigation sites on existing SFPUC lands or on acquired sites (under development).	All WSIP projects	Biological resources; water quality; agricultural resources	No construction required
CSYS-4	CCSF (SFPUC)	Watershed and Environmental Improvement Program (WEIP)	The WEIP would seek to identify, prioritize, protect, and restore lands within the hydrologic boundaries, which contribute to SFPUC source waters in the Alameda Creek, Peninsula, and Tuolumne River watersheds. This program would ensure the delivery of high-quality water to Bay Area communities and the preservation and restoration of significant ecological resources throughout SFPUC watershed lands (under development).	All WSIP projects	Biological resources; water quality	No construction required

TABLE 4.17-6 (Continued)
OTHER SFPUC SYSTEMWIDE CUMULATIVE PROJECTS AND IMPACTS RELATED TO WSIP FACILITIES

Cumulative Project No.	Jurisdiction	Project Name	Project Description	Potentially Contributing WSIP Project[a]	Potential Cumulative Impact Topics	Estimated Construction Schedule
CSYS-6	CCSF (SFPUC)	Expansion of Solar and Renewable Energy Generation in San Francisco	The CCSF plans to expand the San Francisco's solar and renewable energy resources, including the formation of public-private partnerships that would leverage new state legislation and available financing mechanisms to facilitate and support the development of large-scale solar and other renewable energy resources on public and private property in the city. The plan would boost solar generation from less than 2 megawatts today to nearly 35 megawatts in the future (SFPUC, 2007e).	N/A	Energy resources	TBD

[a] A WSIP facility that, in conjunction with the cumulative project, could contribute to a potential cumulative impact, depending on construction timing or affected resources.

[a] Cumulative projects in the same vicinity as a WSIP facility with proposed schedules that have start or end dates within two years of each other. See Tables 4.17-1 through 4.17-6 for the names and descriptions of the potentially cumulative projects.

[b] For SFPUC projects, a project is considered to have a direct cumulative impact with a WSIP project if construction would occur at the same facility or within a distance that could result in direct physical environmental effects. Projects that could have a direct cumulative effect but don't have a defined schedule are indicated as "Possibly Direct"; these projects could possibly have overlapping construction schedules with the indicated WSIP facility, depending on the timing of construction. For the Sunol Valley Region, a project is considered to have an indirect effect if it would contribute to traffic on Calaveras Road or regional roads (Highway 84). Sunol Valley projects without a defined schedule are included in the list of indirect projects because they could cumulatively contribute to areawide or regional traffic, air quality, and noise impacts.

[c] For non-SFPUC projects (public and private), a project is considered to have a direct cumulative impact with a WSIP facility if construction would occur within a distance that could result in direct physical environmental effects. Projects that could have a direct cumulative effect but don't have a defined schedule are indicated as "Possibly Direct;" these projects could have overlapping construction schedules with the indicated WSIP facility, depending on the timing of construction. A few non-SFPUC projects that have a defined schedule are also considered to have indirect effects because the size, location, or regional attraction of these projects would contribute to areawide or regional effects, such as traffic, air quality, and noise impacts. These include SJC-19, the Mountain House development; BDC-9, Cisco Field, the proposed Oakland A's ballpark; BDC-15, the proposed 49er's Stadium Complex; and BDC-26, the South Bay Salt Pond Restoration Project, a 15,000-acre wetland restoration project.

Major Projects in WSIP Project Area with Potential for Cumulative Impacts

SOURCE: ESA + Orion; SFPUC, 2006

SFPUC Water System Improvement Program . 203287

Figure 4.17-2b
Major Projects in WSIP Project Area with Potential for Cumulative Impacts

As shown in Tables 4.17-1 through 4.17-6, the cumulative projects identified in the WSIP study area include development projects (e.g., residential, commercial, industrial, educational, and hospital uses), transportation infrastructure projects (e.g., freeways, roadways, and rail), and utility infrastructure projects (water, wastewater, and power facilities), with construction schedules ranging from 2006 to 2068. In these tables, the column entitled *Potential Cumulative Impact Areas* for each project presents a general list of the types of impacts that could be associated with the listed projects; no site-specific environmental review was conducted for each listed project. Additionally, the cumulative impact areas identified for the listed projects in these tables would relate mostly to construction, since the primary facility impacts associated with the WSIP would occur during construction.

Most projects' construction schedules range between 2006 and 2010, although some extend to about 2015. There are a few that extend beyond 2017 (2021 to 2048) and one project that extends to 2068.[3] Table 4.17-7 shows that construction of most WSIP projects would be underway by 2008–2010 and completed by 2012–2013, and also indicates which cumulative projects could have overlapping construction schedules with each WSIP project.
Tables 4.17-1 through 4.17-6 indicate the following:

- <u>*San Joaquin Region*</u>. There are 25 identified projects that could potentially contribute to cumulative impacts in the San Joaquin Region (Table 4.17-1). Nineteen of these projects are public or private development projects located in adjacent jurisdictions, while six are planned SFPUC infrastructure projects near Tesla Portal or Thomas Shaft. As indicated in Table 4.17-1, cumulative development in this region would involve the following: over 1,700 residential units, 700,000 square feet of commercial/office space, more than 2.5 million square feet of light/medium/heavy industrial space, expansion of agricultural operations, expansion of hospital facilities, and various highway improvements. Mountain House, a new community between Tracy and Livermore with approximately 16,000 residential units as well as commercial, educational, and business park uses, represents the largest potentially cumulative development project in the San Joaquin Region.

  Although construction schedules for a number of listed projects are unknown or yet to be determined, all but three of the projects with estimated construction schedules would be completed by 2017. The exceptions are the Kaiser Modesto Medical Center, Phase C, (completion by 2025), RMC Pacific Vernalis Quarry Mining and Reclamation Project (completion by 2068), and Mountain House (completion by 2048). Table 4.17-7 indicates that construction of up to 24 projects could directly overlap with WSIP projects in this region.

- <u>*Sunol Valley Region*</u>. There are 30 identified projects that could potentially contribute to cumulative impacts in the Sunol Valley Region (Table 4.17-2). Six of these projects are public or private development projects located in adjacent jurisdictions, while 24 are planned SFPUC infrastructure projects near the Sunol Valley Water Treatment Plant (WTP), Alameda Portals, Sunol Yard, Alameda Siphons, or the Sunol Valley Region in general. As indicated in Table 4.17-2, cumulative development in this region would involve the following: quarry expansions, road and highway improvements, and a Chevron pipeline relocation.

[3] RMC Pacific Vernalis Quarry Mining and Reclamation Project, SJC-17, a sand and gravel extraction project proposed to operate in San Joaquin and Stanislaus Counties until 2068.

Although construction schedules for a number of listed projects are unknown or yet to be determined, all but one of the projects with estimated construction schedules would be completed by 2012. The exception is Mission Valley Rock Company Quarries, which would continue to operate and expand until 2045 and beyond. Table 4.17-7 indicates that construction of up to 26 projects could directly overlap with WSIP projects in this region, while up to 37 additional projects could indirectly overlap.[4]

- *Bay Division Region*. There are 42 identified projects that could potentially contribute to cumulative impacts in the Bay Division Region (Table 4.17-3). Twenty-six of these projects are public or private development projects located in adjacent jurisdictions, while 16 are planned SFPUC infrastructure projects near the Bay Division Pipelines Nos. 1, 2, 3, or 4 or the Bay Division Region in general. As indicated in Table 4.17-2, cumulative development in this region would involve the following: over 1,500 residential units, more than 2.5 million square feet of commercial/office/research and development (R&D) space, over 2 million square feet of hospital replacement/expansion space, electricity generation and transmission facilities, rail service extension (including BART), a college campus, a major-league baseball stadium, football stadium complex, tidal wetland restoration, and various highway improvements.

  Although construction schedules for a number of listed projects are unknown or yet to be determined, all of the projects with estimated construction schedules would be completed by 2014. Table 4.17-7 indicates that construction of up to 41 projects could directly overlap with WSIP projects in this region, while up to 4 additional projects could indirectly overlap.

  Peninsula Region. There are 41 identified projects that could potentially contribute to cumulative impacts in the Peninsula Region (Table 4.17-4). Four of these projects are public or private development projects located in adjacent jurisdictions, while 37 are planned SFPUC infrastructure projects near the Harry Tracy WTP or the Peninsula Region in general. As indicated in Table 4.17-4, cumulative development in this region would involve the following: more than 700 residential units as well as commercial uses.

  Although construction schedules for a number of listed projects are unknown or yet to be determined, all but eight of the projects with estimated construction schedules would be completed by 2010. The SFPUC Sunset Supply Pipeline Inspection (M40 to M50) project, to be completed by 2021, would be the last project in the region to be constructed. Table 4.17-7 indicates that construction of up to 42 projects could directly overlap with WSIP projects in this region.

- *San Francisco Region*. There are 33 identified projects that could potentially contribute to cumulative impacts in the San Francisco Region (Table 4.17-5). Seven of these projects are public or private development projects located in adjacent jurisdictions, while 36 are planned SFPUC infrastructure projects near the San Francisco Region in general.[5] As indicated in Table 4.16-1, cumulative development in this region would involve the following: over 232 residential units, approximately 26,000 square feet of office/commercial/R&D space, expansion or improvements to parks and schools (up through college level), and traffic calming measures.

---

4 See Table 4.16-9, footnotes b and c, for definitions of "direct" and "indirect."
5 Of these, 10 SFPUC projects have unknown or undefined locations. Therefore, potential overlap with these projects could not be determined.

Although construction schedules for a number of listed projects are unknown or yet to be determined, all but four of the projects with estimated construction schedules would be completed by 2014. The exceptions are four SFPUC projects involving storm drainage, wastewater, and transformer improvements that are scheduled for completion by 2030. Table 4.17-7 indicates that construction of up to 29 projects could directly overlap with WSIP projects in this region.

- *Entire Region – Systemwide*. Six identified systemwide cumulative projects involving multiple sites have the potential to overlap with many of the WSIP projects. However, construction activities associated with these projects would be very limited in terms of area (involving installation of pipe, valves, and electronic equipment at existing facilities) and timeframe, which would minimize the potential for overlap. Two of these projects are habitat protection, enhancement, or restoration projects and would not involve construction. Therefore, the potential contribution of these projects to the construction and operational impacts identified below would not be cumulatively considerable, and the projects are not considered further in this analysis.

  The WSIP PEIR Notice of Preparation (SFPUC, 2005b) identified four WSIP projects that are not considered in the cumulative impact analysis below. They are as follows:

- *Slipline Bay Division Pipeline 4 PCCP Sections (formerly BD-3)*. This project would be located along the alignment of the Bay Division Pipelines Nos. 3 and 4 and could overlap with WSIP projects also located along this alignment. However, this project consists of a conditions assessment only, and no construction activities or schedule have been identified. If the conditions assessment were to indicate the need for pipeline rehabilitation, construction would not occur until after the WSIP projects have been completed. Therefore, this project would not contribute to any cumulative impacts identified below for the WSIP and other cumulative development near WSIP projects.

- *SFPUC/EBMUD Intertie (formerly BD-5), Capuchino Valve Lot (formerly PN-3), and University Mound Reservoir (formerly SF-4)*. These projects are not contiguous with any of the WSIP facilities analyzed in Sections 4.3 through 4.15. Therefore, these projects would not contribute to any cumulative construction and operational impacts identified below for the WSIP in combination with other nearby SFPUC and non-SFPUC development projects (listed in Tables 4.17-1 through 4.17-6).

4.17.3 Cumulative Facility Impacts

In general, there are two categories of cumulative impacts that could result from implementation of the WSIP in combination with other projects identified in Tables 4.17-1 through 4.17-6: (1) direct cumulative impacts related to facility construction and operation; and (2) indirect or secondary cumulative impacts due to planned growth that would result from increased water supply. This section evaluates the direct cumulative impacts of facility construction and operation. Secondary growth impacts resulting from increased water supply are evaluated in Chapter 7, Growth Inducement Potential and Secondary Effects of Growth, which describes the environmental effects associated with planned growth (including the proposed and approved non-SFPUC projects listed in Tables 4.17-1 through 4.17-6). It should be noted that the projects listed in these tables represent recent, present, and future projects in the vicinity of WSIP facilities. This section focuses on the cumulative impacts of projects that overlap geographically and projects with overlapping schedules (shown in Table 4.17-7).

Significance Criteria

The City and County of San Francisco has not formally adopted significance standards for impacts related to cumulative effects, but generally considers that implementation of the proposed program would have significant cumulative impacts if it were to:

- Have impacts that would be individually limited but cumulatively considerable ("cumulatively considerable" means that the incremental effects of a project are significant when viewed in connection with the effects of past, present, and probable future projects)

WSIP impacts that would be "individually limited" are based on the impact analyses and significance criteria presented in Sections 4.3 through 4.15 for the various environmental resource topics.

Impact Summary

Potential cumulative impacts of the WSIP are described in this section by environmental resource topic, since the geographic scope of the impact can vary by topic. Each impact discussion below assesses the potential for the WSIP as a whole to contribute to significant cumulative impacts when considered in combination with the effects of other projects listed in Tables 4.17-1 through 4.17-6. Cumulative impact significance determinations for the entire WSIP study area are presented by environmental topic in **Table 4.17-8**.

Land Use and Visual Quality

Impact 4.17-1: Cumulative disruption of established communities, changes in existing land use patterns, and impacts on the existing visual character.

With respect to land use and visual impacts, the geographic scope of potential cumulative impacts encompasses the WSIP facility sites and immediate vicinities, including major construction staging areas (when known). However, major developments in the region are considered when characterizing overall regional changes in established land use patterns and visual quality.

Tables 4.17-1 through 4.17-6 indicate that cumulative development in the WSIP study area (including the San Joaquin, Sunol Valley, Bay Division, Peninsula, and San Francisco Regions) would result in development of over 20,000 residential units; more than 3 million square feet of commercial, office, or R&D uses; more than 2 million square feet of medical/hospital facilities; and more than 2.5 million square feet of industrial uses. Cumulative development would also include expansion of educational facilities (schools and colleges), transportation projects (including highway improvements, expansion of transit services), infrastructure improvements (including electricity generation/transmission and pipeline facilities), and quarry expansions. Such levels of development could disrupt established communities and significantly alter existing land use patterns

TABLE 4.17-8
SUMMARY OF CUMULATIVE FACILITIES IMPACTS

Impact Number and Topic	Cumulative Impacts
4.17-1a: Land Use	LS
4.17-1b: Visual Quality	LS
4.17-2: Geology, Soils, and Seismicity	B/LS
4.17-3: Hydrology and Water Quality	LS
4.17-4: Biological Resources	LS
4.17-5: Cultural Resources	PSU
4.17-6: Traffic, Transportation, and Circulation	PSU
4.17-7: Air Quality	PSU
4.17-8: Noise and Vibration	PSU
4.17-9: Public Services and Utilities	LS
4.17-10: Recreational Resources	LS
4.17-11: Agricultural Resources	LS
4.17-12: Hazards	LS
4.17-13: Energy Resources	LS

NOTE: The significance determinations presented in this table assume implementation of all SFPUC standard construction measures, federal/state/local regulations, and mitigation measures identified in Chapter 6.

B = Beneficial impact
LS = Less than Significant impact, no mitigation required
PSU = Potentially Significant Unavoidable impact

in some parts of the WSIP study area (particularly in rural areas such as the San Joaquin Region, where the Mountain House and Patterson Gardens projects are located). However, cumulative development can be expected to occur consistent with each jurisdictional agency's planned development (as specified in their general plans).

The WSIP projects would contribute incrementally to cumulative land use changes where the acquisition of easements or land could permanently displace existing land uses at discrete locations adjacent to or near specific facility sites. However, as described in Section 4.16 under Impact 4.16-1a, the WSIP would not result in a collective or additive impacts associated with land use displacement, and, as described in Section 4.3, implementation of SFPUC construction measures and Measures 4.3-1 and 4.3-2 would reduce the WSIP's potential land use impacts to a less-than-significant level. The cumulative projects listed in Tables 4.17-1 through 4.17-6 include some SFPUC infrastructure and water facilities projects similar to the proposed WSIP facilities; however, these projects would be almost entirely within existing SFPUC facility sites, would not result in land use changes, and there would be limited, if any, overlap of additional land acquisition at the same locations as the WSIP projects. Therefore, the WSIP's residual contribution to cumulative impacts on land use would not be cumulatively considerable (*less than significant*).

The cumulative projects listed in Tables 4.17-1 through 4.17-6 include numerous major development projects that could substantially alter the visual character of areas within the WSIP study area, particularly in rural areas such as the San Joaquin Region. With a few exceptions (e.g., Mountain House and Patterson Gardens, which are located in and west of the San Joaquin Region), most of the areas where cumulative development would occur are in or adjacent to urbanized areas, minimizing the potential for significant cumulative changes in visual quality. These cumulative projects would, by and large, add to the urban/developed character of the region. When considered in combination with these projects, the WSIP's incremental contribution to long-term visual impacts, with proposed mitigation (Measure 4.3-3), would not be cumulatively considerable (*less than significant*).

Geology, Soils, and Seismicity

Impact 4.17-2: Cumulative exposure of people or structures to geologic and seismic hazards.

The geographic scope of potential cumulative geologic and seismic impacts encompasses the WSIP facility sites and immediate vicinities. These types of impacts are generally site specific and depend on local geologic and soil conditions.

As described in Sections 4.4 and 4.16, the WSIP consists of projects to strengthen and improve water system components that could be subject to seismic hazards in the event of an earthquake on one of the regional faults, and to provide redundancy in the system should substantial damage and/or a failure of part of the system occur. In addition, several potentially cumulative SFPUC projects would improve the seismic safety of water system facilities, including pipeline repairs and replacements, and would therefore cumulatively contribute to *beneficial* effects related to the seismic safety of the regional water system.

Other potential geologic and seismic impacts associated with implementation of the WSIP, which include impacts related to slope instability during construction, erosion, alteration of topography, squeezing ground, and expansive or corrosive soils (Impacts 4.4-4 through 4.4-9), would be site-specific (dependent on local geologic and soil conditions) and would be less than significant or mitigated on a site-specific basis (Measures 4.4-1, 4.4-4, and 4.4-9). Similarly, impacts for the cumulative projects listed in Tables 4.17-1 through 4.17-6 would also be less than significant with compliance with applicable regulations (e.g., Uniform Building Code) or would be mitigated on a site-specific basis. With site-specific mitigation, the WSIP's contribution to any localized cumulative impacts related to geology, soils, and seismicity would not be cumulatively considerable (*less than significant*).

Hydrology and Water Quality

Impact 4.17-3: Cumulative impacts related to the degradation of water quality, alteration of drainage patterns, increased surface runoff, and flooding hazards.

The geographic scope of potential cumulative hydrology and water quality impacts encompasses the SFPUC watershed lands, the multiple creeks, streams, and associated drainage areas within the WSIP study area, as well as San Francisco Bay, which ultimately receives drainage from all WSIP regions (except for sites on the west side of San Francisco, which drain to the Pacific Ocean).

Sections 4.5 and 4.16 (Impact 4.16-4) address program-level and collective hydrology and water quality impacts associated with implementation of the WSIP. The WSIP projects in conjunction with other projects identified in Tables 4.17-1 through 4.17-6 would not result in cumulative water quality and hydrology effects related to increased erosion and sedimentation, construction-related discharges of treated water or groundwater produced during dewatering, or operational discharges of treated water (Impacts 4.5-1, 4.5-3a, 4.5-3b, and 4.5-5), because these projects would incorporate best management practices for temporary and permanent erosion control as well as for other construction-related discharges, implement an inspection and maintenance program, and include corrective actions should any permit exceedance occur in accordance with SFPUC Construction Measure #3 and National Pollutant Discharge Elimination System (NPDES) discharge regulations. As described in Section 4.5, the NPDES discharge regulations are designed to protect water quality on a regionwide basis and incorporate measures to protect beneficial uses of water bodies based on overall consideration of past, present, and future conditions within the region. With compliance with permit conditions and implementation of control measures specified in the permit, any residual impact of the WSIP on regionwide water quality would not be cumulatively considerable (*less than significant*).

The WSIP projects would contribute to a cumulative increase in impervious surfaces in each WSIP region, potentially resulting in increased discharges of stormwater and related pollutants (Impact 4.5-6). However, projects located in the Sunol Valley, Bay Division, and Peninsula Regions, which drain to lower (or south) San Francisco Bay, would be subject to municipal stormwater permitting requirements (depending on the extent of impervious surfaces created or replaced); these requirements would include incorporation of post-construction stormwater controls that (1) minimize the stormwater flow rate and quantity to prevent offsite erosion and flooding, and (2) minimize stormwater pollutant discharges to the maximum extent possible, as specified in the stormwater management plan required under NPDES regulations. With compliance with permitting requirements and implementation of control measures, any residual contribution of the WSIP to regionwide or localized cumulative water quality impacts related to an increase in impervious surfaces would not be considerable for these regions (*less than significant*). Furthermore, many of the potentially cumulative projects would involve redevelopment within an existing impervious area, and replacement of the existing impervious surfaces would trigger the need to comply with updated municipal stormwater permitting requirements and to implement improved post-construction stormwater controls. Overall, such compliance would be beneficial to water quality in San Francisco Bay and other receiving waters.

In the San Joaquin Region and parts of the San Francisco Region, municipal stormwater permitting requirements would not apply. However, in the San Joaquin Region, most of the cumulative increases in impervious surfaces would result from construction of approximately 17,700 residential units, 700,000 square feet of commercial/office space, more than 2.5 million square feet of light/medium/heavy industrial space, and various highway improvements. The increase in impervious surfaces from WSIP projects in this region would be approximately 26,000 square feet, a minor contribution when compared with the total impervious surfaces associated with cumulative development, and the WSIP projects would incorporate post-construction stormwater controls that (1) minimize the stormwater flow rate and quantity to prevent offsite erosion and flooding, and (2) minimize stormwater pollutant discharges to the maximum extent possible, as specified in the stormwater management plan required under NPDES regulations or Measure 4.5-6. The WSIP projects would contribute less than 1 percent of the impervious surfaces in the San Joaquin Region, and would incorporate post-construction stormwater management controls such that the residual effects on stormwater and related pollutants would be minimal. Therefore, the WSIP's contribution to cumulative increases in discharges of stormwater and related pollutants in the San Joaquin Region would not be considerable (*less than significant*).

Because most of San Francisco is developed with impervious surfaces, construction of new projects in the San Francisco Region would generally involve replacement of existing surfaces and would not result in an increase in stormwater flows to the city's combined sewer system. Therefore, neither the WSIP projects nor other cumulative projects would be expected to contribute to an increase in the number or frequency of combined sewer overflows. Furthermore, stormwater discharges to the combined system are regulated under San Francisco's NPDES permit in conformance with the Combined Sewer Overflow Control Policy and all new development would likely incorporate improved stormwater controls, which would reduce the rate and quantity of stormwater discharged to the combined sewer system. With compliance with the applicable permit requirements, the WSIP projects would not be expected to contribute to an increase in the number or frequency of combined sewer overflows. Therefore, the WSIP's potential impacts related to an increase in impervious surfaces would not be cumulatively considerable for the San Francisco Region (*less than significant*).

None of the WSIP projects would contribute to a cumulative impact related to the alteration of drainage patterns that would result in offsite flooding, erosion, or sedimentation (Impact 4.5-6), because all projects would be required to implement SFPUC Construction Measures #3 and #10 (onsite water quality and project site measures) as well as comply with NPDES permits, which would require implementation of temporary and permanent erosion control measures in accordance with the regulatory-approved stormwater pollution prevention plan and stormwater management plan, or comply with erosion control measures enforced through Article 4.1 of the San Francisco Public Works Code in San Francisco. Other cumulative projects would be subject to similar requirements. The WSIP's potential impacts related to an alteration of drainage patterns would not be cumulatively considerable in any of the WSIP regions.

Impacts related to the diversion of flood flows and contribution of sediments and contaminants to flood flows during construction activities (Impact 4.5-4) would be mitigated to a less-than-significant level through implementation of flood flow protection measures (Measure 4.5-4a). Although projects located within 100-year floodplains could result in cumulative flooding impacts, the SFPUC would design facilities to avoid effects on flood flows. Therefore, the WSIP's incremental contribution to flooding impacts would not be cumulatively considerable (*less than significant*). Furthermore, identified private developments would be subject to local policies, which restrict new development within 100-year floodplains and specify measures for reducing flooding impacts.

Biological Resources

Impact 4.17-4: Cumulative loss of sensitive biological resources.

The geographic scope of potential biological resources impacts encompasses the wildlife and plant habitats of affected species in the WSIP study area (including wetlands, sensitive habitats, and riparian habitat).

Section 4.6 evaluates the impacts of each WSIP project on biological resources, including wetlands, sensitive habitats as defined by the California Department of Fish and Game, as well as heritage trees, special-status plant and wildlife species, and riparian habitat potentially subject to state and federal protection. As indicated in Tables 4.17-1 through 4.17-6, there could be cumulative impacts on sensitive biological resources located throughout the WSIP study area. These tables indicate that cumulative development in the WSIP study area (including the San Joaquin, Sunol Valley, Bay Division, Peninsula, and San Francisco Regions) would result in development of over 20,000 residential units; more than 3 million square feet of commercial, office, or R&D uses; more than 2 million square feet of medical/hospital facilities; and more than 2.5 million square feet of industrial uses. Cumulative development would also include expansion of educational facilities (schools and colleges), transportation projects (including highway improvements, expansion of transit services), infrastructure improvements (including electricity generation/transmission and pipeline facilities), and quarry expansions. Past, present, and projected future development within the Bay Area and Central Valley regions has and will result in significant unavoidable impacts on biological resources, regardless of whether the WSIP is implemented or not.

The cumulative impacts on biological resources resulting from the WSIP in conjunction with projects listed in Tables 4.17-1 through 4.17-6 are best described as bioregional effects, operating beyond the level of individual plants or animals.[6] For example:

[6] This section addresses cumulative impacts within the WSIP study area, which spans from San Francisco on the west to Oakdale Portal on the east. See Section 5.7 for cumulative impacts within areas east of Oakdale Portal (Tuolumne River watershed).

- Genetic diversity impacts on small populations that become reduced and isolated by development
- Impacts on wildlife movement due to habitat fragmentation
- Suppression of natural disturbance regimes (e.g., fire, flood) as projects are constructed, operated, and maintained
- Reduced population recovery opportunities from stochastic events (e.g., random events such as disease)

Compliance with applicable state and federal regulations, general plan conservation measures, and project-specific permitting requirements would mitigate these bioregional effects to some extent. For the WSIP, implementation of mitigation measures that address wetlands and special-status species protection, habitat restoration, and tree protection (Measures 4.6-1 through 4.6-3) as well as combining habitat compensation through a coordinated program such as the Habitat Reserve Program or other means (Measure 4.16-4a) to address bioregional effects could provide additional protection of affected biological resources, thereby ensuring that the WSIP's contribution to these cumulative bioregional effects would be *less than significant*.

Tables 4.17-1 through 4.17-6 include approximately six cumulative projects in the Sunol Valley, Bay Division, and Peninsula Regions designed to restore, protect, and enhance biological resources through the implementation of conservation measures (e.g., open space acquisition) in the WSIP study area. These projects include the Alameda and Peninsula Watershed Management Plans, habitat conservation plans for the SFPUC's Alameda and Peninsula watersheds, the SFPUC's Watershed and Environmental Improvement Program, and the South Bay Salt Pond Restoration Project at the south end of San Francisco Bay. Additional enhancement, restoration, and protection projects are identified and discussed in Section 5.7, Cumulative Projects and Impacts Related to WSIP Water Supply and System Operations. Although these projects do not specifically address biological impacts of the WSIP, they would provide an overall net benefit in terms of these cumulative bioregional effects.

Cultural Resources

Impact 4.17-5: Cumulative increase in impacts on archaeological, paleontological, and historical resources.

The geographic scope of potential cumulative impacts on cultural resources encompasses the WSIP facility improvement project sites and immediate vicinities, and other SFPUC projects near WSIP sites.

As described in Section 4.7, there is a potential to encounter previously undiscovered cultural resources, including archaeological and paleontological resources, during construction of WSIP facilities; however, implementation of recommended mitigation measures would reduce impacts to a less-than-significant level. The potential to encounter cultural resources associated with the other cumulative projects listed in Tables 4.17-1 through 4.17-6 is unknown, but does exist. However, since the WSIP's impacts on archaeological and paleontological resources would be site-specific and mitigated to a less-than-significant level with implementation of Measure 4.7-1, the WSIP's contribution to any such impacts would not be cumulatively considerable (*less than significant*).

As described in Impact 4.7-4 and in Section 4.16, Collective Impacts Related to WSIP Facilities, under Impact 4.16-5, implementation of the WSIP could alter historical resources within the SFPUC regional water system, but only has the potential to cause a collective impact on historic districts (if historic districts are determined to be present) within the Sunol Valley and Peninsula Regions. As shown on the tables, the SFPUC has implemented or proposes to implement other projects along the regional water system. These other projects generally involve varying degrees of facility repair, upgrade, and improvement. None of the projects listed in the tables would cause impacts on known historical resources that could also be affected by WSIP projects.

Similar to the analysis presented in Section 4.16, the WSIP contribution to potential cumulative effects would not be cumulatively considerable in the San Joaquin and Bay Division Regions, but could be cumulatively considerable in the Sunol Valley and Peninsula Regions. In the San Joaquin and Bay Division regions, the WSIP facility improvement projects are primarily pipeline projects located within the SFPUC's existing rights-of-way; there would be little overlap in the construction impact area of these projects and those of other development and infrastructure projects in these regions. SFPUC Construction Measure #9 along with mitigation measures identified in Chapter 6 (Measures 4.7-3 and 4.7-4a through 4.7-f) address the potential cultural resource effects of the projects in these regions and would minimize the contribution of these projects to cumulative effects.

There are several WSIP projects as well as several other SFPUC projects that have been implemented or are proposed in the Sunol and Peninsula Regions. In combination, these projects could result in significant impacts on individual historical resources or on potential historic districts (if historic districts were determined to be present in either region). More detailed, site-specific analysis of individual WSIP projects will be conducted during project-level environmental review, which may support a determination that the WSIP projects in these two regions would not make a considerable contribution to cumulative effects. Until this project-level analysis is completed, this PEIR conservatively considers the potential cumulative effect of the WSIP projects in the Sunol Valley and Peninsula Regions to be *potentially significant and unavoidable.* Even if implementation of Measures 4.7-4a through 4.7-4f could reduce the severity of the impact, this PEIR conservatively considers the impact to be significant. Project-level analysis may determine that the impact is less than significant or that additional mitigation measures are available to reduce the significant impact to a less-than-significant level.

Traffic, Transportation, and Circulation

Impact 4.17-6: Cumulative traffic increases on local and regional roads.

The geographic scope of potential cumulative traffic impacts includes regional facilities (e.g., highways and freeways) and local roads providing access to WSIP sites.

Tables 4.17-1 through 4.17-6 present the planned public and private projects that could be under construction during the WSIP construction period (2007 to 2014). The majority of these projects are related to planned and proposed commercial and residential development throughout the five regions. Cumulative traffic impacts associated with these developments include temporary short-term traffic increases related to construction vehicles traveling to and from the site, as well as long-term vehicle trips generated by the new land uses. A number of projects in Tables 4.17-1 through 4.17-6 involve extension and/or widening of existing roadways (primarily within the San Joaquin Region), and capacity and safety improvements along highway corridors and at interchanges (e.g., Highways 84, 99, and 132; I-680 and I-880). These transportation projects would not generate long-term vehicle trips, but would accommodate cumulative traffic growth.

The WSIP and other cumulative development projects listed in Tables 4.17-1 through 4.17-6 would result in long-term cumulative traffic increases. Most of the cumulative operational traffic increases would be generated by the development of more than 20,000 residential units, more than 3 million square feet of commercial/office/R&D uses, more than 2 million square feet of medical/hospital facilities, and more than 2.5 million square feet of industrial uses. The WSIP-related increases in operational traffic due to increased chemical deliveries or inspections (as described in Section 4.8) would not likely be discernible from future background increases in traffic. For the majority of the WSIP facility sites, periodic operations and maintenance of the facilities would be similar to existing operations and would not result in any new vehicle trips to the area. Some new and upgraded facilities would result in additional employees (up to two per location) and increased chemical deliveries (on average about one additional delivery per day). At these locations, there would be up to three vehicle trips to and three vehicle trips from the project site on a daily basis. Because this increase in vehicle trips on the roadway network would be minimal, the WSIP's contribution to cumulative traffic increases during operation of the proposed WSIP facility improvement projects would not be cumulatively considerable (*less than significant*).

Construction of the WSIP projects would result in short-term cumulative traffic increases. These cumulative impacts would be temporary and would only occur during the WSIP construction period (2007 to 2014). The following assessment of WSIP cumulative impacts therefore focuses on the WSIP's contribution to construction-related multi-regional and localized cumulative impacts.

The WSIP projects, both individually and collectively, would contribute incrementally to cumulative construction-related impacts, particularly when travel routes of individual drivers cross multiple roadways affected by WSIP projects, other SFPUC projects, and other public and private construction projects within one or more region, and/or when construction vehicles utilize regional facilities. Cumulative impacts would include increased travel times, although the extent and duration of delay would vary depending on individual driver origins and destinations, time of travel, and use of alternate routes. Implementation of Measures 4.16-6a and 4.17-6 would serve to offset the WSIP's contribution to regionwide cumulative traffic impacts, but would not reduce impacts to a less-than-significant level. Therefore, the WSIP's contribution to regionwide cumulative traffic impacts is considered to be *potential significant and unavoidable*.

As described in Impact 4.16-6, the WSIP projects would collectively result in short-term increases in vehicle trips, increased potential for traffic safety conflicts, reduced access to and parking at adjacent land uses, disruptions to transit service, and increased wear-and-tear on designated haul routes. The localized impacts of WSIP projects would be reduced to a less-than-significant level with implementation of Measure 4.8-1, and the collective WSIP impacts would be reduced to a less-than-significant level with implementation of Measures 4.16-6a, 4.16-6b, and 4.16-6c; nonetheless, the WSIP could still contribute to localized cumulative construction-related traffic impacts when considered in combination with the projects listed in Tables 4.17-1 through 4.17-6.

These localized cumulative construction-related traffic impacts could occur as a result of: (1) cumulative projects that generate increased traffic at the same time on the same roads as the WSIP facility projects, causing increased congestion and delays; and (2) infrastructure projects in roads used by WSIP construction workers and trucks, which could affect detour routes around WSIP work zones or delay WSIP-generated vehicles past the work zones of the other projects. In addition to cumulative (additive) effects on traffic flow conditions, the WSIP and other cumulative projects could prolong the period of disruption (although not all disruption would be significant) in traffic flow on roadways affected by cumulative traffic.

The overlap of WSIP projects and other cumulative projects is presented in Table 4.17-7. The potential localized cumulative construction-related traffic impacts by region are characterized as follows:

- *San Joaquin Region*. As indicated in Table 4.16-3, development of the WSIP in conjunction with other public/private developments in this region could result in significant cumulative increases in construction-related traffic on regional roadways (e.g., Highways 132 and 99, I-5). Construction of the WSIP in combination with other SFPUC projects could result in significant cumulative increases in traffic on local roadways providing access to Tesla Portal and Thomas Shaft.

- *Sunol Valley Region*. As indicated in Table 4.17-2, development of the WSIP in conjunction with other public/private developments and SFPUC projects in this region could result in significant cumulative increases in construction-related traffic on regional roads (e.g., Calaveras Road, Highway 84, I-680). Construction of the WSIP in combination with other SFPUC projects could result in significant cumulative increases in traffic on Calaveras Road, which could conflict with businesses (nurseries, quarries) in the Sunol Valley.

- *Bay Division Region*. As indicated in Table 4.17-3, construction of the WSIP in combination with other public/private developments in this region could result in significant cumulative traffic impacts on local and regional roads (e.g., the I-880 corridor, I-680, the Highway 101 corridor including various interchanges, the University Avenue/Highway 84 interchange, and arterial streets providing access to SFPUC facilities such as Paseo Padre Parkway and Mowry Boulevard in Fremont). Cumulative construction-related traffic impacts could occur near at-grade rail crossings proposed in Fremont, Newark, East Palo Alto, and Menlo Park if the Dumbarton Rail Corridor Project was under construction or operating at the same time WSIP facilities were being constructed. Cumulative construction-related traffic impacts could occur on local access roads to SFPUC facilities wherever WSIP facility construction overlapped with other SFPUC facility construction (see Table 4.17-7).

- *Peninsula Region*. As indicated in Table 4.17-4, construction of the WSIP facilities in combination with other public/private developments in this region could result in cumulative construction-related impacts on local or regional roads (e.g., various Highway 101, I-280, and I-380 freeway interchanges). Cumulative construction-related traffic impacts could occur on local access roads to SFPUC facilities in this region where WSIP facility construction overlaps with other SFPUC facility construction (see Table 4.16-9).

- *San Francisco Region*. As indicated in Table 4.17-6, construction of the WSIP in combination with other public/private developments in this region could result in significant cumulative traffic impacts on local access streets (e.g., the Highway 101/Airport Boulevard/I-380 interchange and Oyster Point ramps, Highway 101/Bayshore Boulevard ramps, and major arterials including Bayshore Boulevard, Geneva Avenue, Brotherhood Way). Cumulative construction-related traffic impacts could occur on local access roads to SFPUC facilities in this region where WSIP facility construction overlaps with other SFPUC facility construction (see Table 4.17-7).

- *Systemwide Projects*. Construction of the systemwide projects listed in Table 4.17-6 would result in traffic increases on access routes to existing SFPUC facilities at multiple locations within the system between Oakdale Portal and the San Francisco Bay Area. In general, construction of these systemwide improvements would not occur within or across public roads. Because of the short-term nature and minimal construction activities associated with these projects, their contribution to cumulative construction-related traffic would not likely be considerable. However, given the unspecified location and timing of these projects, their potential to contribute to significant cumulative construction-related traffic impacts cannot be completely ruled out.

Given the lack of certainty about the timing of many of the projects shown in Tables 4.17-1 through 4.17-6, significant cumulative traffic and circulation impacts could occur on some roadways, such as Calaveras Road in the Sunol Valley. Implementation of traffic control plans (as specified in Measure 4.8-1) and coordination of these traffic control plans by a SFPUC WSIP construction coordinator (as specified in Measure 4.16-6a) would reduce the WSIP's contribution to cumulative impacts in overlapping areas. However, some traffic disruption and increased delays would still occur during WSIP construction, even with mitigation. When added to traffic delay and disruption effects of other projects listed in Tables 4.17-1 through 4.17-6, it is possible that significant cumulative construction-related traffic impacts on local or regional roadways could still occur.

Caltrans, county agencies, and local jurisdictions would issue encroachment permits for public and private project construction affecting public rights-of-way (e.g., roadway widening, in-road sewer replacement, interchange improvements), which would generally mitigate the construction impacts of such projects. However, because a traffic control plan might not always be required as part of every project approval, most construction traffic associated with new development might not be regulated or monitored. Significant cumulative impacts could occur during simultaneous construction of nearby projects, particularly since the SFPUC would have no control over construction schedules or traffic from other projects outside its jurisdiction. For example, construction activities of one or more projects that adversely affect roadway capacity, combined with construction vehicle traffic traveling to and from these projects and nearby development projects, could result in increased delays due to traffic diversions and substantial increases in truck traffic. Reasonably practical mitigation measures are not available to regulate construction activities of all overlapping projects within the five regions. Coordination of maintenance traffic, construction traffic generated by other SFPUC projects, and WSIP-related construction traffic (see Measure 4.17-6) would help minimize the WSIP's contribution to cumulative construction-related impacts on local and regional roadways. However, interagency coordination of construction traffic might not always be possible; therefore, these localized cumulative traffic impacts would be *potentially significant and unavoidable*.

Air Quality

Impact 4.17-7: Cumulative increases in construction and/or operational emissions in the region.

Criteria Pollutants

The geographic scope for cumulative air quality impacts is the San Joaquin Valley Air Basin and San Francisco Bay Area Air Basin for regionwide impacts, and haul routes for localized impacts.

As described in Section 4.9, potential air quality impacts associated with implementation of the WSIP include increased dust and equipment emissions during construction, exposure to diesel particulate matter (DPM), emissions from ventilation fans, emissions during operation of the WSIP facility improvement projects, odors, secondary emissions from power use, and conflicts with regional and statewide air quality planning (Impacts 4.9-1 through 4.9-7). The WSIP, in combination with other cumulative projects listed in Tables 4.17-1 through 4.17-6, would result in regionwide cumulative increases in air emissions during project operations. The majority of cumulative increases in air pollutant emissions would be due to regional traffic increases and energy use associated with development of over 20,000 residential units, more than 3 million square feet of commercial/office/R&D uses, more than 2 million square feet of medical/hospital facilities, and more than 2.5 million square feet of industrial uses. The WSIP's emissions during facility operation would be associated primarily with equipment operation, not maintenance-related traffic increases. Therefore, with required compliance of WSIP equipment with the Bay Area Air Quality Management District (BAAQMD) and the San Joaquin Valley Air Pollution Control District (SJVAPCD) air quality regulations, the WSIP's contribution to operational cumulative air quality impacts would not be considerable (see Section 4.16.2 for discussion of WSIP collective operational air quality impacts). New emissions sources during project operations would be primarily limited to minor increases in traffic due to project maintenance and emergency generators (approximately 10 generators, operating only during power outages and testing exercises).

Where construction of WSIP facility improvement projects overlaps with other cumulative projects (see Table 4.17-7), regional cumulative increases in construction-related air quality emissions in both air basins would also occur. Although both the BAAQMD and SJVAPCD consider construction-related emissions to be less than significant with implementation of each district's standard control measures (as specified in Measures 4.9-1a through 4.9-1d), there would still be a residual contribution from each project to the region's nonattainment status for ozone and particulate matter (PM_{10} and $PM_{2.5}$) in both air basins. Therefore, the WSIP's contribution to construction-related, regionwide cumulative air quality impacts on the nonattainment status for ozone and particulate matter is considered *potentially significant and unavoidable.*

When WSIP construction projects overlap with construction of other cumulative projects (see Table 4.17-7), it is possible that localized cumulative increases in DPM emissions could occur along haul routes, potentially exposing sensitive receptors to elevated DPM levels. Given the lack of certainty about the timing of many of the projects listed in these tables, it is prudent to conclude that significant cumulative increases in DPM are possible on streets that might serve as common haul routes. Coordination of all SFPUC-related maintenance traffic, construction traffic generated by other SFPUC projects, and WSIP-related construction traffic (see Measure 4.17-6) would help minimize the potential for cumulative construction-related DPM impacts on local roadways. However, the SFPUC would have no control over construction schedules or traffic from other projects outside its jurisdiction, and interagency coordination of construction traffic might not always be possible. Therefore, localized DPM impacts are considered *potentially significant and unavoidable*.

GHG Emissions

Sources of GHGs from WSIP projects, including those associated with construction equipment, increases in vehicle traffic and use of refrigerants during facility operations, and secondary operational increases in GHG emissions resulting from electricity generation would overlap with similar sources of GHG emissions from other projects. However, as documented previously, increases in GHG emissions from these sources associated with WSIP projects would be minimal and the contribution from the WSIP projects would not result in a considerable contribution to cumulative GHG emissions.

GHG emissions from peak project construction activities would represent 0.0022 percent of the statewide total of GHG emissions during the time these peak construction activities are carried out. WSIP projects largely involve improvements to existing operations and would result in few new operational activities associated with GHG emission increases.

The WSIP would also result in secondary operational increases in GHG emissions as a result of electricity generated to meet the WSIP's increase in energy demand (Impact 4.9-7). Although electricity for the WSIP projects would be derived primarily from hydroelectric sources, power would need to be purchased by current customers of the SFPUC Power Enterprise from the grid or other sources when less hydroelectric power is available, particularly during the summer and fall months. Power generation is regional in nature and could occur outside the San Francisco and San Joaquin Valley air basins or outside of California. Therefore, the WSIP's incremental increase in power demand during project operations (the portion that is not from hydroelectric or alternative energy sources) would indirectly serve to sustain rather than reduce current GHG emissions from these emission sources. The WSIP projects at completion would create approximately 14,260 metric tons of CO_2-equivalent emissions by consuming hydroelectric power that is no longer available to current users. Compared to the current annual inventory of 427,000,000 metric tons in California, this represents 0.0033 percent of that inventory. Planned increases in water distribution and treatment system efficiencies would offset a limited portion of the increased power demand, but not enough to eliminate the increase in GHG emissions that would result from WSIP-diverted electrical power. Nevertheless, the total increased power demand associated with the operation of the WSIP projects is a small fraction of total state demand.

These minor increases in GHG emissions would be offset in several ways. As the CARB's Early Action Measures and CEC's greenhouse gases emission performance standard for local, public-owned electric utilities become effective (see discussion under Regulatory Framework, Greenhouse Gas Emissions Limits), the SFPUC will implement them as required to reduce GHG emissions from the WSIP project operations. Also, continuing implementation of GHG reduction actions by the CCSF and SFPUC, and additional GHG reduction actions that SFPUC will take as part of the WSIP project (see above under "Existing Setting"), would assure that the WSIP projects would not conflict with the State's goals of reducing GHG emissions to 1990 levels by 2020. Therefore, the cumulative contribution of GHG emissions associated with the WSIP to GHG emissions from other sources as a whole would be less than significant.

As part of implementation of the WSIP, the SFPUC will be required to implement mitigation measures to address other identified impacts that would also reduce GHG emissions. They include exhaust controls (Measures 4.9-1b, 4.9-1d and 4.16-7a), waste reduction measures (Measure 4.11-2) and energy efficiency measures (Measure 4.15-2). In addition, CARB regulations (Title 13 of the California Code of Regulations, Sections 2480 and 2485), which limit idling of diesel-fueled commercial motor vehicles, would help to limit GHG emissions associated with WSIP-related construction vehicles.

Noise and Vibration

Impact 4.17-8: Cumulative increases in construction-related and operational noise.

The geographic scope of potential cumulative noise impacts encompasses the WSIP sites and their immediate vicinities as well as areas adjacent to access and haul routes to the WSIP sites.

As described in Section 4.10 and Section 4.16 (Impact 4.16-9), noise increases associated with construction and operation of proposed WSIP facilities would be specific to each facility site, except in the event that any cumulative project sites adjoined WSIP facility sites or used the same haul/delivery/access routes. Cumulative projects listed in Tables 4.17-1 through 4.17-6 would presumably be subject to applicable noise regulations (e.g., local noise ordinance and guidelines), while all WSIP projects would be required to implement noise control measures (SFPUC

Construction Measure #6, compliance with local noise ordinances to the extent feasible, and/or Measure 4.10-1a). With site-specific mitigation for all projects, regionwide or multi-regional cumulative noise impacts at any adjoining construction sites would be less than significant.

Potential cumulative impacts could occur if other cumulative projects generated truck traffic and used the same delivery/haul/access routes at the same time as the WSIP projects, causing localized cumulative construction-related noise increases. Given the lack of certainty about the timing of many of the projects in Tables 4.17-1 through 4.17-6, it is prudent to conclude that significant cumulative truck noise increases are possible on streets that might serve as common haul routes. Cumulative traffic increases on regional roadways such as freeways, highways, and arterials would not likely alter noise levels significantly along these routes (identified in Tables 4.17-1 through 4.17-6), given the high ambient noise levels that typically occur along these types of streets. However, if cumulative truck traffic increases occurred on any local residential streets providing access to SFPUC facilities, cumulative noise increases could be significant. As required in Measures 4.10-2a and 4.10-2b, limiting the hourly truck volumes and restricting truck operations on local residential streets would help reduce the WSIP's contribution to this cumulative impact. Coordination of maintenance traffic, construction traffic generated by other SFPUC projects, and WSIP-related construction traffic (see Measure 4.17-8) would help minimize the WSIP's contribution to cumulative construction-related impacts on local and regional roadways. However, interagency coordination of construction traffic might not always be possible; therefore, these localized cumulative noise impacts would be *potentially significant and unavoidable*.

Public Services and Utilities

Impact 4.17-9: Cumulative impacts related to disruption of utility service or relocation of utilities.

The geographic scope of potential cumulative public services and utilities impacts encompasses the WSIP sites, immediate vicinities, and the service areas of regional service/utility providers.

As described in Section 4.16, Impact 4.16-9, construction of the WSIP projects could disrupt utility services or require temporary or permanent relocation of utilities. Construction of other cumulative development in the region would also increase the potential for such utility impacts. These potential impacts would be site-specific rather than additive and would be mitigated on a site-specific basis (presumably including cumulative development). Therefore, the WSIP would not result in localized cumulative impacts on existing public utilities.

As discussed under Impact 4.16-9, the WSIP's demand on landfills represents less than approximately one percent of the total existing landfill capacity in the region. Therefore, the WSIP's contribution to cumulative construction-related demand on regional landfill capacity would not be cumulatively considerable, and the impact would be *less than significant*.

Recreational Resources

Impact 4.17-10: Cumulative effects on recreational resources during construction.

The geographic scope of potential cumulative recreational impacts encompasses the WSIP sites and immediate vicinities. However, major developments in the area are considered when characterizing overall cumulative regional impacts on recreational resources.

As described in Section 4.12 and Section 4.16, Impact 4.16-10, construction activities associated with some WSIP facilities could temporarily disrupt access to or use of recreational facilities within the WSIP study area. However, given the availability and diversity of recreational opportunities in the vicinity of the WSIP projects and the region as a whole, the diversion of recreationists to alternative facilities would not likely result in overcrowding and associated deterioration of recreational resources. Since the private development projects listed in Tables 4.17-1 through 4.17-6 would be located on privately owned lands, they would not likely directly affect publicly owned recreational facilities. Since the identified road improvement projects would be located in roadways, they would also not be likely to directly affect recreational facilities. However, if other SFPUC projects listed in the tables were located within recreational facilities and coincided with construction of WSIP projects, localized cumulative disruption of recreational facilities could result. Implementation of SFPUC construction measures (including advanced notification) and coordination with recreational facility managers and schools (Measures 4.12-1a and 4.12-1b) would reduce the WSIP's impact to a less-than-significant level, and any residual effects of the WSIP would not contribute considerably to any regionwide cumulative impacts on recreational resources (*less than significant*).

Agricultural Resources

Impact 4.17-11: Cumulative conversion of farmland to nonagricultural uses.

The geographic scope of potential cumulative agricultural resources impacts encompasses the WSIP sites and their immediate vicinities. However, major developments in non-urbanized areas are considered when characterizing overall cumulative regional impacts on farmland.

As described in Section 4.16, Impact 4.16-11, implementation of the WSIP would result in less-than-significant regionwide collective impacts on agricultural resources. When other cumulative development projects listed in Tables 4.17-1 through 4.17-6 are considered (specifically, the 300-acre Patterson Gardens and the 659-acre RMC Pacific Vernalis Quarry Mining and Reclamation Project, located in the San Joaquin Region), there would be a cumulative conversion of farmland to nonagricultural uses in the San Joaquin Region. While the WSIP would not contribute to any regionwide cumulative loss of farmland in the Bay Area (Sunol Valley, Bay Division, Peninsula, and San Francisco Regions), it could incrementally contribute to the regional cumulative loss of farmland in the San Joaquin Region. The regional loss of farmland in the Central Valley is a concern due to the rapid pace of urban development and associated conversion of agricultural land to nonagricultural uses. Therefore, siting WSIP facilities to avoid prime agricultural lands or to offset any loss of such lands (Measure 4.13-2) would reduce the WSIP's contribution such that its contribution to the regionwide cumulative loss of farmland would not be considerable (*less than significant*).

Hazards

Impact 4.17-12: Cumulative effects related to hazardous conditions and exposure to or release of hazardous materials.

The geographic scope of impacts associated with hazards and hazardous materials encompasses the WSIP sites and their general vicinities, particularly WSIP facilities near urbanized industrial uses and areas of wildland fire hazard.

As described in Section 4.14, the potential to encounter hazardous materials or hazardous conditions during construction would be less than significant or mitigated to a less-than-significant level at all sites through project-specific assessment of hazards and compliance with regulatory requirements. Due to the site-specific nature of hazardous materials impacts and mitigation measures, there would be no potential for cumulative effects from construction of WSIP projects in conjunction with other cumulative development listed in Tables 4.17-1 through 4.17-6.

Similarly, impacts related to the potential for accidental releases of chemicals stored at the water treatment plants would also be site-specific and not additive. Compliance with hazardous materials regulations (including preparation or updating of hazardous materials business plans at all sites, and preparation of a risk management plan for the new use of ammonia, if required, at the Sunol Valley WTP and changes to the risk management plan for changes in the use of ammonia at the Harry Tracy WTP) would ensure that site-specific impacts are less than significant.

Due to the site-specific nature of these impacts, compliance with applicable laws and regulations, and implementation of SFPUC construction measures and mitigation measures identified in Section 4.14, there would be no potential for regionwide or localized cumulative effects related to the exposure to hazardous materials during construction or operation of the WSIP projects.

As discussed in Section 4.16, Impact 4.16-12, there would be an increased risk of wildland fires during WSIP construction in high fire hazard areas. If construction of cumulative development overlapped in high fire hazard areas, there could be a cumulative increase in wildland fire risk, particularly in areas such as the Sunol Valley where access and haul roads would be shared. The potentially compounded increase in wildland fire risk could place an additional burden on local fire departments, particularly if access for emergency vehicles were impeded. With site-specific mitigation (Measure 4.8-1) and compliance with Public Resources Code provisions governing the use of construction equipment in fire-prone areas, the WSIP's residual contribution to any localized cumulative wildland fire impacts would not be considerable (*less than significant*).

Construction of the WSIP projects could also contribute to a cumulative impact related to hazardous waste disposal. However, as discussed in Impact 4.16-12, based on worst-case estimates, the WSIP's potential hazardous waste disposal requirements would represent approximately 1.5 percent of the total existing hazardous waste disposal capacity in the region, and less than 1 percent of the disposal volume expected to be available by 2013. Therefore, the WSIP's contribution to this cumulative impact on hazardous waste disposal capacity would not be considerable (*less than significant*).

Energy Resources

Impact 4.17-13: Cumulative increases in the use of nonrenewable energy resources.

As described in Section 4.15 and Section 4.16, Impact 4.16-13, existing energy consumption for operation of the SFPUC regional water system in the WSIP study area totals approximately 44 million kilowatt-hours (kWh), and operation of the WSIP facilities would increase the SFPUC's regionwide energy consumption by approximately 39 million kWh, an 89 percent increase over existing conditions. As discussed in Impact 4.16-13, the net loss in available hydroelectric energy as a result of WSIP implementation would be 30 million kWh, less than 0.1 percent of the estimated total energy usage in the counties within the WSIP study area.

The potentially cumulative SFPUC projects listed in Tables 4.17-1 through 4.17-6 would not substantially increase energy use in the WSIP region, because they would generally not involve an increase in energy use during operation of WSIP facilities, would be non-energy-intensive improvements to the water system, would be upgrades that would include energy efficiency improvements, or would include improvements to facility electrical systems. In addition, the New Electrical Transmission Line from Newark to San Francisco (BDP-16) would improve electricity transmission capabilities to San Francisco. Furthermore, future implementation of large-scale solar and other renewable energy resources on public and private property in the city under project CSYS-5 would help offset any increase in the use of hydroelectric power generated by SFPUC Power Enterprise, although the amount cannot be quantified at this time.

On the other hand, implementation of the cumulative non-SFPUC development projects listed in Tables 4.17-1 through 4.17-6 would contribute to increased energy consumption in Tuolumne, San Joaquin, Alameda, Santa Clara, San Mateo, and San Francisco Counties. However, these projects would generally not use hydroelectric power produced by SFPUC Power Enterprise and would be required to meet Energy Efficiency Standards for Residential and Nonresidential Buildings (see Section 14.15), which would ensure that energy is not used in a wasteful manner for these projects. Furthermore, the increase in energy consumption from these projects is accounted for in the 1.2 percent annual increase projected by the California Energy Commission, as discussed in Section 4.15. Because the net loss in available hydroelectric energy as a result of

WSIP implementation would be less than 0.1 percent of the estimated total energy usage in the counties within the WSIP study area, the WSIP's contribution to cumulative increases in long-term energy demand would not be considerable (*less than significant*).

Construction activities associated with WSIP projects in all regions would require the use of fuels to operate construction equipment and transport employees and materials. Implementation of exhaust control measures (limiting idling time and performing low-emissions tune-ups, as specified in Measures 4.9-1b and 4.9-1d) would ensure that fuels are not used in a wasteful or inefficient manner. Therefore, the WSIP's contribution to the regionwide cumulative increase in construction-related energy consumption would not be considerable (*less than significant*).

ATTACHMENT 4-A
Mitigation for Chapter 4 Impacts

Introduction

Chapter 6, Mitigation Measures, presents the SFPUC construction measures and all mitigations measured identified to address significant impacts of the WSIP discussion in all impact sections of this PEIR. This attachment is an excerpt from Chapter 6 that presents the SFPUC construction measures and all mitigation measures for the PSM and PSU impacts described in Chapter 4. Mitigation measures for impacts identified in Sections 4.2 through 4.15 are presented under the respective environmental resource topic, such as Land Use or Biological Resources. Mitigation measures for collective and cumulative impacts (Sections 4.16 and 4.17) are also presented under the appropriate environmental resource topic, rather than under a separate heading, so that similar measures are grouped together. As stated above, all mitigation measures are numbered to correspond to the same impact numbers, although in some cases, the same measure would mitigate more than one impact and the numbering corresponds to the first impact identified and cross-referenced so that measures are not duplicated.

SFPUC Construction Measures

The following SFPUC standard construction measures apply to all proposed WSIP facility improvement projects. The SFPUC standard construction measures are aimed at minimizing disruptions to surrounding neighborhoods, resources, and land uses during any SFPUC construction, maintenance, or repair activity or project that requires CEQA review. As required by the SFPUC, each project must include the SFPUC standard construction measures in the construction contract or project implementation procedures, as appropriate.

Some of the SFPUC standard construction measures may not be appropriate for certain kinds of projects, but each of the measures must be addressed, either by explaining why the measure is not applicable to the particular site, undertaking the activities listed, or undertaking further investigation and developing a more detailed work plan to address the issue.

1. *Neighborhood Notice*: The SFPUC will provide reasonable advance notification to the businesses, owners and residents of adjacent areas potentially affected by the Water System Improvement Program (WSIP) projects about the nature, extent and duration of construction activities. Interim updates should be provided to such neighbors to inform them of the status of the construction.

Where schools would be affected, the SFPUC will coordinate with school facility managers to schedule construction for time periods with the least impact on school activities and facilities to ensure student safety and to minimize disruption to educational and recreational uses of the school property.

2. *Seismic and Geotechnical Studies*: Projects will incorporate review of existing information and, if necessary, new engineering investigations to provide relevant geotechnical information about the particular site and project, including a characterization of the soils at the site, and the potential for subsidence and other ground failure. Construction will address any recommendations by such geotechnical reports to ensure seismic stability and reliability of the proposed project. All SFPUC projects must be designed for seismic reliability and minimum potential water loss and property damage. All components of the water system improvement program must be designed to continue water service during a major earthquake.

3. *On-Site Air and Water Quality Measures during Construction*: All construction contractors must take measures to minimize fugitive dust and dirt emissions resulting from the construction, and implement measures to minimize any construction effects on local air and water quality, including a local storm drain system or watercourse. These measures could include preparation of a Stormwater Pollution Prevention Plan (SWPPP), if required by the California Regional Water Quality Control Board. At a minimum, construction contractors should undertake the following measures, as applicable, to minimize any adverse effects:

    - Erosion and sedimentation controls tailored to the site and project
    - Dust control plan
    - Placement of straw rolls around each of the nearby stormwater inlets;
    - Preservation of existing vegetation;
    - Installation of silt fences;
    - Use of wind erosion control (e.g. – geotextile or plastic covers on stockpiled soil);
    - Sweeping of nearby streets at least once a day; and/or;
    - Stabilization of site ingress/egress locations to minimize erosion.
    - Spraying the disturbed areas of the site, or any stockpiled soil, with water to minimize fugitive dust emissions.

4. *Groundwater*: If groundwater is encountered during any excavation activities, the construction contractor shall prepare a dewatering plan so that water is discharged to the stormwater system in compliance with the local standards and discharge permit requirements.

5. *Traffic*: Each contractor shall prepare a traffic control plan which will minimize the impacts on traffic and on-street parking on any streets affected by construction of the proposed project. As appropriate, SFPUC or the contractor will consult with local traffic and transit agencies.

6. *Noise*: The contractor will comply with local noise ordinances regulating construction noise to the extent feasible, and will undertake efforts to minimize any noise disruption to nearby neighbors and sensitive receptors during construction.

7. *Hazardous Materials*: Appropriate measures will be implemented to characterize and dispose of hazardous materials should they be encountered during excavation and construction. Contract specifications will mandate full compliance will all applicable local, state and federal regulations related to the identification, transportation and disposal of hazardous materials/soils. As necessary, a spill prevention and countermeasure plan will be prepared.

   A qualified environmental professional will conduct any necessary site assessment. The site assessment would include a regulatory database review to identify permitted hazardous materials and environmental cases in the vicinity of each project no more than three months before construction, and a review of appropriate standard information sources to determine the potential for soil or groundwater contamination to occur. Follow-up sampling would be conducted as necessary to characterize soil and groundwater quality prior to construction and, if needed, site investigations or remedial activities would e performed in accordance with applicable laws. The environmental professional would prepare a report documenting the activities performed, summarize the results and make recommendations for appropriate handling of any contaminated materials during construction. A contingency plan would also be prepared identifying measures to be taken should unanticipated contamination be identified during construction. Construction contractors will conduct asbestos and lead abatement in accordance with established regulations.

8. *Biological Resources*: As an initial matter, SFPUC project managers will screen the project site and area to determine whether biological resources may be affected by construction activities. In the event further investigation is necessary, the SFPUC will comply with all requirements for investigation, analysis and protection of biological resources. A qualified biologist must conduct any required biological screening survey. The biologist will review standard information sources to determine special status species with the potential to occur on the project site. The biologist would carry out a site survey by walking or driving over the project site, as appropriate, to note the general resources and whether any habitat for special-status species is present. The biologist would then document the survey with a brief letter report or memo, setting forth the date of the visit, whether habitat for special-status species is present, providing a map or description showing where sensitive areas exist within the site, and identifying any appropriate avoidance measures.

9. *Cultural Resources*: As an initial matter, SFPUC project managers will screen the project site and area to determine whether cultural resources, including archaeological and other historical resources, may be affected by construction activities. In the event further investigation is necessary, the SFPUC will comply with all requirements for investigation, analysis and protection of cultural resources.

   CEQA considers paleontological resources to be "cultural resources." Any screening for cultural resources would include screening for archaeological, paleontological and historic resources. For projects requiring excavation, deep grading, well drilling or tunneling into geologic material at sites identified as having high potential for encountering paleontological resources, a state-registered professional geologist or qualified professional paleontologist will conduct a site-specific evaluation of the paleontological sensitivity. The assessment will include a report of findings for the SFPUC.

   A qualified archaeologist, historian or paleontologist will conduct all cultural resources survey and screening work. Screening surveys for cultural resources would include a cultural resources records search to be conducted at the appropriate office member of the California Historical Resources Information System. A field survey will be conducted if determined necessary after the cultural resources records search. Any impacts on identified cultural resources will be avoided to the extent feasible.

Any initial historic resource screening will identify historic resources on the project site as well as adjacent to the project site.

It is possible that project work may affect accidentally discovered buried or submerged cultural resources. Any contractor must distribute the Planning Department archaeological resource "ALERT" sheet to any person involved in soil-disturbing activities. If there is any indication of an archaeological or a paleontological resource during the soils disturbing activity of the project, the contractor shall immediately suspend any soils disturbing activities in the area and notify the SFPUC of such discovery. The SFPUC will then work with the Planning Department's Environmental Review Officer to determine what additional measures should be implemented, based on reports from a qualified archaeological or paleontological consultant.

10. *Project Site*: The SFPUC will conduct construction activities on SFPUC-owned lands to the extent feasible and minimize the need for use of non-SFPUC-owned land during construction. In cases where construction easement or staging areas are needed on non-SFPUC land, the SFPUC will restore these areas to their prior condition so that the owner may return them to their prior use, unless otherwise arranged with the property owner. The site will be maintained to be clean and orderly. Construction staging areas will be sited away from public view where possible. Nighttime lighting will be directed away from residential areas.

    Upon project completion, the construction contractor will return the SFPUC project site to its general condition before construction, including re-grading of the site and re-vegetation of disturbed areas.

Mitigation Measures to Minimize Facilities Impacts

Plans and Policies (Section 4.2)

None applicable.

Land Use and Visual Resources (Section 4.3)

Program Measures

Facility Siting Studies

Measure 4.3-2: It is the policy of the SFPUC to construct and operate its facilities on SFPUC-owned lands to the extent feasible. When use of SFPUC-owned land is not feasible, and where additional permanent easement or land acquisition is required, the SFPUC will conduct project-specific facility siting studies and implement these studies' recommendations to avoid or minimize impacts on existing land uses to the maximum extent feasible. Siting studies will identify and evaluate alternative site locations, access roads, building configurations and facility operations to minimize or avoid land use impacts. The studies will also consider existing and planned land uses on and adjacent to proposed facility sites and rights-of-way on non-SFPUC-owned land. To the extent feasible, the SFPUC will implement the recommendations in the siting studies.

Architectural Design

Measure 4.3-4a: The design of permanent new, above-ground facilities will consider the existing visual character of the site and surrounding area, including the visibility of facilities and related structures from scenic highways and scenic roads. Structures will be designed to incorporate building features and design elements that are compatible with the surroundings.

Landscaping Plans

Measure 4.3-4b: The SFPUC will prepare and implement landscaping plans to restore project sites to their pre-construction condition such that short-term construction disturbance does not result in long-term visual impacts. To retain the existing visual character of the site and surrounding area, disturbed areas will be recontoured and revegetated and recontoured to pre-construction condition. Landscape vegetation will include noninvasive, and where possible, native grasses, shrubs, and trees similar to existing landscaping. The SFPUC will monitor landscape plantings annually for five years after project completion to ensure that sufficient ground coverage has developed and will implement additional measures, such as replanting or modifying irrigation systems, as determined necessary.

Landscape Screens

Measure 4.3-4c: In addition to revegetation of disturbed areas, the landscaping plans will include new plantings and landscape berms to screen views of new structures and equipment from scenic roads to the extent possible, provided that such landscaping does not affect security of SFPUC facilities.

Minimize Tree Removal

Measure 4.3-4d: The SFPUC will minimize or avoid the removal of existing trees that currently screen existing and proposed sites of WSIP facilities by modifying the proposed alignments of new temporary and permanent roads to the extent feasible. The SFPUC will consult with a qualified arborist regarding the minimum buffer zones required to prevent root damage to remaining trees and to provide the SFPUC with any necessary maintenance requirements for remaining trees. Also, the arborist will develop and assist the SFPUC in implementing an appropriate landscaping plan (see Measure 4.3-4b, above), including tree replacement, that is compatible with project operation and maintenance.

Reduce Lighting Effects

Measure 4.3-5: To the extent possible, all permanent exterior lighting will incorporate cutoff shields and non-glare fixture design. All permanent exterior lighting will be directed onsite and downward. In addition, new lighting will be oriented to ensure that no light source is directly visible from neighboring residential areas and will be installed with motion-sensor activation. In addition, highly reflective building materials and/or finishes will not be used in the designs for proposed structures, including fencing and light poles. Vegetation selected for landscaping will be selected, placed and maintained to minimize offsite light and glare in surrounding areas as part of the landscaping plans described in Measure 4.3-4b.

Collective Measures

Construction Coordination at Irvington Portal

Measure 4.16-1a: If construction schedules of multiple WSIP projects occurring at and near Irvington Portal coincide or overlap, the SFPUC will coordinate with construction contractor(s) and neighbors to minimize disturbance of residents in the adjacent neighborhood to the extent practicable. Such coordination will need to balance the duration of construction with the magnitude of construction-related impacts on the same sensitive receptors.

Geology, Soils and Seismicity (Section 4.4)

Program Measures

Quantified Landslide Analysis

Measure 4.4-1: If the screening analysis conducted in accordance with SFPUC Construction Measure #2 identifies any landslide hazards, affected WSIP facilities will, to the extent feasible, be located away from known landslides, very steep hillsides, debris-flow source areas, the mouths of steep sidehill drainages, and the mouths of canyons that drain steep terrain. However, where these landslide hazard areas cannot be avoided, a more quantified analysis (including a site-specific geologic investigation and a slope stability analysis to determine the potential for landsliding) should be performed as part of the geotechnical investigation. Recommendations identified in the site-specific geotechnical report regarding the potential for landsliding, including appropriate construction measures, will be incorporated into the project designs to minimize the potential for damage to project facilities.

Subsidence Monitoring Program

Measure 4.4-4: As part of the project-specific CEQA review for the New Irvington Tunnel (SV-4) and BDPL Reliability Upgrade (BD-1), the SFPUC will analyze the potential for ground subsidence to occur during tunneling, and will identify project-specific trigger levels that would require corrective action should subsidence occur. As determined to be necessary, the tunnel contractor will implement a subsidence monitoring program during tunneling to detect subsidence, including measurements of groundwater levels, surface and subsurface settlement, ground movement and displacement, and movement in existing infrastructure as needed. The SFPUC will implement corrective actions, such as increased tunnel support, if measured displacement reaches the specified trigger levels.

Characterize Extent of Expansive and Corrosive Soil

Measure 4.4-9: If the screening analysis conducted in accordance with SFPUC Construction Measure #2 identifies a potential for expansive or corrosive soils, the site-specific geotechnical investigation will include a characterization of the presence and extent of expansive and corrosive soil at the project facility site. The results and recommendations of the investigation will be incorporated into the final project design.

Surface Water Hydrology and Water Quality (Section 4.5)

Program Measures

Site-Specific Groundwater Analysis and Identified Measures

Measure 4.5-2: As part of the project-specific CEQA review for the New Irvington Tunnel project (SV-4), the SFPUC will inventory springs and wells in the area of the planned tunnel and conduct a project-specific analysis of the potential for tunnel dewatering to stop or decrease spring flow, lower groundwater levels in nearby wells, or to otherwise cause adverse effects on groundwater resources and beneficial uses of the groundwater. If a significant impact is identified, then measures such as altering groundwater withdrawal rates and/or providing an alternate water supply for affected users will be implemented to ensure that groundwater resources or beneficial uses are not adversely affected.

Flood Flow Protection Measures

Measure 4.5-4a: In construction contract specifications, the SFPUC will require the contractor(s) to include, in their erosion control measures or SWPPP prepared for the project, a measure prohibiting the stockpiling of soil, storage of hazardous materials, and stockpiling of construction materials in flood zones, where practical. Where construction would occur in large flood zones, making it impractical to implement this requirement, the erosion control measures or SWPPP will include measures for protecting stockpiled soil, sources of hazardous materials, and stockpiled construction materials from exposure to flood waters.

Site-Specific Flooding Analysis and Identified Measures

Measure 4.5-4b: As part of the project-specific CEQA review for the Alameda Creek Fishery (SV-1) and New Irvington Tunnel (SV-4) projects, the SFPUC will conduct a site-specific analysis of the potential for flooding as a result of project implementation. If a dam or concrete weir is installed in Alameda Creek under the Alameda Creek Fishery project, the analysis will include, at a minimum, the stream flow data and planned design and operation of the dam or weir to prevent flooding impacts. For the New Irvington Tunnel project, the analysis will include design measures needed to ensure that upstream water levels are not affected, bridge abutments are protected from damage due to flood flows and would not adversely redirect flood flows, and that bridge pilings are protected from scour.

Stormwater Treatment and Groundwater Monitoring

Measure 4.5-5: If treated stormwater is used to augment Lake Merced water levels, the project-level CEQA analysis for the Local Groundwater Projects (SF-2) will include measures to ensure that use of stormwater does not promote eutrophication of the lake and provisions for implementing these measures. The project-level CEQA analysis will also evaluate the potential for groundwater quality degradation due to the use of treated stormwater to augment lake levels. If necessary, the SFPUC will implement a groundwater monitoring program in the vicinity of Lake Merced to monitor for degradation of groundwater quality. Monitoring will include water quality sampling for total coliform bacteria, total nitrogen, nitrate, nitrite, total organic carbon, parameters for which drinking water quality criteria have been established, and any other potential pollutants of concern. The project-level CEQA documentation will identify corrective actions that would be implemented should groundwater quality degradation be identified, such as additional treatment of water used to augment water levels in Lake Merced.

Appropriate Source Control and Site Design Measures

Measure 4.5-6: For projects located in areas not covered by a municipal stormwater permit and disturbing less than one acre of land during construction, the SFPUC will implement appropriate source control and site design measures that 1) minimize the stormwater flow rate and quantity to prevent off-site erosion and flooding; and 2) minimize stormwater pollutant discharges to the maximum extent possible. These measures will ensure compliance with applicable water quality criteria and goals and protect the beneficial uses of the receiving water.

Biological Resources (Section 4.6)

Program Measures

Wetlands Assessment

Measure 4.6-1a: As part of project-specific CEQA review, a qualified wetland scientist will review project plans, airphotos, and topographic maps and conduct a site visit to determine whether wetlands are present and could be affected by the project. If the review shows that wetlands could be affected, the wetland scientist will perform a formal wetland delineation and develop mitigation as per Measure 4.6-1b, below.

Compensation for Wetlands and Other Biological Resources

Measure 4.6-1b: If the wetland delineation indicates that the WSIP project will affect jurisdictional wetlands or aquatic resources, then, in accordance with state and federal permit requirements, the SFPUC will avoid and minimize direct and indirect impacts such as erosion and sedimentation, alteration of hydrology, and degradation of water quality. As a first priority, the SFPUC will implement (1) avoidance measures. For unavoidable impacts, the SFPUC will implement (2) minimization of unavoidable impacts, (3) restoration procedures, and (4) compensatory creation or enhancement to ensure no net loss of wetland extent or function.

In addition to wetlands, the SFPUC will compensate for sensitive riparian and upland habitats and habitats which support key special-status species or other species of concern lost as a result of WSIP project construction and operation. Similar habitat will be identified, protected, restored, enhanced, created and managed off-site[1] to ensure no net loss of habitat extent or function. For each WSIP project, a qualified biologist will quantify the magnitude and extent of impacts to wetlands, sensitive habitats, and key special-status species and other species of concern, and the SFPUC will develop and implement restoration and/or compensation plans that meet the appropriate regulatory requirements and permit conditions with respect to restoration and/or compensation ratios. Compensation ratios typically range from a minimum of 1:1 for common habitats to 2:1 or higher for rare and sensitive habitats. If individual project requirements of the RWQCB, CDFG, or USFWS differ somewhat from these ratios, they are still intended to achieve the same purpose of full restoration and/or compensation, to mitigate project impacts to less than

1 Off-site means the compensatory action is located other than within the project construction footprint, but could be on lands already under SFPUC ownership. Measure 4.6-2 addresses compensatory actions to be taken within the construction footprint.

significant levels, and to ensure no net reduction in the populations of any species listed as threatened or endangered by the state or federal resource agencies.

The SFPUC will obtain required permits for each project and comply with applicable environmental regulations addressing sensitive habitats and species. Compensatory lands, including those restored or enhanced as well as those acquired or designated as protected as part of program or project mitigation, will be established in perpetuity with a commitment that such lands will not be used for any purpose that conflicts with the primary purpose of maintaining intact wildlife and plant habitat.

One alternative for implementing off-site habitat compensation is the Habitat Reserve Program (HRP) currently being developed by the SFPUC. The purpose of the HRP is to provide a comprehensive, coordinated approach to mitigation and related regulatory compliance for WSIP projects. This related SFPUC project is described further in Chapter 3.0, Section 3.11. Under the proposed HRP, the SFPUC would proceed as soon as possible with securing (through designation, management agreement, conservation easement, or acquisition of fee title) and improving lands to be used for habitat compensation so that mitigation is underway before or concurrent with habitat loss related to WSIP project activities, further ensuring no net loss of resources. CEQA environmental review for the proposed HRP will commence in 2007 and is targeted for implementation as soon as possible thereafter. Once the HRP is approved and implemented, the SFPUC will use this as one vehicle or method for implementing the mitigation requirements for individual WSIP projects. Otherwise, where appropriate and necessary, the SFPUC will develop and implement appropriate habitat compensation mitigation for individual WSIP projects.

Habitat Restoration/Tree Replacement

Measure 4.6-2: If the biological screening survey identifies sensitive habitats or heritage trees, the following measures, as modified and applied to WSIP projects, will be implemented:

- Temporarily-impacted sensitive habitats (natural communities identified as sensitive by CDFG, and USFWS-designated critical habitat) would be restored to their pre-project condition.

- If specific trees to be removed are designated as heritage trees (or similar local designation), then SFPUC will replace the trees, consistent with requirements in local ordinances. If such heritage trees occur near extensive areas of sensitive habitats, locally collected, native species will be used as replacement trees where possible.

- Where possible, the loss of sensitive habitats will be minimized by coordinating WSIP projects to make repeated use of staging/construction areas and access roads. For example, tunnel spoils could be considered for borrow material for other projects.

Protection Measures During Construction for Key Special-Status Species and Other Species of Concern

Measure 4.6-3a: The following general practice measures, as modified and applied to the WSIP projects, will be implemented if the initial biological screening survey (SFPUC Construction Measure #8) indicates the potential for the presence of key special-status species and other species of concern:

- Preconstruction surveys for key special-status species and other species of concern will be conducted by a qualified biologist to verify their presence or absence. Surveys will occur during the portion of the species’ life cycle when the species is most likely to be identified within the appropriate habitat. Key special-status species and other species of concern will be avoided during construction when possible.

- A worker awareness program (environmental education) will be developed and implemented to inform project workers of their responsibilities in regards to sensitive biological resources.

- An environmental inspector will be appointed to serve as a contact for issues that may arise concerning implementation of mitigation measures, and to document and report on adherence to these measures during construction.

- Loss of habitat will be minimized through the following measures: (1) the number and size of access routes and staging areas and the total area of the project activity will be limited to the minimum necessary to achieve the project goal; (2) the introduction or spread of invasive non-native plant species and plant pathogens will be avoided or minimized by developing and implementing a weed control plan; and (3) all areas temporarily disturbed by construction will be revegetated to pre-project or native conditions, as specified in project-specific revegetation plans.

Standard Mitigation Measures for Specific Plants and Animals

Measure 4.6-3b: Table 6-1 identifies the key special-status species mitigation measures that the program analysis indicates would apply to each WSIP project. Measures listed in **Table 6-2** (listed by species) are generic measures and will be modified to fit site-specific conditions and applied to each WSIP project wherever special-status species could be affected by the projects. Surveys required under Measure 4.6-3a will refine the list of species that could be affected by a project. Table 6-1 is intended as the minimum necessary actions. In addition to adopting the generic measures, as more site-specific information is available, project-specific CEQA analysis may identify additional measures for key special-status species and additional measures for other species.

Pipeline and Water Treatment Plant Treated Water Discharge Restrictions

Measure 4.6-4: Planned discharges of regional system water from the WSIP pipelines and water treatment plants (such as crossover facilities) to creeks, rivers or other natural water bodies will be designed to minimize impacts to riparian and aquatic resources to the extent feasible. This will include dechlorination and/or pH adjustment facilities and energy dissipation structures that avoid or reduce bank erosion. In addition, the facilities should include design features to avoid or minimize temperature effects on aquatic resources; or alternatively, whenever possible, planned discharges should be scheduled to occur in the winter, when stream flows are high and temperatures low in the receiving waters to avoid or minimize temperature effects.

Note: Project-specific CEQA documents would review recent special-status species lists relevant to the habitats present.

All codes are defined in Table 6-2.

Vernal pool invertebrates:
- Vernal pool fairy shrimp
- Conservancy fairy shrimp
- Vernal pool tadpole shrimp

Vernal pool species:
- Succulent owl's-clover
- Hoover's spurge
- Colusa grass
- San Joaquin Valley Orcutt grass
- Hairy Orcutt grass
- Greene's tuctoria

Salt marsh species:
- Western snowy plover
- California clapper rail
- California black rail
- Salt marsh harvest mouse

Riparian and Reservoir species:
- Least Bell's vireo
- Valley elderberry longhorn beetle
- Riparian woodrat
- Delta button-celery
- Bald eagle

Fishes:
- Green sturgeon (San Joaquin Valley only)
- Chinook salmon
- Central Valley DPS steelhead
- Central California Coast DPS steelhead
- Rainbow trout (Alameda watershed)

Native grassland species:
- Bay checkerspot butterfly
- Callippe silverspot butterfly
- Fountain thistle (Peninsula)
- Marin dwarf flax (Peninsula)
- San Mateo woolly sunflower (Peninsula)

TABLE 6-2 (MEASURE 4.6-3b)
STANDARD PROGRAMMATIC BIOLOGICAL RESOURCES MITIGATION MEASURES

Biological Resource Species and Status	Standard Mitigation Measures for Specific Plants and Animals
Invertebrates	
Valley Elderberry Longhorn Beetle (FT/--)	**I.1:** A biological monitor will accompany tree/brush clearing crews. The monitor will flag all elderberry shrubs in the tree clearing zone and be present during tree clearing operations in the vicinity of flagged shrubs to ensure that elderberry shrubs are not cut. If avoidance is not feasible, habitat impacts will be mitigated in accordance with the Programmatic Biological Opinion (PBO) for Valley elderberry longhorn beetle, issued by the USFWS Sacramento Field Office in 1996.
Vernal Pool Crustaceans Vernal pool fairy shrimp (FT/--) Conservancy fairy shrimp (FE/--) Vernal pool tadpole shrimp (FE/--)	**I.2:** Suitable habitat for vernal pool invertebrates will be avoided. If infeasible, impacts will be mitigated in accordance with the PBO for vernal pool invertebrates, issued by the USFWS Sacramento Field Office in 1995. Surveys may be conducted, with USFWS approval, to establish whether or not listed invertebrates are present.
Bay Checkerspot Butterfly (FT/--), Callippe Silverspot Butterfly (FE/--)	**I.3:** Suitable habitat for Bay checkerspot and Callippe silverspot butterflies will be avoided
Fishes	
Central Valley fall- and late-fall run DPSChinook salmon (FC/--) Central Valley DPS steelhead (FT/--) Green sturgeon Southern District DPS (FT/--) Central Coast DPS Steelhead (FT/--) Rainbow trout (--/--)	**F1:** For construction activity in anadromous fish-bearing streams, a biological monitor with appropriate permits will be present during all construction activities to relocate fish as necessary.
Reptiles and Amphibians	
California Red-Legged Frog (FT/CSC) Foothill yellow-legged frog (--/CSC)	**RA.1:** A PBO for construction impacts on red-legged frog was prepared by the USFWS (Federal Register, 1999). The general mitigation measures, above, and the measures listed below, are taken largely from the PBO and may be modified by a project-specific BO. The foothill yellow-legged frog has no legal protection under FESA; however, all potential FYLF habitat is also considered potential habitat for CRLF and these protection measures would be applied in any case. • The name and credentials of a biologist qualified to act as a construction monitor will be submitted to the USFWS for approval at least 15 days prior to commencement of work. • The USFWS-approved biologist will survey the site two weeks prior to the onset of work activities and immediately prior to commencing work. If frog adults, tadpoles, or eggs are found, the approved biologist will contact the USFWS to determine whether relocating any life stages is appropriate. • If worksites require dewatering, the intakes will be screened with a maximum mesh size of 5 millimeters. • The USFWS-approved biologist will remove and destroy from within the project area any individuals of non-native species, such as bullfrogs, crayfish, and centrarchid fishes, to the maximum extent possible.

TABLE 6-2 (MEASURE 4.6-3b) (Continued)
STANDARD PROGRAMMATIC BIOLOGICAL RESOURCES MITIGATION MEASURES

Biological Resource Species and Status	Standard Mitigation Measures for Specific Plants and Animals
Reptiles and Amphibians (cont.)	
California Tiger Salamander (FT/CSC)	**RA.2:** In addition to measures described for California red-legged frog, which would serve to protect California tiger salamander, the following measures will minimize adverse effects to California tiger salamander.
	• A preconstruction survey will be conducted at each site to identify suitable burrow aestivation areas. Aestivation habitat will be defined as the presence of two or more small mammal burrows greater than 1 inch in diameter within a 10-foot-diameter area and within 10 feet of proposed construction sites (i.e., the presence of a single isolated gopher hole would not be considered habitat). As feasible within the context of the work area, aestivation areas will be temporarily fenced and avoided.
	• At locations where aestivation burrows are identified and cannot be avoided, aestivation burrows will be excavated by hand prior to construction and individual animals moved to natural burrows or artificial burrows constructed of PVC pipe within 0.25 mile of the construction site.
	• To ensure compliance with these measures and minimize California tiger salamander take, a qualified biological monitor will be present during all construction operations at locations with suitable aestivation burrows. Construction sites where potential habitat has been identified will be surveyed by a qualified biologist for California tiger salamander. Surveys would be appropriately timed with respect to salamander activity and proposed construction activities.
	• Surveys would include drift fences and pitfall traps within construction sites to identify and relocate animals. Following removal of individuals, construction areas will be fenced with temporary silt fencing.
San Francisco Garter Snake (FE/CE/CP)	**RA.3:** San Francisco garter snake is a California fully protected species, and incidental taking must be avoided. Therefore, in addition to measures RA.1 and RA.2, above, for construction activities in occupied habitat the work area will be fenced with frog- and snake-proof mesh fence, or 4- x 8-foot plywood panels joined lengthwise, with escape funnels to allow egress, but not access, by San Francisco garter snake.
Alameda Whipsnake (FT/CT)	**RA.4:** Construction-related impacts on individual Alameda whipsnakes will be minimized and/or avoided through the development and implementation of an Alameda whipsnake protection and monitoring plan, to be approved by the USFWS during informal consultation under FESA. Protective measures outlined in RA.1 will apply to all areas of known or potential habitat for Alameda whipsnake. In addition, it will include:
	• Sites within Alameda whipsnake habitat will be hand-cleared, or a qualified biologist will do surveys and relocate the snake immediately prior to equipment clearing.
	• Activities that could harm or harass Alameda whipsnake will be avoided or minimized.
	• Upland habitats used by Alameda whipsnake will be restored as feasible, and lost habitat will be compensated according to an agreed-upon ratio.
Birds	
Swainson's Hawk (FSC/CT)	**B.1:** To avoid disrupting nesting Swainson's hawks, construction activities at known nesting locations will occur prior to the nesting season (March 1 through September 15). Alternatively, if construction activities take place during the nesting season, a qualified biologist will conduct a preconstruction survey no more than two weeks before the start of construction and report whether or not there are nesting Swainson's hawks within 1,320 feet of any project (access permitting). If there are nesting Swainson's hawks within the 1,320-foot buffer areas, construction will be delayed until the CDFG has been consulted to determine suitable avoidance measures. A potential avoidance measure may include delaying all construction activity within 1,320 feet of an active Swainson's hawk nest until the adult and/or juvenile hawks are no longer using the nest as the center of their activity.

TABLE 6-2 (MEASURE 4.6-3b) (Continued)
STANDARD PROGRAMMATIC BIOLOGICAL RESOURCES MITIGATION MEASURES

Biological Resource Species and Status	Standard Mitigation Measures for Specific Plants and Animals
Birds (cont.)	
Western Burrowing Owl (FSC/CSC)	**B.2:** No more than two weeks before construction, a survey for burrows and burrowing owls will be conducted by a qualified biologist within 500 feet of the project (access permitting). The survey will conform to the protocol described by the California Burrowing Owl Consortium (1993), which includes up to four surveys on different dates if there are suitable burrows present. **B.3:** If occupied owl burrows are found within the survey area, a determination will be made by a qualified biologist, in consultation with the CDFG, as to whether or not work will affect the occupied burrows or disrupt reproductive behavior. If it is determined that construction will not affect occupied burrows or disrupt breeding behavior, construction will proceed without any restriction or mitigation measures. If it is determined that construction will affect occupied burrows during August through February, the subject owls will be passively relocated from the occupied burrow(s) using one-way doors. There will be at least two unoccupied burrows suitable for burrowing owls within 300 feet of the occupied burrow before one-way doors are installed. Artificial burrows will be in place at least one-week before one-way doors are installed on occupied burrows. One-way doors will be in place for a minimum of 48 hours before burrows are excavated. If it is determined that construction will physically affect occupied burrows or disrupt reproductive behavior during the nesting season (March through July), then avoidance is the only mitigation available. Construction will be delayed within 300 feet of occupied burrows until it is determined that the subject owls are not nesting or until a qualified biologist determines that juvenile owls are self-sufficient or are no longer using the natal burrow as their primary source of shelter.
Raptors including bald eagle (FD/CE/CFP)	**B.4: Raptor nests:** • In consultation with CDFG and USFWS trees with unoccupied raptor nests (stick nests or cavities) may only be removed prior to March 1, or following the nesting season. • A survey to identify active nests will be conducted by a qualified biologist no more than two weeks before the start of construction at project sites from February 1 through July 30. • Construction activities within 0.5 mile of an active bald eagle nest may not occur between February 1 and July 31. • Active raptor nests located within 500 feet of the project will be mapped, to the extent allowed by access. • If an active raptor nest is found within 500 feet of the project, a determination will be made by a qualified biologist, in consultation with the CDFG, as to whether or not construction work will affect the active nest or disrupt reproductive behavior. • If it is determined that construction will not affect an active nest or disrupt breeding behavior, construction will proceed without any restriction or mitigation measure. • If it is determined that construction will affect an active raptor nest or disrupt reproductive behavior, then avoidance is the only mitigation available. Construction will be delayed within 300 feet of such a nest until a qualified biologist determines that the subject raptors are not nesting or until any juvenile raptors are no longer using the nest as their primary day and night roost.
Least Bell's vireo (FE/CE)	**B.5:** Protection for least Bell's vireos depend principally on seasonal avoidance of habitat during the nesting season and protection of suitable habitat. To avoid working during the active breeding season, construction activities in suitable habitat (dense willows [*Salix* sp.], mulefat [*Baccharis glutinosa*], or California wild rose [*Rosa californica*] may not proceed until July 15 unless approved by the USFWS and CDFG, as appropriate.
California Black Rail (FE/CE), California Clapper Rail (FSC/CT/CFP)	**B.6:** When working within 100 feet of salt or brackish marshland (e.g., the BDPL Reliability Upgrade, BD-1), presume presence for either species during the period from February 1 to August 31, and schedule construction to begin no earlier than September 1 and end no later than January 31.

TABLE 6-2 (MEASURE 4.6-3b) (Continued)
STANDARD PROGRAMMATIC BIOLOGICAL RESOURCES MITIGATION MEASURES

Biological Resource Species and Status	Standard Mitigation Measures for Specific Plants and Animals
Birds (cont.)	
Western Snowy Plover (FT/CSC)	**B.7:** When project activities are in or adjacent to suitable habitat (e.g., portions of the BDPL Reliability Upgrade, BD-1) no earlier than September 1 and no later than January 31, no measures are necessary; however, between March 15 and August 31 the following will be observed: • A qualified biologist will conduct preconstruction surveys two weeks and one week before the start of work. If western snowy plovers or their nests are not observed, then the project activity may proceed; or • If a western snowy plover is observed within a 50-foot perimeter of the location of the construction activity two weeks or one week before, a qualified biologist will observe the activities of the bird(s) to determine if nesting behavior is exhibited. If either nesting behavior or a nest is observed within a 50-foot perimeter of the location of the activity, then the activity will be delayed until either nesting is abandoned or completed.
Mammals	
Salt Marsh Harvest Mouse (FE/CE/CFP)	**M.1:** When project activities are in or adjacent to suitable habitat (e.g., portions of the BDPL Reliability Upgrade, BD-1), vehicles will be confined to existing roads where possible, and disturbed areas will be revegetated with brackish marsh species. Crews will use matting, pontoon boards, or other comparable methods whenever feasible to minimize impacts on vegetation. The placement of mats will be verified by a qualified biologist before their placement to minimize habitat impacts. Crews will work exclusively from mat boards and boardwalks to minimize the trampling of vegetation. A qualified biologist will be available during the course of the maintenance work. In situations where habitat is to be permanently disturbed, project-specific take avoidance measures (such as fencing and trapping to exclude salt marsh harvest mouse) will be developed, since the mouse is a California fully protected species, and incidental taking must be avoided.
San Joaquin Kit Fox (FE/CT)	**M.2:** The following reasonable and prudent measures will be followed to avoid direct or indirect project-related disturbances and impacts on San Joaquin kit fox. Prior to the commencement of construction activities, a qualified biologist will survey for potential kit fox dens within the area to be disturbed and will photograph, mark, and map the dens. Disturbance of all known San Joaquin kit fox dens will be avoided. Limited destruction of potential dens may be allowed, provided the following procedures are implemented: • Potential dens occurring within the construction area will be monitored for three days with tracking medium or an infrared beam camera to determine current usage. If no kit fox activity is observed during this period, the den would be destroyed immediately to preclude subsequent use. If kit fox activity is observed, the den will be considered a known den. • Project-related vehicles will observe a 20-mph speed limit in habitat areas except as posted on county roads and state and federal highways. Off-road traffic outside the designated project area will be prohibited. • To prevent accidental entrapment of kit fox or other animals during construction, all excavated or deep-walled holes or trenches greater than 2 feet will be covered at the end of each workday by plywood or similar materials, or provided with escape routes constructed of earth fill or wooden planks. Before such holes are filled they will be thoroughly inspected for trapped animals. • Kit foxes are attracted to den-like structures such as pipes and may enter stored pipe and become trapped or injured. All construction pipes, culverts, or similar structures with a diameter of 4 inches or greater that are stored at construction sites for one or more overnight periods will be thoroughly inspected for kit foxes before the pipe is subsequently buried, capped, or otherwise used or moved in any way.

TABLE 6-2 (MEASURE 4.6-3b) (Continued)
STANDARD PROGRAMMATIC BIOLOGICAL RESOURCES MITIGATION MEASURES

Biological Resource Species and Status	Standard Mitigation Measures for Specific Plants and Animals
Mammals	
Riparian Woodrat (FE/CSC)	**M.3:** If construction will involve surface disturbance or vegetation removal in riparian habitat in the San Joaquin Region, a biologist will carry out a preconstruction survey to determine the presence or any signs of riparian woodrat, such as stick nests. Such areas will be avoided if feasible. If avoidance is not feasible, a protection and monitoring plan will be developed and approved by the USFWS during formal consultation under FESA.
Plants	
Vernal Pool Plants Succulent Owl's-Clover ((FE/CE) Hoover's Spurge (FT/--) Colusa Grass (FT/CE) San Joaquin Valley Orcutt grass (FT/CE) Greene's Tuctoria (FE/CR) Hairy Orcutt Grass (FE/CE)	**P.1:** The avoidance measures for vernal pool crustaceans will also apply to vernal pool special-status plants. Surveys to ascertain presence are highly recommended, and if first-year surveys occur during unusually low rainfall conditions, a second year of surveys, if possible, will help to establish whether avoidance measures are needed.
Riparian Plants Delta button-celery (FSC/CE)	**P.2:** The state endangered Delta button-celery occurs on clay soils on the sparsely vegetated margins of seasonally flooded floodplains and swales. Periodic flooding maintains the species' habitat through sustenance of seasonal wetlands and reduction of competition due to scouring. If a population of this species is located in an area proposed for construction, the preferred action is to avoid it if possible. The CDFG might allow salvage and restoration of the site, since this is a species that depends on ongoing disturbance to maintain its habitat. However, such strategies generally involve several years of treatment and post-treatment monitoring, so the simplest approach is to avoid impacts if possible.
Large-Flowered Fiddleneck (FE/CE)	**P.3:** Surveys for large-flowered fiddleneck will be carried out at an appropriate time of year for projects located within the known range of the species (Corral Hollow and hills immediately to the west). Any populations found will be avoided. An approved biological monitor will be present during all surface clearing activities.
San Mateo Woolly Sunflower (FE/CE), Marin Western Flax (FT/CT) Fountain thistle (FE/CE)	**P.4:** Surveys for San Mateo woolly sunflower, fountain thistle and Marin western flax will be carried out at an appropriate time of year for projects located within the known range of the species. Any populations found will be avoided. An approved biological monitor will be present during all construction activities. A plan will be developed to protect populations located along Crystal Springs and Polhemus Roads where project-related construction vehicle traffic will occur. Where populations cannot be avoided, salvage of plants or seed will be implemented, along with a program to compensate for losses.

Status Codes: FE-Federal Endangered; FT-Federal Threatened; FC-Federal Candidate; FSC-Federal Species of Concern. FD-Federal Delisted; CE-California Endangered; CT-California Threatened; CR-California Rare; CFP-California Fully Protected

Collective Measures

Bioregional Habitat Restoration Measures

Measure 4.16-4a: Bioregional effects (those beyond the level of individual plants or animals and impacts not readily associated with any particular project) could result from the collective construction of WSIP facilities and the cumulative effects of implementing WSIP projects along with other proposed projects. Combined collective and cumulative bioregional effects that will need to be addressed as part of future mitigation efforts include the following:

- Compound impacts on functional units of habitat as WSIP projects simplify vegetation structure and increase “edge” (the boundary between two different habitats);
- Increased habitat impacts due to the spread of weedy, non-native plant species;
- Genetic diversity impacts on small populations that become reduced and isolated by development;
- Impacts on wildlife movement due to habitat fragmentation;
- Suppression of natural disturbance regimes (e.g., fire, flood) as projects are constructed, operated, and maintained; and
- Reduced population recovery opportunities from stochastic events (e.g., random events such as disease).

When implementing habitat compensation mitigation required for individual WSIP facility projects, the SFPUC shall do so in a manner that addresses the above bioregional effects and includes the following conservation principles:

- The parcels are either contiguous with other areas of relatively undisturbed habitat or are themselves large enough to support most of the species associated with the habitat;
- The distribution of mitigation lands will allow movement of plants and animals between them or from them to habitats otherwise conserved (e.g. as described in The Wilderness Society, 2001); and
- Implementation of habitat compensation mitigation for individual WSIP facility projects will be combined and implemented through a coordinated program with other mitigation efforts, such as through the Habitat Reserve Program (HRP), and shall meet these standards:
    - Long-term management of these lands stipulates maintaining natural disturbance regimes (e.g., through prescribed burning);
    - Long-term control actions for non-native species are applied; and
    - Contingencies are considered which address sharing biological materials and information with other conservation land stewards.[2] This might include

[2] For example, the California Department of Parks and Recreation (CDPR), East Bay Regional Parks District (EBRPD), and the Midpeninsula Regional Open Space District (MROSD).

restoring suitable sites with plants brought from another protected area once a weed infestation has been brought under control, or animal relocation if done strictly for the purpose of genetic diversity or recovery, and with the approval of the regulatory agencies.

Coordination of Construction Staging and Access

Measure 4.16-4b: When construction schedules for WSIP projects affecting the same areas overlap, the SFPUC will coordinate construction contractor(s) to the extent practicable to minimize surface disturbance associated with access roads, laydown areas, and staging areas.

Cultural Resources (Section 4.7)

Program Measures

Suspend Construction Work if Paleontological Resource is Identified

Measure 4.7-1: This mitigation measure builds on SFPUC Construction Measure # 9 for cultural resources, which requires that construction work will be suspended immediately if there is any indication of a paleontological resource. When a paleontological resource (fossilized invertebrate, vertebrate, plant or micro-fossil) is discovered at any of the project sites, an appointed representative of the SFPUC will notify a qualified paleontologist, who will document the discovery as needed, evaluate the potential resource, and assess the significance of the find under the criteria set forth in Section 15064.5 of the CEQA Guidelines. When a fossil is found during construction, excavations within 50 feet of the find will be temporarily halted or diverted until the discovery is examined by a qualified paleontologist, in accordance with Society of Vertebrate Paleontology standards (SVP 1995, 1996). The paleontologist will notify the SFPUC to determine procedures to be followed before construction is allowed to resume at the location of the find. If the SFPUC determines that avoidance is not feasible, the paleontologist will prepare an excavation plan for mitigating the effects of the project.

Archaeological Testing, Monitoring, and Treatment of Human Remains

Measure 4.7-2a: SPFUC Construction Measure #9 for cultural resources requires that a pre-construction screening be conducted by a qualified archaeologist. Based on the results of this screening, the Environmental Review Officer (ERO) shall determine if implementation of an archeological testing or archaeological monitoring program or both is the appropriate strategy for avoidance of potential adverse effects to significant archaeological resource. For those projects that require a federal permit and compliance with the NHPA, Section 106, the ERO will review the SHPO-approved requirements in the permit conditions and consider protective approaches that limit undue duplication of efforts.

Archeological Testing Program. The archeological consultant shall prepare and submit to the ERO for review and approval an archeological testing plan (ATP). The archeological testing program shall be conducted in accordance with the approved ATP. The ATP shall identify the property types of the expected archeological resource(s) that potentially could be adversely affected by the proposed project, the testing method to be used, and the locations recommended for testing. The purpose of the archeological testing program will be to determine to the extent possible the presence or absence of any expected archeological resources and to identify and to preliminarily evaluate the integrity and significance of the resource.

At the completion of the archeological testing program, the archeological consultant shall submit a written report of the findings to the ERO. If based on the archeological testing program the archeological consultant finds that significant archeological resources may be present, the ERO in consultation with the archeological consultant shall determine if additional measures are warranted. Additional measures that may be undertaken include additional archeological testing, archeological monitoring, preparation of an archeological research design and treatment plan, or an archeological data recovery program.

Archeological Monitoring Program. The archeological consultant shall prepare and submit to the ERO for review and approval an archeological monitoring plan (AMP). The archeological monitoring program shall be conducted in accordance with the approved AMP. The AMP shall specify what project activities in areas sensitive for buried resources shall be archeologically monitored. Project activities that may require monitoring may include the installation of pipelines and crossover facilities and certain soils-altering activities such as grading and access road construction associated with construction or improvement of water storage facilities. The archaeological monitoring program shall include the following:

- All project contractors shall be advised to be on the alert for evidence of the presence of the expected resource(s), of how to identify the evidence of the expected resource(s), and of the appropriate protocol in the event of apparent discovery of an archeological resource;

- The archeological monitor(s) shall be present on the project site according to a schedule agreed upon by the archeological consultant and the ERO until the ERO has, in consultation with project archeological consultant, determined that project construction activities are unlikely to have effects on significant archeological deposits;

- The archeological monitor shall record and be authorized to collect soil samples and artifactual/ecofactual material as warranted for analysis;

- If an intact archeological deposit is encountered, all soils-disturbing activities within the area specified in the AMP of the deposit shall cease. The archeological monitor shall be empowered to temporarily redirect demolition/excavation/pile driving/construction activities and equipment until the deposit is evaluated. The archaeological consultant shall immediately notify the ERO of the encountered archeological deposit. The archeological consultant shall make a reasonable effort to assess the identity, integrity, and significance of the encountered archeological deposit, and present the findings of this assessment to the ERO.

Whether or not significant archeological resources are encountered, the archeological consultant shall submit a written report of the findings of the monitoring program to the ERO.

Additional Requirements: the following requirements, as applicable, are requisite in implementation of either an archaeological testing or monitoring program.

Archeological Data Recovery Program. The archeological data recovery program shall be conducted in accord with an archeological data recovery plan (ADRP). The archeological consultant, project sponsor, and ERO shall meet and consult on the scope of the ADRP prior to preparation of a draft ADRP. The archeological consultant shall submit a draft ADRP to the ERO. The ADRP shall identify how the proposed data recovery program will preserve the significant information the archeological resource is expected to contain. That is, the ADRP will identify what scientific/historical research questions are applicable to the expected resource, what data classes the resource is expected to possess, and how the expected data classes would address the applicable research questions. Data recovery, in general, should be limited to the portions of the historical property that could be adversely affected by the proposed project. Destructive data recovery methods shall not be applied to portions of the archeological resources if nondestructive methods are practical.

The scope of the ADRP shall include the following elements:

- *Field Methods and Procedures*. Descriptions of proposed field strategies, procedures, and operations.
- *Cataloguing and Laboratory Analysis*. Description of selected cataloguing system and artifact analysis procedures.
- *Discard and Deaccession Policy*. Description of and rationale for field and post-field discard and deaccession policies.
- *Interpretive Program*. Consideration of an on-site/off-site public interpretive program during the course of the archeological data recovery program.
- *Security Measures*. Recommended security measures to protect the archeological resource from vandalism, looting, and non-intentionally damaging activities.
- *Final Report*. Description of proposed report format and distribution of results.
- *Curation*. Description of the procedures and recommendations for the curation of any recovered data having potential research value, identification of appropriate curation facilities, and a summary of the accession policies of the curation facilities.

Human Remains and Associated or Unassociated Funerary Objects. The treatment of human remains and of associated or unassociated funerary objects discovered during any soils disturbing activity shall comply with applicable State laws. This shall include immediate notification of the coroner of the county within which the project is located and in the event of the coroner's determination that the human remains are Native American remains, notification of the California State Native American Heritage Commission (NAHC) who shall appoint a Most Likely Descendant (MLD) (Pub. Res. Code Sec. 5097.98). The archeological consultant, project sponsor, and MLD shall make all reasonable efforts to develop an agreement for the treatment of, with appropriate dignity, human remains and associated or unassociated funerary objects (CEQA Guidelines. Sec. 15064.5(d)). The agreement should take into consideration the appropriate excavation, removal, recordation, analysis, custodianship, curation, and final disposition of the human remains and associated or unassociated funerary objects. State law allows 24 hours to reach agreement on these matters. If the MLDs do not agree on the reburial method, the Project will follow Section 5097.98(b) of the California Public resources code which states, "the landowner or his or her authorized representative shall reinter the human remains and items associated with Native American burials with appropriate dignity on the property in a location not subject to further subsurface disturbance."

Final Archeological Resources Report. The archeological consultant shall submit a Draft Final Archeological Resources Report (FARR) to the ERO that evaluates the historical significance of any discovered archeological resource and describes the archeological and historical research methods employed in the archeological testing/monitoring/data recovery program(s) undertaken. Information that may put at risk any archeological resource shall be provided in a separate removable insert within the final report. Once approved by the ERO, copies of the FARR shall be distributed as follows: the relevant California Historical Resources Information System Information Center shall receive one (1) copy and the ERO shall receive a copy of the transmittal of the FARR to the Information Center. The Major Environmental Analysis division of the Planning Department (MEA) shall receive three copies of the FARR along with copies of any formal site recordation forms (CA DPR 523 series) and/or documentation for evaluation under National Register of Historic Places/California Register of Historical Resources criteria. The SFPUC shall receive copies of the FARR as requested in number. In instances of high public interest in or the high interpretive value of the resource, the ERO may require a different final report content, format, and distribution than that presented above.

Accidental Discovery Measures

Measure 4.7-2b: SFPUC Construction Measure # 9 for cultural resources requires that construction activities be suspended immediately if there is any indication of an archaeological resource.

To avoid any potential adverse effect from the proposed project on accidentally discovered buried or submerged historical resources as defined in CEQA Guidelines Section 15064.5(a)(c), the project sponsor shall distribute the Planning Department archaeological resource "ALERT" sheet to the project prime contractor; to any project subcontractor (including demolition, excavation, grading, foundation, pile driving, etc. firms); or utilities firm involved in soil disturbing activities within the project site. Prior to any soil disturbing activities being undertaken, each contractor is responsible for ensuring that the "ALERT" sheet is circulated to all field personnel including, machine operators, field crew, pile drivers, supervisory personnel, etc. The project sponsor shall provide the Environmental Review Officer (ERO) with a signed affidavit from the responsible parties (prime contractor, subcontractor(s), and utilities firm) to the ERO confirming that all field personnel have received copies of the "ALERT" sheet.

If the ERO determines that an archeological resource may be present within the project site, the project sponsor shall retain the services of a qualified archeological consultant. The archeological consultant shall advise the ERO as to whether the discovery is an archeological resource, retains sufficient integrity, and is of potential scientific/historical/cultural significance. If an archeological resource is present, the archeological consultant shall identify and evaluate the archeological resource. The archeological consultant shall make a recommendation as to what action, if any, is warranted. Based on this information, the ERO may require, if warranted, specific additional measures to be implemented by the project sponsor.

Measures might include: preservation in situ of the archeological resource; an archaeological monitoring program; or an archeological testing program. If an archeological monitoring program or archeological testing program is required, it shall be consistent with the MEA guidelines for such programs. The ERO may also require that the project sponsor immediately implement a site security program if the archeological resource is at risk from vandalism, looting, or other damaging actions.

The project archeological consultant shall submit a Final Archeological Resources Report (FARR) to the ERO that evaluates the historical significance of any discovered archeological resource and describing the archeological and historical research methods employed in the archeological monitoring/data recovery program(s) undertaken. Information that may put at risk any archeological resource shall be provided in a separate removable insert within the final report. Once approved by the ERO, copies of the FARR shall be distributed as follows: the relevant California Historical Resources Information System Information Center shall receive one (1) copy and the ERO shall receive a copy of the transmittal of the FARR to the Information Center. The MEA shall receive three copies of the FARR along with copies of any formal site recordation forms (CA DPR 523 series) and/or documentation for nomination to the National Register of Historic Places/California Register of Historical Resources. The SFPUC shall receive copies of the FARR as requested in number. In instances of high public interest in or the high interpretive value of the resource, the ERO may require a different final report content, format, and distribution than that presented above.

Protection of Historic Districts

Measure 4.7-3: The city’s water system facilities affected by WSIP facility projects will be assessed by a qualified historian for their potential contribution to an historic district, following the guidelines identified under Impact 4.7-3. To qualify as an historic district, each resource within that potential district would need to be reliant upon the other resources within the district to be historically significant. Impacts on one resource within the potential district may or may not affect the others, and this conclusion would determine the ultimate significance of the impact.

If an historic district would be affected by one or more proposed WSIP facility projects, the SFPUC, in consultation with the ERO, will develop mitigation measures for effects with attention to the potential district as a whole, with utmost effort made to maintain the district’s function, appearance, cohesive site organization, and ability to convey historic significance. Appropriate measures may also include but not be limited to: refinement of facility sites to minimize effects on district appearance and site organization as well as visual screening efforts to reduce the impact of adding new facilities or otherwise modifying the landscape.

Should an historic district be identified at the project level, it should be recorded as such, using the four National/California Register criteria of significance to explain its historical importance as a cohesive group of resources. The district should be documented by completing the State of California Department of Parks and Recreation 523 forms, using a 523D (District) form as an umbrella record to unify the 523A (Primary Record) and 523B (Building, Structure, Object) forms completed for each individual resource within the potential district, and submitting them to SHPO.

Alternatives Identification and Resource Relocation

Measure 4.7-4a: If a project proposes to demolish or remove a historical resource, including individual historic resources and/or historic districts, the SFPUC will attempt to identify feasible project alternatives that eliminate or reduce the need for demolition or removal to the greatest extent possible. The SFPUC will pursue and implement these project alternatives to the extent feasible, consistent with the goals and objectives of the WSIP.

Relocation of a resource will always be preferable to demolition, although relocation might not mitigate impacts to a less-than-significant level. If preservation of the affected historical resource at the current site is determined to be infeasible, the structure shall, if feasible, be stabilized and relocated to other nearby sites appropriate to their historic setting and general environment. This may not be possible in some cases, like in the replacement of Calaveras Dam (if it were identified as a historical resource for the purposes of CEQA). After relocation, the resource shall be treated according to preservation, rehabilitation, or restoration standards, as appropriate, that follow the Secretary of the Interior's *Standards.* This will ensure that the building, structure, object, site, or district retains historic integrity and its historic significance (Measure 4.7-4c). If the affected historical resource can neither be preserved at its current site nor moved to an alternative site and is to be demolished, the SFPUC shall consult with local historical societies and governmental agencies regarding salvage of materials from the affected historical resource for public information or reuse in other locations. Demolition may proceed only after any significant historic features or materials have been identified, preserved (as feasible), and their removal completed.

Representative features such as aqueduct/pipe sections, valves subject to replacement, decorative elements, or plaques/inscriptions from buildings or other portions of structures demolished as a part of the WSIP projects could be preserved and displayed. Most of these types of structures are of sufficient size that they would form "monumental" commemorative structures. For example, an original pipeline valve replaced by modern equipment might be mounted and displayed on publicly accessible SFPUC property with informative placards. Such displays, if located in other jurisdictions, might be subject to those jurisdiction's requirements related to public art, safety, and liability considerations.

Historical Resources Documentation

Measure 4.7-4b: Documentation of a historical resource, including resources identified as contributors to a historic district or as individually significant, prior to demolition or removal is a standard mitigation measure. Such documentation is often tied to meeting the documentation standards of the Historic American Buildings Survey/Historic American Engineering Record (HABS/HAER). The publication *Recording Historic Structures: Historic American Buildings Survey/Historic American Engineering Record* (Burns, 1989) provides four levels of documentation corresponding to the level of importance of the historic resource to be documented. For the purpose of this PEIR, the standards for photography in Documentation Levels III and IV have been modified to allow for the use of digital photographs instead of large-format negatives.

<u>*Documentation Level I*</u>:

1. Drawings: a full set of measured drawings depicting existing or historic conditions.

2. Photographs: photographs with large-format negatives of exterior and interior views; photocopies with large-format negatives of select existing drawings or historic views where available. Photographs would follow the HABS/HAER Photographic Specifications.
3. Written data: history and description.

Documentation Level II:

1. Drawings: select existing drawings, where available, should be photographed with large-format negatives or photographically reproduced on Mylar.

2. Photographs: photographs with large-format negatives of exterior and interior views, or historic views, where available. Photographs would follow the HABS/HAER Photographic Specifications.
3. Written data: history and description.

Documentation Level III:

1. Drawings: sketch plan.
2. Photographs: digital photographs of exterior and interior views.
3. Written data: architectural data form.

Documentation Level IV:

1. Drawings: sketch plan.
2. Photographs: digital photographs of exterior and interior views.
3. HABS/HAER inventory cards.

Digital photography will follow the standards in the National Register of Historic Places and National Historic Landmarks Survey, Photo Policy Expansion, March 2005 (Table VV). Digital image files would be burned to archival-quality disks, such as the eFilm Archival Gold CD-R or DVD-R; or MAM-A Mitsui Gold Archive CD-R or DVD-R.

The SFPUC will prepare, or retain a consultant to prepare, documentation of historical resources prior to any construction work associated with demolition or removal. The appropriate level of documentation will be selected by a qualified professional who meets the standards for history, architectural history, and/or architecture (as appropriate) set forth by the Secretary of the Interior (*Secretary of the Interior's Professional Qualification Standards*, 36 CFR 61) in consultation with a preservation specialist assigned by the San Francisco Planning Department and the local jurisdiction if deemed appropriate by the Planning Department. In addition to the four levels of documentation listed above, salvage and/or interpretive display may also be required if determined appropriate. The professional in history, architectural history and/or architecture (as appropriate) will prepare the documentation and submit it for review and approval by the Planning Department's preservation specialist. One set of the documentation will be archived at each of the following repositories: San Francisco Planning Department, SFPUC, the History Room of the San Francisco Public Library and the Water Resources Center Archive at the University of California Berkeley. Additional dissemination of documentation to local historical societies or historic preservation organizations may be appropriate. The San Francisco Planning Department will identify additional appropriate recipients of historical documentation during the project-level analysis.

Secretary of the Interior's Standards for Treatment of Historic Properties

Measure 4.7-4c: Compliance with the *Secretary of the Interior's Standards for the Treatment of Historic Properties* would reduce potential impacts associated with the alteration or modification of a historical resource (including historic districts and individually eligible resources) to a less-than-significant level. (In accordance with CEQA Section 15064.5(b)(3), a project that follows the *Secretary of the Interior's Standards for the Treatment of Historic Properties with Guidelines for Preserving, Rehabilitating, Restoring, and Reconstructing Historic Buildings* or the *Secretary of the Interior's*

Standards for Rehabilitation and Guidelines for Rehabilitating Historic Buildings is generally considered to have impacts of a less-than-significant level.)

The SFPUC will prepare materials describing and depicting the proposed project, including but not limited to plans, drawings, and photographs of existing conditions (digital, following the standards in Measure 4.7-4a as well as proposed project plans, drawings, specifications, and description). Prepared materials will be submitted to the San Francisco Planning Department. The Planning Department will review the proposed project, for compliance with the *Secretary of the Interior's Standards for the Treatment of Historic Properties*.

If a project is determined to be inconsistent with the *Secretary of the Interior's Standards for the Treatment of Historic Properties*, the SFPUC will pursue and implement redesign of the project to the extent feasible, consistent with the goals and objectives of the WSIP, such that consistency with the standards is achieved.

Historic Resources Survey and Redesign

Measure 4.7-4d: The SFPUC will undertake a historic resources survey within a designated area of potential effect that encompasses the proposed project to identify and evaluate potential historical resources, including districts, which may exist within or partially within the project's study area or area of potential effect. The survey will be conducted by a qualified professional who meets the *Secretary of the Interior's Professional Qualification Standards* for architectural history, history, or architecture (36 CFR 61).

If a survey identifies one or more historical resources in the projects' study area, or area of potential effect (i.e. historically significant resources), the qualified professional will then assess the impact the project may have on those historical resources. If the project will cause a substantial adverse change to a historical resource, the SFPUC will prepare materials describing and depicting the proposed project, including but not limited to plans, drawings, and photographs of existing conditions (digital, following the standards in Measure 4.7-1a) as well proposed project plans, drawings, specifications, and description. Prepared materials will be submitted to the San Francisco Planning Department. The San Francisco Planning Department will assign a preservation specialist to review the proposed project, for compliance with the *Secretary of the Interior's Standards for the Treatment of Historic Properties*.

If a project is determined to be inconsistent with the *Secretary of the Interior's Standards for the Treatment of Historic Properties*, the SFPUC will pursue and implement redesign of the project to the extent feasible, consistent with the goals and objectives of the WSIP, such that consistency with the standards is achieved.

Historic Resources Protection Plan

Measure 4.7-4e: A qualified historian will prepare a plan that specifies procedures for protecting historical resources and a monitoring method to be employed by the contractor while working near these resources. At a minimum, the plan will address the operation of construction equipment near adjacent historical resources, storage of construction materials away from adjacent resources, and education/training of construction workers about the significance of the historical resources.

Preconstruction Surveys and Vibration Monitoring

Measure 4.7-4f: If vibration-related impacts could impact historical resources, one or more geotechnical investigations by a California-licensed geotechnical engineer will be included as part of the proposed project. The SFPUC and its contractors will follow the recommendations of the final geotechnical reports regarding any excavation and construction for the project. The SFPUC will ensure that the construction contractor conducts a preconstruction survey of existing conditions and monitors the adjacent buildings for damage during construction, if recommended by the geotechnical engineer. Any preconstruction surveys and construction monitoring would include the services of a professional meeting the *Secretary of the Interior's Professional Qualification Standards* for architecture.

Traffic, Transportation, and Circulation (Section 4.8)

Program Measures

Traffic Control Plan Measures

Measure 4.8-1a: SFPUC Construction Measure #5 for traffic requires each contractor to prepare a traffic control plan to minimize traffic and on-street parking impacts on any streets affected by construction of the proposed program. SFPUC and construction contactor(s) will prepare and implement a traffic control plan, and coordinate with Caltrans and local jurisdictions, as appropriate, for affected roadways and intersections. Each project may require the implementation of different measures, depending on the project's site-specific construction details, the characteristics of the transportation network, and daily and peak hour vehicle, pedestrian and bicycle volumes. As applicable, elements of the traffic control plan could include, but are not necessarily limited to, the following:

- Circulation and detour plans will be developed to minimize impacts on local street circulation. Flaggers and/or signage will be used to guide vehicles through and/or around the construction zone.
- Truck routes designated by cities and counties will be identified in the traffic control plan. Haul routes that minimize truck traffic on local roadways and residential streets will be utilized to the extent possible.
- Sufficient staging areas will be provided for trucks accessing construction zones to minimize disruption of access to adjacent land uses, particularly at entries to onsite pipeline construction within residential neighborhoods.
- Access to driveways and private roads will be maintained by using steel trench plates. If access must be restricted for brief periods, property owners will be notified in advance.
- Construction vehicle movement will be controlled and monitored through the enforcement of standard construction specifications by onsite inspectors.
- Along major arterials, truck trips will be scheduled outside of the peak morning and evening commute hours to the extent possible.

- Lane closures will be limited during peak hours to the extent possible. Outside of allowed working hours or when work is not in progress, roads will be restored to normal operations, with all trenches covered with steel plates.

- Where possible, pipeline construction work in roadways will be limited to a width that, at a minimum, maintains alternate one-way traffic flow past the construction zone. Parking may be prohibited if necessary to facilitate construction activities or traffic movement. If the work zone width will not allow a 10-foot-wide paved travel lane, then the road will be closed to through-traffic (except emergency vehicles), and detour signing on alternative access roads will be used.

- Pedestrian and bicycle access and circulation will be maintained during project construction where safe to do so. If construction activities encroach on a bicycle lane, warning signs will be posted that indicate bicycles and vehicles are sharing the lane.

- Detours will be included for bicycles and pedestrians in all areas potentially affected by project construction.

- All equipment and materials will be stored in designated contractor staging areas on or adjacent to the worksite, in such a manner to minimize obstruction of traffic.

- Locations will be identified for parking by construction workers, either within the construction zone or, if necessary, at a nearby location with transport provided between the parking location and the worksite.

- Roadside safety protocols will be implemented. Advance "Road Work Ahead" warning signs and speed control (including signs informing drivers of state-legislated double fines for speed infractions in a construction zone) will be provided to achieve required speed reductions for safe traffic flow through the work zone.

- Construction will be coordinated with facility owners or administrators of sensitive land uses such as police and fire stations (including all fire protection agencies), transit stations, hospitals, and schools. Facility owners or operators will be notified in advance of the timing, location, and duration of construction activities and the locations of detours and lane closures.

- Construction will be coordinated with local transit service providers, including temporary relocation of bus routes or bus stops in work zones as necessary.

- Roadway right-of-ways will be repaired or restored to their original conditions or better upon completion of construction.

- To the extent applicable, the traffic control plan will conform to the *California Manual on Uniform Traffic Control Devices for Streets and Highways: Part 6 Temporary Traffic Control* and *Caltrans' 2006 Standard Plans.*

Coordination of Individual Traffic Control Plans

Measure 4.8-1b: To the extent that the adopted SFPUC Construction Measure #5 does not contain such provisions already, or the provisions are not required for a project as a result of local encroachment or right-of-way permit conditions, the contract specifications for individual contracts within a single WSIP project will include the following:

- In the event that more than one construction contract is issued for work along existing or new pipelines, and where construction could occur within and/or across multiple streets in the same vicinity, the SFPUC and construction contractor(s) will coordinate the traffic control plans in order to mitigate the impact of traffic disruption. The coordinated plan will include measures that address overlapping construction schedules and activities, truck arrivals and departures, lane closures and detours, and the adequacy of on-street staging requirements.

Accommodation of Displaced Public Parking Supply for Recreational Visitors

Measure 4.8-4: Due to the potential displacement of designated parking areas where limited parking is available for adjacent public uses, traffic control plans prepared as part of SFPUC Construction Measure #5 and Measure 4.8-1a will include an additional measure to accommodate any anticipated visitor parking demand that would be displaced by proposed projects at public recreational facilities.

Collective Measures

SFPUC WSIP Projects Construction Coordinator

Measure 4.16-6a: Due to the potential for overlapping project activities and construction vehicles to affect travel within and across the five regions, the SFPUC will identify a qualified construction coordinator responsible for coordinating the project-specific traffic control plans developed as part of Measure 4.8-1a, and for developing a public information campaign (e.g., internet website, radio and newspaper updates) to inform the public of construction activities, detour routes, and alternate routes. Throughout the seven-year construction schedule for the WSIP projects, the SFPUC construction coordinator will work with local and regional agencies to pursue additional traffic mitigation measures to minimize local and regional traffic impacts and will incorporate these measures into the project-specific traffic control plans, as appropriate.

Combined San Joaquin Traffic Control Plan

Measure 4.16-6b: Due to the potential for overlapping project schedules in the San Joaquin Region near Tesla Portal, the SFPUC will develop [or the SFPUC's construction contractor(s) will be required to develop] a San Joaquin Traffic Control Plan that coordinates the project-specific traffic control plans developed as part of Measure 4.8-1a and identifies additional measures to minimize the combined impacts of multiple WSIP project construction traffic on I-580, Chrisman Road, and Vernalis Road. As applicable, these measures will be developed consistent with the standards of San Joaquin County, Stanislaus County, and Caltrans and could include:

- Additional traffic control devices, such as traffic signals at key intersections providing access to local roadways and land uses
- Additional traffic control personnel at key locations to facilitate vehicular traffic flow during peak periods of truck activity
- Adjustments in truck arrival and departure schedules for the various facilities (e.g., staggering departures)

Combined Sunol Valley Traffic Control Plan

Measure 4.16-6c: Due to the potential for overlapping project schedules in the Sunol Valley Region as well as for construction traffic to use Calaveras Road as an access route to all projects sites, the SFPUC or its construction contractor(s) will develop a Sunol Valley Traffic Control Plan that coordinates the project-specific traffic control plans developed as part of Measure 4.8-1a and identifies additional measures to minimize the impacts of construction traffic on Calaveras Road and I-680. As applicable, these measures will be developed consistent with the standards of Alameda County and Caltrans and could include:

- Additional traffic control devices, such as traffic signals at key intersections providing access to local roadways and land uses. Traffic signals could facilitate access onto Calaveras Road at intersections and also allow for gaps in truck traffic flow to facilitate access from driveways along Calaveras Road.
- Additional traffic control personnel at key locations to facilitate vehicular traffic flow during peak periods of truck activity.
- Adjustments in truck arrival and departure schedules for the various facilities (e.g., staggering departures).
- Public information regarding periods when construction traffic on Calaveras Road would be greatest.
- Working with Caltrans to determine if warning signs, such as a “Slow Trucks” sign (California Code W51), would be appropriate to inform drivers that slow-moving trucks may interfere with the flow of traffic on I-680.

Cumulative Measures

SFPUC WSIP Projects Construction Coordinator – Other Agencies

Measure 4.17-6: As required in Measure 4.8-1, contractors will be required to submit traffic control plans to the SFPUC, and in Measure 4.16-6a, the SFPUC will be required to identify a WSIP construction coordinator who will be responsible for coordinating the project-specific traffic control plans. The SFPUC WSIP construction coordinator will also consider the effects of any traffic generated by SFPUC maintenance activities and other SFPUC projects (as listed in Tables 4.17-1 through 4.17-6). The SFPUC WSIP construction coordinator will also coordinate with Caltrans, other county agencies, and local jurisdictions responsible for reviewing and/or approving the construction of other identified private and public development projects (as listed in Tables 4.17-1 through 4.17-6) so as to minimize traffic impacts on local access roads, particularly local streets where sensitive receptors (e.g., schools, residences, or hospitals) are located.

Air Quality (Section 4.9)

Program Measures

SJVAPCD Dust Control Measures

Measure 4.9-1a: In the San Joaquin Region, the SJVAPCD has determined that compliance with the following Regulation VIII (Fugitive PM_{10} Prohibitions) and Regulation IX (Mobile and Indirect Sources, Rule 9510, where applicable) control measures would mitigate PM_{10} impacts to a less-than-significant level. The SFPUC will include these measures, where applicable, in contract specifications:

SJVAPCD Basic Control Measures (applies to all construction sites)

- All disturbed areas, including storage piles, that are not being actively utilized for construction purposes, shall be effectively stabilized of dust emissions using water, chemical stabilizer/suppressant, covered with a tarp or other suitable cover, or vegetative ground cover.
- All onsite unpaved roads and offsite unpaved access roads shall be effectively stabilized of dust emissions using water or chemical stabilizer/suppressant.
- All land clearing, grubbing, scraping, excavation, land leveling, grading, cut and fill, and demolition activities shall be effectively controlled of fugitive dust emissions utilizing application of water or by presoaking.
- When materials are transported offsite, all material shall be covered, or effectively wetted to limit visible dust emissions, and at least 6 inches of freeboard space from the top of the container shall be maintained.
- All operations shall limit or expeditiously remove the accumulation of mud or dirt from adjacent public streets at the end of each workday. The use of dry rotary brushes is expressly prohibited except where preceded or accompanied by sufficient wetting to limit the visible dust emissions. Use of blower devices is expressly forbidden.
- Following the addition of materials to, or the removal of materials from, the surface of outdoor storage piles, said piles shall be effectively stabilized of fugitive dust emissions utilizing sufficient water or chemical stabilizer/suppressant.
- Within urban areas, trackout shall be immediately removed when it extends 50 or more feet from the site and at the end of each workday.
- Any site with 150 or more vehicle trips per day shall prevent carryout and trackout.

SJVAPCD Enhanced Control Measures (also applies when required to mitigate significant PM_{10} impacts)

- Traffic speeds on unpaved roads shall be limited to 15 mph.
- Sandbags or other erosion control measures shall be installed to prevent silt runoff to public roadways from sites with a slope greater than 1 percent.

SJVAPCD Additional Control Measures (also applies to construction sites that are large in area, located near sensitive receptors, or which for any other reason warrant additional emissions reductions)

- Wheel washers shall be installed for all exiting trucks, or all trucks and equipment leaving the site shall be washed off.
- Wind breaks shall be installed at windward side(s) of construction areas.
- Excavation and grading activity shall be suspended when winds exceed 20 mph and, regardless of windspeed, an owner/operator must comply with Regulation VIII's 20 percent opacity limitation.
- The area subject to excavation, grading, and other construction activity at any one time shall be limited.

SJVAPCD Rule 9510, Indirect Source Review, Section 6.1, Construction Equipment Emissions (applies to any project subject to discretionary approval by a public agency that ultimately results in the construction of a new building, facility, or structure or reconstruction of a building, facility, or structure for the purpose of increasing capacity or activity and also involving 9,000 square feet of space).

- 6.1.1: The exhaust emissions for construction equipment greater than fifty (50) horsepower used or associated with the development project shall be reduced by the following amounts from the statewide average as estimated by the ARB:
  - 6.1.1.1: 20% of the total NO_x emissions, and
  - 6.1.1.2: 45% of the total PM_{10} exhaust emissions.
- 6.1.2: An applicant may reduce construction emissions on-site by using less-polluting construction equipment, which can be achieved by utilizing add-on controls cleaner fuels, or newer lower emitting equipment.
- 6.3: The requirements listed in Section 6.1 above can be met through any combination of on-site emission reduction measures or off-site fees.

SJVAPCD Exhaust Control Measures

Measure 4.9-1b: To limit exhaust emissions within the San Joaquin Region, the SJVAPCD specifies the following exhaust controls for heavy-duty equipment (scrapers, graders, trenchers, earthmovers, etc.). The SFPUC will include these measures, where applicable, in contract specifications:

- Alternative-fueled or catalyst-equipped diesel construction equipment shall be used.
- Idling time (e.g., 10-minute maximum) shall be minimized.
- The hours of operation of heavy-duty equipment and/or the amount of equipment in use shall be limited.

- Fossil-fueled equipment shall be replaced with electrically driven equivalents (provided they are not run via a portable generator set).
- Construction shall be curtailed during periods of high ambient pollutant concentrations; this may include ceasing construction activity during the peak hour of vehicular traffic on adjacent roadways.
- Activity management (e.g., rescheduling activities to reduce short-term impacts) shall be implemented.

BAAQMD Dust Control Measures

Measure 4.9-1c: In the Sunol Valley, Bay Division, Peninsula, and San Francisco Regions, the BAAQMD has determined that implementation of the following control measures would mitigate PM_{10} impacts to a less-than-significant level. The SFPUC will include these measures, where applicable, in contract specifications:

BAAQMD Basic Control Measures (applies to all construction sites)

- All active construction areas shall be watered at least twice daily.
- All trucks hauling soil, sand, and other loose debris shall be covered *or* all trucks shall be required to maintain at least 2 feet of freeboard on public roads.
- All unpaved access roads, parking areas, and staging areas at construction sites shall either be paved, watered three times daily, or nontoxic soil stabilizers shall be applied.
- All paved access roads, parking areas, and staging areas at construction sites shall be swept daily (with water sweepers).
- If visible soil material is carried onto adjacent public streets, adjacent streets shall be swept daily (with water sweepers).

BAAQMD Enhanced Control Measures (also applies to sites over four acres)

- All inactive construction areas (previously graded areas inactive for 10 days or more) shall be hydroseeded or nontoxic soil stabilizers shall be applied.
- Exposed stockpiles (dirt, sand, etc.) shall be enclosed, covered, and watered, or nontoxic soil binders shall be applied.
- As feasible, traffic speeds on unpaved roads shall be limited to 15 mph.
- Sandbags or other erosion control measures shall be installed to prevent silt runoff to public roadways.
- Disturbed areas shall be replanted as quickly as possible.

BAAQMD Optional Control Measures (also applies to construction sites that are large in area, located near sensitive receptors, or which for any other reason warrant additional emissions reductions)

- Wheel washers shall be installed for all exiting trucks, or all trucks and equipment leaving the site shall be washed off.
- Wind-breaks or trees/vegetative wind-breaks shall be installed at windward side(s) of construction areas.
- Excavation and grading activity shall be suspended when winds exceed 25 mph.
- The area subject to excavation, grading, and other construction activity at any one time shall be limited.

BAAQMD Exhaust Control Measures

Measure 4.9-1d: To limit exhaust emissions within the Sunol Valley, Bay Division, Peninsula, and San Francisco Extended Regions, the SFPUC will implement the following exhaust controls, where applicable:

- Grid power will be used instead of diesel generators at all construction sites where it is feasible to connect to grid power. While it may not be practical to connect to grid power for pipeline projects (since construction sites keep moving along the alignments), grid power shall be used for projects with fixed locations, such as tunnel entry and exit shafts/portals.
- All WSIP contracts specifications shall include Sections 2480 and 2485, Title 13, California Code of Regulations, which limit the idling of all diesel-fueled commercial vehicles (weighing over 10,000 pounds, both California- or non-California-based trucks) to 30 seconds at a school or five minutes at any location. In addition, the use of diesel auxiliary power systems and main engines shall be limited to five minutes when within 100 feet of homes or schools while the driver is resting.
- All WSIP contracts specifications shall include Section 93115, Title 17, California Code of Regulations, Airborne Toxic Control Measure for Stationary Compression Ignition Engines, which specifies fuel and fuel additive requirements; emission standards for operation of any stationary, diesel-fueled, compression-ignition engines; and operation restrictions within 500 feet of school grounds when school is in session.
- A schedule of low-emissions tune-ups shall be developed and such tune-ups shall be performed on all equipment, particularly for haul and delivery trucks. A log of required tune-ups shall be maintained and a copy of the log shall be submitted to the SFPUC on a monthly basis for review.
- Low-sulfur fuels shall be used in all stationary and mobile equipment.

Health Risk Screening or Use of Soot Filters

Measure 4.9-2a: If truck volumes associated with a particular project along a particular haul route exceed 40,000 truck trips over the entire construction period, a health risk screening will be completed. If a potentially significant impact is indicated, a site-specific health risk assessment (HRA) will be completed for the project. Any separate project-level analysis will consider DPM emission rates at the time of construction since emission rates are expected to decline in the future. Based on the site-specific HRA, a mitigation program will be developed implementing one or more the following methods of reducing DPM emission or exposure to a less-than-significant level:

- Modify haul routes to reduce exposure.
- Require use of biodiesel fuel, which reduces DPM emissions.
- Require new construction equipment to be utilized. Newer construction equipment is far cleaner than old equipment.
- Require that the vehicle fleet include trucks with soot filters (particulate traps) within the equipment fleet.
- Temporarily vacate affected receptors.
- Any other effective means of reducing DPM emissions or exposure.

Vacate SFPUC Land Managers' Residences in Sunol Valley

Measure 4.9-2b: The two SFPUC Land Managers' residences in the Sunol Valley will be vacated during construction of the Calaveras Dam (SV-2) or Treated Water Reservoirs (SV-5) projects. Alternatively, a health risk screening could be completed to determine health risks at these residences from either of these two projects. If a potentially significant impact is indicated, a health risk assessment will be completed, and measures will be implemented, as set forth in Measure 4.9-2a.

Tunnel Gas Odor Control

Measure 4.9-3: For any projects that would require a tunnel ventilation system, if hydrogen sulfide gas or any other odorous gases (including diesel exhaust) are encountered during tunnel excavation and become a nuisance odor problem (i.e., odor complaints are received), water scrubbers will be added to the ventilation system and appropriate chemicals will be added to remove the nuisance odors.

Collective Measures

Dust and Exhaust Control Measures for All WSIP Projects

Measure 4.16-7a: Measures 4.9-1a through 4.9-1d requires specific projects to implement dust and exhaust control measures. To address collective construction-related air quality impacts, these measures will be required for all WSIP projects as applicable and required by SJVAPCD and BAAQMD.

Health Risk Screening or Use of Soot Filters for All Projects in the San Joaquin and Sunol Valley Regions

Measure 4.16-7b: Measure 4.9-2a requires specific projects to either conduct a health risk assessment or use soot filters to reduce DPM emissions associated with haul trucks. To address collective DPM impacts, this measure will be required for all WSIP projects in the

San Joaquin and Sunol Valley Regions. This measure would only apply in the Sunol Valley Region if, under Measure 4.9-2b, the SFPUC elects not to vacate the two SFPUC Land Managers' residences in the Sunol Valley. If this requirement is applied to the New Irvington Tunnel project (SV-4), it shall be applied to both the Sunol Valley and Fremont tunnel portals, taking into account truck traffic from other WSIP projects in the vicinity of both portals.

Vacate SFPUC Land Managers' Residences for All Projects in the Sunol Valley Region

Measure 4.16-7c: Measure 4.9-2b requires the two SFPUC Land Managers' residences in the Sunol Valley to be vacated during construction of the Calaveras Dam (SV-2) and Treated Water Reservoirs (SV-5) projects. Alternatively, a health risk screening could be completed to determine health risks at these residences. If a potentially significant impact is indicated, a health risk assessment will be completed. To address collective DPM impacts, this measure will be required for all WSIP projects in the Sunol Valley Region.

Noise and Vibration (Section 4.10)

Program Measures

Noise Controls

Measure 4.10-1a: SFPUC Construction Measure #6 for noise requires compliance with local noise ordinances to the extent feasible. Many of these ordinances restrict hours when construction can occur, but do not specify noise limits for construction noise. For most projects, the SFPUC will conduct construction activities during the daytime hours to the extent feasible. However, if nighttime construction cannot be avoided, noise generated by these activities will be required to comply with applicable noise ordinance nighttime limits or not exceed 50-dBA sleep interference criterion (with windows open at night) to the extent feasible.

To ensure that construction noise impacts are mitigated to a less-than-significant level, all WSIP projects located within 500 feet of any noise-sensitive receptors (e.g., residences, schools, childcare centers, churches, hospitals, and nursing homes) will be required to implement appropriate noise controls to reduce daytime construction noise levels to meet the 70-dBA daytime speech interference criterion to the extent feasible. For nighttime construction, all WSIP projects located within 3,000 feet of any noise-sensitive receptors will be required to implement appropriate noise controls to maintain noise levels at or below any applicable ordinance nighttime noise limits or the 50-dBA nighttime sleep interference criterion to the extent feasible. Such controls could include any of the following, as appropriate:

- Best available noise control techniques (including mufflers, intake silencers, ducts, engine enclosures, and acoustically attenuating shields or shrouds) will be used for all equipment and trucks in order to minimize construction noise impacts. If feasible, construction equipment noise will not exceed the mitigated noise levels listed in **Table 4.10-4** (see measure below for limits on impact equipment).

- If impact equipment (e.g., jack hammers, pavement breakers, and rock drills) is used during project construction, hydraulically or electric-powered equipment will be used wherever feasible to avoid the noise associated with compressed-air exhaust from pneumatically powered tools. However, where use of pneumatically powered tools is unavoidable, an exhaust muffler on the compressed-air exhaust will be used (a muffler can lower noise levels from the exhaust by up to about 10 dBA). External jackets on the tools themselves will be used, where feasible, which could achieve a reduction of 5 dBA. Quieter procedures, such as drilling rather than impact equipment, will be used whenever feasible.

- Pile holes will be pre-drilled wherever feasible to reduce potential noise and vibration impacts. Where feasible, sonic or vibratory pile drivers will be used instead of impact pile drivers (sonic pile drivers are only effective in some soils).

- Pile driving activities shall be prohibited during the evening and nighttime hours (7 p.m. to 7 a.m.).

- Operation of equipment requiring use of back-up beepers will be avoided near sensitive receptors to the extent feasible during nighttime hours (10 p.m. to 7 a.m.).

- Stationary noise sources will be located as far from sensitive receptors as feasible. If they must be located near receptors, adequate muffling (with enclosures where feasible and appropriate) will be used to ensure local noise ordinance limits are met to the extent feasible. Enclosure opening or venting will face away from sensitive receptors. If any stationary equipment (e.g., ventilation fans, generators, dewatering pumps) is operated beyond the time limits specified by the pertinent noise ordinance, this equipment will conform to the affected jurisdiction's pertinent day and night noise limits to the extent feasible.

- Material stockpiles as well as maintenance/equipment staging and parking areas will be located as far as feasible from residential and school receptors.

- Wherever feasible, pipeline alignments will be located at least 100 feet away from sensitive receptors.

- Where pipeline construction zones are within 100 feet of school classrooms or childcare facilities, pipeline construction activities (or at least the noisier phases of construction) will be scheduled on weekend or school vacation days to the extent feasible, avoiding weekday hours when schools are in session. If construction must occur when school is in session, interior noise levels in classrooms will not exceed 60 dBA if possible to avoid speech interference problems, which would allow for a maximum exterior noise level of 70 to 80 dBA, depending on whether windows are open or closed.

- Given the long duration of construction activities at tunnel shafts/portals and proposed nighttime activities, tunnel-related construction activities will be designed to comply with nighttime noise limits specified in local noise ordinances. Measures that could be implemented to comply with these limits include: using quiet ventilation fans (pure tone components of fan noise will be considered), using line power instead of generators, erection of temporary sound barriers, restricting heavy equipment operation during the nighttime hours, using nonmetallic containers in the muck removal system to prevent clanging/banging noises, limiting controlled detonations in the tunnel shaft/portal vicinities to the daytime hours, retrofitting windows/doors of affected homes, and/or prohibiting use of backup alarms on equipment during the nighttime hours.

- Where controlled detonation activities will occur, surrounding cities and residents should be notified of the blasting schedule, indicating the time range when blasting could occur (hours and duration).

- Proposed jack-and-bore pits will be located as far from sensitive receptors as technically feasible. If ventilation fans, dewatering pumps, or generators are required as part of this type of pipeline crossing, such equipment will comply with daytime and nighttime noise limits specified in pertinent noise ordinances to the extent feasible (also see Measure 4.9-1d in Section 4.9, Air Quality, for additional restrictions on generator operation).

- Wherever necessary, temporary or permanent noise barriers will be erected to maintain construction noise levels at or below the 70-dBA daytime speech interference criterion and the 50-dBA nighttime sleep interference criterion.

- A designated project liaison will be responsible for responding to noise complaints during the construction phases. The name and phone number of the liaison will be conspicuously posted at construction areas and on all advanced notifications. This person will take steps to resolve complaints, including periodic noise monitoring, if necessary. Results of noise monitoring will be presented at regular project meetings with the project contractor, and the liaison will coordinate with the contractor to modify any construction activities that generated excessive noise levels to the extent feasible.

- A reporting program will be required for each project that documents complaints received, actions taken to resolve problems, and effectiveness of these actions.

Vacate SFPUC Caretaker’s Residence at Tesla Portal

Measure 4.10-1b: The SFPUC caretaker’s residence at Tesla Portal will be vacated during construction of the Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) projects as well as those portions of the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects located at Tesla Portal.

Limit Hourly Truck Volumes

Measure 4.10-2a: In addition to SFPUC Construction Measure #6 for noise, which requires compliance with local noise ordinances to the extent feasible, haul and delivery truck routes for all WSIP projects will avoid local residential streets and will follow local designated truck routes to the extent feasible. Total project-related haul and delivery truck volumes on any particular haul truck route will be limited to 80 trucks per hour.

Restrict Truck Operations

Measure 4.10-2b: Haul and delivery trucks will be prohibited from operating within 200 feet of any residential uses during the nighttime hours (10 p.m. to 7 a.m.). If there are receptors, but they are beyond 200 feet from the haul route, limited truck operations will be allowed during the more sensitive nighttime hours, but noise generated by these operations cannot exceed the 50-dBA sleep interference criterion at the closest receptors. If trucks must operate during these hours and residential uses are located within 200 feet of the haul route, deliveries will be made to staging areas outside residential areas, then transferred to the construction site during daytime hours (7 a.m. to 7 p.m.).

Vacate SFPUC Land Manager's Residence

Measure 4.10-2c: To minimize nighttime noise impacts, the SFPUC Land Manager's residence adjacent to Alameda East Portal will be vacated during off-site truck operations associated with the New Irvington Tunnel project (SV-4), if truck operations occur during the nighttime hours (10 p.m. to 7 a.m.) and are estimated to exceed the 50-dBA sleep interference criterion at this residence.

Vibration Controls to Prevent Cosmetic or Structural Damage

Measure 4.10-3a: To prevent cosmetic or structural damage to adjacent or nearby structures, the SFPUC will incorporate restrictions into all contract specifications (primarily for sheetpile driving, pile driving, or tunnel construction activities), whereby surface vibration will be limited to 0.2 in/sec PPV for continuous vibration (e.g., vibratory equipment and impact pile drivers) and 0.5 in/sec PPV for controlled detonations at the closest receptors to ensure that cosmetic or structural damage does not occur.

Limit Vibration Levels at or Below Vibration Perception Threshold

Measure 4.10-3b: For nighttime construction activities, the SFPUC will maintain vibration levels at or below the vibration perception threshold (0.012 in/sec PPV) at adjacent properties (or in accordance with local ordinances) to the extent feasible. If vibration complaints are received during facility construction, operational adjustments will be made (e.g., restricting use of equipment causing vibration disturbance during the nighttime hours or slowing the pace of its operation), as necessary, to reduce vibration annoyance effects.

Limit Tunnel-Related Detonation to Daylight Hours

Measure 4.10-3c: The SFPUC will limit controlled detonation associated with tunnel construction to the daylight hours, Monday through Saturday.

Collective Measures

Limiting Hourly Truck Volumes and Restricting Truck Operations on Haul Routes for Multiple WSIP Projects

Measure 4.16-8a: Measures 4.10-2a and 4.10-2b outline restrictions and guidelines for daytime and nighttime truck operations on local roadways. To address collective truck-related noise impacts, these measures will be applied to total haul and delivery truck volumes on any particular haul truck route that are attributable to all WSIP projects, including the Tesla Portal, Irvington Portal, Lower Crystal Springs Dam vicinities as well as haul routes in San Francisco Region. Therefore, total truck volumes from all WSIP projects on a particular route will not exceed 80 trucks per hour (so as not to exceed the 70-dBA speech interference criterion during the daytime hours) and will be restricted near sensitive receptors (to meet the 50-dBA sleep interference criterion) during the nighttime hours.

Vacate Land Manager's Residence for All Projects in Sunol Valley Region

Measure 4.16-8b: Measure 4.10-2c requires the SFPUC Land Manager's residence adjacent to Alameda East Portal to be vacated during construction truck operations associated with the New Irvington Tunnel project (SV-4). To address collective noise impacts, this residence will be vacated during construction truck operations associated with all WSIP projects in this region, if collective daytime truck volumes exceed the 70-dBA speech interference criterion (7 a.m. to 10 p.m.) or nighttime truck volumes exceed the 50-dBA sleep interference criterion (10 p.m. to 7 a.m.).

Cumulative Measures

Coordination of Truck Traffic on Local Streets

Measure 4.17-8: The SFPUC WSIP construction coordinator designated in Measure 4.17-6 will also be responsible for coordinating truck traffic generated on these same streets by SFPUC maintenance activities and other SFPUC projects (as listed in Tables 4.17-1 through 4.17-6) so that SFPUC-related truck noise increases are maintained at or below threshold levels specified in Measures 4.10-2a and 4.10-2b to the extent feasible (80 trucks per hour along a haul/delivery route and restricted nighttime truck operations).

Public Services and Utilities (Section 4.11)

Program Measures

Notify Neighbors of Potential Utility Service Disruption

Mitigation 4.11-1a: As part of the neighborhood notice, the SFPUC will notify residents and businesses in project area of potential utility service disruption two to four days in advance of construction.

Locate Utility Lines Prior to Excavation

Measure 4.11-1b: Prior to excavation, the SFPUC or its contractors will locate overhead and underground utility lines, such as natural gas, electricity, sewer, telephone, fuel, and water lines, that may be encountered during excavation work prior to opening an excavation.

Confirmation of Utility Line Information

Measure 4.11-1c: The SFPUC or its contractors will find the exact location of underground utilities by safe and acceptable means. Information regarding the size, color, and location of existing utilities must be confirmed before construction activities commence.

Safeguard Employees from Potential Accidents Related to Underground Utilities

Measure 4.11-1d: While any excavation is open, the SFPUC or its contractors will protect, support, or remove underground utilities as necessary to safeguard employees.

Notify Local Fire Departments

Measure 4.11-1e: The SFPUC or its contractors will notify local fire departments any time damage to a gas utility results in a leak or suspected leak, or whenever damage to any utility results in a threat to public safety.

Emergency Response Plan

Mitigation 4.11-f: The SFPUC will develop an emergency response plan in the event of a leak or explosion prior to commencing construction activities.

Prompt Reconnection of Utilities

Measure 4.11-2g: The SFPUC or its contractors will promptly reconnect any disconnected utility lines.

Coordinate Final Construction Plans with Affected Utilities

Measure 4.11-1h: The SFPUC or its contractors will coordinate final construction plans and specifications with affected utilities.

Waste Reduction Measures

Measure 4.11-2: The following requirements will be incorporated into contract specifications for each WSIP project:

The contractor(s) will obtain any necessary waste management permits prior to construction and will comply with conditions of approval attached to project implementation. As part of the waste management permit process, the contractor(s) will submit a solid waste recycling plan to the affected agencies. Elements of the plan will likely include, but are not necessarily limited to, the following:

- Identification of the types of debris that will be generated by the project and identify how all waste streams will be handled.
- Actions to reuse or recycle construction debris and clean excavated soil to the extent possible.
- Actions to divert at least 50% of inert solids (asphalt, brick, concrete, dirt, fines, rock, sand, soil, and stone) from disposal in a landfill.

Recreational Resources (Section 4.12)

Program Measures

Coordination with Golf Course/Recreational Facility Managers

Measure 4.12-1: Where golf courses or other recreational facilities would be directly affected by pipeline construction, the SFPUC will coordinate with facility managers to minimize adverse impacts on golfers and other recreational users.

Appropriate Siting of Proposed Facilities

Measure 4.12-2: The SFPUC will locate WSIP project facilities on park and recreation properties in consultation with park planning staff to minimize the direct loss of recreation and play space and to minimize any inconvenience to park, playground, or golf course users associated with the installation of non-recreational facilities within recreational areas.

Agricultural Resources (Section 4.13)

Program Measures

Supplemental Noticing and Soil Stockpiling

Measure 4.13-1a: For the San Joaquin Pipeline projects (SJPL System, SJ-3, and SJPL Rehabilitation, SJ-4), as part of the SFPUC Construction Measure #1 for neighborhood notice, advanced notification will include the name and number of an SFPUC staff person who can be contacted to discuss special needs and to work out accommodations to minimize temporary disruption to agricultural activities. The SFPUC will stockpile and replace topsoil in mapped areas of Prime and Unique Farmland and Farmland of Statewide Importance that would be temporarily disturbed by pipeline construction, unless other actions are required under specific agreements with individual land owners. (The SFPUC typically holds easements for work on its projects, but prior owners may have residual rights to use the rights-of-way for agricultural purposes. The SFPUC will work with farmers under the terms of these agreements.)

Avoidance or Soil Stockpiling

Measure 4.13-1b: The SFPUC will minimize any potential impacts on agricultural lands in the Sunol Valley by avoiding these resources wherever possible. Where this is not possible, topsoil along the pipeline right-of-way will be stockpiled, replaced, and hydroseeded to prevent erosion, unless other actions are required as a result of contracts affecting use of the property or under specific agreements with individual land owners.

Siting Facilities to Avoid Prime Farmland

Measure 4.13-2: The SFPUC will avoid areas identified as Prime Farmland, Unique Farmland, or Farmland of Statewide Importance in the siting of facilities for the 40-mgd Treated Water project (SV-3), Treated Water Reservoirs project (SV-5), and ancillary power supply facilities for the SJPL System project (SJ-3). If avoidance is not feasible, the SFPUC will adopt a permanent set-aside for an equivalent acreage of similarly-valued farmland in the area.

Hazards (Section 4.14)

Program Measures

Site Health and Safety Plan

Measure 4.14-1a: For all projects requiring excavation where the site assessment conducted in accordance with SFPUC Construction Measure #7 indicates the potential to encounter hazardous materials in the soil or groundwater, the contractor will prepare a site health and safety plan identifying the chemicals present, potential health and safety hazards, monitoring to be performed during site activities, soils-handling methods required to minimize the potential for exposure to harmful levels of any chemicals identified in the soil, appropriate personnel protective equipment, and emergency response procedures.

Materials Disposal Plan

Measure 4.14-1b: For all projects requiring excavation where the site assessment conducted in accordance with SFPUC Construction Measure #7 indicates the potential to encounter hazardous materials in the soil, the contractor will prepare a materials disposal plan that specifies the disposal method and approved disposal site for the soil and will provide written documentation that the disposal site will accept the waste.

Coordination with Property Owners and Regulatory Agencies

Measure 4.14-1c: Based on regulatory agency file reviews conducted in accordance with SFPUC Construction Measure #7, the SFPUC will assess the potential to encounter unacceptable levels of hazardous materials at known environmental cases, for construction activities to cause groundwater plume migration or interfere with ongoing remediations at known environmental cases, and for increased water levels in reservoirs or lakes to inundate known environmental cases. Should the review indicate that the project could encounter unacceptable levels of hazardous materials or interfere with a remediation, the SFPUC will contact the site owner (or responsible SFPUC department for the Peninsula Sportsmen’s Club and Pacific Rod and Gun Club) and responsible regulatory agency to determine appropriate construction modifications or remediation necessary to avoid adverse effects during construction and operation of the project. Construction modifications will be designed to reduce groundwater plume migration or interference with the remediation; alternatively, modifications will be made to the remediation activities during construction to reduce interference with remediation activities to avoid encountering unacceptable levels of hazardous materials. The SFPUC will implement the requirements of the responsible regulatory agency.

Health Risk Screening and Airborne Asbestos Monitoring Plan

Measure 4.14-2: For tunneling projects where soil or rock containing naturally occurring asbestos has been identified, the SFPUC will conduct a health risk screening assessment to identify acceptable levels of asbestos in tunnel emissions based on site conditions and proximity to receptors. Prior to operation of the tunnel exhaust system, the contractor will be required to prepare an airborne asbestos monitoring plan for approval by the BAAQMD. The plan will specify the identified asbestos criterion, monitoring that will be conducted to identify asbestos concentrations in tunnel emissions, sampling methods, analytical methods, and corrective actions that will be taken if the asbestos criterion is exceeded. Additional dust filtration will be added to the tunnel exhaust system if the criterion is exceeded.

Hazardous Building Materials Surveys and Abatement

Measure 4.14-5: For all WSIP projects involving demolition or renovation of existing facilities, the SFPUC will retain a registered environmental assessor or a registered engineer to perform a hazardous building materials survey for each structure prior to demolition or renovation activities. If any friable asbestos-containing materials, lead-containing materials, or hazardous components of building materials are identified, adequate abatement practices, such as containment and/or removal, will be implemented prior to demolition or renovation. Any PCB-containing equipment or fluorescent lights containing mercury vapors will also be removed and disposed of properly.

Energy Resources (Section 4.15)

Program Measures

Incorporation of Energy Efficiency Measures

Measure 4.15-2: Consistent with the Energy Action Plan II priorities for reducing energy usage, the SFPUC will ensure that energy efficient equipment is used in all WSIP projects. A repair and maintenance plan will also be prepared for each facility to minimize power use. The potential for use of renewable energy resources (such as solar power) at facility sites will be evaluated during project-specific design.

5 WSIP Water Supply and System Operations – Setting and Impacts

5.1 Introduction and Approach

CHAPTER 5

WSIP Water Supply and System Operations – Setting and Impacts

Chapter 5 Sections

5.1 Overview

5.1.1 Introduction

This chapter addresses the water supply and system operations aspects of the Water System Improvement Program (WSIP) and evaluates the potential environmental impacts of the proposed changes in water supply sources and regional water system operations. These impacts are generally distinct from the impacts associated with proposed construction and operation of the WSIP facility improvement projects described in Chapter 4, although there are some areas of overlap, which are described where appropriate. Together, Chapters 4 and 5 of this Program Environmental Impact Report (PEIR) present the impacts associated with implementation of the San Francisco Public Utilities Commission's (SFPUC) proposed program.

The impact discussions in Chapter 5 are organized by watershed and related drainages and reservoirs, rather than by environmental resource topics as in Chapter 4. This is because the water supply and system impacts are dependent on the local characteristics of each watershed and related resources. In this chapter, each watershed or water resource is discussed as a whole. There are three watershed areas of interest along the SFPUC's regional system: the Tuolumne River system, the Alameda Creek system, and the Peninsula system (including Pilarcitos Creek) (see **Figure 5.1-1**). In addition, the Westside Groundwater Basin is analyzed as a separate resource area only with respect to WSIP impacts on the groundwater resources, since the facilities-related

SFPUC Water System Improvement Program . 203287

Figure 5.1-1
Overview of Water Supply Watersheds
in the SFPUC Regional Water System

effects of construction and operation of the WSIP groundwater projects are evaluated in Chapter 4. Together, these watersheds and related water resources constitute the "program area" affected by the proposed water supply and system operations of the WSIP (Chapter 4, Section 4.1 defines the "study area," which encompasses the areas affected by proposed WSIP facilities).

For each watershed and related drainage area, this chapter addresses impacts on all environmental resources that could be affected by the proposed water supply option and system operations included in the proposed program: surface water hydrology, geomorphology, water quality, groundwater, fisheries and aquatic resources, riparian resources, recreational and visual resources, and, where applicable, water supplies and energy. Other resource topic areas analyzed in Chapter 4—land use, geology/soils/seismicity, cultural resources, traffic/transportation/ circulation, air quality, noise/vibration, public services and utilities, agricultural resources, and hazards—are not addressed in Chapter 5, since these resource areas would not be affected by changes in water supply and system operations (see Appendix B for more discussion).

Chapter 5 provides a *project-level* impact analysis of implementing: (1) the proposed WSIP water supply option to serve the projected 2030 average annual customer water purchase requests of 300 million gallons per day (mgd), and (2) the future regional system operations associated with meeting the WSIP's water supply and delivery reliability level of service objectives. Specifically, Chapter 5 provides a detailed analysis of the effects of increasing the average annual diversion from the Tuolumne River to serve customer purchase requests during both nondrought and drought periods through 2030. The project-level analysis evaluates the effects on the hydrology and related resources in the Tuolumne River, Alameda Creek, and Peninsula watersheds. Project-level mitigation measures have been identified, where appropriate, to address potentially significant impacts.

This detailed analysis is intended to fully address the effects of implementing the proposed WSIP water supply option through 2030 without the need for additional environmental review, with one exception. The exception that will require additional CEQA review is associated with the effects of the WSIP facility improvement project, Groundwater Projects (SF-2), on groundwater resources. The analyses in Sections 5.3 through 5.5 include the project-level impacts of taking additional water from the Tuolumne River to provide potable water from the regional system during nondrought years to serve those customers in San Mateo County that currently use groundwater from the Westside Basin; however, Chapter 5 does not evaluate the project-level impacts on the Westside Groundwater Basin of extracting the water from the basin during drought years. Section 5.6 analyzes the effects of the proposed conjunctive-use program and local groundwater projects on groundwater resources at a program-level, and subsequent project-level impact analysis of the proposed groundwater extraction activities on groundwater resources will be required, as appropriate, as specific well facilities are proposed under the WSIP facility improvement project for Groundwater Projects (SF-2).[1]

1 Chapter 4 analyzes the program-level effects of implementing facilities needed for the Groundwater Projects (SF-2) and Recycled Water Projects (SF-3), and separate, project-level CEQA review on those facilities will be required. The project-level analysis of the proposed water supply option in Chapter 5 includes the effects of incorporating recycled water into systemwide operations.

5.1.2 Chapter Organization

Chapter 5 is organized as follows. Section 5.1 provides a description of the WSIP water supply option and system operations analyzed in this chapter as well as a general discussion of the approach to the analysis and rationale used in the impact evaluation for all watersheds. It describes the modeling tool used in the analysis and the chief assumptions made regarding system operations in the future. Specific differences in approach that are unique to each watershed are described in the individual sections. In addition, this overview section presents the definitions of significance determinations used throughout the chapter.

Section 5.2 presents a review of the plans, policies, and regulatory framework as they apply to relevant water supply issues as well as to watershed management of affected resources. In addition, the general regulatory framework for water and biological resources is included in this section, and specific details applicable to each watershed are provided in subsequent sections.

Section 5.3 covers the Tuolumne River drainage from Hetch Hetchy Reservoir to the river's confluence with the San Joaquin River and, as appropriate, also discusses the Delta.

Section 5.4 addresses the portion of the Alameda Creek watershed and major tributaries where it would be affected by the regional water system.

Section 5.5 encompasses drainage areas within the SFPUC Peninsula watershed, including the watersheds of San Mateo, Pilarcitos, and San Andreas Creeks and associated reservoirs.

Section 5.6 discusses the Westside Groundwater Basin resources that could be affected by the proposed WSIP groundwater projects, including both the local project in San Francisco as well as the regional projects proposed as part of the conjunctive-use program.

Section 5.7 presents an analysis of cumulative effects associated with the water supply sources and related resources. The section describes other past, present, and reasonably foreseeable future projects that could affect the same water resources and related environmental resources as the WSIP (as described in Sections 5.3 through 5.6) and evaluates the potential cumulative effects of implementing the WSIP in combination with those projects.

5.1.3 Proposed Water Supply Option and System Operations

This section reiterates the description of the proposed water supply option, as presented in Chapter 3.0, since it is the focus of the Chapter 5 impact analysis. The proposed water supply option addresses both the delivery reliability and water supply levels of service proposed under the WSIP, which are both associated with the projected increase in customer purchase requests (demand) through the year 2030. The proposed delivery reliability level of service is to increase the reliability of the regional system to serve average day customer demand of 300 mgd under a range of operating conditions, including providing for local reservoir replenishment and during planned maintenance, unplanned outages, and loss of water from any one water source. The proposed water supply levels of service are as follows: (1) to fully meet customer purchase requests in nondrought years through the planning year 2030, estimated to be 300-mgd average annual delivery, and (2) to provide drought-year delivery with a maximum systemwide cutback of 20 percent in any one year of a drought.

Although no major changes are proposed under the WSIP with respect to regional system operations, there would be some operational refinements (described in Chapter 3, Section 3.7). The proposed facility improvements would upgrade and in some cases expand the system, allowing changes in operations that provide increased flexibility as well as increased delivery reliability. In particular, local Bay Area reservoirs would be maintained at higher water levels for longer periods of time under the WSIP than under the existing condition. By keeping water stored in local reservoirs, geographically close to the customers' demand, the SFPUC would be able to respond to service needs during a drought or other emergency, such as an unplanned facility outage.

Proposed Nondrought-Year Water Supplies

During nondrought conditions, the SFPUC proposes to serve the increased 35 mgd in average annual purchase requests through a combination of conservation, water recycling, and groundwater supply programs in San Francisco supplemented with increased diversions from the Tuolumne River. Under the proposed water supply option, the SFPUC would implement conservation, water recycling, and groundwater supply programs in the SFPUC retail service area to achieve the equivalent of 10 mgd of supply in all years (drought and nondrought).

The SFPUC proposes to serve the increase in customer purchase requests that are not served by conservation, water recycling, and groundwater supply programs through increased use of Tuolumne River water under its existing water rights and additional management of the local watershed resources with the restoration of the storage capacity of Calaveras and Crystal Springs Reservoirs. The regional system would continue to maximize its use of local watershed water supplies. This increased diversions from the Tuolumne River include additional diversions needed to serve 2030 purchase requests as well as maintaining local storage for supply reliability and implementation of Westside Basin conjunctive-use program.

Proposed Drought-Year Water Supplies

During drought years under the WSIP, the SFPUC would continue to use the nondrought-year water supplies described above and would make use of the following additional resources and measures to meet the 2030 needs:

- <u>*Water transfers*</u>. Obtain up to an equivalent of 26 mgd of supplemental Tuolumne River water through water transfer agreements with TID and MID such that water would be available for diversion in drought years.
- <u>*Groundwater conjunctive-use program in the Westside Basin, San Mateo County*</u>. Utilize the extraction component of a groundwater conjunctive-use program in the Westside Groundwater Basin in northern San Mateo County to provide the equivalent of approximately 6 mgd of water during prolonged drought to groundwater pumpers. This includes providing potable water to groundwater pumpers and in-lieu groundwater recharge during nondrought years in return for reduced groundwater pumping during drought years.

- *Restoration of Calaveras and Crystal Springs Reservoir capacities*. Restore the historical operating storage capacities at Calaveras Reservoir to provide an equivalent of 7 mgd of additional water supply and at Crystal Springs Reservoir to provide an equivalent of 1 mgd of additional supply.

- *Rationing*. Implement up to 20 percent systemwide rationing if necessary in combination with use of the above supplemental water supplies.

To ensure that the water supplies would be available by 2030, the SFPUC is currently in the planning phase of the design and construction of needed facilities and is pursuing required agreements with other agencies. The SFPUC would secure these water supplies in phases as required to meet the increased customer demand between now and 2030, as reflected in **Figure 5.1-2**. Figure 5.1-2 shows the average annual historical customer deliveries as well as the projected future average annual demand. The figure indicates that between 2005 and 2030, the total customer purchase requests are estimated to increase by 35 mgd (annual average), from an annual average of 265 mgd to an annual average of 300 mgd. Retail customer demand would increase by about 1 mgd,[2] and the remaining increase would be from wholesale customers (see also Chapter 3, Table 3.4). Half of this increased demand is expected to occur before 2020, and the remaining by 2030.

This chapter evaluates the effects of implementing this proposed combination of actions and supplemental supplies to meet water supply and delivery needs and performance objectives through 2030.

Annual Average Historical and
Projected Future Customer Purchase Requests

2 The SFPUC retail service area high-range purchase estimate of 91 mgd assumes that San Francisco groundwater supply would be part of the regional water system supply.

5.1.4 Approach to the Analysis

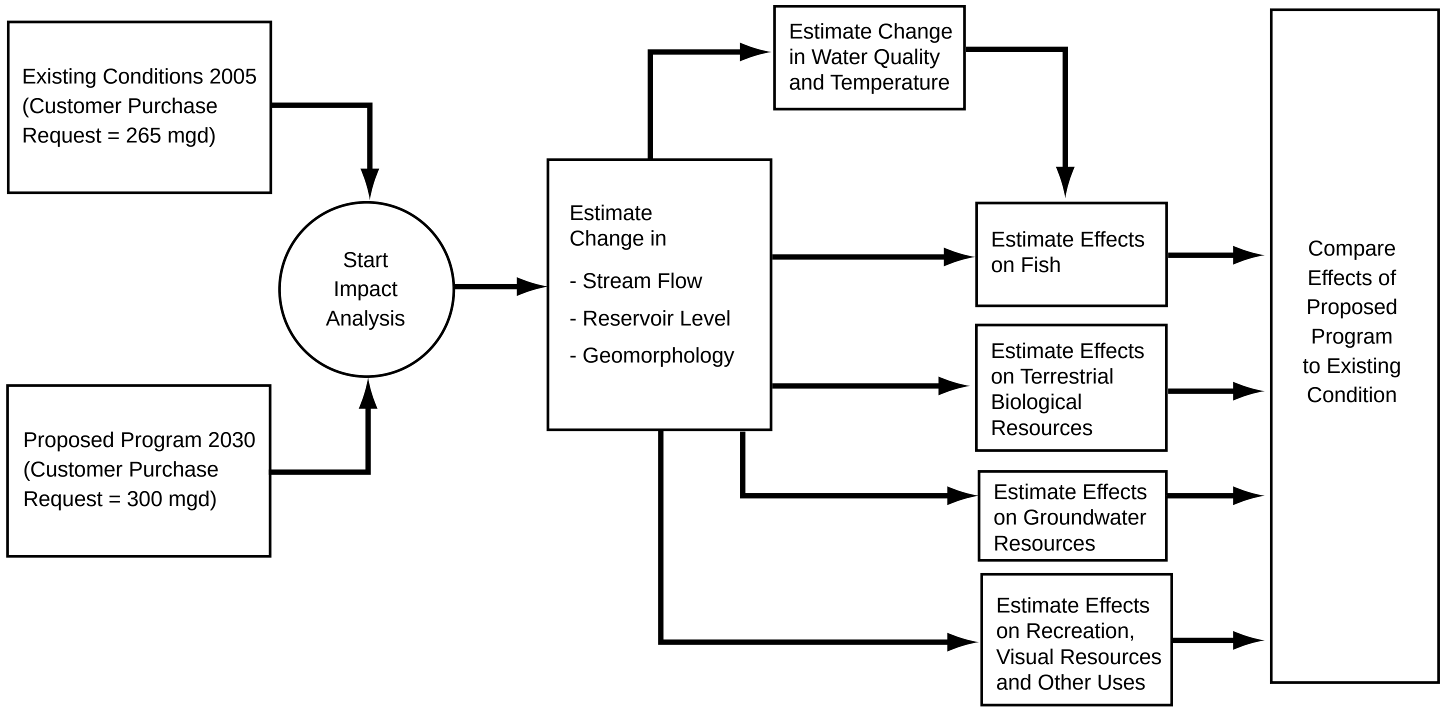
As part of WSIP implementation, additional water would be diverted from the Tuolumne River above the current average annual diversion levels in order to serve customer water delivery requirements and the other level of service goals established for the regional system through 2030. The analyses presented in Sections 5.3, 5.4, and 5.5 focus on the effects of this additional water diversion and of the related system operations needed to store and move that water from the Tuolumne River through the regional system of reservoirs and conveyance facilities to customers in the Bay Area. The analysis considers future system operations following implementation of all proposed WSIP projects in order to determine the effects that any adjustments in operations might have on the hydrology and related environmental resources in the three affected watersheds—the Tuolumne River, Alameda Creek, and Peninsula watersheds.

Relationship of Affected Resources

The basic approach to determining the potential impacts on water and related resources was the same for the three affected watersheds. First, changes in flow in the rivers and/or creeks and changes in water levels in each of the reservoirs were evaluated. These are the primary physical environmental changes that could occur with implementation of the water supply component of the WSIP, and these changes provide the basis for evaluating the potential related effects on other environmental resources. **Figure 5.1-3** depicts the interrelationships between, and among, changes in stream flow and reservoir storage levels and the potentially affected environmental resources.

Changes in stream flow under to the WSIP, which would primarily result from changes in the timing and quantity of water released from system reservoirs, were used to assess changes in the geomorphic processes for local streams (i.e., the sediment transport and channel-forming properties that define the nature of a stream course and its associated habitats). Stream flow and reservoir water level changes were then used to estimate changes in water quality. The chief water quality parameters that could be affected by changes in stream flow and reservoir levels are temperature and dissolved oxygen, and these parameters are the focus of the water quality analysis. The combination of changes in flow, reservoir levels, and water quality was then used to determine potential impacts on fisheries resources. Changes in flow and reservoir levels were also used to identify potential impacts on riparian habitat and related terrestrial biological resources. Finally, changes in flow and reservoir levels were used to identify potential impacts on water-related recreation, including whitewater rafting, boating, and fishing, and water-related visual resources. For the Tuolumne River watershed, the changes in flow and reservoir levels were also used to identify potential effects on downstream users and on energy supplies due to potential changes in hydropower generation.

The SFPUC operates and manages the regional water system (including the Tuolumne River system, the Alameda Creek system, and the Peninsula watershed system) in accordance with a complex and dynamic set of operational procedures that respond to changing climatic and hydrologic conditions, legal and regulatory requirements, water supply demands, and needs for maintenance, repair, and replacement of system facilities. In order to assess the changes to these systems that could occur under the WSIP, it was necessary to employ a computer modeling tool



SOURCE: ESA + Orion

SFPUC Water System Improvement Program . 203287

Figure 5.1-3
Approach to Impact Analysis on Water Resources

with the capability of addressing the many factors involved in system operations and management and thus enabling a comparison of the "before" and "after" program conditions. The modeling tool and approach used for analysis are described in the following section.

Hetch Hetchy/Local Simulation Model

The amount of water available to the SFPUC varies from year-to-year depending on meteorological conditions, water rights, and statutory and contractual obligations, including the Raker Act. The SFPUC operates its water system to meet customer water demand as fully and efficiently as it can, despite the fact that the amount of water available to it varies from year-to-year. The operations of the water system are complex, involving numerous reservoirs, pipelines, and pumping plants. The SFPUC utilizes a computerized mathematical model to assist in the evaluation of its water systems operations—the Hetch Hetchy/Local Simulation Model (HH/LSM), a water supply planning model (SFPUC, 2007a). This model is the best available tool for depicting the overall regional water system operations under a range of conditions and is similar to the models used by other water purveyors in the United States to depict their water system operations and to plan for system improvements.

A general overview of this modeling tool and the basic assumptions about the system included in the model are described in this section. **Appendix H1** provides a more detailed description of the model and how it was used for the PEIR water supply and system operations impact analysis; **Appendix H2** provides supporting details and an explanation of the 2007 raw data output from the model.

Following publication of the Draft PEIR, the SFPUC conducted updated model runs in 2008 using more recent input assumptions for several model parameters as part of its ongoing system planning and management. The revised input assumptions included: adjusted capacity for Crystal Springs Reservoir from recent survey data; more accurate assumptions for Pilarcitos facilities operations; improved data regarding the historical hydrology in the Alameda Creek watershed; updated agricultural demands in the Modesto and Turlock Irrigation Districts service area to be consistent with data used in recent statewide planning documents; and a refinement of water release protocols at Don Pedro Reservoir. Review of the 2008 model output indicated that the results are generally consistent with the 2007 results used in the Draft PEIR analysis, and that the analyses and impact determinations presented in the Draft PEIR remain valid. With one exception, no changes in the impact approach, analysis or conclusions presented in the Draft PEIR are necessary for the water supply and system operations impact assessments that were based on the 2007 results. The sole exception is the approach to the impact analysis of Pilarcitos watershed resources, for which only semi-quantitative data were previously available. Therefore, the 2008 data were used to conduct a refined impact analysis of the Pilarcitos watershed resources; no new impacts were identified. The results of the refined impact analysis for the Pilarcitos watershed are summarized in Chapter 13 (Section 13.3, pp. 13-6 to 13-7).

[The updated HH/LSM Assumptions and Results were included as an appendix to the Comments and Responses document. Please refer to Appendix O (Vol. 8).]

Representation of the Regional System in the Model

The HH/LSM incorporates detailed information about key aspects of the SFPUC regional water system, including facilities (i.e., reservoir and conveyance capacities) and operating procedures and “rules” that determine how and when water is moved through the system to customers. The operating procedures include responses to seasonal variation in demand, allocation of demand to customer groups, and procedures to maximize the use of local watershed supplies, while the rules include responses to regulatory requirements for instream flows and compliance with Raker Act obligations. As described in Chapters 2 and 3, water system operations can be generally delineated between rules and strategies affecting the operation of the Bay Area water system and rules and strategies affecting the operation of the Hetch Hetchy system. Although generally discussed separately, the two systems are integrally linked and are interdependent on each other in order to maximize water availability and quality.

For the Hetch Hetchy system, the HH/LSM integrates operations at SFPUC’s three major reservoirs in the Tuolumne River watershed—Hetch Hetchy Reservoir, Lake Lloyd, and Lake Eleanor—with the operation of TID/MID’s Don Pedro Reservoir, due to the SFPUC’s water bank account in Don Pedro Reservoir (described in Chapter 2, Section 2.5.2). The operation of these reservoirs and the water bank account is guided by two primary objectives: (1) to conserve reservoir storage so as to optimize supply to SFPUC customers, and (2) to fulfill San Francisco’s Raker Act obligation to bypass Tuolumne River flow to TID and MID. Underlying the operations at the SFPUC’s reservoirs are the minimum fishery release requirements prescribed for Hetch

Hetchy Reservoir, Lake Lloyd, and Lake Eleanor. Water that is released from San Francisco's reservoirs and not diverted to SFPUC customers, together with runoff that originates below San Francisco's reservoirs, flows to Don Pedro Reservoir. The HH/LSM simulates TID/MID's operation of Don Pedro Reservoir, including simulation of canal diversions, flood control operations, and releases to meet fishery release requirements below La Grange Dam. The model also simulates the accounting for the SFPUC's water bank account.

The model uses a watershed runoff forecasting routine (for snowmelt and rainfall) that projects the amount of runoff that can be expected to flow into each reservoir for a particular time period. Once the amount of runoff is projected, this amount is compared to the availability of reservoir storage and the anticipated releases required from the reservoir to meet downstream flow requirements and the diversions needed for water deliveries to SFPUC customers. If a reservoir is projected to spill, the model incorporates discretionary releases that the SFPUC manages to enhance hydropower generation. The model uses a monthly time step. This forecasting and decision process occurs sequentially each month of the period being modeled.

For the local Bay area system, the model depicts the regional system as a linked series of inflows, reservoirs, conveyance routes, and areas of water demand. Numerous operational constraints are incorporated, including considerations for downstream channel conveyance capacity, treatment plant capacity, and water transmission capacity. The Bay Area system is operated to maximize the efficient use of local Bay Area watershed runoff and supplemented with Tuolumne River water resources. The model establishes optimal storage levels for each Bay Area reservoir by season; this relates to how the SFPUC manages reservoir storage levels to lower reservoir storage space prior to the rainy season and then to raise the level through the dry season. In San Antonio, Crystal Springs, and San Andreas Reservoirs, the model assumes that reservoir space is filled first with Bay Area watershed runoff and then supplemented with Tuolumne River water by late spring in order to ensure maximum local reservoir storage through the summer season.

Simulation of System Operations

Simulation Period

The model simulates system operations over the course of an 82-year sequential hydrologic period from July 1920 through September 2002. The model includes actual, measured historical information about the hydrology (the amount of runoff estimated from either snowmelt and/or rainfall) that occurred in each year over the 82-year record for each of the three watershed areas under consideration: the Tuolumne River system, the Alameda Creek system, and the Peninsula watershed system. This 82-year period includes many different types and sequences of actual hydrological events, ranging from flood events to droughts of different magnitude and duration. Because natural surface water systems are dynamic and runoff and flow vary each year, and as it is not possible to predict future precipitation, it is a necessary and standard industry practice to use a long-term historical record to represent the range of hydrologic conditions that can be expected in the future. The long-term 82-year historical record is used in the model to represent the range of hydrologic conditions that could occur in the future[3] and to assess both how the

3 The potential effect of climate change on the SFPUC's regional system is addressed in Section 5.7 under Cumulative Impacts.

system would perform in terms of meeting the WSIP level of service objectives and what types of impacts the program might have under a range of conditions.

The modeling tool uses information on actual historical hydrology but does not “predict” or necessarily precisely depict the past, historical operation of the system. The historical operation of the system in an actual year will differ from the operations simulated by the model for that year as a result of day-to-day adjustments made by the system operators, who constantly modify operations throughout the year to respond to changing conditions related to weather, demand, water quality, or facilities conditions (e.g., maintenance or unplanned facilities outages). While many of these factors are built into the model, the model cannot account for all the actual operations and adjustments made throughout each year. The objective of using the modeling tool is to assess the effect of system changes on future operations over a broad range of realistic hydrologic conditions.

Hydrologic Year Definitions

As described in detail in Appendix H1, all years in the 82 years of historical hydrology were ranked and grouped into hydrologic year types according to river and creek flow. Five hydrologic categories were used to depict the range of wet to dry years, depending on the hydrologic index. The hydrologic year types are defined differently for different watershed and drainage areas affected by the WSIP (referred to as the hydrologic index) in order to accurately reflect each area’s unique hydrology. A hydrologic year is from October to September.

Hydrologic year types for the Tuolumne River above Don Pedro Reservoir are classified based on the SFPUC’s calculation of unimpaired flow[4] for the Tuolumne River at La Grange. The 20 percent of years when unimpaired inflow to Don Pedro Reservoir was lowest were designated as dry years; the next driest 20 percent of years were designated as below-normal years, and so on. This index uses the following year types: wet, above normal, normal, below normal, and dry.

Hydrologic year types for the Tuolumne River below La Grange Dam are classified according to the California Department of Water Resources’ San Joaquin River Index, which defines the following categories: wet, above normal, below normal, dry, and critically dry. This index was used to analyze Don Pedro Reservoir operations because release requirements from Don Pedro Reservoir at La Grange Dam are tied to this index.

Hydrologic year types for the Alameda Creek and Peninsula watersheds are also classified by the 20 percent grouping technique and are based on the SFPUC’s estimation of local inflow into its five San Francisco Bay Area reservoirs. Annual flow into each of the reservoirs was summed for each water year. The 20 percent of years when total runoff into the five reservoirs was lowest were designated dry years. The next driest 20 percent of years were designated below-normal years, and so on. This index uses the following year types: wet, above normal, normal, below normal, and dry.

4 The natural river flow that existed prior to the placement of upstream water diversions, storage reservoirs, or other impediments.

Model Assumptions and Output

The model evaluates system operations, performance, and effects on reservoir storage and reservoir releases (i.e., streamflow below the dam) under a given set of operating parameters utilizing the 82 years of historical hydrology. A differing set of operational objectives and/or a change in the physical configuration of the water system could result in different operations, system performance, and effects on reservoir storage and releases. The model is used to compare alternative operational objectives and system configurations. For the impact analysis presented in this chapter, the model was employed to simulate operations and the effects of those operations under an existing conditions scenario (2005) and under a WSIP scenario (2030).

Model Assumptions and Inputs

The model uses input information on key aspects of the regional water system, including the level of annual water delivery provided by the system, the maximum rationing to be allowed during a drought, and the state of the facilities (e.g., reservoir and conveyance capacities and configurations). **Table 5.1-1** summarizes the differences in key assumptions between the existing conditions and WSIP scenarios that were incorporated into the model and used in the CEQA impact analysis.

TABLE 5.1-1
MODELING ASSUMPTIONS USED IN THE CEQA ANALYSIS

Parameter	Existing Conditions Scenario	WSIP Scenario
Planning year	2005	2030
Customer purchase requests (average annual delivery) (mgd)	265 mgd	300 mgd
Average annual demand from regional system water supply sources (Tuolumne River and local watersheds)	265 mgd	290 mgd
Average annual delivery from other sources (recycled water, groundwater, conservation)	See note a	10 mgd[b]
System firm yield[c]	219 mgd	256 mgd
Maximum systemwide rationing during a drought	No policy cap – up to 25%	20%
WSIP facility improvement projects	None	All WSIP projects

[a] San Francisco and many of its retail and wholesale customers currently utilize recycled water, groundwater, and/or conservation practices to some extent, which is reflected in the 265 mgd average annual delivery.

[b] The 10 mgd reflects proposed implementation of recycled water, groundwater, and conservation projects in San Francisco to benefit the regional water system.

[c] System firm yield is defined as the average annual water delivery that can be sustained by the regional water system during an extended drought. The SFPUC uses an 8.5-year design drought for planning purposes. Due to the 2001 DSOD operational restrictions on Calaveras Dam, the system firm yield was 219 mgd as of September 2005, when the NOP for the PEIR was published. Normal system firm yield is 226 mgd, which reflects Calaveras Reservoir operating at its historical capacity.

The existing conditions scenario reflects the key information about the system for the year 2005, in accordance with CEQA guidance on the appropriate timeframe for determining the environmental baseline to be used for impact analysis.[5] The average annual water delivery from the regional system for the base year was 265 mgd. The existing conditions (2005) scenario reflects the regional system facilities as they were in 2005 (and remain today), including the restricted capacity at both Calaveras and Crystal Springs Reservoirs.

As described in Chapter 2, Section 2.2, the California Department of Water Resources, Division of Safety of Dams (DSOD) imposed operational restrictions on Calaveras Reservoir storage capacity in December 2001, which reduced the reservoir's normal capacity of 96,850 acre-feet to approximately 37,800 acre-feet. Prior to the DSOD restriction, Calaveras Reservoir had been operated at its full capacity for over 70 years (since completion of the Alameda Creek Diversion Dam and Tunnel in 1931). As a result of this restricted capacity, the SFPUC has had to significantly reduce its diversions through the Alameda Creek Diversion Dam compared to its 70 -year-long historical operations. The current capacity restriction will remain in effect—and thus the storage capacity will continue to be limited—until such time that the Calaveras Dam Replacement project (SV-2) is implemented. This project is scheduled for completion in 2012, at which time the restricted reservoir capacity will have been part of system operations for approximately 10 years. In order to present the most consistent baseline condition under CEQA, this PEIR uses an existing conditions scenario that reflects the current restriction on Calaveras Reservoir capacity, despite the fact that the reservoir had been operating at full capacity for 70 years. Implementation of the WSIP (specifically the Calaveras Dam Replacement project) would result in a change to these current operating conditions, restoring them in large part to conditions similar to the prior 70 years of operation. This PEIR examines the potential impacts of these changes.

The capacity of Crystal Springs Reservoir has been restricted since 1983 (also described in Chapter 2, Section 2.2.5); therefore, for this reservoir as well, an existing conditions scenario with restricted capacity is assumed, in compliance with CEQA.

As shown on Table 5.1-1, for the WSIP (2030) scenario, the model incorporates information about the expected average annual water delivery from the regional system in 2030, which under the WSIP is proposed to be 290 mgd. The other 10 mgd of supply needed to serve the total 2030 average annual customer purchase requests of 300 mgd is proposed to come from a combination of recycled water, groundwater, and conservation projects in San Francisco, to be implemented as part of the WSIP. The WSIP (2030) scenario also assumes that all proposed facility improvement projects have been fully implemented. This scenario thus includes the restoration of full storage capacity at Calaveras Reservoir and Crystal Springs Reservoir.

---

5 CEQA Guidelines Section 15125(a) states that an EIR must include a description of the physical environmental conditions in the vicinity of the project, as they exist at the time the notice of preparation (NOP) is published, and that this environmental setting will normally constitute the baseline physical conditions against which the lead agency determines whether an impact is significant. The NOP for the WSIP PEIR was published in September 2005.

In addition to the input assumptions shown in Table 5.1-1, the model includes, for both the existing condition and WSIP scenarios, the same assumptions and rules for compliance with statutory and contractual obligations, including the Raker Act and minimum instream flow requirements.

Model Outputs

Once the operation of the regional water system was modeled under each scenario, the model provided output information about system performance under that scenario in terms of the WSIP system objectives and about the timing and amount of water in reservoir storage and released from the system reservoirs downstream. In general, the model provides information on a monthly basis. **Table 5.1-2** summarizes key output information provided by the model.

During actual system operations, operators make decisions about how much water to retain in storage and how much water to release from system reservoirs on an hourly, daily, or weekly basis in response to changing conditions. The model does not report these changes at this level of detail. Like other computer models used elsewhere in California to predict the impacts of proposed projects on complex water storage and delivery systems (e.g., the Central Valley Project and State Water Project), the HH/LSM identifies monthly levels in various storage facilities and water bodies, and does not have the necessary precision to deal with hourly, daily, or weekly operational decisions. The state of the art in modeling has not yet reached the point where such precision is possible. In most cases, however, the monthly information about changes in reservoir storage and reservoir releases downstream was adequate for the purpose of assessing the nature, magnitude, and frequency of potential physical changes and environmental impacts associated with operations under the proposed WSIP program scenario compared to the existing condition. In those cases where more detailed information is needed for impact analysis than is available from monthly data, the SFPUC system operators were consulted about daily or weekly operations and, where available, historical data on the system operation were reviewed. Thus, in these instances, the conclusions set forth in the PEIR reflect not only the results of the HH/LSM, but also input from the experienced system operators regarding how they would likely respond to the kinds of issues that might arise on a daily a weekly basis.

Model Limitations

The HH/LSM is the best available tool for depicting changes in the overall regional water system operations; however, as explained above and further explained here, in some cases, limitations inherent in the model required that the analysis be supplemented by additional data.

[Paragraph has been deleted per responses to comments or staff-initiated text changes (Vol. 7, Chapter 16).]

TABLE 5.1-2
HH/LSM OUTPUT PARAMETERS
(Data provided as monthly time step for 82 years of historical hydrology)

Feature	Output Parameter
TUOLUMNE RIVER SYSTEM	
Unimpaired Inflow (acre-feet)	Inflow to Hetch Hetchy Reservoir Inflow to Lake Lloyd Inflow to Lake Eleanor Unregulated Flow below Hetch Hetchy Reservoir
End-of-Month Storage (acre-feet)	Hetch Hetchy Reservoir Storage Lake Lloyd Storage Lake Eleanor Storage Don Pedro Water Bank Account Storage Don Pedro Reservoir Storage Total Up-Country Reservoir Storage Total Hetch Hetchy System Storage
Releases (acre-feet)	Hetch Hetchy Reservoir Release to Stream Hetch Hetchy Reservoir Release to Canyon Tunnel Lake Lloyd Release to Stream Lake Lloyd Release to Holm Powerhouse Lake Eleanor Release to Stream Lake Eleanor Tunnel to Lake Lloyd
Evaporation (acre-feet)	Hetch Hetchy Reservoir Lake Lloyd Lake Eleanor
San Joaquin Pipeline (acre-feet)	SJPL Flow from Lower Cherry Aqueduct Total SJPL
Precipitation (inches)	Hetch Hetchy Precipitation – Accumulated
Power Production (MWh)	Moccasin Powerhouse Kirkwood Powerhouse Holm Powerhouse Total
Unimpaired Runoff (acre-feet)	Unimpaired Runoff at La Grange Dam TID, MID, and SFPUC Rights and Entitlements Unimpaired Runoff Available to San Francisco
Don Pedro Operations (acre-feet)	Inflow Storage Don Pedro Reservoir Flood Control Limit Don Pedro Reservoir Evaporation (San Francisco) Total Don Pedro Reservoir Evaporation Don Pedro Reservoir Power – MWh Total MID Diversion at La Grange Dam Total TID Diversion at La Grange Dam La Grange Minimum Release Requirement Total La Grange Dam Release to River Total Release from Don Pedro Reservoir
Water Bank Account (acre-feet)	Water Bank Account Balance Water Bank Account Maximum Transfer to Water Bank Account
Miscellaneous	SFPUC Shortage Level Hetch Hetchy Minimum Stream Release (acre-feet)
LOCAL SYSTEM (ALAMEDA CREEK AND PENINSULA WATERSHEDS)	
Calaveras (MG)	Calaveras Reservoir Storage Calaveras Reservoir Inflow from Arroyo Hondo Calaveras Reservoir Inflow from Upper Alameda Creek Calaveras Reservoir Release to San Antonio Reservoir Calaveras Reservoir Release to Sunol Valley WTP Calaveras Reservoir Release to Calaveras Creek Calaveras Reservoir Spill to Calaveras Creek Calaveras Reservoir Evaporation

TABLE 5.1.2 (Continued)
HH/LSM OUTPUT PARAMETERS
(Data provided as monthly time step for 82 years of historical hydrology)

Feature	Output Parameter
San Antonio (MG)	San Antonio Reservoir Storage
	San Antonio Reservoir Inflow from San Antonio Creek
	San Antonio Reservoir Inflow from Calaveras Reservoir/SJPL
	San Antonio Reservoir Release to Sunol Valley WTP
	San Antonio Reservoir Release to San Antonio Creek
	San Antonio Reservoir Evaporation
Crystal Springs (MG)	Crystal Springs Reservoir Storage
	Crystal Springs Reservoir Inflow from San Mateo Creek
	Crystal Springs Reservoir Inflow from San Andreas Reservoir
	Crystal Springs Reservoir Inflow from Bay Division Pipelines
	Crystal Springs Reservoir Pumping to San Andreas Reservoir
	Crystal Springs Reservoir Pumping to Coastside CWD
	Crystal Springs Reservoir Release to San Mateo Creek
	Crystal Springs Reservoir Spill to San Mateo Creek
	Crystal Springs Reservoir Evaporation
San Andreas (MG)	San Andreas Reservoir Storage
	San Andreas Reservoir Inflow from Watershed
	San Andreas Reservoir Inflow from Crystal Springs, San Mateo Creek & Pilarcitos
	San Andreas Reservoir Release to Harry Tracy WTP
	San Andreas Reservoir Release to San Mateo Creek
	San Andreas Reservoir Spill to San Mateo Creek
	San Andreas Reservoir Evaporation
Pilarcitos (MG)	Pilarcitos Reservoir Storage
	Pilarcitos Reservoir Inflow
	Pilarcitos Reservoir Release to San Andreas Reservoir
	Pilarcitos Reservoir Release for Stone Dam Diversion to Coastside CWD
	Pilarcitos Reservoir Pre-Release to Pilarcitos Creek
	Pilarcitos Reservoir Spill to Pilarcitos Creek
	Pilarcitos Reservoir Evaporation
Stone Dam (MG)	Stone Dam Inflow (Accretion)
	Stone Dam Release to Coastside CWD
	Stone Dam Release to Crystal Springs Reservoir
Reservoir Storage (MG)	Total Reservoir Storage – East Bay
	Total Reservoir Storage – Peninsula
	Total Local Storage
	Maximum Targeted Total Local Storage
Demand (MGD)	Delivery to South Bay Demand Center
	Delivery to Crystal Springs Demand Center
	Delivery to San Andreas Demand Center
	Delivery to In-City Demand Center
	Total Delivery to Demand Centers (not including Coastside CWD)
Demand (MG)	Delivery to South Bay Demand Center
	Delivery to Crystal Springs Demand Center
	Delivery to San Andreas Demand Center
	Delivery to In-City Demand Center
	Total Delivery to Demand Centers (not including Coastside CWD)
San Joaquin Pipelines	SJPL Flow – MG
	SJPL Flow – MGD
SJPL (MG)	SJPL Flow to Crystal Springs Reservoir – MG
	SJPL Flow to San Antonio Reservoir – MG
West Basin Reservoir (MG)	Beginning of Month Storage
	West Basin Reservoir – Input Resulting from San Andreas Gradient Deliveries
	West Basin Reservoir – Input Resulting from Crystal Springs Gradient Deliveries
	End of Month Storage
Desalination Project (MG)	Input from Desalination Project
Treatment Plant Delivery (MGD)	Calaveras Reservoir Flow to Sunol Valley WTP
	San Antonio Reservoir Flow to Sunol Valley WTP
	Sunol Valley WTP Production
	Harry Tracy WTP Production

[yellow box] Indicates data used in the PEIR analysis

Coastside CWD = Coastside County Water District; MG = million gallons; MGD = million gallons per day; MWh = megawatt-hours; MID = Modesto Irrigation District; SJPL = San Joaquin Pipelines; TID = Turlock Irrigation District; WTP = water treatment plant.

The HH/LSM was used to estimate baseline and with-WSIP flows in the Tuolumne River, Alameda Creek, and Pilarcitos Creek. However, the model results were not solely relied upon when evaluating flows in creeks immediately downstream of SFPUC reservoirs that normally have minimal flow or are affected by SFPUC operations for time periods less than a month in duration. This is because the model uses a monthly time interval. The model does not simulate day-to-day variations in water levels or releases to a stream, but instead provides an average water level and an average release in a given month. The inability of the model to illustrate short-term variations is generally not problematic when simulating continuous phenomena like storage or water level in a reservoir or flow in a perennial stream. However, in some cases, the modeling limitation of only providing information at a monthly time interval required additional considerations, such as SFPUC operator experience and knowledge, when simulating intermittent phenomena such as infrequent spills or releases from reservoirs that may last only a few days.

Flow in San Mateo Creek downstream of Lower Crystal Springs Dam provides an example. The SFPUC system operators rarely release water from Crystal Springs Reservoir to San Mateo Creek, and flow in the creek below the dam typically occurs only from seepage from the dam and groundwater infiltration. The SFPUC operators attempt to capture and retain as much runoff as possible from the upper San Mateo Creek watershed in Crystal Springs Reservoir. In all but wet years, the SFPUC captures all of the runoff from the upper watershed. In wet months of wet years, the operators of the reservoir obtain frequent weather forecasts and manage the reservoir to capture as much runoff as possible from the sequence of winter storms that cross the watershed. The operator's decisions with respect to reservoir management are made on a day-to-day, sometimes hour-to-hour, basis. In certain circumstances during wet hydrologic conditions, the operators must release water from the reservoir to the creek due to unpredictable weather conditions and their limited ability to make further adjustments to reservoir levels and other systemwide operations. Releases from Crystal Springs Reservoir to San Mateo Creek are based on day-to-day changes in operations and thus cannot be modeled using the HH/LSM. Consequently, the model does not provide a refined prediction of the magnitude and timing of infrequent and short-term releases from the reservoir. Similarly, the model does not provide a precise prediction of the magnitude and timing of releases from San Antonio Reservoir and flow in San Antonio Creek downstream of the reservoir. However, HH/LSM results are sufficient to depict the general trends of WSIP effects on these parameters on a monthly basis.

For the reasons noted above, HH/LSM results were not used to predict the magnitude and timing of spills or releases from Crystal Springs and San Antonio Reservoirs. In addition, HH/LSM results were not used to predict the magnitude and timing of spills or releases from Crystal Springs Reservoir. In these cases, the likely effects of the WSIP were determined through a review of historical data and consultation with individuals knowledgeable about the past and predicted future reservoir operating practices as well as output from the updated 2008 HH/LSM results.

In additional instances, such as the analyses of flow effects below Hetch Hetchy Reservoir and below the Alameda Creek Diversion Dam, HH/LSM results were refined or tiered to provide additional insight into the effects of the WSIP on stream flow for time periods of less than a month.

[Additional discussion on water resources modeling was prepared as part of the Comments and Responses document. Please refer to Section 13.3, Updated Water System Assumptions and Modeling (Vol. 7, Chapter 13), and Section 14.5, Master Response on Water Resources Modeling (Vol. 7, Chapter 14).]

Use of Model Results to Show Water Supply Sources

Figures 5.1-4 and **5.1-5** present model results showing the relative contributions of the various water supply sources to the regional system for the 82-year period of hydrologic record under existing conditions (2005) and WSIP conditions (2030), respectively. The figures illustrate the combination of supply sources the regional system would use year-to-year to serve customer deliveries if it were operated over a series of years similar in terms of climate conditions to those that occurred from 1920 to 2002 under the two scenarios. The figures depict how relative contributions of water supply sources available to the SFPUC would vary from year to year and show the frequency and extent of shortages and rationing that would occur if there were dry years and drought sequences similar to those that occurred during this period.

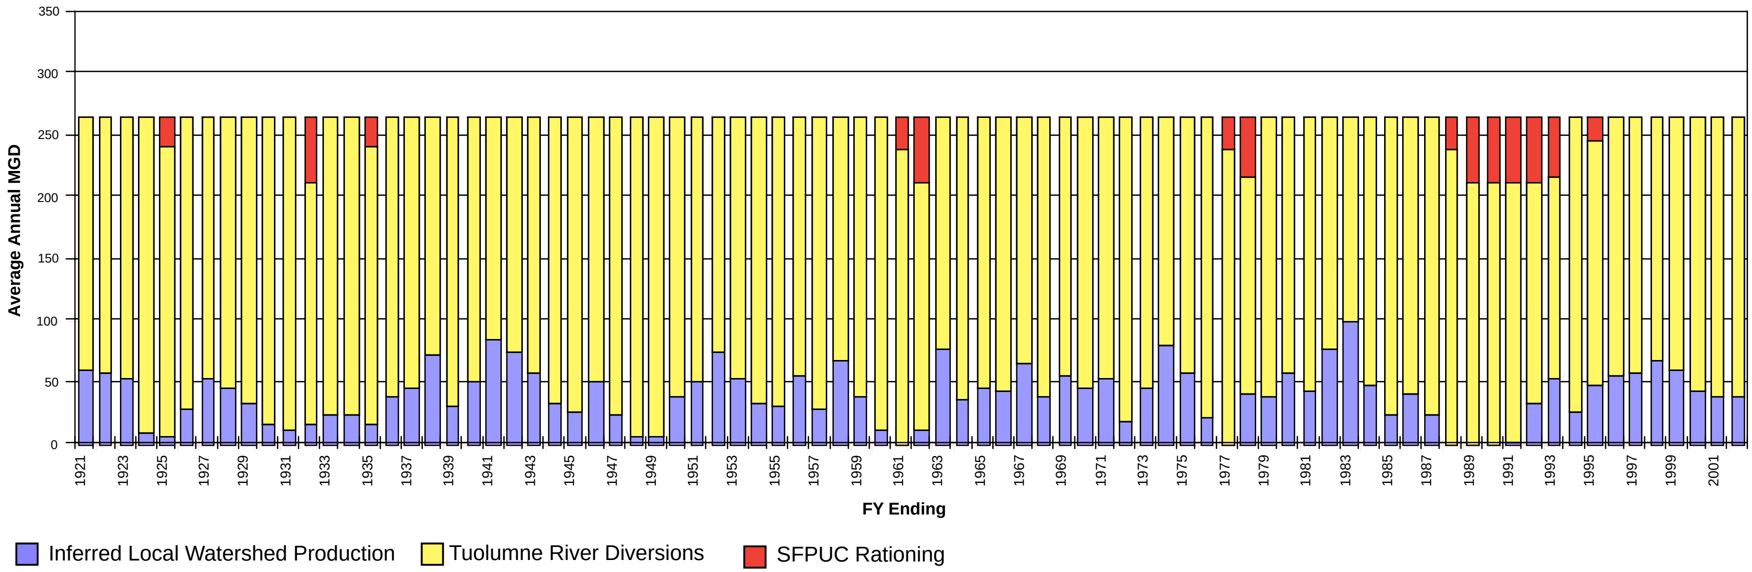
The figures indicate that there currently is, and would continue to be, a wide annual variation in the amount of water available from the various water sources under both current and future conditions. This, in turn, results in a wide variation in the changes in stream flow and reservoir water levels that would occur under the WSIP compared to the existing condition. Therefore, the impact analysis presented in this chapter addresses the effects of this range of variation in stream flow and reservoir level changes on the potentially affected watersheds and associated resources.

5.1.5 Impact Significance Determinations

The significance criteria used in this PEIR are based on San Francisco Planning Department, Major Environmental Analysis (MEA) guidance regarding the environmental effects to be considered significant. MEA guidance is, in turn, based on the CEQA Guidelines Appendix G with some modifications. In cases where potential environmental issues associated with the WSIP are identified but are not clearly addressed by MEA's guidance, additional impact significance criteria are presented. Appendix B of this PEIR presents the MEA Initial Study checklist as it applies to the WSIP, and indicates the criteria applicable to the WSIP and discussed in the various chapters in the PEIR. The significance criteria used for each environmental topic/resource area are presented in each section of Chapter 5 following the setting and before the discussion of impacts.

For the impact analyses, the following categories are used to determine impact significance:

> **Not Applicable/No Impact (N/A).** An impact is considered not applicable to the WSIP water supply or system operations if the environmental resource or impact potential does not occur within the project area or the area of potential effect. For example, an impact on a biological resource may not be applicable if the WSIP would not result in changes in stream flow for a specific reach of a creek.
>
> **Beneficial (B).** An impact is considered beneficial if it is determined that WSIP water supply or system operations would improve an environmental resource or result in a beneficial effect on the environment.
>
> **Less than Significant (LS).** This determination applies if there is a potential for limited impact, but the impact does not constitute a substantial adverse effect that qualifies under the significance criteria as a significant effect. LS impacts do not require mitigation.



This figure illustrates what combination of supply sources the regional system would use year to year under existing conditions to meet the existing system delivery demand of 265 mgd if it were operated over a long series of years similar in terms of climate conditions to those that occurred between 1920 and 2002. This 82-year simulation illustrates how the relative contribution of water supply sources available to the SFPUC would vary year to year and shows the frequency and extent of supply shortages and rationing that would occur if there were dry years and drought periods similar to those that occurred during this historic period.

NOTES: (1) This figure illustrates a conceptual breakdown of water sources available to the SFPUC regional system. Local Watershed Production (inferred) is estimated as the difference between the amount of water delivered to system customers and the amount of water provided by the San Joaquin pipeline (Tuolumne River) and extracted from the Westside Basin groundwater aquifer. This estimate does not account for the source of Bay Area system reservoir storage used to serve deliveries or the partial use of San Joaquin pipeline deliveries for replenishment of Bay Area system reservoirs.

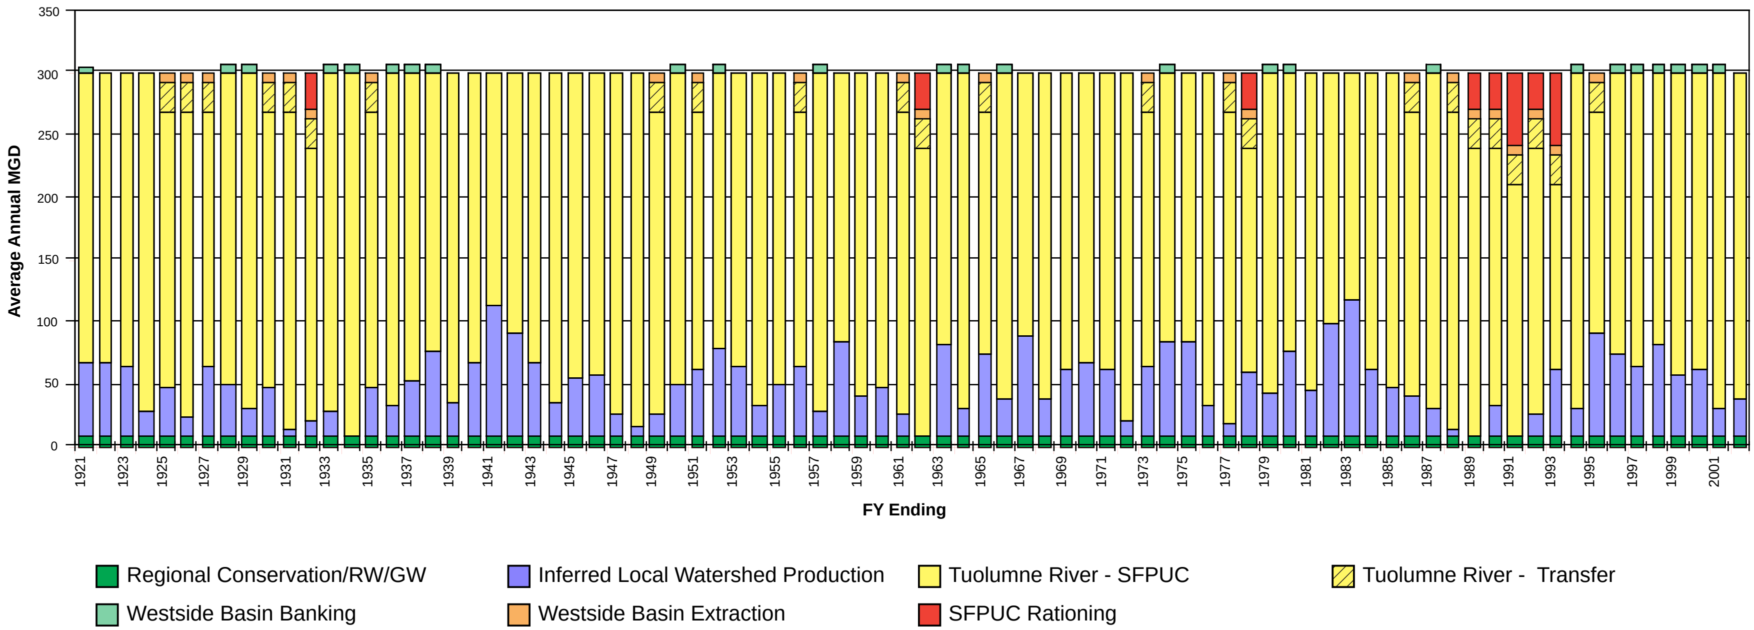
SFPUC Water System Improvement Program . 203287

Figure 5.1-4
Water Supply Sources and Shortages – Existing Conditions (265 mgd Delivery)



This figure illustrates what combination of supply sources the regional system would use year to year under future 2030 conditions to meet the future demand of 300 mgd if it were operated over a long series of years similar in terms of climate condition to those that occurred between 1920 and 2002. This 82-year simulation illustrates how the relative contribution of water supply sources available to the SFPUC would vary year to year and shows the frequency and extent of supply shortages and rationing that would occur if there were dry years and drought periods similar to those that occurred during this historic period.

NOTES: (1) This figure illustrates a conceptual breakdown of water sources available to the SFPUC regional system. Local Watershed Production (inferred) is estimated as the difference between the amount of water delivered to system customers and the amount of water provided by the San Joaquin pipeline (Tuolumne River) and extracted from the Westside Basin groundwater aquifer. This estimate does not account for the source of Bay Area system reservoir storage used to serve deliveries or the partial use of San Joaquin pipeline deliveries for replenishment of Bay Area system reservoirs.
(2) Deliveries in excess of 300 mgd represent banking of water into the Westside Basin groundwater aquifer under the proposed Westside Basin Groundwater conjunctive use program.

SFPUC Water System Improvement Program . 203287

Figure 5.1-5
Water Supply Sources and Shortages – 2030 WSIP Conditions (300 mgd Delivery)

Potentially Significant, Mitigable (PSM) / Significant Mitigable (SM). These determinations apply if there is a potential for a substantial adverse effect that meets the significance criteria, but implementation of mitigation measures would reduce the impact to a less-than-significant level. In cases where the analysis cannot conclusively determine the extent of adverse effects, the PEIR errs on the conservative side by identifying the impact as “potentially” significant; the impacts identified as "potentially significant" are treated as significant impacts in this PEIR. Similarly, “significant, mitigable” applies if there is certainty that a substantial adverse effect that meets the significance criteria would occur, but implementation of mitigation measures would reduce the impact to a less-than-significant level. In either event, the mitigation measures identified in this PEIR are expected to reduce any significant effects to a less-than-significant level.

Potentially Significant, Unavoidable (PSU) / Significant, Unavoidable (SU). These determinations apply to impacts that are potentially significant or significant, but for which there appears to be no feasible mitigation available to reduce them to a less-than-significant level. Mitigation might be available to lessen the effect of the impact, but the residual effect, even after implementation of the measure, would remain significant and therefore unavoidable. Alternatively, the PSU determination is applied in cases where mitigation might lessen the effect of an impact, but it is unknown if the mitigation could effectively reduce the impact to a less-than-significant level. When the effectiveness of a mitigation measure is unknown, the PEIR errs on the conservative side and applies this determination. The impacts identified as potentially significant are treated as significant impacts in this PEIR.

In each section of this chapter, a summary table is provided at the beginning of each impact discussion to summarize the potential impacts and to indicate the level of impact significance. The impact discussions for the WSIP water supply and system operations are organized by watershed or affected water resource. Impacts are numbered by section, and corresponding numbers are used to identify the mitigation measures presented in Chapter 6.

5.2 Plans and Policies

5.2 Plans and Policies

Section 5.2 Subsections

5.2.1 Overview

The purpose of this section is two-fold: (1) to provide an overview of the federal, state, and local plans and policies governing the SFPUC's water supply, including water quality, water use, and natural resource protection; and (2) to describe program consistency with applicable, adopted land use and resource plans and policies relevant to the WSIP water supply option and system operations, pursuant to CEQA Guidelines Section 15125(d).

The regulatory overview for Chapter 5 is summarized in this section to avoid repetition of the general description of applicable environmental regulations in the various sections of this chapter. Because Chapter 5 is organized by watersheds and related drainage areas rather than by environmental resources, only those aspects of the regulations specifically applicable to each watershed are presented in the respective sections. For example, the regulatory overview for Chapter 5 presented in this section includes a general description of the Clean Water Act and the Porter-Cologne Water Quality Control Act, but the description of applicable water quality control plans (WQCPs), beneficial uses, and water quality objectives are described separately in Sections 5.3.3, 5.4.3, and 5.5.3 for the Tuolumne River, Alameda Creek, and Peninsula watersheds, respectively.

The analysis in this section complements that presented in Section 4.2, Plans and Policies, which focuses on land use plans and policies relevant to construction and operation of the proposed WSIP facility improvement projects. Together, Sections 4.2 and 5.2 provide an evaluation of project consistency with the overall plans and policies relevant to the proposed program.

5.2.2 Regulatory Framework

In general, implementation and enforcement responsibility of governmental regulations flows down from federal and state jurisdictions to the regional, county, and municipal levels. Although the federal government establishes programs and sets minimum standards that are applicable nationwide, state and local jurisdictions have the authority to set more stringent standards than those established under federal law. The SFPUC currently complies with all applicable federal, state, and local regulations regarding municipal water supplies and would continue to do so under the WSIP. Responsible agencies and applicable federal, state, and local statutes and agreements are discussed below. **Table 5.2-1** summarizes the applicability of the statutes and agreements to the proposed WSIP water supply and system operations.

Federal Agencies

U.S. EPA Office of Water

The U.S. Environmental Protection Agency (U.S. EPA) Office of Water, established in 1970, is the primary federal agency responsible for implementation of the Clean Water Act and Safe Drinking Water Act. The U.S. EPA Office of Water provides guidance, specifies scientific methods and data collection requirements, establishes contaminant thresholds, and provides oversight to state and local governments for compliance with the Clean Water Act and Safe Drinking Water Act.

U.S. Army Corps of Engineers

The U.S. Army Corps of Engineers (Corps) evaluates permit applications for essentially all construction activities that occur in the nation's waters, including wetlands. Corps permits are also necessary for any work, including construction and dredging, in the nation's navigable waters. The Corps enforces the provisions of Section 404 of the Clean Water Act.

U.S. Fish and Wildlife Service

The mission of the U.S. Fish and Wildlife Service (USFWS) is to provide leadership in protecting fish and wildlife, conserving species habitats, and engaging citizens in the shared stewardship of America's natural resources. The USFWS's primary responsibilities involve the protection of migratory birds, endangered species, certain marine animals, and freshwater and anadromous fish through various regulations, including the Federal Endangered Species Act, the Federal Power Act, and Section 404 of the Clean Water Act.

National Marine Fisheries Service

The National Marine Fisheries Service (NMFS) is the primary federal agency involved with the stewardship of marine resources and their habitats through science-based conservation and management. The NMFS receives its ocean stewardship responsibilities under many federal laws, including the Federal Endangered Species Act, Section 404 of the Clean Water Act, and the Federal Power Act.

The Department of the Interior and the Department of Agriculture

The Department of the Interior (DOI) and the Department of Agriculture are the primary federal agencies involved with regulation under and enforcement of the Raker Act (see Chapter 2, Section 2.4.2, for further description of the Raker Act).

TABLE 5.2-1
APPLICABLE FEDERAL, STATE, AND LOCAL STATUTES AND AGREEMENTS

Statute or Agreement / Responsible Agency[a]	Summary Description	Associated Statutes and Plans	Applicability to WSIP Water Supply and System Operations Issues
Federal			
Clean Water Act / U.S. EPA, Corps, USFWS, NMFS	Primary federal law governing water quality. Prescribes basic federal laws for regulating discharges of pollutants into waters of the U.S., including establishing water quality standards for contaminants in surface waters, establishing wastewater and effluent discharge limits from various industry categories, and imposing requirements for controlling nonpoint-source pollution.	Section 303(d), Section 404, various others	Discussed and analyzed by watershed in Sections 5.3.3, 5.3.6, 5.4.3, 5.4.6, 5.5.3, and 5.5.6.
Safe Drinking Water Act / U.S. EPA	Sets health-based standards for drinking water quality to protect against naturally occurring and man-made contaminants that can be found in drinking water.	National Primary and Secondary Drinking Water Regulations	Described in Chapter 2, Section 2.4.1, regarding existing system, and in Chapter 3, Section 3.5.1, regarding proposed program.
Raker Act / U.S. Congress	Granted the City and County of San Francisco (CCSF) rights-of-way to certain public lands, including public lands in Yosemite National Park and Stanislaus National Forest, to develop water and power.		Described in Chapter 2, Section 2.4.2, and in Chapter 3, Sections 3.6 and 3.7, regarding existing and proposed water supply and operations.
Wilderness Act / U.S. Congress	Established the National Wilderness Preservation System to be composed of federally owned lands designated by Congress as wilderness areas, to be administered in such a manner that will leave them unimpaired for future use.	National Wilderness Preservation System	Designation of the 459-square-mile Tuolumne River watershed above Hetch Hetchy Reservoir as a wilderness area provides unique measures of protection to the watershed. Discussed in Section 5.2.3.
Wild and Scenic Rivers Act / BLM, NPS, USFS	Preserves the free-flowing characteristics and outstanding values of designated rivers while allowing uses compatible with the management goals of that river.	Management plans and concept plans for designated rivers	Described in Section 5.2.3 and evaluated in Section 5.2.4 for consistency. Discussed and analyzed in Section 5.3.7 regarding biological resources, as well as in Section 5.3.8 regarding visual resources.
Endangered Species Act / USFWS, NMFS	Provides broad protection for species of fish, wildlife, and plants that are listed as threatened or endangered in the U.S. or elsewhere.	Habitat conservation plans	Discussed by watershed in Sections 5.3, 5.4, and 5.5, under Fisheries and Terrestrial Biological Resources.
New Don Pedro Project FERC Settlement Agreement / FERC	Established a revised instream flow schedule for New Don Pedro Project operation and outlined a strategy for recovery of Tuolumne River Chinook salmon.	Habitat Restoration Plan for the Lower Tuolumne River Corridor (guidance document)	Discussed in Chapter 2, Section 2.5, under Institutional Considerations, in Chapter 3, Section 3.8, regarding proposed operations, and Sections 5.3.6, Fisheries, and 5.3.7, Biological Resources.

TABLE 5.2-1 (Continued)
APPLICABLE FEDERAL, STATE, AND LOCAL STATUTES AND AGREEMENTS

Statute or Agreement / Responsible Agency[a]	Summary Description	Associated Statutes and Plans	Applicability to WSIP Water Supply and System Operations Issues
State of California			
California Water Code / DWR and SWRCB	Contains the basic provisions regarding management of the state's water resources as well as the legislative findings for the California Water Plan.	California Water Plan, Water Reuse Law, California Recycling Act, Urban Water Management Planning Act, Wholesale Regional Water System Security and Reliability Act, etc.	Used in ongoing management and operation of the regional water system as well as in development of the WSIP.
California Water Code, Sections 10610–10656, Urban Water Management Planning Act / DWR	Requires urban water suppliers that provide water to 3,000 or more customers, or that provide over 3,000 acre-feet of water annually, to prepare an urban water management plan (UWMP) every five years.	UWMPs prepared by the CCSF and applicable Bay Area Water Supply and Conservation Agency (BAWSCA) members	Information in the UWMPs of the CCSF and BAWSCA members was used in the development of the WSIP 2030 level of service for water supply, as discussed in Chapter 3, Section 3.4.4, and Chapter 7; the San Francisco UWMP is analyzed in Section 5.2.
California Water Code, Sections 73500–73514, Wholesale Regional Water System Security and Reliability Act (AB 1823) / California legislature / DHS	Requires the SFPUC to operate the regional water system in a manner that will not adversely affect the water system. Includes the Water First Policy, which specifies that the CCSF shall assign higher priority to the delivery of water to the Bay Area than to the generation of electrical power.	WSIP (referred to as a capital improvement program in the legislation but renamed as the WSIP)	Part of WSIP development, goals, objectives, and operations, as described in Chapter 2, Section 2.4, and Chapter 3, Sections 3.4 and 3.7.
Porter-Cologne Water Quality Control Act / SWRCB, RWQCBs	Established SWRCB and RWQCBs as the principal state agencies with primary responsibility for the coordination and control of water quality. Established a comprehensive program for the protection of water quality and beneficial uses of water. Applies to surface waters (including wetlands), groundwater, and point and nonpoint sources of pollution.	Water quality control plans (WQCPs) designate legally binding beneficial uses of water for water bodies, including wetlands, assign water quality objectives (criteria) to protect those uses, and establish appropriate implementation programs.	Discussed and analyzed by watershed in Sections 5.3, 5.4, and 5.5, in the Surface Water Quality and Groundwater sections.
California Safe Drinking Water Act / DHS	Strengthens minimum requirements found in the federal Safe Drinking Water Act. Establishes drinking water standards that are at least as stringent as, and sometimes more stringent than, those established under the federal act.	Drinking water requirements, including Primary and Secondary Maximum Contaminant Levels	Discussed in Chapter 2, Section 2.4.1, and Chapter 3, Section 3.5.1, pertaining to WSIP water quality objectives.
San Joaquin River Agreement / SWRCB	Provides the basis for the development of the Vernalis Adaptive Management Program (VAMP) study and identifies where the water to support the VAMP study would be obtained.	Vernalis Adaptive Management Program (Experimental study)	Discussed in Sections 5.2 and 5.3.1.
McAteer-Petris Act / BCDC	Promotes responsible planning and regulation of San Francisco Bay. Establishes BCDC as the agency responsible for carrying out the provisions of the act and of the SF Bay Plan.	San Francisco Bay Plan	Described in Section 5.2.3 and evaluated in Section 5.2.4 for consistency. Analyzed in Section 5.3.3.

TABLE 5.2-1 (Continued)
APPLICABLE FEDERAL, STATE, AND LOCAL STATUTES AND AGREEMENTS

Statute or Agreement / Responsible Agency[a]	Summary Description	Associated Statutes and Plans	Applicability to WSIP Water Supply and System Operations Issues
State of California (cont.)			
California Fish and Game Code / Fish and Game Commission and CDFG	Provides a system for the restoration and preservation of California's fish and wildlife resources	California Endangered Species Act (CESA), California Environmental Quality Act (CEQA), Lake and Streambed Alterations	CEQA review of the proposed water supply and system operations aspects of the WSIP is presented in Chapter 5, including the impacts of the WSIP on species listed under CESA, as discussed in Sections 5.3.7, 5.4.6, and 5.5.6.
Regional and Local			
San Francisco City Charter / CCSF	Establishes many of the procedures and requirements for initiative ordinances and declarations of policy.	San Francisco General Plan San Francisco Sustainability Plan SFPUC Alameda Watershed Management Plan SFPUC Peninsula Watershed Management Plan SFPUC Stewardship Policy	Sets forth guidance and authority of the SFPUC for construction, management, supervision, maintenance, extension, expansion, and operation of the regional water system.

[a] Responsible agencies are as follows:

BLM = Bureau of Land Management
CCSF = City and County of San Francisco
Corps = U.S. Army Corps of Engineers
DHS = California Department of Health Services
DWR = California Department of Water Resources
FERC = Federal Energy Regulatory Commission
NMFS = National Marine Fisheries Service
NPS = National Park Service
RWQCB = Regional Water Quality Control Board
SFPUC = San Francisco Public Utilities Commission
SWRCB = State Water Resources Control Board
U.S. EPA = U.S Environmental Protection Agency
USFS = U.S. Forest Service
USFWS = U.S. Fish and Wildlife Service

Bureau of Land Management

The Bureau of Land Management (BLM), an agency within the U.S. Department of the Interior, administers America's public lands within a framework of numerous laws, including the federal Wild and Scenic Rivers Act. The BLM manages a wide variety of resources and uses, including fish and wildlife habitat, wilderness areas, timber, and archaeological, paleontological, and historical sites.

National Park Service

The National Park Service (NPS) is a bureau of the U.S. Department of the Interior. The NPS is responsible for the oversight of nearly 400 natural, cultural, and recreational sites across the nation, including scenic rivers and trails. The NPS is also responsible for the management of Yosemite National Park, administration of the designated wild and scenic reaches of the Tuolumne River under the Wild and Scenic Rivers Act, and preparation of the *Tuolumne Wild and Scenic River Comprehensive Management Plan* and the *Tuolumne Meadows Concept Plan* (both in development).

Federal Statutes and Agreements

Clean Water Act

The Clean Water Act, enacted by Congress in 1972 and amended several times since inception, is the primary federal law regulating water quality in the U.S. and forms the basis for several state and local laws throughout the country. Its objective is to reduce or eliminate water pollution in the nation's rivers, streams, lakes, and coastal waters. The Clean Water Act prescribes the basic federal laws for regulating discharges of pollutants into waters of the U.S., including setting water quality standards for contaminants in surface waters, establishing wastewater and effluent discharge limits from various industry categories, and imposing requirements for controlling nonpoint-source pollution. At the federal level, the Clean Water Act is administered by the U.S. EPA. At the state and regional levels, the act is administered and enforced by the State Water Resources Control Board (SWRCB) and the Regional Water Quality Control Boards (RWQCBs).

Section 404 of the Clean Water Act established a program to regulate the discharge of dredged or fill material into waters of the U.S., including wetlands. Activities in waters of the U.S. regulated under this program include the placement of fill for development, water resource, infrastructure, and mining projects. Section 404 requires a permit before dredged or fill material may be discharged into waters of the U.S., unless the activity is exempt from Section 404 regulation. Under Section 401 of the Clean Water Act, every applicant for a federal permit for any activity that may affect waters of the state must obtain a water quality certification that the proposed activity will comply with state water quality standards.

Safe Drinking Water Act

The Safe Drinking Water Act, passed by Congress in 1974 for the purpose of protecting public health, regulates public drinking water supplies derived from various sources, including rivers, lakes, reservoirs, springs, and groundwater wells. The federal Safe Drinking Water Act is implemented by the U.S. EPA. The Safe Drinking Water Act is discussed in more detail in Chapter 2, Section 2.4.1.

National Forest Management Act

The National Forest Management Act, enacted by Congress in 1976, is the primary statute governing the administration of national forests. The act requires the Secretary of Agriculture to assess forest lands, and to develop and implement a resource management plan for each unit of the National Forest System. The management plans must: ensure consideration of both economic and environmental factors; provide for wildlife and fish; provide for the diversity of plant and animal communities; ensure timber harvesting will occur only where water quality and fish habitat are adequately protected from serious detriment; and ensure clearcutting and other harvesting will occur only where it may be done in a manner consistent with the protection of soil, watersheds, fish, wildlife, recreation, aesthetic resources, and regeneration of the timber resource. The management plans must be updated at least once every 15 years. In the overall WSIP region, the Sierra Nevada Framework is the management plan governing Stanislaus National Forest. The provisions of the Sierra Nevada Framework are implemented by the U.S. Forest Service.

Raker Act

The Raker Act, passed by Congress in 1913, granted to the City and County of San Francisco (CCSF) rights-of-way to certain public lands, including public lands in Yosemite National Park and Stanislaus National Forest, to develop water and power. (See Chapter 2, Section 2.4.2, for further description.)

Wilderness Act

The Wilderness Act,[1] enacted by Congress in 1964, established a National Wilderness Preservation System composed of federally owned and designated wilderness areas. The purpose of the National Wilderness Preservation System is to preserve wilderness areas for future use and enjoyment. Human activities in designated wilderness areas are limited to those that leave no long-term impact on the land or that have little or no effect on the natural resources of the area. With limited exceptions, no commercial enterprises or permanent roads are allowed within a wilderness area.

The portion of the Tuolumne River watershed that drains into Hetch Hetchy Reservoir (459 square miles) is entirely within Yosemite National Park, and approximately 95 percent of the watershed is federally designated wilderness. This designation provides unique measures of protection to the watershed. The NPS manages Yosemite National Park to preserve the resources that contribute to Yosemite's uniqueness and attractiveness in accordance with the goals and principles of the 1964 Wilderness Act (USFS, 1986).

Wild and Scenic Rivers Act

In 1968, Congress enacted the Wild and Scenic Rivers Act[2] for the purpose of preserving the free-flowing characteristics and outstanding values of designated rivers while allowing uses compatible with the management goals of designated rivers. Specifically, designation as a Wild and Scenic River prohibits the federal government from licensing or permitting hydroelectric dams or major diversions along the designated reaches. The act also provides for the management of federal public lands within the corridor of the designated river. Segments are classified into one of three designations that are based on the level of existing development (and not on a description of any particular values): *wild* segments are wild, unroaded, and undeveloped; *scenic* segments are generally undeveloped, but may have occasional road crossings and riverside structures that are visually screened from the river; and *recreational* segments are generally developed with roads, bridges, and structures (Friends of the River, 2007).

---

1 The Wilderness Act of 1964, Pubic Law Sections 88–577; 16 United States Code Sections 1131–1136.

2 The California Wild and Scenic Rivers Act of 1972 (Public Resources Code, Sections 5093.50 et seq.), modeled after the federal Wild and Scenic Rivers Act, does not designate any rivers that would be affected by WSIP projects.

In 1984, Congress designated 83 miles of the main stem of the Tuolumne River, from its source to Don Pedro Reservoir, as a wild and scenic river, as shown in **Figure 5.2-1**. The classification and mileage of the designated reach is as follows: 47 miles wild, 23 miles scenic, and 13 miles recreational. A total of 54 miles of the designated river are located within Yosemite National Park (not including Hetch Hetchy Reservoir, which was excluded from the designation), and 29 miles of the designated river are located outside of Yosemite National Park (USFWS, 2007). In accordance with the Wild and Scenic Rivers Act, federal agencies are required to prepare a comprehensive management plan for designated rivers within three years of designation to guide future management decisions. The designation does not affect any rights, obligations, privileges, or benefits granted under the Raker Act. The NPS administers wild and scenic rivers that flow wholly or partly within the boundaries of the national park system; the Secretary of Agriculture administers wild and scenic rivers that flow wholly or partly within the boundaries of national forests.

Endangered Species Act

The Federal Endangered Species Act of 1973 provides broad protection for species of fish, wildlife, and plants that are listed as threatened or endangered in the U.S. or elsewhere. Provisions of the act provide for the listing of species, preparation of recovery plans, and designation of critical habitat for listed species. Federal agencies must follow the act's provisions when taking actions that may jeopardize listed species. The Federal Endangered Species Act is enforced by the USFWS and NMFS. The California Endangered Species Act generally parallels the main provisions of the federal law and is administered by the California Department of Fish and Game (CDFG).

Federal Power Act

The Federal Power Act of 1920 requires hydropower project owners to obtain a license from the Federal Energy Regulatory Commission (FERC). Among other purposes, FERC is charged with protecting fish and wildlife, including related spawning grounds and habitat, as well as mitigating impacts on recreation. The Federal Power Act authorizes the USFWS and NMFS to issue mandatory fishway prescriptions to ensure adequate protection, mitigation, and enhancement of fish and wildlife and their habitats. The Hetch Hetchy Project is statutorily exempt from provisions of the Federal Power Act. The Don Pedro Project is subject to FERC jurisdiction for its hydropower operations.

New Don Pedro Project FERC Settlement Agreement

Executed in 1995 by Tuolumne River stakeholder groups, the FERC Settlement Agreement established a revised instream flow schedule for New Don Pedro Project operation and outlined a strategy for recovery of Tuolumne River Chinook salmon (TID/MID, 1996). The revised flow schedule and a monitoring program were subsequently ordered by FERC in 1996, when FERC amended the license for the New Don Pedro Project to incorporate the settlement agreement flow schedules. The agreement requires implementation of measures to improve Chinook salmon habitat and increase populations, including increased flows, habitat rehabilitation and improvement, and measures to improve smolt survival. The FERC order required TID and MID

Figure 5.2-1
Tuolumne River, Wild and Scenic River Designation

to file a 10-year report on the success of the flow modifications, and non-flow mitigation measures were reevaluated in 2005 (TID/MID, 2005). In 2000, the Tuolumne River Technical Advisory Committee (TRTAC), completed the *Habitat Restoration Plan for the Lower Tuolumne River Corridor* (TRTAC, 2000) as the primary planning product of the Settlement Agreement. The restoration plan is to be used by the Tuolumne River Technical Advisory Committee to help fulfill its obligations to FERC under the Settlement Agreement. It is a technical resource document intended to aid in identifying areas of potential habitat improvement and to provide guidance for restoring or rehabilitating these areas (see Section 5.2.3 for further description of the plan). The restoration plan has not been formally adopted by any federal, state or local agency.

State Agencies

California Department of Water Resources

The Department of Water Resources (DWR) is responsible for the overall management of California's water resources. Duties performed by the DWR include, but are not limited to, developing strategies for managing the state's water resources, including updates of the *California Water Plan*; operating and maintaining the State Water Project; and providing policy direction and legislative guidance on water and energy issues.

The DWR owns and operates Del Valle Reservoir in the Alameda Creek watershed. The DWR constructed this facility primarily for flood control and recreational purposes as well as to provide regulatory flows in the South Bay Aqueduct (DWR, 1997). Since 1969, through a series of agreements among the DWR, Alameda County Water District, and Zone 7 Water Agency, local water has been stored for later release and subsequent beneficial use by the water districts under their SWRCB permits. The disposition of stored local inflow is determined by the districts. Water can be released into Arroyo del Valle, released into the South Bay Aqueduct, exchanged for an equivalent amount of South Bay Aqueduct water, or any combination of the foregoing (DWR, 1997). Under the current agreement, the DWR is allowed to use local inflow at times when the districts cannot use all or part of this supply.

California Department of Health Services

The California Department of Health Services (DHS) is responsible for the enforcement of the Safe Drinking Water Act and regulation of public water systems through the Drinking Water Program. DHS activities include field inspections of water systems, source water assessments, issuance of operating permits, review of plans and specifications for new facilities, enforcement actions for noncompliance with laws and regulations, and promotion of water system security. The DHS also regulates the use of recycled water by establishing water quality standards and treatment reliability criteria for recycled water under Title 22 of the California Code of Regulations.

California Fish and Game Commission

The California Fish and Game Commission (Commission) has the statutory authority to formulate guidance policies for the California Department of Fish and Game (CDFG). The Commission has over 200 powers and duties listed in the statutes of the Fish and Game Code. Principal among these are legislatively granted powers for the regulation of the sport take and possession of birds, mammals, fish, amphibians, and reptiles. The Commission oversees the establishment of wildlife areas and ecological reserves and regulates their use, and prescribes the terms and conditions under which permits or licenses may be issued by the CDFG. A primary responsibility of the Commission is to afford an opportunity for full public input and participation in the decision- and policy-making process of adopting regulations or taking other actions related to the well-being of California's fish and wildlife resources.

The Commission sets policy for the CDFG, while the CDFG is the lead state agency charged with implementing, safeguarding, and regulating the uses of fish and wildlife.

California Department of Fish and Game

The mission of the CDFG is to manage California's diverse fish, wildlife, and plant resources, and the habitats upon which they depend, for their ecological values and for their use and enjoyment by the public. The CDFG enforces multiple programs dedicated to the conservation and preservation of habitats and species in California, including the California Endangered Species Act (CESA), California Environmental Quality Act (CEQA), and California Fish and Game Code. Under CESA, the CDFG is responsible for consulting with state lead agencies to determine if their actions would affect a state-listed threatened or endangered species. Under CEQA, the CDFG is responsible for consulting with lead and responsible agencies and providing the requisite biological expertise to review and comment upon environmental documents and impacts arising from project activities. The CDFG is also responsible for enforcing the provisions of the California Fish and Came Code.

State Water Resources Control Board

The SWRCB, created in 1967, has the primary authority over state water rights and water quality policy. The SWRCB is responsible for the enforcement of the Porter-Cologne Water Quality Control Act (Division 7 of the California Water Code), which deals with potential discharges into water bodies that could result in adverse impacts on water quality. The regulations enacted by the SWRCB are enforced by the nine regional boards at the local and regional level.

California Regional Water Quality Control Boards

The mission of the California RWQCBs is to develop and enforce water quality objectives and implementation plans that will best protect the beneficial uses of the state's waters, recognizing local differences in climate, topography, geology, and hydrology. The RWQCBs engage in a number of water quality functions in their respective regions. One of the most important is preparing and periodically updating WQCPs. The San Francisco Bay and Central Valley RWQCBs are the relevant boards reviewing WSIP projects.

State Statutes and Agreements

California Fish and Game Code

The Fish and Game Code provides a system for the protection of California's fish and wildlife resources and includes: provisions related to fish and wildlife protection and conservation; fish and game management; wetlands mitigation banking; endangered species; and operation of dams, conduits, and screens.

California Water Code

The California Water Code contains the fundamental provisions related to management of the state's water resources. The California Water Code requires that water resources of the state be put to beneficial use to the fullest possible extent, and that waste, unreasonable use, or unreasonable method of use be prevented. Acts contained under the California Water Code relevant to the WSIP include the Water Reuse Law, Urban Water Management Planning Act, California Water Recycling Act, and Wholesale Regional Water System Security and Reliability Act.

Urban Water Management Planning Act

The Urban Water Management Planning Act, enacted in 1983 by the state legislature, requires urban water suppliers that provide water to 3,000 or more customers, or that provide over 3,000 acre-feet of water annually, to prepare an urban water management plan (UWMP). UWMPs are updated every five years and must describe and evaluate existing and planned sources of water supply; discuss the reliability of the water supply with respect to seasonal or climatic shortages; describe demand management measures to be implemented by the water supplier; and provide an implementation strategy and schedule for any future planned water supply projects and water supply programs. The act is administered by the DWR (California Water Code Sections 10620–10621).

Wholesale Regional Water System Security and Reliability Act and Water First Policy

California Assembly Bill No. 1823 (AB 1823), known as the Wholesale Regional Water System Security and Reliability Act, imposed various requirements on wholesale water systems. The bill, adopted in 2002, required the SFPUC, acting on behalf of the CCSF, to adopt a capital improvement program by February 1, 2003; to adopt an emergency response plan by September 1, 2003; to distribute available water during any interruption to customers on an equitable basis; to continue operating reservoirs in Tuolumne County in a manner that ensures hydroelectric power generation does not cause any reasonably anticipated impacts on water service; and to assign a higher priority to water Bay Area deliveries than to power generation (California Water Code Sections 73500–73514). The act also includes the SFPUC's Water First Policy.

The Water First Policy, contained in Section 73504(b) of the California Water Code, was formally established in the San Francisco City Charter following adoption of AB 1823 by the state legislature and approval of Proposition E by San Francisco voters. Under this policy, the SFPUC must place water service to the Bay Area before the generation of hydroelectric power. (See Chapter 2, Section 2.4.3 for additional information on AB 1823.)

McAteer-Petris Act

The McAteer-Petris Act was passed by the state legislature in 1965 to promote responsible planning and regulation of San Francisco Bay. The act designates the San Francisco Bay Conservation and Development Commission (BCDC) as the agency responsible for maintaining and carrying out the provisions of the act and the SF Bay Plan (for additional information on the act, see Chapter 4, Section 4.2, p. 4.2-8).

Porter-Cologne Water Quality Control Act

The Porter-Cologne Water Quality Control Act was passed by the state legislature in 1969 and is the primary statute covering the quality of waters in California. The act specifies water quality provisions and discharge requirements for regulating the discharge of waste that could affect the quality of state waters. Under the act, the SWRCB has the ultimate authority over state water rights and water quality policy. The nine RWQCBs are responsible for the oversight of water quality on a day-to-day basis at the local and regional level.

California Safe Drinking Water Act

The California Safe Drinking Water Act, administered by the DHS, strengthens the minimum requirements found in the federal Safe Drinking Water Act and establishes drinking water standards that are at least as stringent as, and sometimes more stringent than, those established under the federal act. California’s development of drinking water standards for MTBE is an example of its more aggressive standards.

San Joaquin River Agreement

The 1995 Water Quality Control Plan (WQCP) for the San Francisco/Sacramento–San Joaquin Delta Estuary included water quality and flow objectives pertaining to the San Joaquin River basin. Disputes over the science supporting the flow objective for the San Joaquin River as measured in Vernalis (shown in Section 5.3, Figure 5.3-1) led to the development of an experimental program to develop an adaptive fishery management plan and the water supplies to support that plan. The San Joaquin River Agreement, adopted by the SWRCB in April 1998, provided the basis for development of the Vernalis Adaptive Management Program (VAMP) and identified where much of the water to support the VAMP study would be obtained (specifically, from the San Joaquin River Group Authority). The VAMP is an experimental management program designed to protect juvenile Chinook salmon migrating from the San Joaquin River through the Delta (San Joaquin River Group Authority, 1999). The VAMP study is summarized below in Section 5.2.3 and discussed in more detail in Section 5.3.1.

Local and Regional Agencies

City and County of San Francisco

As a department of the CCSF, the SFPUC has authority over the management, use, and control of the regional water system pursuant to the San Francisco City Charter, Section 8B.121. Chapter 3, Section 3.3, presents the mission of the SFPUC relative to the objectives of the WSIP, and Section 3.13 describes the role of the CCSF and its various departments with respect to the actions and approvals required for adoption of the WSIP.

San Francisco Bay Conservation and Development Commission

The San Francisco Bay Conservation and Development Commission (BCDC) is the agency responsible for maintaining and carrying out the provisions of the McAteer-Petris Act and the SF Bay Plan. In the public interest, BCDC is authorized to control bay filling and dredging and bay-related shoreline development. Due to the regulatory authority of the State Water Resources Control Board (SWRCB), San Francisco Bay Regional Water Quality Control Board, U.S. Environmental Protection Agency, and the U.S. Army Corps of Engineers, BCDC's scope of authority over water quality issues is limited. (For additional information on BCDC's regulatory authority, see Chapter 4, Section 4.2, p. 4.2-8.)

Alameda Creek Watershed Regional Agencies

In addition to the CCSF, three regional resource agencies have jurisdiction within the Alameda Creek watershed. There are no local or regional resource agencies with jurisdiction over areas within the Tuolumne and Peninsula watersheds or the Westside Groundwater Basin (beyond those described in Chapter 3, Section 3.13, related to the conjunctive-use program) that could be affected by the proposed water supply and system operations.

Alameda County Flood Control and Water Conservation District

The Alameda County Flood Control and Water Conservation District (ACFCWCD) works specifically to protect county citizens from flooding hazards. The ACFCWCD is responsible for planning, designing, and inspecting flood control projects; maintaining flood control infrastructure; assisting in planning new developments to preserve the integrity of the flood control system; and providing public outreach and enforcement of pollution control regulations governing county waterways.

Zone 7 Water Agency

Zone 7 Water Agency, one of 10 active zones of the ACFCWCD, covers the eastern portion (425 square miles) of Alameda County, including Pleasanton, Livermore, and Dublin. Zone 7's entire service area lies within the Alameda Creek watershed. Unlike the other zones, Zone 7 was created by state law and has its own board of directors. Zones 7's water resource management responsibilities include providing a wholesale treated drinking water supply, monitoring and protecting surface water and groundwater quality, operating and maintaining a water treatment system, and managing floodwaters and stormwater for public safety and protection of property. In September 2005, Zone 7 adopted the updated *Urban Water Management and Water Shortage Contingency Plan*, which addresses operations as well as water supply and demand.

Zone 7 is the water quality management agency for the Alameda Creek watershed above the town of Niles. The agency does not generally participate in the management of SFPUC lands, with the exception of managing groundwater activities and monitoring development in the Zone 7 service area for erosion potential and channel capacity impacts through the CEQA process.

Zone 7 also serves as a water wholesaler, with supplies originating from local groundwater sources, imported water from the State Water Project, and local water stored in Del Valle Reservoir. The agency is also responsible for mitigating flood hazards in its service area and has undertaken channelization projects on sections of Arroyo de la Laguna, Arroyo del Valle, and Arroyo Mocho.

East Bay Regional Park District

The East Bay Regional Park District's (EBRPD) Sunol and Ohlone Regional Wilderness preserves are within the watersheds of Alameda Creek (below Calaveras Reservoir) and San Antonio Reservoir, respectively. Watershed management activities in these preserves can affect water quality in those receiving waters. The EBRPD has worked with the SFPUC on a number of fish enhancement projects in the watershed, including cattle fencing to keep livestock out of sensitive riparian areas.

Local Regulation

The only local regulation relevant to the WSIP is the San Francisco City Charter.

San Francisco City Charter

The San Francisco City Charter was adopted on November 7, 1995, and became effective July 1, 1996. In November 2002, the voters adopted Proposition E, which amended the charter as it relates to the SFPUC. The charter establishes many of the procedures and requirements for initiative ordinances and declarations of policy. Where the charter does not address a particular aspect of the initiative process, applicable provisions of California law apply. As specified in Section 8B.122 of the charter, the SFPUC is required to develop, periodically update, and implement programs consistent with the following goals and objectives related to water resources:

(1) Provide water and clean water services to San Francisco and water service to its wholesale customers while maintaining stewardship of the system by the City;

(2) Establish equitable rates sufficient to meet and maintain operation, maintenance, and financial health of the system;

(3) Provide reliable water and clean water services and optimize the systems' ability to withstand disasters;

(4) Protect and manage lands and natural resources used by the SFPUC to provide utility services consistent with applicable laws in an environmentally sustainable manner. Operate hydroelectric generation facilities in a manner that causes no reasonably anticipated adverse impacts on water service and habitat;

(5) Develop and implement priority programs to increase and to monitor water conservation and efficiency systemwide;

(6) Utilize state-of-the-art innovative technologies where feasible and beneficial;

(7) Develop and implement a comprehensive set of environmental justice guidelines for use in connection with its operations and projects in the city;

(8) Create opportunities for meaningful community participation in development and implementation of the SFPUC's policies and programs; and

(9) Improve drinking water quality with a goal of exceeding applicable drinking water standards if feasible.

5.2.3 Relevant Plans, Policies, and Planning Actions

U.S. Forest Service, Sierra Nevada Framework

In January 2001, the U.S. Forest Service adopted the Sierra Nevada Forest Plan Amendment (SNFPA or Sierra Nevada Framework), a plan for the management of 11 national forests and 11.5 million acres of national forest land in the Sierra Nevada mountain range, including Stanislaus National Forest. In January 2004, in response to concerns about the flexibility and compatibility of the SNFPA with other programs related to wildland fire management, the U.S. Forest Service amended the Sierra Nevada Framework to provide additional provisions for fire and fuels treatments. The amended Framework outlines procedures used to manage and protect forests, wildlife habitats, and communities from a variety of threats, including catastrophic fires, and provides a programmatic framework within which project-level decisions are designed and implemented. Key aspects of the SNFPA include: a commitment to restoration and protection of old-growth forest habitat; protection of all trees greater than 30 inches on 11 million of the 11.5 million acres of public land managed by the U.S. Forest Service; designation of riparian conservation areas; improvement and protection of suitable habitat for California spotted owl (*Strix occidentalis occidentalis*), northern goshawk (*Accipiter gentiles*), and willow flycatcher (*Empidonax traillii*); adoption of an integrated vegetation management strategy with the primary objective of protecting communities and modifying landscape-scale fire behavior to reduce the size and severity of fires; and provisions for increased land use management, including grazing, timber production, road construction, and recreation activities. The SNFPA is administered by the U.S. Forest Service (USDA Forest Service, 2004). As no WSIP facility improvement projects are proposed within Stanislaus National Forest, and the resources protected by the SNFPA would not be affected by the WSIP water supply and system operations, the WSIP would be consistent with the provisions of the SNFPA.

Regional Natural Resource Protection Plans

Many of the federal and state statutes and agreements summarized in Section 5.2.2 form the basis for development of the regional natural resource protection plans and policies described in this section. These plans and policies play an important role in the SFPUC's current and future operation of the regional water system by establishing guidelines for the protection of fish, wildlife, and riparian habitat and by setting enforceable water quality objectives/criteria for surface waters potentially affected by the regional water system. As indicated below, the plans and policies are in various stages of development; only some of the plans and policies are adopted and many are either under development or in a study or experimental stage.

Bay Delta Conservation Plan

The Bay Delta Conservation Plan (BDCP) is an effort driven by Delta water users to provide for the conservation and management of certain aquatic species, both listed and non-listed, and their habitats, while providing for regulatory assurances related to water supply reliability and water quality for the Sacramento–San Joaquin River Delta. Activities that would be covered under the BDCP include water supply operations related to the State Water Project and the Central Valley Project, and the power plant operations of the Mirant Corporation. Under the BDCP, water users would pay for new infrastructure, wetlands restoration, and other related projects in return for guaranteed stable water supplies. As the BDCP is still under development and is not yet adopted, no determination regarding potential conflicts of the WSIP with its provisions has been made.

Tuolumne Wild and Scenic River Management Plan

The *Tuolumne Wild and Scenic River Management Plan* (Wild and Scenic Plan) was approved in 1986 and is administered by the U.S. Forest Service, Pacific Southwest Region. The Wild and Scenic Plan, applicable only to the 29 miles of the Tuolumne Wild and Scenic River located outside of Yosemite National Park (see Figure 5.2-1), provides direction for managing the use of federal lands within the boundaries of the designated corridor and for protecting the unique qualities of the designated river. The Wild and Scenic Plan does not apply to the exercise of the CCSF's water rights under the existing Raker Act grant, as stated in the Wild and Scenic Rivers Act (Section 3 [a] [53] Tuolumne, California) as follows: "Nothing in this section is intended or shall be construed to affect any rights, obligations, privileges, or benefits granted under any prior authority of law including chapter 4 of the Act of December 13, 1913, commonly referred to as the Raker Act (38 Stat. 242) and including any agreement or administrative ruling entered into or made effective before the enactment of this paragraph [September 28, 1984]."

The Wild and Scenic Plan includes general management objectives and guidelines applicable to the entire designated corridor as well as reach-specific management prescriptions and recreational improvement opportunities assigned to particular management areas. All land uses within the designated corridor are subject to the provisions of the Wild and Scenic Plan. Selected management objectives, standards, and guidelines applicable to the entire designated corridor are listed below.

Management Objectives

Physical Setting Opportunities – Fish and Wildlife

1. Provide habitat for management of indicator species including threatened, endangered, and sensitive species. These include peregrine falcon, bald eagle, mule deer, western gray squirrel, yellow warbler, and Sierra Nevada red fox.

Physical Setting Opportunities – Timber

1. Manage vegetation to protect and enhance Wild and Scenic River values, placing special emphasis on protecting streamside vegetation.

Physical Setting Opportunities – Water

1. Maintain or improve the existing high water quality for fisheries, aesthetics, and other ecological considerations. Give priority to protection of water quality in cases of conflict with other resource uses. Prevent alteration of natural channels or stream banks that would significantly affect the free-flow of water, the appearance of the stream, fish habitat, or water quality.

Physical Setting Opportunities – Lands

2. Work with proponents and operators of hydroelectric projects outside of the corridor to provide mitigation to eliminate or minimize adverse environmental impacts and to provide for recreation opportunities created by the project that will meet the objectives of this management plan.

Managerial Setting Opportunities

5. Manage the Tuolumne Wild and Scenic River and its immediate environment to preserve its free-flowing condition and to protect its outstandingly remarkable values.[3] Provide opportunities for public recreation and other resources based on the classification of each river segment.

Standards and Guidelines

Fish and Wildlife

- <u>Fish and Wildlife Habitat Coordination (C1-WS)</u>. Maintain and enhance habitat for fish and wildlife species.

- <u>Stream Fisheries Habitat Improvement and Maintenance (C2-WS)</u>. Provide medium- to high-quality habitat for resident trout species (rainbow, brown, and brook) according to the habitat capability model.

- <u>Riparian and Meadow Vegetation Management (C4-WS)</u>. Provide cover and forage for fish and wildlife species associated with riparian habitats by maintaining medium- to high-habitat quality according to the Habitat Quality Criteria for Riparian Habitat.

Specific impacts on potentially affected resources covered in this plan—including water, fish and wildlife, vegetation, recreational, and visual resources—resulting from implementation of the proposed WSIP water supply and system operations are analyzed in this chapter in the corresponding subsections of Section 5.3.

Tuolumne Wild and Scenic River Comprehensive Management Plan, General Management Plan for Yosemite National Park, and Wilderness Management Plan

The NPS is currently in the process of preparing a comprehensive management plan for the 54 miles of designated wild and scenic river within Yosemite National Park, as mandated by the Wild and Scenic Rivers Act. This reach of designated river includes portions of the river extending from the Tioga Pass Entrance and Lyell Canyon to the Poopenaut Valley, as shown in Figure 5.2-1. The lands immediately surrounding Hetch Hetchy Reservoir are not included in the plan area; environmental stewardship of these lands is the responsibility of the SFPUC and is performed in coordination with the NPS, as described in Chapter 2, Section 2.3.8. However, the six-mile reach of the Tuolumne River, downstream of Hetch Hetchy Reservoir, that passes through the Poopenaut Valley is covered under this plan.

---

3 Outstandingly remarkable values are defined by the Wild and Scenic Rivers Act as the unique characteristics that make a river worthy of special protection.

The intended purpose of the plan currently under development, known as the *Tuolumne Wild and Scenic River Comprehensive Management Plan* (Tuolumne River Plan), is to establish the overall goals and vision for the river corridor. It will provide broad, conceptual-level management objectives that may amend the *General Management Plan for Yosemite National Park* (1980) for the river corridor. The Tuolumne River Plan is not intended to include specific implementation strategies or plans. Concurrent with the Tuolumne River Plan, the NPS is also developing an implementation plan for Tuolumne Meadows that will be guided by the Tuolumne River Plan. Public scoping related to development of the two plans was completed in September 2006, and the draft environmental impact statement is scheduled for release in 2008, with the final report expected in 2009 (NPS, 2006b, 2007).

As part of the development of the Tuolumne River Plan, the NPS developed a draft report entitled *Tuolumne Wild and Scenic River Outstandingly Remarkable Values* (NPS, 2006a). This report presents the proposed revision of the outstandingly remarkable values for the portion of the Tuolumne Wild and Scenic River within Yosemite National Park. Outstandingly remarkable values are identified for natural (ecologic, hydrologic, geologic, and biologic), sociocultural (prehistoric, historic, scenic, and recreational), and scientific values by river segment and for the corridor as a whole. A final report will incorporate comments received during public scoping and review of the draft Tuolumne River Plan and become the foundation for the final Tuolumne River Plan. The *Outstandingly Remarkable Values* includes specific description of cultural, historic, hydrologic, geologic, biologic, scenic, and recreational attributes of the reach of the Tuolumne River below Hetch Hetchy Reservoir, including the Poopenaut Valley, potentially affected by the proposed water supply and system operations.

Much of the area around the Tuolumne River is federally designated as wilderness and is covered under the NPS's *Wilderness Management Plan*. The general guidance and direction for the *Wilderness Management Plan* currently derive from the *General Management Plan for Yosemite National Park*, the Wilderness Act, and NPS policy. When the *Wilderness Management Plan* is updated, the NPS will incorporate guidance and direction established by the Tuolumne River Plan.

Although the Tuolumne River Plan is still under development, specific impacts on potentially affected resources to be covered in the plan—including water, biological, recreational, and visual resources—resulting from implementation of the proposed WSIP water supply and system operations are analyzed in this chapter in the corresponding subsections of Section 5.3.

Vernalis Adaptive Management Program

The VAMP, a product of the San Joaquin River Agreement and officially initiated as part of SWRCB Decision 1641, is a 12-year experimental adaptive management program to study the effects of alterations in San Joaquin River flows and Delta pumping rates on the migration of salmon within the San Joaquin River basin. Under the VAMP, a barrier was installed at the head of Old River, and different amounts of water are released down the San Joaquin River, curtailing exports from the Delta by the State Water Project and Central Valley Project to varying degrees for one month in the spring when juvenile salmon are migrating. Information on the effects of different river flow and export rates on migrating salmon is being gathered and may be used to establish future standards for their protection. The VAMP is administered by the parties to the San Joaquin River Agreement, including the U.S. Bureau of Reclamation, DWR, CDFG, USFWS, and San Joaquin River Group Authority.

The VAMP is discussed in this chapter because the WSIP would affect flows in the Tuolumne River, a tributary to the San Joaquin River and the Sacramento–San Joaquin Delta. Specific impacts on potentially affected resources covered in this plan—including flows in the San Joaquin River—resulting from implementation of the proposed WSIP water supply and system operations are discussed in Section 5.3.1 of this chapter. The VAMP is not an adopted plan, but rather a temporary experimental program; however, it is expected that either the VAMP or a "VAMP-like" program will be continued when the current program expires.

Habitat Restoration Plan for the Lower Tuolumne River Corridor

Under the 1995 FERC Settlement Agreement (described above and in Chapter 2, Section 2.5.2), the TRTAC is responsible for developing and implementing a Chinook salmon restoration plan and salmon management and habitat restoration activities as part of the strategy to address a decline in fall-run Chinook salmon in the lower Tuolumne River (FERC, 1996). The *Habitat Restoration Plan for the Lower Tuolumne River Corridor* (TRTAC, 2000) is a technical resource document, not an adopted plan, intended to aid the TRTAC in identifying areas of potential habitat improvement and in restoring or rehabilitating these areas.

The restoration plan integrates salmon ecology and geomorphic and hydrologic processes into a riverwide and reach-specific plan. The plan includes goals and strategies to guide future management, specific monitoring objectives, a comprehensive list of all potential restoration sites and actions, and conceptual designs for 14 high-priority restoration projects.

The restoration plan describes how cumulative water storage and diversion projects in the lower Tuolumne River watershed have led to a reduction in annual water yield below La Grange Dam, reductions in the magnitude and variability of the annual hydrograph,[4] and a reduction in the magnitude, duration, and frequency of winter floods. The restoration plan promotes the recovery of Chinook salmon and the river's natural animal and plant communities through the reestablishment of fluvial geomorphic functions, processes, and characteristics. The plan includes the following riverwide restoration goals for the Tuolumne River:

- A continuous river floodway from La Grange Dam to the confluence of the San Joaquin River
- A continuous riparian corridor from La Grange Dam to the San Joaquin River confluence, with a minimum width of 500 feet and a width of up to 2,000 feet near the San Joaquin River
- A dynamic alluvial channel maintained by flood hydrographs of variable magnitude and frequency adequate to periodically initiate geomorphic processes
- The establishment of variable stream flows to benefit salmon and other aquatic resources

[4] A chart that illustrates the pattern of flow in a stream as a function of time.

- Chinook salmon habitat created and maintained by natural processes, sustaining a resilient, naturally reproducing Chinook salmon population
- Self-sustaining, dynamic, native woody riparian vegetation
- Continual revision of the adaptive management program, addressing areas of scientific uncertainty that will improve our understanding of river ecosystem processes and refine future restoration and management

Specific impacts on potentially affected resources covered in this plan—including water, geomorphological, biological, recreational, and visual resources—resulting from implementation of the proposed WSIP water supply and system operations are addressed in this chapter in the corresponding subsections of Section 5.3, and information from this plan is used as a resource for mitigation strategies.

Water Quality Control Plans

Each RWQCB is required to develop, adopt, and implement a Water Quality Control Plan (WQCP), also known as a Basin Plan, for its respective region. The WQCP is the master policy document that contains descriptions of the legal, technical, and programmatic bases of water quality regulation. WQCPs identify beneficial uses of surface waters and groundwater within the corresponding region; specify water quality objectives and standards for both surface water and groundwater; and develop the actions necessary to maintain the standards in order to control nonpoint and point sources of pollutants to the state's waters.

WQCPs are adopted and amended by the RWQCBs and approved by the SWRCB. Adoption of or revisions to the surface water objectives/standards contained in the WQCPs are subject to U.S. EPA approval. All discretionary projects requiring permits from the RWQCB (i.e., waste discharge requirements and National Pollutant Discharge Elimination System permits) must implement WQCP requirements, taking into consideration the beneficial uses to be protected.

Two adopted WQCPs govern the management of surface and ground waters that could be affected by proposed WSIP system operations. The Central Valley WQCP covers the Sacramento and San Joaquin River basins, including the Tuolumne River watershed. The San Francisco Bay/Delta WQCP covers those portions of Alameda, Contra Costa, Marin, Napa, San Mateo, San Francisco, Santa Clara, Solano, and Sonoma Counties that drain to the San Francisco Bay Estuary, including the Delta, as well as areas draining to the Pacific Ocean; this plan includes the Alameda Creek watershed, the Peninsula watershed (including San Mateo and Pilarcitos Creeks), and the Westside Groundwater Basin. Water objectives/standards contained in the WQCPs are enforceable against the SFPUC. Specific impacts on water quality associated with implementation of the proposed WSIP water supply and system operations are analyzed by watershed in Sections 5.3.3, 5.4.3, and 5.5.3 of this chapter.

San Francisco Bay Plan

The SF Bay Plan, completed and adopted by BCDC in 1968, is an enforceable plan that guides the protection and use of San Francisco Bay and its shoreline. For a discussion of the SF Bay Plan's applicability to individual WSIP facility projects, see Section 4.2 (Vol. 2, Chapter 4, p. 4.2-16).

The SF Bay Plan is founded on the belief that water quality in San Francisco Bay will be maintained at levels sufficiently high to protect the beneficial uses of the bay. The SF Bay Plan includes findings and policies related to freshwater inflow and changes in salinity. The freshwater inflow findings contained in the SF Bay Plan stress the importance of maintaining a balance between fresh and saltwater. The related policies assert that the impact of freshwater diversions should be monitored by the SWRCB to ensure compliance with water quality standards.

Regional Habitat Conservation Plans

Habitat conservation plans (HCPs) are land use and biological planning documents that provide comprehensive, long-term conservation measures for species listed as threatened or endangered under the California and Federal Endangered Species Acts, or for species that could be listed in the future. One adopted HCP covering an area that could be affected by WSIP implementation was identified (see separate discussion below of SFPUC HCPs). In 1995, the City of Waterford prepared an HCP for the incidental take of valley elderberry longhorn beetle (VELB) on the Tuolumne River at the discharge point of its wastewater treatment facility, located between La Grange Dam and the city of Modesto. The HCP involved the removal of about 150 elderberry bushes on five acres and the installation of over 800 small bushes.

Alameda Creek Watershed Management Planning Efforts

Multiple stakeholders in the Alameda Creek watershed area, including the SFPUC, Alameda County Water District, ACFCWCD, Zone 7, EBRPD, and various environmental interest groups, are involved in ongoing planning efforts to manage the Alameda Creek watershed. Although no specific plans have been adopted, planning efforts include the development of a comprehensive management plan for the watershed; the plan, which is being prepared in conjunction with the Alameda Creek Fisheries Restoration Workgroup, will focus on restoring steelhead to the Alameda Creek watershed. In October 2006, 17 public agencies and nonprofit organizations[5] signed a formal agreement to collaborate on stream flow requirements for steelhead, other native fish and wildlife, and drinking water supplies (Alameda Creek Fisheries Restoration Workgroup, 2006). This planning effort is discussed in the Alameda Creek watershed fisheries section and in cumulative analysis of the WSIP water supply and system operations, in Sections 5.4.5 and 5.7, respectively.

[5] Participating organizations in the Alameda Creek Fisheries Restoration Workgroup include: the Alameda County Water District, Alameda County Flood Control and Water Conservation District, Alameda Creek Alliance, Coastal Conservancy, Zone 7, Pacific Gas and Electric Company, SFPUC, Alameda County Resource Conservation District, American Rivers, California Department of Fish and Game, East Bay Regional Park District, National Marine Fisheries Service, Natural Resources Defense Council, San Francisco Bay Regional Water Quality Control Board, U.S. Army Corps of Engineers, U.S. Natural Resources Conservation Service, and U.S. Fish and Wildlife Service.

Pilarcitos Creek Watershed Restoration Plan

Developed in coordination with the California Department of Fish and Game, Regional Water Quality Control Board, and a citizen's advisory committee, the *Pilarcitos Creek Restoration Plan* (Philip William & Associates, Ltd., 1996) details the major issues of concern regarding Pilarcitos Creek and its tributaries, and prioritizes alternatives to significantly enhance the physical and biological attributes of the watershed. The alternatives involve reducing sedimentation in the creek and its tributaries, enhancing fish migration and rearing and riparian habitat, and providing educational resources. Not an adopted plan, this document and its subsequent updates serve as a guide to restoration projects and related activities in the Pilarcitos watershed. It is considered in this chapter with respect to providing documentation of existing conditions in the Pilarcitos watershed and potential mitigation strategies for potential impacts associated with the WSIP water supply option and system operations.

Pilarcitos Creek Integrated Watershed Management Plan

The Pilarcitos Creek Restoration Workgroup[6] is currently developing the *Pilarcitos Creek Integrated Watershed Management Plan*, the intended purpose of which is to "determine how to more effectively manage the competing beneficial uses of water from Pilarcitos Creek and promote balanced solutions that satisfy environmental, public health, recreational, and economic interests. An important component of the plan will be an assessment of existing conditions and a strategy for addressing the actions necessary for the protection and restoration of [steelhead trout] and other species of concern that depend on aquatic and riparian habitats throughout the watershed" (San Mateo County Resource Conservation District, 2006). The plan will build on the 1996 *Pilarcitos Creek Restoration Plan*, and a Memorandum of Understanding has been developed among the 19 participants in the workgroup to outline the process for developing the plan (Pilarcitos Creek Restoration Workgroup, 2007). It is expected that the *Pilarcitos Creek Integrated Watershed Management Plan* will be completed in 2008. This plan is considered in the cumulative analysis of the WSIP water supply and system operations, as discussed in Section 5.7.

City and County of San Francisco Plans and Policies

Chapter 4, Section 4.2, Plans and Policies, provides an overview of the relationship of CCSF planning documents to the WSIP and discusses the specific CCSF plans and policies that pertain to the WSIP facility improvement projects. This section focuses on those plans and polices that relate to the WSIP water supply and system operations.

San Francisco General Plan

Section 4.2.2 provides an overview of the San Francisco General Plan. Although the majority of policies contained in the general plan were developed for lands within San Francisco and are not generally relevant to extraterritorial lands, several policies and objectives provided in the Environmental Protection Element are relevant to the proposed operational changes and sources of water supply under the WSIP. The Fresh Water sub-element of the Environmental Protection Element of the San Francisco General Plan includes objectives aimed at the protection of freshwater resources (Objective 6) in conjunction with responsible utilization of these resources for water supply (Objective 5). Policies associated with the reliability of the regional water system include Policy 5.1 and Policy 5.2. Policy 5.3 and Policy 5.4 address water quality; Policy 6.1 specifies the continued implementation of a leak detection program; and Policy 6.2 deals with water reclamation. The Flora and Fauna sub-element of the Environmental Protection Element deals with the protection of plant and animal life (Objective 8) and specifies the protection of plant and animal species and their habitats through coordination with animal protection programs (Policy 8.1, Policy 8.2, Policy 8.3). Specific impacts on potentially affected

6 Participating organizations in the Pilarcitos Creek Restoration Workgroup include: the SFPUC, California State Parks, San Mateo County Resource Conservation District, San Francisco Bay Regional Water Quality Control Board, Pilarcitos Creek Advisory Council, City of Half Moon Bay, Coastside County Water District, Committee for Green Foothills, Gulf of the Farallones National Marine Sanctuary, Half Moon Bay Fishermans Association, Midpeninsula Regional Open Space District, California Department of Fish and Game, Monterey Bay National Marine Sanctuary, National Marine Fisheries Service, Peninsula Open Space Trust, Pilarcitos Creek Advisory Committee, San Mateo County Farm Bureau, Sewer Authority Mid-Coastside, and Surfrider Foundation–San Mateo Chapter.

resources covered in this plan—including water and biological resources—resulting from implementation of the WSIP water supply and system operations are analyzed by watershed in the corresponding sections of this chapter.

San Francisco Sustainability Plan

The San Francisco Board of Supervisors endorsed the *San Francisco Sustainability Plan* in 1997, but has not committed the City to perform the actions addressed in the plan. The plan serves as a blueprint for sustainability, with many of its individual proposals requiring further development and public comment. The underlying goals of the plan are to maintain the physical resources and systems that support life in San Francisco and to create a social structure that will allow such maintenance. The plan is divided into 15 topic areas, 10 that address specific environmental issues (air quality; biodiversity; energy, climate change, and ozone depletion; food and agriculture; hazardous materials; human health; parks, open spaces and streetscapes; solid waste; transportation; and water and wastewater), and five that are broader in scope and cover many issues (economy and economic development, environmental justice, municipal expenditures, public information and education, and risk management). Under the topic "Water," there are goals addressing water reuse, water quality, adequacy of water supply, groundwater supply, and infrastructure. Each topic area in the plan has a set of indicators to be used over time in determining whether San Francisco is moving in a sustainable direction in that particular area (CCSF, 1997).

Specific impacts on potentially affected resources addressed in this plan—including water and groundwater resources—resulting from implementation of the WSIP water supply and system operations are analyzed by watershed in the corresponding sections of this chapter.

San Francisco Urban Water Management Plan

As discussed in *2005 Urban Water Management Plan for the City and County of San Francisco*, approximately 96 percent of the city's total water supply is provided by the SFPUC regional water system. The remaining 4 percent of the water demand is met through locally produced, nonpotable groundwater and secondary-treated recycled water used for irrigation. San Francisco overlies all or part of seven groundwater basins. Of these, only the Westside Basin and the Lobos Basin are considered adequate for municipal supplies. Groundwater pumped from wells located in Golden Gate Park and at the San Francisco Zoo is used by the Recreation and Park Department for irrigation. Tertiary-treated recycled water from the SFPUC's Southeast Water Pollution Control Plant is used on a limited basis for washdown operations.

The 2005 UWMP identifies various local water supply plans and programs that represent potential options to maximize resources and minimize the need to import water. These include ongoing implementation of water conservation programs; implementation of the *Recycled Water Master Plan* (SFPUC, 2006a), which explores additional opportunities for recycled water use in San Francisco; and implementation of the *Draft North Westside Basin Groundwater Management Plan*, which identifies several new local groundwater projects to produce an additional 2 million gallons per day of groundwater for potable purposes (SFPUC, 2005).

Information in the UWMPs of both the retail and wholesale customers of the regional water system, including the CCSF and applicable Bay Area Water Supply and Conservation Agency members, was used in the development of the WSIP level of service water supply goal for 2030.

SFPUC Watershed Management Plans

The SFPUC has adopted watershed management plans for CCSF-owned lands in the Alameda and Peninsula watersheds to provide a policy framework for activities and actions on watershed lands. Watershed lands are managed by the SFPUC Natural Resources Division, Land and Resource Management Section. The plans provide goals, policies, and management actions that address watershed activities and reflect the unique qualities of each watershed. Changes in system operations proposed under the WSIP would be required to conform to the goals, policies, and management actions contained in the Alameda and Peninsula Watershed Management Plans (WMPs) as well as applicable environmental codes and regulations. Specific impacts on affected resources covered in these plans—including water, biological, recreational, and visual resources—resulting from implementation of the WSIP water supply and system operations are analyzed for the Alameda and Peninsula watersheds in the corresponding sections of this chapter.

For both watershed plans, the SFPUC considers water quality protection as the first and foremost goal. The goals and policies are organized around the primary goal of water quality protection and six secondary goals pertaining to water supply, natural resource protection, watershed protection, land use compatibility, fiscal management, and public awareness. The primary and secondary goals were established by the Watershed Planning Committee, a group of SFPUC division and department representatives who assisted in plan development and review. The primary and secondary goals in common to both watershed management plans are as follows:

- *Primary Goal*: Maintain and Improve Source Water Quality to Protect Public Health and Safety
- *Secondary Goals*:
  - Maximize water supply
  - Preserve and enhance the ecological and cultural resources of the watershed
  - Protect the watersheds, adjacent urban areas, and the public from fire and other safety hazards
  - Continue existing compatible uses and provide opportunities for potential compatible uses on watershed lands, including educational, recreational, and scientific uses
  - Provide a fiscal framework that balances financial resources, revenue-generating activities, and overall benefits and an administrative framework that allows implementation of the watershed management plans
  - Enhance public awareness of water quality, water supply, conservation, watershed protection issues

Alameda Watershed Management Plan

The SFPUC's Alameda WMP is described in Chapter 4, Section 4.2, in the context of WSIP facilities improvement projects located in the Alameda watershed. The Alameda watershed lands are shown in Figure 2.2. The Alameda WMP provides a policy framework for the SFPUC to make consistent decisions about the activities, practices, and procedures that are appropriate on CCSF-owned lands in the Alameda watershed to protect the watershed and ensure a pure and reliable supply for San Francisco. The plan applies best management practices for the protection of water and natural resources and their conservation, enhancement, restoration, and maintenance and is intended to be used by the SFPUC as watershed management implementation guidelines.

Peninsula Watershed Management Plan

The SFPUC's Peninsula WMP is described in Chapter 4, Section 4.2, in the context of WSIP facilities improvement projects located in the Peninsula watershed. The Peninsula watershed lands are shown in Figure 2.3.The Peninsula WMP was developed in the same manner as the Alameda WMP and consists of the same primary and secondary goals as those contained in the Alameda WMP; however, some policies contained in the plan have been formulated to address the specific management issues of the Peninsula watershed.

SFPUC Habitat Conservation Plans

As part of watershed management plan implementation, the SFPUC is in the process of developing HCPs for the Alameda and Peninsula watersheds, as discussed in Chapter 4, Section 4.2. Both watersheds contain known habitat for sensitive species, and the HCPs are being developed in compliance with federal and state regulations for endangered species protection. The draft HCP for the Alameda watershed is scheduled for public review in 2007, and the draft HCP for the Peninsula watershed is scheduled for public review in 2008. Both plans will require preparation of a joint environmental impact report/environmental impact statement before the SFPUC can consider adoption and begin implementation. (See Chapter 4, Section 4.2, for additional information regarding the development of HCPs for the SFPUC Alameda and Peninsula watersheds.)

Although the HCPs are still under development, specific WSIP impacts on the resources anticipated to be covered in the plans—particularly steelhead and other federal- or state-listed biological resources—are analyzed for the Alameda and Peninsula watersheds in the corresponding sections of this chapter.

SFPUC Water Enterprise Environmental Stewardship Policy

Adopted in June 2006, the Water Enterprise Environmental Stewardship Policy established the long-term management direction for CCSF-owned lands and natural resources affected by operation of the SFPUC regional water system within the Tuolumne River, Alameda Creek, and Peninsula watersheds (SFPUC, 2006b). It also addresses rights-of-way and properties in urban surroundings under SFPUC management. The policy includes the following specifically relevant to the proposed water supply and system operations:

- The SFPUC will proactively manage the watersheds under its responsibility in a manner that maintains the integrity of the natural resources, restores habitats for native species, and enhances ecosystem function.
- To the maximum extent practicable, the SFPUC will ensure that all operations of the SFPUC water system (including water diversion, storage, and transport), construction and maintenance of infrastructure, land management policies and practices, purchase and sale of watershed lands, and lease agreements for watershed lands protect and restore native species and the ecosystems that support them.
- It is the policy of the SFPUC to operate the SFPUC water system in a manner that protects and restores native fish and wildlife downstream of SFPUC dams and water diversions, within SFPUC reservoirs, and on SFPUC watershed lands.
- Releases from SFPUC reservoirs will mimic the variation of the seasonal hydrology (e.g., magnitude, timing, duration, and frequency) of their corresponding watersheds in order to sustain the aquatic and riparian ecosystems upon which these native fish and wildlife species depend (consistent with the SFPUC mission, existing agreements, and applicable state and federal laws).
- The SFPUC will actively monitor the health of the terrestrial and aquatic habitats, both under SFPUC ownership and affected by SFPUC operations, in order to continually improve ecosystem health.

The Environmental Stewardship Policy calls for implementation and update of the Alameda and Peninsula WMPs (described above), development of habitat conservation plans for the Alameda and Peninsula watersheds (described above), and development and implementation of the Watershed Environmental Improvement Program (described in Chapter 3, Section 3.12, WSIP-Related Activities), as well as specific integration of this policy into the WSIP and individual infrastructure projects.

General Plans of Potentially Affected Counties

Chapter 4, Section 4.2.2, describes the applicability of city and county general plan policies to the WSIP facility improvement projects; much of that discussion also applies to the proposed WSIP water supply and system operations. No local agency approvals other than those of the CCSF are expected to be needed for the proposed water supply and system operations (see Chapter 3, Section 3.13). Any county required to determine consistency of a part of the WSIP with their general plan pursuant to California Government Code 65402(b) would be notified by the SFPUC prior to implementation. Notwithstanding the limited authority of cities and counties over implementation of the WSIP, where CCSF-owned facilities are sited and operated outside of San Francisco, the SFPUC seeks to work cooperatively with cities and counties to avoid conflicts with local plans and policies. For the WSIP, a key issue for local agencies that receive all or part of their water from the SFPUC is whether the WSIP adequately addresses community goals regarding water service for existing and future land uses; this topic is addressed in Section 4.2.3. A second issue of importance to local agencies is whether implementation of the WSIP would be consistent with community goals regarding resource protection. Counties in which WSIP operations could result in surface water or groundwater hydrology impacts and/or secondary biological effects include the following:

- Tuolumne
- Stanislaus
- Alameda
- San Joaquin
- Santa Clara
- San Mateo

Table 5.2-2 presents an overview of policies and goals from these counties' general plans that address water resources management and biological resources. The issues shown in the table are addressed in the impact analyses presented in Chapter 5. The only significance criterion applicable to the impact analysis in Chapter 5 regarding WSIP compatibility with certain aspects of local land use plans and polices is "Conflict with the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, or state habitat conservation plan." This impact is analyzed in Sections 5.3.7, 5.4.6, and 5.5.6, Terrestrial Biological Resources in the Tuolumne, Alameda Creek, and Peninsula watersheds, respectively.

TABLE 5.2-2
SUMMARY OF GENERAL PLAN POLICIES OF COUNTIES WITH SURFACE WATER AND GROUNDWATER RESOURCES POTENTIALLY AFFECTED BY THE PROPOSED WSIP WATER SUPPLY AND SYSTEM OPERATIONS

Resource Area	Summary Description of General Plan Policy
Water Resources Management	Preserve water resources for all beneficial uses of water; ensure the adequate quantity and quality of water for municipal and industrial uses, agriculture, recreation, fish and wildlife, and Delta outflows for salinity repulsion.
	Recognize surface water resources of state and national significance for which environmental and scenic values must be protected; minimize alteration of natural water bodies; support "properly timed, sufficient flows" in rivers.
	Protect groundwater resources.
Biological Resources	Develop comprehensive watershed management plans to assure that cumulative impacts on water quality, reservoir operations, and watershed resources are addressed and mitigated.
	Recognize and protect resources of significant biological and ecological importance; protect habitats of rare and endangered fish and wildlife species; maintain adequate stream/river flows for salmon migration; protect fish and wildlife habitat and recreational uses when implementing water diversion projects; require that water projects contain safeguards to protect fish and wildlife; design public projects to avoid damage to freshwater and stream environments; require mitigation of impacts on sensitive areas (e.g., riparian habitats, vernal pools, rare plants, flyways, and other waterfowl habitats); restore freshwater habitats.
	Protect and restore natural resources like wetlands and riparian areas; achieve a "no net loss" of wetland areas through avoidance, protection, and appropriate mitigation; protect riparian habitat along rivers and natural waterways; address potential impacts on waterways and wetlands resulting from increased erosion and siltation.

Specific impacts on affected resources addressed in these plans—including water, biological, recreational, and visual resources—resulting from implementation of the WSIP water supply and system operations are analyzed by watershed in the corresponding sections of this chapter.

5.2.4 Plan Consistency Evaluation

The evaluation of plan/policy consistency in this section is based on the applicability of adopted plans and policies to the proposed WSIP water supply and system operations and associated effects. The consistency evaluation in this PEIR represents the best attempt to advise the decision-makers as to whether the proposed program is consistent with applicable *adopted* land use and resource plans and policies. No consistency determination is made for draft plans/policies, plans in development, guidance/planning documents, or agreements. However, the resources addressed in the draft plans/policies or guidance/planning documents are evaluated in the impact analyses in the appropriate sections of this chapter. In general, implementation of the WSIP would be consistent with natural resource and other applicable plans described in Section 5.2.3, particularly with respect to the WSIP sustainability goal of managing natural resources and physical systems to protect watershed ecosystems and with implementation of mitigation measures identified in this PEIR.

Consistency with Regional Natural Resource Protection Plans

WQCPs [water quality control plans] identify water quality issues and prescribe enforceable water quality objectives/criteria for specific water bodies and their tributaries. Because these standards are based on designated beneficial uses of the respective waterways, violation of the water quality objectives/criteria can adversely affect fish, wildlife, and other protected resources. SFPUC operations currently comply with water quality standards contained in the WQCPs, and the WSIP goals and objectives would be consistent with the applicable WQCPs. Further, as future SFPUC operations would be consistent with the water quality standards contained in the WQCPs, SFPUC operations would also be consistent with the SF Bay Plan freshwater inflow policies. The potential impacts of WSIP implementation on water quality in the Tuolumne River watershed and Sacramento–San Joaquin Delta, Alameda Creek watershed, Peninsula watershed, and Westside Groundwater Basin are analyzed in Sections 5.3.3, 5.4.3, 5.5.3, and 5.6, respectively.

One adopted HCP covering an area that could be affected by WSIP implementation was identified; this plan was prepared by the City of Waterford for the incidental take of valley elderberry longhorn beetle (VELB) on the Tuolumne River at a location between La Grange Dam and Modesto. The goals and objectives of the WSIP would be consistent with this HCP, and, as described in Section 5.3.7, implementation of the WSIP would not adversely affect the VELB or elderberry population in this plan area.

Consistency with CCSF Plans and Policies

San Francisco General Plan

The San Francisco General Plan provides general environmental resource policies related to the protection of natural resources, including freshwater resources. The WSIP goals and objectives would be consistent with the goals and objectives of this plan, and more specifically with policies related to freshwater resources. The impact analyses presented in Sections 5.3 through 5.7 of this chapter assess the potential for physical environmental impacts from implementation of the WSIP water supply and system operations. The impact analyses identify a variety of potentially significant physical impacts under all environmental topics, but, as described in those sections, many of these impacts would be reduced to a less-than-significant level with implementation of mitigation measures and compliance with applicable regulations, as outlined in Chapter 6.

San Francisco Sustainability Plan

The *San Francisco Sustainability Plan* was developed for the purpose of addressing San Francisco's long-term environmental sustainability. Water supply goals relevant to the WSIP deal with ensuring a sustainable and adequate water supply; maximizing public health by providing safe drinking water; ensuring public input into the water planning process; restoring and enhancing groundwater supplies; and upgrading infrastructure in a timely and environmentally sound manner. The WSIP water supply and system operations, and particularly the WSIP sustainability objective, would be consistent with the goals of the Sustainability Plan. The WSIP would be consistent with goals pertaining to increasing water reuse, ensuring an adequate water supply under normal and extraordinary conditions, restoring groundwater supplies, and upgrading infrastructure.

San Francisco Urban Water Management Plan

The *2005 Urban Water Management Plan for the City and County of San Francisco* evaluates regional water system reliability and the SFPUC's existing and planned sources of water supply. The plan describes demand management measures to be implemented and provides an implementation strategy and schedule for future planned projects and schedules. Information in the UWMP was used in the development of WSIP levels of service and complements the operational strategy and future water supplies proposed under the WSIP. Therefore, the WSIP is and would be inherently consistent with the UWMP.

Consistency with Adopted SFPUC Plans and Policies

Alameda and Peninsula Watershed Management Plans

Watershed management plans prepared by the SFPUC for the purpose of water resource management and planning provide much of the framework used in the development of various components of the WSIP. The Peninsula and Alameda WMPs are designed to improve the SFPUC's ability to protect its overall watershed as well as the specific resources that make up the watershed. The WMPs include goals and policies related to maximizing the local water supply and improving source water quality to protect public health and safety; these goals are aligned with the goals of the WSIP. As part of implementing the WMPs, the SFPUC Natural Resources Division will review WSIP activities proposed within these watersheds for conformity with the WMPs as well as for compliance with environmental codes and regulations; thus, changes in system operations proposed under the WSIP would be reviewed for conformity with the goals, policies, and management actions contained in the Alameda and Peninsula WMPs. Overall, the WSIP would be consistent with the WMPs. Potential impacts of WSIP system operations on water quality and biological resources in the Alameda and Peninsula watersheds are described in Sections 5.4 and 5.5 of this chapter.

SFPUC Water Enterprise Environmental Stewardship Policy

The WSIP would be consistent with the underlying goals of the Water Enterprise Environmental Stewardship Policy, particularly with respect to the WSIP sustainability goal and the WSIP objective to manage natural resources and physical systems to protect watershed ecosystems. The Stewardship Policy implementation strategy specifically calls for integration of the policy into the WSIP. However, implementation of the proposed water supply and system operations would affect stream flow in the Tuolumne River, Alameda Creek, and Peninsula watersheds, as analyzed and described in Sections 5.3.1, 5.4.1, and 5.5.1. This operational change and resultant effects on stream flow could in turn affect native fish and wildlife downstream of SFPUC dams and water diversions, within SFPUC reservoirs, and on SFPUC watershed lands. Impacts on fisheries and the terrestrial biological resources in the Tuolumne River, Alameda Creek, and Peninsula watersheds are analyzed in Sections 5.3.6, 5.3.7, 5.4.5, 5.4.6, 5.5.5, and 5.5.6. Mitigation measures described in Chapter 6 identify operational approaches to managing releases from SFPUC reservoirs and other measures to reduce impacts on fisheries and other biological resources.

Consistency of WSIP Operations with the General Plans of Potentially Affected Counties

Overall, the WSIP water supply and system operations would be generally consistent with the community goals related to water resources protection described above. Through preparation of this PEIR and attendant scoping and public outreach efforts, the CCSF has systematically identified significant environmental impacts associated with the WSIP as well as feasible measures and alternatives to avoid or substantially lessen such effects. The impact analyses presented in this PEIR reflect the intent of general plan policies related to the protection of water resources. As detailed throughout the rest of Chapter 5, most of the environmental impacts associated with the proposed water supply and system operations would be reduced to a less-than-significant level with measures proposed as part of the WSIP or otherwise committed to by the SFPUC.

5.3 Tuolumne River System and Downstream Water Bodies

Section 5.3 Subsections

5.3.1 Stream Flow and Reservoir Water Levels

The following setting section describes the streams and reservoirs in the Tuolumne River watershed and downstream that could be affected by the WSIP. The impact section (Section 5.3.1.2) provides a description of the changes in stream flow and reservoir water levels that would result from implementation of the WSIP.

5.3.1.1 Setting

The Tuolumne River flows from the crest of the Sierra Nevada westward to its confluence with the San Joaquin River. The San Joaquin River flows north to the Sacramento–San Joaquin Delta. Water from the Delta discharges to the San Francisco Bay Estuary and the Pacific Ocean.

Surface water bodies in the Tuolumne River system that could be affected by the proposed program include the Tuolumne River, Cherry Creek, Eleanor Creek, and a quarter-mile reach of Moccasin Creek. Several reservoirs could be affected by the WSIP, including Hetch Hetchy Reservoir, Lake Lloyd, Lake Eleanor, and Don Pedro Reservoir. Because the Tuolumne River drains to the San Joaquin River and the Sacramento–San Joaquin Delta, these water bodies could also be affected by the WSIP. The proposed program could affect flow in the streams and water levels and water quality in the reservoirs.

Tuolumne River

General Description

The Tuolumne River rises in Yosemite National Park and flows approximately 130 miles to its confluence with the San Joaquin River about 10 miles west of the city of Modesto. Its headwaters are streams that descend the slopes of Mount Lyell and Mount Dana in the Sierra Nevada and join to form the river itself at Tuolumne Meadows. The Tuolumne River drains an area of 1,958 square miles. Its watershed is shown in **Figure 5.3.1-1**.

From Tuolumne Meadows (at an elevation of 8,600 feet above sea level), the river descends rapidly through a deep canyon in wilderness areas of Yosemite National Park to Hetch Hetchy Reservoir (at an elevation of about 3,500 feet). Six miles below O'Shaughnessy Dam, which impounds Hetch Hetchy Reservoir, the Tuolumne River leaves Yosemite National Park and enters the Stanislaus National Forest. Except for a short reach at Early Intake Reservoir, the river flows unimpeded through a deep canyon for approximately 40 miles, from O'Shaughnessy Dam to the upstream end of Don Pedro Reservoir.

Don Pedro Reservoir is at an elevation of about 500 feet. Several tributaries, including Cherry Creek, Jawbone Creek, the Clavey River, the North Fork of the Tuolumne River, and Turnback Creek, join the river from the north between Hetch Hetchy and Don Pedro Reservoirs. The South Fork of the Tuolumne joins the river from the south. Moccasin Creek and Woods Creek drain directly into Don Pedro Reservoir.

Below Don Pedro Reservoir, the Tuolumne River flows 2.3 miles to La Grange Dam, where water is diverted into two irrigation canals. Below La Grange Dam, the Tuolumne River descends through the Sierra Nevada foothills to the floor of the San Joaquin Valley and on to its confluence with the San Joaquin River, which is at an elevation of about 60 feet above sea level. This reach of the river flows through land used primarily for irrigated agriculture. A major tributary, Dry Creek, joins the river from the north in the city of Modesto.

Runoff in the Tuolumne River basin is produced by rainfall and snowmelt. Rainfall runoff occurs primarily in the Sierra foothills and the valley floor between December and March. Runoff from the upper basin is produced by snowmelt and occurs primarily between April and July. Annual runoff in the Tuolumne River basin is highly variable. Average annual "unimpaired" runoff[1] at Don Pedro Reservoir is estimated to be about 1.85 million acre-feet for the period from 1918 to 1991. The maximum estimated value is 3.84 million acre-feet in 1969, and the minimum is 0.39 million acre-feet in 1977 (Beck, 1992).

Stream Flow and Water System Operations

Flow in the Tuolumne River remained unaffected by humans until the 1860s, when water from the lower reaches of the river began to be diverted for agricultural irrigation. In 1871, a private company constructed Wheaton Dam near the site of present-day La Grange Dam. Wheaton Dam was used to divert water into irrigation canals. In 1887, the newly formed Turlock Irrigation District (TID) and Modesto Irrigation District (MID) constructed a new diversion dam, La Grange Dam, to replace Wheaton Dam (TID/MID, 2005).

1 Unimpaired flow at a point on a river is the flow that would have occurred if there were no upstream water diversions or storage reservoirs. For the Tuolumne River, it is roughly equivalent to "natural flow"; that is, the flow that would have occurred prior to Euro-American settlement.

Figure 5.3.1-1b
Tuolumne River Watershed,
Don Pedro Reservoir to San Joaquin River

Early in the 20th century, development of the Tuolumne River accelerated. In 1918, the City and County of San Francisco (CCSF) completed Lake Eleanor, a reservoir on Eleanor Creek. Eleanor Creek is a tributary of Cherry Creek, which is itself a tributary of the Tuolumne River. Hetch Hetchy Reservoir and the original Don Pedro Reservoir, on the main stem of the river, were completed in 1923 (Hetch Hetchy by the CCSF and Don Pedro Reservoir by TID and MID). Hetch Hetchy Reservoir was expanded in 1938. In 1955, the CCSF completed Lake Lloyd on Cherry Creek. In 1971, TID and MID completed the new Don Pedro Reservoir, a much larger reservoir two miles downstream of the site of the original Don Pedro Reservoir (SFPUC, 2005).

Hetch Hetchy Reservoir, Lake Eleanor, and Lake Lloyd are owned by the CCSF and operated by the SFPUC, and Don Pedro Reservoir is owned and operated by TID and MID. The CCSF paid a portion of the construction costs of Don Pedro Reservoir and in return has indirect access to, and control of, a portion of the storage capacity of the reservoir by means of a water banking arrangement with the districts.[2]

Figure 5.3.1-2 is a diagrammatic representation of the natural features of the Tuolumne River showing the water and hydropower facilities that affect flow in the river. The figure also shows the approximate storage capacity of the reservoirs and the electrical generation capacity of the hydropower facilities.

The SFPUC diverts water from Hetch Hetchy Reservoir in the upper Tuolumne River basin and conveys it to the Bay Area in the Hetch Hetchy Aqueduct. The Hetch Hetchy Aqueduct consists of a series of facilities extending from Hetch Hetchy Reservoir to Crystal Springs Reservoir in San Mateo County (see Figure 2.1 in Chapter 2). Water leaves Hetch Hetchy Reservoir in the Canyon Power Tunnel, which delivers water to Kirkwood Powerhouse at Early Intake. Water leaving the powerhouse is either returned to the Tuolumne River or discharged into the Mountain Tunnel. The Mountain Tunnel conveys water to Priest Reservoir and Moccasin Powerhouse. Water discharged from Moccasin Powerhouse is either returned to the Tuolumne River via Moccasin Reservoir and Moccasin Creek or discharged to the Foothill Tunnel for conveyance to the Bay Area. Priest and Moccasin Reservoirs are small reservoirs used to control flow into Moccasin Powerhouse and regulate discharge of water to Moccasin Creek.

The SFPUC diverts an average of 244,000 acre-feet per year (afy) (218 million gallons per day [mgd]) from the Tuolumne River at Hetch Hetchy Reservoir and uses it for municipal water supply to about 2.4 million people in Tuolumne, Alameda, Santa Clara, San Mateo, and San Francisco Counties. Additional water is diverted at Hetch Hetchy Reservoir for hydropower generation at Kirkwood Powerhouse, but is returned to the Tuolumne River below Early Intake. The water diverted by the SFPUC for water supply represents about 32.5 percent of the average annual unimpaired runoff at Hetch Hetchy Reservoir, which is estimated to be 749,607 acre-feet. **Figure 5.3.1-3** shows the historical record of water storage in Hetch Hetchy Reservoir, as reflected in water levels, from 1989 to 2005.

2 The SFPUC does not have direct access to its portion of storage in Don Pedro Reservoir. Instead, the SFPUC diverts water at Hetch Hetchy Reservoir by withholding water that TID and MID are entitled to receive under the Raker Act, thereby reducing the SFPUC's storage in Don Pedro Reservoir.

SFPUC Water System Improvement Program . 203287

Figure 5.3.1-3
Hetch Hetchy Reservoir, Historical Water Levels, 1989 to 2005

The SFPUC uses most of the water impounded in Lake Lloyd to generate electrical power at Holm Powerhouse. Water released from the powerhouse returns to Cherry Creek and is used to satisfy TID's and MID's flow entitlement. Water impounded in Lake Eleanor is conveyed to Lake Lloyd and then to Holm Powerhouse for electric power generation. **Figures 5.3.1-4** and **5.3.1-5** show the historical record of water storage in Lake Lloyd and Lake Eleanor, respectively, as reflected in water levels, from 1989 to 2005.

TID and MID divert water from the Tuolumne River at La Grange Dam. Water is conveyed to users in the two districts' service areas via the Modesto and Turlock Canals. Most of the users of water from the two canals are farmers, but some water is used for municipal supply by the city of Modesto. TID and MID divert an annual average of about 867,000 acre-feet from the Tuolumne River. **Figure 5.3.1-6** shows the historical record of water storage in Don Pedro Reservoir, as reflected in water levels, from 1989 to 2005. Average annual unimpaired runoff at La Grange Dam is estimated to be 1,850,000 acre-feet. Thus, TID and MID currently divert 49.6 percent of the estimated average unimpaired flow of the Tuolumne River at La Grange. Together, the SFPUC, TID, and MID divert and use about 62.8 percent of the estimated average unimpaired flow of the Tuolumne River at La Grange.

Table 5.3.1-1 shows monthly average flows in the Tuolumne River below Hetch Hetchy Reservoir, below La Grange Dam, and at Modesto under current conditions, calculated from stream gaging records. Monthly average flows below Hetch Hetchy Reservoir range from 382 to 2,293 cubic feet per second (cfs) and peak in the late spring and early summer as the snow in the Sierra Nevada melts. Monthly average flows in the Tuolumne River below La Grange range from 243 to 1,884 cfs. Monthly average flows in the river at Modesto range from 431 to 2,236 cfs. Monthly average flows below La Grange and at Modesto peak in the late winter and early spring as a result of rainfall runoff and releases from Don Pedro Reservoir. Water may be released from Don Pedro Reservoir in the late winter and spring to provide capacity in the reservoir for floodwaters and snowmelt.

Reservoirs and diversions have altered the magnitude and seasonal patterns of flow in the Tuolumne River. Prior to construction of the reservoirs, the river experienced large and sustained flows in the spring as snow melted at higher elevations in the watershed. Now a portion of the spring flows is stored in the reservoirs for later municipal or agricultural use. Peak flows below reservoirs, particularly the large Don Pedro Reservoir, are greatly reduced from their historical value. The two-year return-period flood flow in the Tuolumne River downstream of La Grange Dam is 4,100 cfs; its predevelopment value was 21,000 cfs. The 20-year return-period flood flow on the Tuolumne River downstream of La Grange Dam is 11,000 cfs; its predevelopment value was 59,000 cfs (FERC, 1996).

As discussed below, various regulations and agreements require that reservoir operators maintain minimum flows in the Tuolumne River and its tributaries downstream of dams. During the late summer and early fall, the required minimum flows may be greater than those that occurred prior to development.

Minimum Releases to Support Fisheries

Dams and reservoirs alter the pattern of flow in the streams they impound. Depending on their size and type of use, these facilities can completely eliminate flow in the streams below the dams. The owners of some dams and reservoirs, including the SFPUC, MID, and TID, have agreed to make minimum releases to stream channels below dams to support fish and aquatic life.

Below Hetch Hetchy Reservoir. In accordance with an agreement with the U.S. Department of the Interior, the SFPUC releases a minimum stream flow from Hetch Hetchy Reservoir.[3] Minimum flow requirements depend on the hydrologic year type and are shown in **Table 5.3.1-2**. Releases in normal, dry, and critical years total at least 59,235, 50,019, and 35,215 acre-feet. The SFPUC must release an additional 64 cfs into the river below Hetch Hetchy Reservoir when the diversion through Canyon Tunnel exceeds 920 cfs. Finally, the agreement provides for an additional supplemental release, depending on hydrologic year type, subject to the completion of a fish habitat study and the determination of appropriate timing for the release. Once made, releases cannot be diverted below O'Shaughnessy Dam (i.e., at Early Intake); they flow down the Tuolumne River, are supplemented by tributary flow and releases at Kirkwood Powerhouse, and enter Don Pedro Reservoir.

3 Stipulation for the Amendment of Rights-of-Way for Canyon Power Project Approved by Secretary of the Interior on May 26, 1961, to fulfill the conditions set forth in Provision 6 of said Amended Permit, dated January 31, 1985, *as modified by*, Modification for Kirkwood Powerhouse Unit No.3 to Stipulation for Amendment of Rights-of-Way for Canyon Power Project Approved by Secretary of the Interior on May 26, 1961, to fulfill the conditions set forth in Provision 6 of said Amended Permit, as dated March 10, 1987.

December	50 cfs		40 cfs		35 cfs

[a] Precipitation indicators in inches are cumulative, measured at Hetch Hetchy Reservoir, starting October 1. For example, if October 1 through December 31 precipitation is greater than or equal to 8.80 inches, refer to year type A schedule for January.
[b] Runoff indicators in acre-feet are the calculated inflow into Hetch Hetchy Reservoir commencing on the previous October 1 of each year.

SOURCE: See Footnote 3, page 5.3.1-12.

Below Lake Lloyd. The minimum required stream flow below Lake Lloyd is 5 cfs from October through June and 15 cfs from July through September.

Below Lake Eleanor. In years when no pumping occurs between Lake Eleanor and Lake Lloyd, the minimum required stream flow below Lake Eleanor is 5 cfs from October through June and 15.5 cfs from July through September. In years when pumping occurs, the minimum required stream flow is 5 cfs from November through February, 10 cfs from March 1 through April 14, 20 cfs from April 15 through September 15, and 10 cfs from September 16 through October.

Below Don Pedro Reservoir/La Grange Dam. TID and MID are required to maintain minimum stream flows in the Tuolumne River at La Grange Bridge below Don Pedro Reservoir and La Grange Dam as a condition of their license to operate the Don Pedro Project (issued by the Federal Energy Regulatory Commission, or FERC). Minimum required releases are 100 to 300 cfs from October 1 to 15 and 150 to 300 cfs from October 16 to May 31, depending on hydrologic conditions. From June 1 to September 30, the minimum required releases range from 50 to 250 cfs depending on hydrologic conditions. Additional pulse releases must be made to assist upstream migrating adult Chinook salmon and downstream migrating juveniles. Minimum annual releases from La Grange Dam, including the pulse releases, vary from at least 94,000 acre-feet in critically dry years to approximately 300,000 acre-feet in above-normal and wet years. A detailed minimum stream flow schedule is shown in **Table 5.3.1-3**.

[Additional discussion on flows in the Tuolumne River was prepared in response to comments on the Draft PEIR. Please refer to Section 14.6, Master Response on Upper Tuolumne River Issues, and Section 14.7, Master Response on Lower Tuolumne River Issues (Vol. 7, Chapter 14).]

San Joaquin River

General Description

The San Joaquin River rises in the Sierra Nevada west of Mammoth Lakes and drains an area of approximately 13,500 square miles. The river flows southwestward, through the Sierra foothills, to the floor of the San Joaquin Valley near the city of Fresno. After reaching the valley floor, it turns and flows northwest for about 100 miles to the Sacramento–San Joaquin Delta. Several major tributaries join the San Joaquin River from the east, including the Fresno, Chowchilla, Merced, Tuolumne, and Stanislaus Rivers. The San Joaquin River watershed is shown in **Figure 5.3.1-7**.

Stream Flow and Water System Operations

Flow in the San Joaquin River is controlled by releases from Millerton Lake on the main stem of the river and from several reservoirs on the San Joaquin's tributaries. Millerton Lake is part of the federal Central Valley Project. It is impounded by Friant Dam, which was completed in 1942. The Central Valley Project's Friant-Kern and Madera Canals convey most of the runoff from the San Joaquin River drainage above Millerton Reservoir to agricultural and urban water users. The U.S. Bureau of Reclamation (USBR) releases enough water at Friant Dam to maintain a flow of 5 cfs past Gravelly Ford, which is 35 miles below the dam, to meet downstream riparian water rights. The reach of the river between Gravelly Ford and Mendota is essentially dry, except when flood releases are being made. In the future, flow will be restored in the San Joaquin River between Friant Dam and the confluence with the Merced River in accordance with a recent settlement agreement between the USBR and an environmental advocacy organization, the Natural Resources Defense Council.

SFPUC Water System Improvement Program . 203287

Figure 5.3.1-7
San Joaquin River Watershed

The San Joaquin River gains water as it flows toward the Sacramento–San Joaquin Delta from agricultural irrigation return flows and tributaries. Flow in the San Joaquin River at Newman upstream of the river's confluence with the Tuolumne River averaged 1,789 cfs based on stream flow gaging records for the period between 1942 and 2004. Flow in the San Joaquin River at Vernalis, upstream of the Delta and downstream of the Tuolumne River confluence, averaged 4,328 cfs based on stream flow gaging records for the period between 1942 and 2004. Mean monthly stream flows at Newman and Vernalis are shown in Table 5.3.1-1. The highest flows occur in February, March, April, and May and the lowest in August and September. A substantial proportion of the increase in San Joaquin River flow between Newman and Vernalis is contributed by the Tuolumne River, which has an average annual flow of 1,265 cfs as measured at Modesto.

Sacramento–San Joaquin Delta

General Description

The Sacramento–San Joaquin Delta is a 600-square-mile area of channels and islands at the confluence of the Sacramento and San Joaquin Rivers. Freshwater draining from a 41,300-square-mile watershed enters the Delta from the Sacramento and San Joaquin Rivers and several smaller rivers. Some of the freshwater is diverted from the Delta channels for municipal and agricultural purposes. The remainder flows through the Delta to the San Francisco Bay Estuary.

The Delta is a tidal region. Every 12.4 hours, the tides cause water to move in and out of the Delta. Most of the time, tides cause a five- to eight-mile back and forth movement of water in the western part of the Delta. The average tidal flow into the Delta on the flood tide and out of the Delta on the ebb tide is 170,000 cfs (Miller, 1993). The movement of freshwater through the Delta is superimposed on the tidal flows. Typical freshwater flows are much smaller than tidal flows, usually in the range of 5 to 15 percent of the tidal flows.

Stream Flow and Water System Operations

On average, about 21 million acre-feet of water reaches the Delta annually, but actual inflow varies widely from year to year and within the year. In 1977, a year of extraordinary drought, Delta inflow totaled 5.9 million acre-feet. In 1983, an exceptionally wet year, Delta inflow was about 70 million acre-feet. On a seasonal basis, average monthly flow into the Delta varies by more than a factor of 10 between the highest month in the winter or spring and the lowest month in the fall (SWRCB, 1997).

The Sacramento River, which enters the Delta from the north, contributes an average of 77 percent of the inflow to the Delta. The San Joaquin River, which enters the Delta from the south, contributes about 15 percent of the inflow. The remainder is contributed by the Mokelumne, Cosumnes, and Calaveras Rivers, which enter the Delta from the east (DWR, 1998).

Most of the Delta islands are used to grow crops. Delta farmers divert water directly from the Delta channels to irrigate their land. A portion of the diverted water is returned to the Delta channels as agricultural return. The average annual net diversion of water for irrigation within the Delta is estimated to be 960,000 acre-feet (San Francisco Estuarine Project, 1992).

California's two largest engineered water systems, the Central Valley Project and the State Water Project, also divert water from the Delta. The Central Valley Project diverts water from Old River in the south Delta at the Jones Pumping Plant (formerly Tracy Pumping Plant) and exports it to Central Valley Project contractors via the Delta-Mendota Canal. Contra Costa Water District, a Central Valley Project contractor, diverts its water from Old River and Rock Slough in the south Delta and Mallard Slough in the west Delta. The State Water Project diverts water from Old River at the Banks Pumping Plant and exports it to customers via the California Aqueduct, the South Bay Aqueduct, and the Central Coast Aqueduct. The State Water Project diverts smaller amounts of water from Barker Slough in the north Delta to serve customers in Napa and Solano Counties. Between 1995 and 2004, the State Water Project diverted an average of 2.4 million afy from the Delta. The Central Valley Project diverts an average of 1.7 million afy from the Delta.

Delta freshwater outflow, commonly referred to simply as Delta outflow, is roughly equal to Delta inflow minus net water diversions in the Delta for use in the Delta and diversions for export. Like Delta inflow, Delta outflow varies widely from month to month and from year to year. Between 1984 and 2004, Delta outflow averaged 16.9 million acre-feet. The greatest annual Delta outflow in the period was 43.5 million acre-feet in 1998. The smallest Delta outflow in the period was 3.9 million acre-feet in 1990 (DWR, 2007). Average monthly Delta outflow for the same period is shown in Table 5.3.1-1. The largest Delta outflow typically occurs in January, February, and March, when surface runoff is high and demand for irrigation water is low. The smallest Delta outflow typically occurs in July, August, September, and October.

The diversion of water by the Central Valley Project, State Water Project, and others in the south Delta as well as upstream depletion of San Joaquin River flows affect the pattern of flow in the Delta channels. Historically, net flow in the Delta channels was toward the San Francisco Bay Estuary. Now, because freshwater inflow to the south Delta from the San Joaquin River is small relative to the diversions at the Banks and Tracy Pumping Plants, net flow in many south Delta channels reverses during summer and fall. Flow in the lower San Joaquin River and the south Delta channels is directed upstream toward the pumping plants rather than downstream toward the estuary (Miller, 1993).

The diminution of flow and flow reversals in the lower San Joaquin River as a result of water diversions by the State Water Project and Central Valley Project are harmful to migrating salmon. In 1990, the California Department of Water Resources (DWR) began installing temporary barriers in several waterways in the south Delta to improve conditions for migrating salmon. Temporary barriers have been placed across the Grant Line Canal, Middle River, and Old River. The purpose of the barriers is to control water levels for irrigators, improve water quality, and direct more water down the lower San Joaquin River for downstream migrating juvenile salmon in the spring and upstream migrating adults in the fall. It is expected that permanent operable barriers will replace the temporary barriers in the future years.

Flow Objectives for the Sacramento–San Joaquin Delta

As noted above, the Sacramento–San Joaquin Delta lies at the heart of California's natural and manmade water systems. The Delta's physical complexity and competing interests for water make management of the Delta difficult. Since water quality objectives alone are insufficient to protect the Delta, regulators have also established objectives for flow. These objectives have been the subject of much controversy and have frequently been revised. Some issues remain unresolved, including the degree to which parties that divert water upstream of the Delta are responsible for meeting Delta objectives. Resolution of these issues could affect all upstream diverters, including the SFPUC, TID, and MID.

The State Water Resources Control Board (SWRCB) is the agency responsible both for setting water quality objectives for the Delta and for issuing and administering water-rights permits in California. The degree to which parties that divert water upstream of the Delta are responsible for maintenance of Delta water quality and flow objectives may ultimately be resolved through a water-rights proceeding.

Water-Rights Decisions

In 1997, the SWRCB began examining long-term alternatives that would enable compliance with the flow objectives for the Delta. Water rights proceedings to determine responsibility for meeting the flow objectives began in 1998 (see Section 5.3.3 for more detail). The water-rights proceedings were to be conducted in eight phases. The SWRCB's policy in the water-rights proceedings was to encourage water agencies to resolve among themselves the responsibilities for meeting the objectives in the 1995 Water Quality Control Plan (WQCP) and to bring their proposals to the SWRCB for approval. In 1999, the SWRCB published a final EIR on the WQCP, which presented the environmental effects of a range of alternatives but did not identify a preferred alternative (SWRCB, 1999).

In late 1999, following Phases 1 through 7 of the Bay-Delta water rights proceedings, the SWRCB issued Water Rights Decision 1641. The SWRCB revised D-1641 in early 2000 by issuing Order WR 2000-02, and again in 2001 by issuing Order WR 2001-05. D-1641 and Order WR 2001-05 contain the water-right requirements to implement the flow objectives for the Delta. D-1641 includes both long-term and temporary requirements that will remain in effect for up to 35 years. Order WR 2001-05 called for partial implementation of the requirements.

In D-1641 and Order WR 2001-05, the SWRCB assigned responsibilities to water-rights holders for specified periods, including the USBR and DWR, in certain watersheds tributary to the Delta. The SWRCB accepted with modifications the proposals made by some water agencies and groups of water agencies with respect to their responsibilities for meeting flow objectives in the Delta. The responsibilities of various parties, including water users in the Sacramento, San Joaquin, Mokelumne, Calaveras, and Cosumnes River watersheds, were defined in D-1641. These responsibilities require that the water users in these watersheds contribute specified amounts of water to protect water quality or implement agreements (including the San Joaquin River Agreement, as described below), and that the USBR and/or DWR ensure the objectives are met in the Delta.

Phase 8 of the water-rights proceedings would have ultimately determined the responsibilities of the Sacramento Valley water-rights holders for meeting the objectives in the 1995 WQCP. The SWRCB's Order WR 2001-05 stayed Phase 8 of the proceedings and required the USBR and DWR to continue to meet certain objectives in the 1995 WQCP until adoption of another decision assigning responsibility for meeting the objectives. During 2002, the USBR, DWR, Sacramento Valley upstream water users, and certain downstream users negotiated a settlement in lieu of continuing Phase 8 of the water-rights proceedings. Beginning in December 2002, the parties to the negotiations executed the Sacramento Valley Water Management Agreement, or Short Term Settlement Agreement. The agreement establishes a planning process for actions that would help meet objectives in the Delta.

Vernalis Adaptive Management Program

Shortly after the Bay-Delta WQCP was published, an association of users of San Joaquin River water filed suit against the SWRCB, challenging the flow objectives in the WQCP. The association claimed that the flow objectives were based on an inadequate understanding of the relationship between flow and salmon survival. In an effort to settle the issue out of court, the San Joaquin River interests collaborated with other water users, environmental groups, and government agencies to develop an alternative that would provide an equivalent level of fishery protection to that provided by the Bay-Delta WQCP. The result was the San Joaquin River Agreement, of which the Vernalis Adaptive Management Program (VAMP) was a key component (San Joaquin River Group Authority, 2007).

The VAMP is an experimental management program designed to protect juvenile Chinook salmon migrating from the San Joaquin River through the Delta. The San Joaquin River Agreement, including the VAMP, was submitted to the SWRCB as a proposal. It was accepted by the SWRCB and made a part of D-1641. In February 2006, however, the Third Appellate District overturned that part of D-1641 and ordered to SWRCB to commence further proceedings to either assign responsibility for meeting the Vernalis pulse-flow objectives in full or to modify those objectives. In December 2006, the SWRCB adopted amendments to the 1995 Bay-Delta WQCP, including allowing for staged implementation through the San Joaquin River Agreement until December 2011.

The VAMP provides for a 31-day pulse flow in the San Joaquin River at Vernalis, together with a reduction in State Water Project and Central Valley Project exports from the south Delta. The pulse usually occurs from mid-April to mid-May, but its timing may be adjusted based on hydrology and fishery conditions. The effects of different flow rates in the lower San Joaquin River and different State Water Project and Central Valley Project export rates on juvenile and smolt Chinook salmon survival are being studied as part of the VAMP. The VAMP is scheduled to end in 2011.

5.3.1.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to stream flow and reservoir water levels, but generally considers that implementation of the proposed program would have a significant impact if it were to:

- Substantially alter stream flows such that they are outside of the range of pre-project conditions and result in adverse hydrologic effects

The stream flow significance threshold is based on the fact that natural stream flows and controlled reservoir levels have varied substantially in the past 50 years, and such variations are a part of the existing baseline. Therefore, variations substantially outside of these past levels due to implementation of the proposed program that would result in an adverse hydrologic effect (such as flooding, dewatering, drainage alteration, or erosion, among others) would be considered a significant direct impact.

This PEIR also considers indirect impacts due to changes in stream flows and reservoir levels. However, for organizational purposes, the indirect impacts are not described in this section of this chapter, but rather in the sections describing the resources that would be indirectly affected by changes in flows and reservoir levels. These include geomorphology, surface water quality, surface water supplies, groundwater, fisheries, terrestrial biological resources, and recreational and visual resources. It should be noted that there might be cases where significant indirect impacts could result from less-than-significant direct flow impacts.

Approach to Analysis

Changes in flow in rivers and streams and changes in reservoir storage and water levels attributable to the WSIP were estimated using the Hetch Hetchy/Local Simulation Model (HH/LSM). An overview of the model is presented in Section 5.1. The HH/LSM simulates water deliveries, reservoir storage, and releases to rivers under different conditions using hydrologic data from the 82-year period 1920 to 2002. Detailed information on the model and the assumptions that underlie it is provided in Appendix H.

The following section addresses the impacts of the WSIP on water levels in Hetchy Hetchy and Don Pedro Reservoirs and flow along the Tuolumne River. WSIP impacts on flow along the San Joaquin River and Sacramento-San Joaquin Delta are also described. In applying the above significance criteria, very infrequent changes in reservoir levels and/or flow are not generally considered to generate a significant effect.

Impact Summary

Table 5.3.1-4 presents a summary of the impacts on stream flow and reservoir levels in the Tuolumne River system and downstream water bodies that could result from implementation of the proposed water supply and system operations.

TABLE 5.3.1-4
SUMMARY OF IMPACTS – STREAM FLOW IN THE TUOLUMNE RIVER SYSTEM AND DOWNSTREAM WATERBODIES

Impact	Significance Determination
Impact 5.3.1-1: Effects on flow along the Tuolumne River below O'Shaughnessy Dam	LS
Impact 5.3.1-2: Effects on flow along Cherry Creek below Cherry Dam	LS
Impact 5.3.1-3: Effects on flow along Eleanor Creek below Eleanor Dam	LS
Impact 5.3.1-4: Effects on flow along the Tuolumne River below La Grange Dam	LS
Impact 5.3.1-5: Effects on flow along the San Joaquin River and the Sacramento–San Joaquin Delta	LS

LS = Less than Significant impact, no mitigation required

Impact Discussion

Impact 5.3.1-1: Effects on flow along the Tuolumne River below O'Shaughnessy Dam.

Reservoir Operations

Hetch Hetchy Reservoir stores water from the upper reaches of the Tuolumne River within Yosemite National Park. During the snowmelt season the reservoir is filled. During the rest of the year, when flow into the reservoir is reduced, the reservoir is drawn down to meet water demand in the service areas of the SFPUC and its customers, instream flow release requirements, and, if necessary, TID's and MID's Raker Act entitlements. Most years, the SFPUC is able to completely refill the reservoir during the snowmelt season. One of the SFPUC's operating goals is to fill the reservoir by the end of June. The WSIP would not change this or any of the SFPUC's other operational goals for Hetch Hetchy Reservoir, but it would affect water levels in the reservoir and the magnitude and timing of releases to the Tuolumne River.

Water Storage and Water Levels in Hetch Hetchy Reservoir

The WSIP would reduce average monthly storage in Hetch Hetchy Reservoir compared to the existing condition. **Figure 5.3.1-8** shows average monthly storage and the range of monthly storage in the reservoir with the WSIP and under existing conditions. The decrease in storage is primarily attributable to increased water demand in the service areas of the SFPUC and its customers. As demand increases, so would diversions of water from Hetch Hetchy Reservoir to supply the SFPUC's customers. Because of the decrease in storage in Hetch Hetchy Reservoir with the WSIP, monthly average water levels would fall by 1 to 10 feet compared to the existing condition.

Figure 5.3.1-9 shows modeled chronological storage in Hetch Hetchy Reservoir and releases to the Tuolumne River using hydrology from the 82-year period 1920 to 2002. The figure compares the WSIP 2030 condition to the existing condition. It shows that, under the existing condition, the SFPUC normally fills Hetch Hetchy Reservoir in the spring and early summer and draws from

Figure 5.3.1-9
Hetch Hetchy Storage and Releases to the Tuolumne River

storage to meet water demand in the summer, fall, and winter. In the early spring, the SFPUC may additionally draw water from the reservoir for power generation, provided it is confident that the coming snowmelt will fill the reservoir.

In the future with the WSIP, the SFPUC would continue to fill the reservoir in the spring and early summer and draw it down during the rest of the year, but the magnitude of the drawdown would be greater than under the existing condition. The reductions in storage and the lowering of water levels attributable to the WSIP would be the greatest in dry years. In average dry years, Hetch Hetchy Reservoir would be drawn down 18 feet more in March (just before refilling begins) than under the existing condition. The WSIP would lower water levels in Hetch Hetchy Reservoir in some months of severe droughts by up to 64 feet compared to the existing condition.

Beginning in July, when the reservoir is usually full, the rate of drawdown with the WSIP would be greater than under the existing condition. As shown in Figure 5.3.1-8, the difference in storage between the two scenarios would increase steadily through the summer, fall, and winter in most years. The pattern would be altered every five years when, with the WSIP, the SFPUC would take a portion of the conveyance system between Hetch Hetchy Reservoir and the Bay Area out of service so it can be maintained. During maintenance, water demand in the Bay Area would be met from local reservoirs, and drawdown of Hetch Hetchy Reservoir would cease for several weeks. On completion of maintenance, drawdown of Hetch Hetchy Reservoir would recommence at an accelerated rate as water is moved to storage in the local reservoirs. The WSIP would not alter water levels in Hetch Hetchy Reservoir such that they would be substantially outside the range experienced under the existing condition. Under the existing condition and in almost all years, the reservoir fills to its maximum capacity of 360,400 acre-feet in the spring and early summer and then is drawn down through the rest of the year. Maximum storage corresponds with a water surface level of 3,806 feet above mean sea level. Only rarely does storage in the reservoir decline below 150,000 acre-feet. A storage capacity of 150,000 acre-feet corresponds with a water surface level of 3,684 feet above mean sea level. Thus, under the existing condition and almost all of the time, the water level fluctuates between 3,806 feet and 3,684 feet, a range of 122 feet. With the WSIP, the water level in Hetch Hetchy Reservoir would fluctuate within the same range almost all of the time.

Occasionally in extended droughts, storage in Hetch Hetchy Reservoir would be drawn down severely. Under the existing condition, the water level in the reservoir would be drawn down to 3,573 feet, or 233 feet below the maximum, once in the 82-year hydrologic record. With the WSIP, the water level would be drawn down to 3,562 feet, or 244 feet below the maximum, once in the hydrologic record. Thus, water levels with the WSIP would remain substantially within the same range as occurs under the existing condition, although very infrequently water levels would decline slightly below the lower end of the range.

Flow in the Tuolumne River Between O'Shaugnessy Dam and Early Intake

Figure 5.3.1-9 shows the frequency and magnitude of modeled chronological releases from Hetch Hetchy Reservoir to the Tuolumne River under the existing condition and with the WSIP. Under the existing condition, releases to the Tuolumne River are at least equal to the required releases to support fisheries shown in Table 5.3.1-2. In many years, the volume of spring snowmelt from the watershed upstream of Hetch Hetchy Reservoir exceeds the capacity of the reservoir and the SFPUC's ability to divert water through Canyon Tunnel. Water that cannot be stored or diverted through Canyon Tunnel is released to the Tuolumne River. Occasionally, during the winter, the SFPUC will release excess inflow produced by warm storms to the Tuolumne River.

In the future with the WSIP, the SFPUC would draw the reservoir down farther in most years than it would under the existing condition. Consequently, with the WSIP, the SFPUC would capture a greater proportion of spring runoff to refill the reservoir. As a result, the volume of water released to the Tuolumne River would be reduced compared to the existing condition.

This circumstance is illustrated by the hydrology that occurred in 1991 and 1992. As shown in Figure 5.3.1-9, by the end of the 1991 conditions, Hetch Hetchy Reservoir would be drawn down to a lower level after WSIP implementation than it would under the existing condition. To refill the reservoir in the fairly dry spring of 1992, the SFPUC would have to capture a larger portion of the spring runoff, with the consequence that releases from the reservoir and flow in the Tuolumne River below the reservoir would be reduced, as indicated in the figure.

Table 5.3.1-5 shows average monthly flows in the Tuolumne River immediately below Hetch Hetchy Reservoir in different hydrologic year types for the existing condition and after WSIP implementation. The percentage change in average monthly flow attributable to the WSIP is also shown in the table. The WSIP would have little or no effect on average monthly flow in most summer, fall, and winter months in all hydrologic year types. In most summer, fall, and winter months, only the required fishery release would be made under the existing condition and with the WSIP. With the WSIP, the number of months in which only the required fishery release would be made would increase slightly. Under the existing condition, the model indicates that the minimum release would be made 85.1 percent of the time (837 months in the 984-month hydrologic record); with the WSIP the minimum release would be made 85.7 percent of the time (843 months in the 984-month hydrologic record).

The WSIP would result in reductions in average monthly flow of up to 30 percent in April, May, and June when the SFPUC fills Hetch Hetchy Reservoir with snowmelt. The greatest percentage reduction in flow would occur in normal, below-normal, and dry years because, in these year types, a greater proportion of the snowmelt currently released to the river would be needed to fill the reservoir. For example, in May of an average dry year, flow in the Tuolumne River below O'Shaughnessy Dam would be 224 cfs under the existing condition; with the WSIP it would be 157 cfs, a reduction of 30 percent.

In individual months in the 82-year hydrologic simulation, the absolute and percentage changes in flow in the Tuolumne River below O'Shaughnessy Dam attributable to the WSIP vary widely. The chronological analysis shows that the maximum percentage reduction in average monthly flow would be 80 to 90 percent, occurring three times in the 82-year hydrologic simulation. For example, under the existing condition, May 1992 flow would be 520 cfs; with the WSIP it would be 50 cfs. Reductions in average monthly flow of 30 percent or more would occur in some months of 20 springs in the 82-year simulation, or about once in every four springs on average.

SOURCE: SFPUC, HH/LSM (see Appendix H).

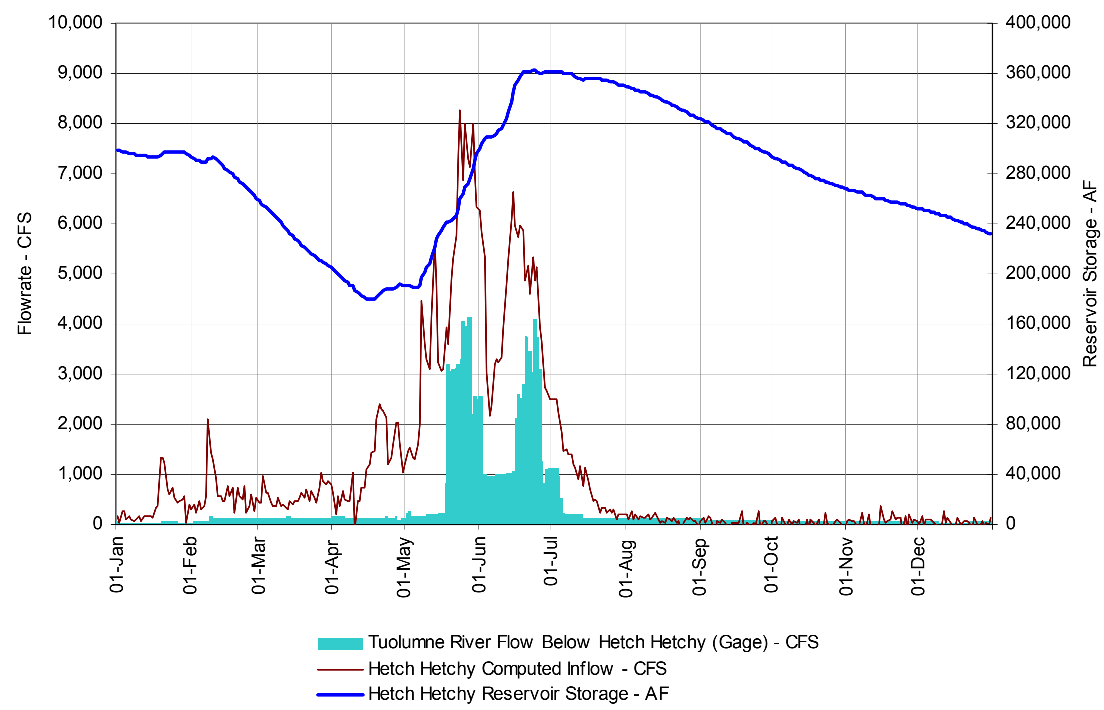
The results presented above are described in terms of average monthly flows because the HH/LSM is a monthly time-step model. The SFPUC's actual operational decisions may occur in smaller time increments, perhaps daily or weekly, depending on meteorological and operational circumstances. For example, if inflow to Hetch Hetchy Reservoir increases rapidly, operators may decide to adjust the rate at which water is routed to Canyon Tunnel or released to the river several times within a month. These within-month operational changes cannot be simulated with the HH/LSM, nor can the model be used to estimate the effects of the WSIP on peak flows in the river, because the peaks may only last for a few hours or days.

Insight into the effects of the WSIP on peak flows below O'Shaughnessy Dam can be obtained by examination of operational data. **Figure 5.3.1-10** shows actual data for 1999, an above-normal year; the greatest effects on peak flows would occur in wet and above-normal years. The figure shows storage in Hetch Hetchy Reservoir falling in the first four months of the year because the rate of withdrawal from the reservoir exceeds the rate of inflow into the reservoir. In April, inflow into the reservoir increases and continues to do so through May. In June, inflow into the reservoir decreases from its peak but remains considerable. Storage in the reservoir increases from its minimum value of about 190,000 acre-feet in mid-April to its maximum value of 360,000 acre-feet in mid-June. The SFPUC reacted to increasing reservoir inflow and diminishing reservoir storage around the middle of May by increasing releases to the Tuolumne River. Measured flow in the Tuolumne River below O'Shaughnessy Dam shows a number of step increases and decreases in flow during May and June lasting several days, as operators balanced reservoir inflow, gains in storage, and releases to the river in response to changing conditions.

If the WSIP had been in place in 1999, and water demand was at 2030 levels, storage in mid-April in Hetch Hetchy Reservoir would have been about 175,000 acre-feet. With the WSIP, operators would need to capture 185,000 acre-feet of runoff to fill the reservoir. Under the existing condition, the operators had to capture 160,000 acre-feet. Needing to capture a higher proportion of runoff with the WSIP than under the existing condition, operators would likely delay releases of water to the Tuolumne River by two to three days. After the initial delay, the releases to the river with the WSIP would follow the same pattern as under the existing condition and would be of a similar magnitude.

The pattern and magnitude of releases from Hetch Hetchy Reservoir to the Tuolumne River with the WSIP in any particular year would depend on meteorological and operational circumstances, as they do under the existing condition. Under the existing condition, there would be no releases from the reservoir to the river in excess of the minimum required release in 15 years of the 82-year hydrologic record. With the WSIP, there would be no releases above the minimum required in 18 years of the 82-year hydrologic record. In years when a release above the minimum required is made, the WSIP would delay the release of water and reduce the total volume of releases to the river in the snowmelt period compared to the existing condition. The WSIP would delay the release of water in excess of minimum requirements by an average of one to two days and could delay the release by up to eight days.[4] The infrequent large peak flows (greater than

[4] The estimates of delay in spring releases are based on the assumption that operators would release water from Hetch Hetchy Reservoir at a rate of 3,000 cfs. A review of past practice indicates that this springtime release rate is typical. If the release rate were to be reduced, as might happen in a dry year, the delay would be extended.



SFPUC Water System Improvement Program ▪ 203287

Figure 5.3.1-10
Hetch Hetchy Reservoir Storage and Inflow, Calendar Year 1999

5,000 cfs) in the river below O'Shaughnessy Dam produced by rapidly melting abundant snowpack would not be affected by the WSIP. Peak flows in years when runoff is less (dry years) might be reduced by the WSIP, depending on decisions made by reservoir operators.

Impact Conclusions

The WSIP would not alter stream flow in the Tuolumne River below O'Shaughnessy Dam such that it would be substantially outside the range experienced under the existing condition, nor would the flow alterations result in adverse hydrologic effects or be sufficient to change the character of the river. Large, infrequent peak flows under the existing condition and with the WSIP would be similar in magnitude. Minimum flows are the subject of an agreement with the U.S. Department of the Interior and would be the same with the WSIP as under the existing condition. The Department of the Interior could increase the minimum flows in the future based on the fish habitat study referred to above. Overall, the effects of the WSIP on flow along the Tuolumne River below O'Shaughnessy Dam would be *less than significant*, and no mitigation measures would be required.

[Additional discussion on impacts on flow in the upper Tuolumne River was prepared in response to comments on the Draft PEIR. Please refer to Section 14.6, Master Response on Upper Tuolumne River Issues (Vol. 7, Chapter 14).]

Impact 5.3.1-2: Effects on flow along Cherry Creek below Cherry Dam.

Reservoir Operations

Lake Lloyd stores water from the upper reaches of Cherry Creek. During the snowmelt season the reservoir is filled. During the rest of the year, when flow into the lake is reduced, the reservoir is drawn down to generate hydroelectric power at the Holm Powerhouse. The releases, which are sized and timed for power generation purposes, also provide opportunities for river rafting and contribute to the releases that the SFPUC must make to satisfy TID's and MID's flow entitlements. Most years, the SFPUC is able to completely refill the lake during the snowmelt season. The WSIP would not change the SFPUC's operational goals for Lake Lloyd, and it would have little or no effect on water levels in the lake and the magnitude and timing of releases to Cherry Creek.

Water Storage and Water Levels in Lake Lloyd

The WSIP would not alter water levels in Lake Lloyd such that they would be substantially outside the range experienced under the existing condition. The WSIP would reduce year-round average monthly storage in Lake Lloyd by about 1,000 acre-feet and average monthly water levels by about 1 foot. Most of the time, storage in Lake Lloyd would be the same with the WSIP as under the existing condition. Infrequent reductions in storage attributable to the WSIP would occur at the end of dry periods, similar to the period that occurred between 1987 and 1992. At the end of dry periods, the SFPUC might release additional water from Lake Lloyd to offset the WSIP-induced reduction in releases from Hetch Hetchy Reservoir. The releases would be needed to satisfy TID's and MID's flow entitlements.

Flow in Cherry Creek

Releases from Lake Lloyd with the WSIP and under the existing condition would be the same and would be at least equal to the fishery release schedule. Thus, the WSIP would have no effect on flow in Cherry Creek.

Impact Conclusions

The WSIP would not alter releases from Lake Lloyd to Cherry Creek. Adverse impacts on flow in Cherry Creek would be *less than significant*, and no mitigation measures would be required.

Impact 5.3.1-3: Effects on flow along Eleanor Creek below Eleanor Dam.

Reservoir Operations

Lake Eleanor stores water from the upper reaches of Eleanor Creek; it fills in the winter and spring of each year and is drawn down in the summer as water is transferred to the lake. The WSIP would not change the SFPUC's operational goals for Lake Eleanor, and it would have little effect on water levels in the lake and the magnitude and timing of releases to Eleanor Creek.

Water Storage and Water Levels in Lake Eleanor

The WSIP would have essentially no effect on monthly storage or water levels in Lake Eleanor compared to the existing condition. The only change in modeled chronological storage using hydrology from the period 1920 to 2002 occurs during the last year of the 1987–1992 drought. Under 2002 conditions with the WSIP, additional water would be transferred from Lake Eleanor to supplement storage in Lake Lloyd. Such a transfer would occur very infrequently. The WSIP would not alter water levels in Lake Eleanor such that they would be substantially outside the range experienced under the existing condition.

Flow in Eleanor Creek below Eleanor Dam

Releases from Lake Eleanor with the WSIP and under the existing condition would be the same and would be at least equal to the fishery release schedule. Thus, the WSIP would have no effect on flow in Eleanor Creek.

Impact Conclusions

The WSIP would not alter releases to Eleanor Creek. Adverse impacts on flow in Eleanor Creek would be *less than significant*, and no mitigation measures would be required.

Impact 5.3.1-4: Effects on flow along the Tuolumne River below La Grange Dam.

Reservoir Operations

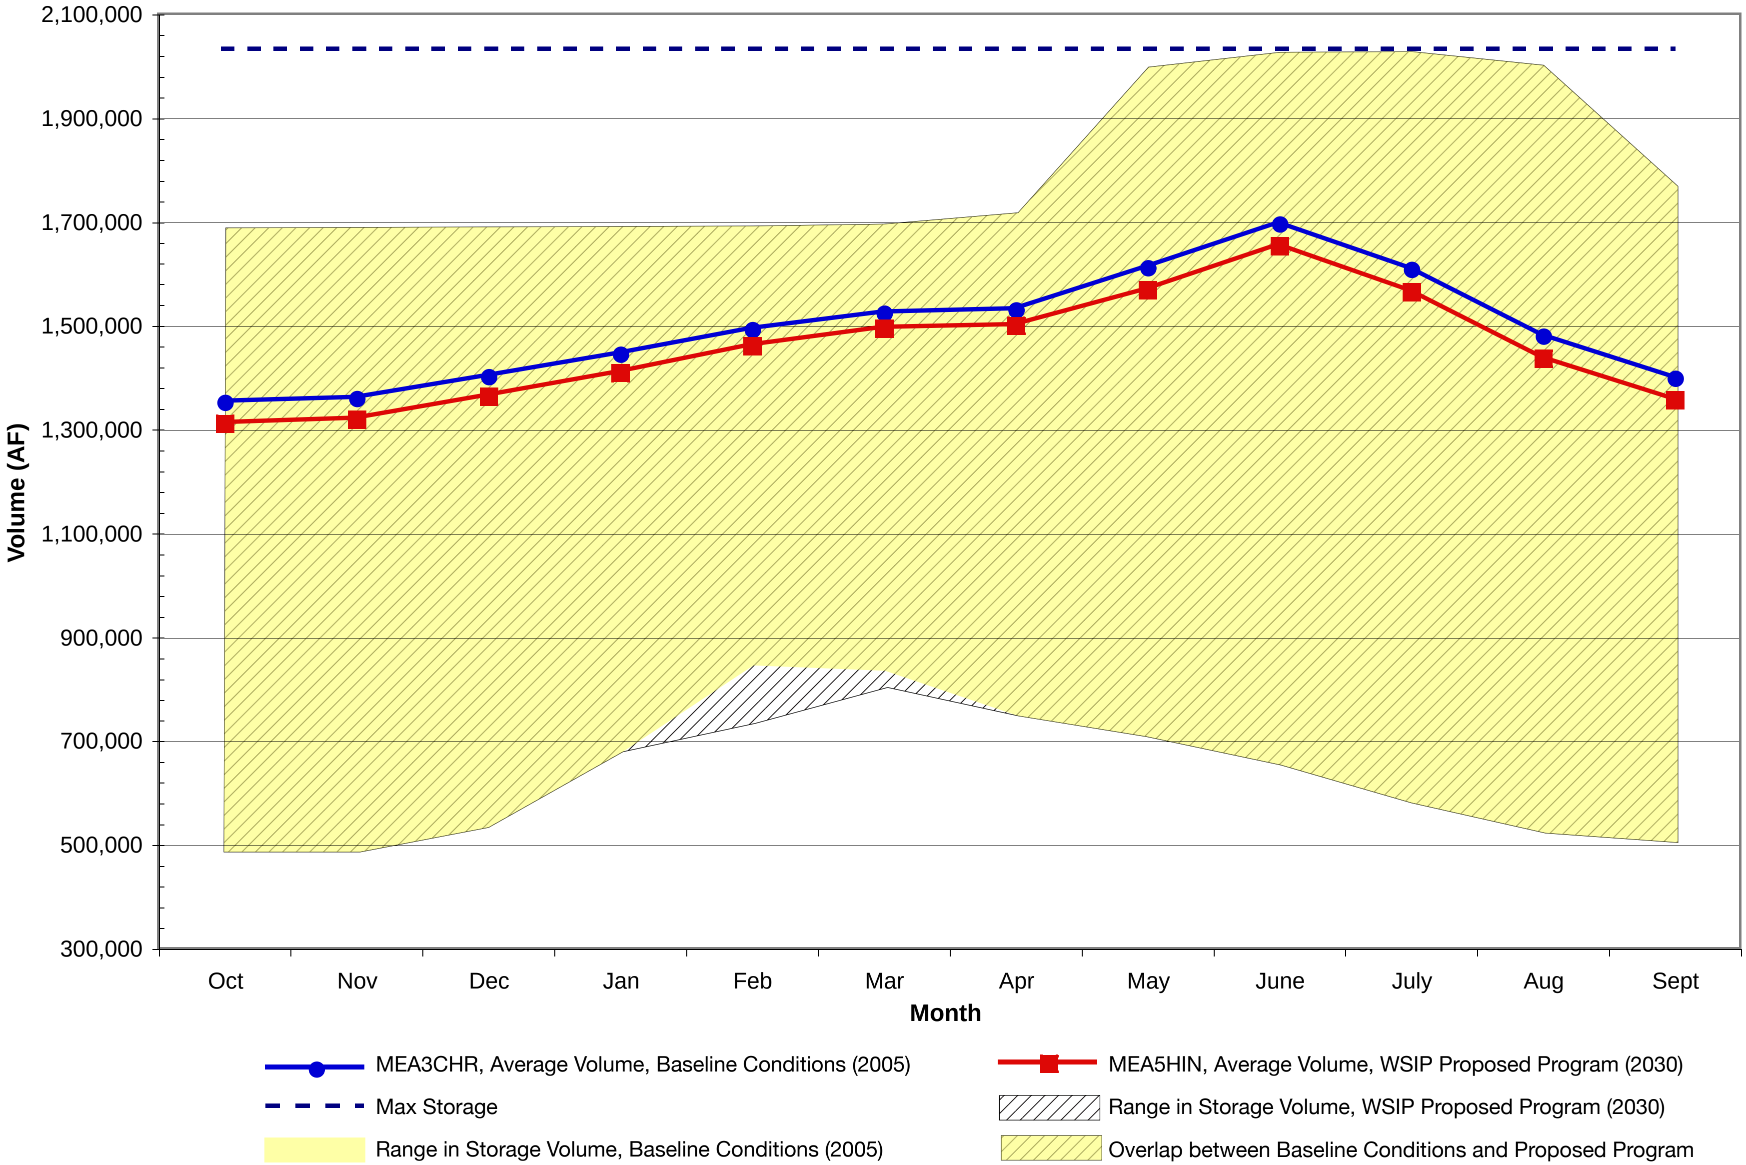
Don Pedro Reservoir, operated by TID, stores water from the upper Tuolumne River. Under typical conditions, the reservoir begins to fill with rainfall runoff from lower elevations in November and continues to fill through the winter and spring with a combination of rainfall runoff and snowmelt from higher elevations. The reservoir is drawn down from June through October to meet demand for irrigation supply in the TID and MID service areas.

Don Pedro Reservoir is a multipurpose facility that provides water supply and flood control benefits as well as recreational opportunities. To provide a prescribed level of downstream flood protection, storage space must be kept available in Don Pedro Reservoir to store floods that might occur. The space maintained in the reservoir for floodwater is referred to as the "flood control reservation." It increases from zero on September 8 to 340,000 acre-feet on October 7. The reservation is maintained at 340,000 acre-feet until April 27, after which it declines to zero again by June 3.

The WSIP would not change TID's operational goals for Don Pedro Reservoir or the flood control reservation requirements, but it would affect water levels in the reservoir and the magnitude and timing of releases to the Tuolumne River.

Water Storage and Water Levels in Don Pedro Reservoir

The WSIP would reduce average monthly storage in Don Pedro Reservoir year-round compared to the existing condition. **Figure 5.3.1-11** shows the average monthly storage and the range of monthly storage in the reservoir with the WSIP and under the existing condition. The



SOURCE: SFPUC, HH/LSM (see Appendix H)

SFPUC Water System Improvement Program . 203287

Figure 5.3.1-11
Average Monthly Storage Volume,
Don Pedro Reservoir

decrease in stored volume is primarily attributable to increased water demand in the service areas of the SFPUC and its customers. As demand increases, so do diversions of water at Hetch Hetchy Reservoir for delivery to the Bay Area. As a result, less water flows down the Tuolumne River to Don Pedro Reservoir. Because of the decrease in stored volume in Don Pedro Reservoir with the WSIP, monthly average water levels would fall by 1 to 10 feet compared to the existing condition.

Figure 5.3.1-12 shows modeled chronological storage in Don Pedro Reservoir and releases to the Tuolumne River at La Grange Dam using hydrology from the period 1920 to 2002. The figure compares the WSIP to the existing condition. It shows that, under the existing condition, TID and MID fills Don Pedro Reservoir in the winter and draws from storage to meet agricultural water demand in the summer and early fall. Because the storage capacity of Don Pedro Reservoir is greater than the average volume of runoff produced in its watershed, TID and MID is unable to fill the reservoir completely every year. Currently, TID and MID is able to fill to its allowable October to April maximum storage capacity about 51 percent of the time and to its maximum physical capacity about 27 percent of the time. In the future with the WSIP, these values would be reduced to 48 percent and 21 percent.

The reductions in stored volume and lowering of water levels attributable to the WSIP would be greatest in critically dry years, particularly following a sequence of dry years. In average critically dry years, Don Pedro Reservoir would be drawn down 10 feet more in September than under the existing condition. The WSIP would lower water levels in Don Pedro Reservoir in some months during severe droughts by up to 27 feet compared to the existing condition.

The WSIP would not alter water levels in Don Pedro Reservoir such that they would be substantially outside the range experienced under the existing condition. Almost all of the time, storage in Don Pedro Reservoir fluctuates between its maximum capacity of 2,080,000 acre-feet, which corresponds with a water level of 834 feet above mean sea level, and 900,000 acre-feet, which corresponds with a water level of 714 feet. Thus, under the existing condition and almost all of the time, the water level fluctuates between 834 feet and 714 feet, a range of 120 feet. With the WSIP, the water level in Don Pedro Reservoir would fluctuate within the same range almost all of the time.

Occasionally, in extended droughts, storage in Don Pedro Reservoir would be drawn down severely. Under the existing condition, the water level in the reservoir would be drawn down to 643 feet, or 191 feet below the maximum, once in the 82-year hydrologic record. With the WSIP, the water level would be drawn down to essentially the same level once in the 82-year hydrologic record, but it would never be drawn down below that level. Thus, water levels with the WSIP would remain substantially within the same range as occurs under the existing condition.

SFPUC Water System Improvement Program ■ 203287

Figure 5.3.1-12
Don Pedro Storage and La Grange Releases to the Tuolumne River

Flow in the Tuolumne River below La Grange Dam

Figure 5.3.1-12 shows the frequency and magnitude of modeled chronological releases from La Grange to the Tuolumne River under the existing condition and with the WSIP. Under the existing condition, releases to the Tuolumne River are at least equal to the fishery release schedule shown in Table 5.3.1-3. In most below-normal or drier years, almost all the winter and spring runoff from the watershed upstream of Don Pedro is captured in the reservoir. In years when the reservoir fills, usually wet or above-normal years, excess water is released to the Tuolumne River.

In the future with the WSIP, MID and TID would draw Don Pedro Reservoir down farther in many years than it would under the existing condition as shown in Figure 5.3.1-12. Consequently, MID and TID would have to capture a greater proportion of spring runoff to refill the reservoir with the WSIP. As a result, the volume of water released to the Tuolumne River would be reduced compared to the existing condition but would be at least equal to the required releases to support fisheries shown in Table 5.3.1-3.

Average monthly flows in the Tuolumne River immediately below La Grange Dam in different hydrologic year types for the existing condition and with the WSIP are shown in **Table 5.3.1-6**. The percentage change in average monthly flow attributable to the WSIP is also shown in the table. The WSIP would have little or no effect on average monthly flow in most summer, fall, and winter months in all hydrologic year types. The WSIP would have no effect on average monthly flow in any months of critically dry years or in most summer months of dry, below-normal, and above-normal years. Only the required fishery release would be made in these months under the existing condition and with the WSIP. With the WSIP, the number of months in which only the required fishery release would be made would increase slightly. Under the existing condition, the model indicates that the minimum release would be made 72.9 percent of the time (717 months in the 984-month hydrologic record); with the WSIP the minimum release would be made 74.6 percent of the time (734 months in the 984-month hydrologic record).

The WSIP would typically result in reductions of less than 10 percent in average monthly flow in the Tuolumne River below La Grange Dam in the November through June period when TID fills Don Pedro Reservoir, although reductions in average monthly flow could be as high as 25 percent. Reductions in flow would occur in some months of all year types, except for critically dry years. For example, in June of an average above-normal year, flow in the Tuolumne River below La Grange Dam would be 408 cfs under the existing condition; with the WSIP it would be 306 cfs, a reduction of 25 percent.

The absolute and percentage changes in flow in the Tuolumne River below La Grange Dam in individual months of wet, above-normal, below-normal, and dry years in the 82-year hydrologic simulation attributable to the WSIP vary widely. The chronological analysis shows that the maximum percentage reduction in average monthly flow attributable to the WSIP would be about 92 percent, occurring in one month in the 82-year hydrologic simulation. In that month, June 1993, the flow below La Grange Dam under the existing condition would be 3,409 cfs; with the WSIP it would be 250 cfs. Reductions in average monthly flow of 30 percent or more would occur in some months of 17 springs in the 82-year simulation, or about once in every four springs on average.

SOURCE: SFPUC, HH/LSM (see Appendix H).

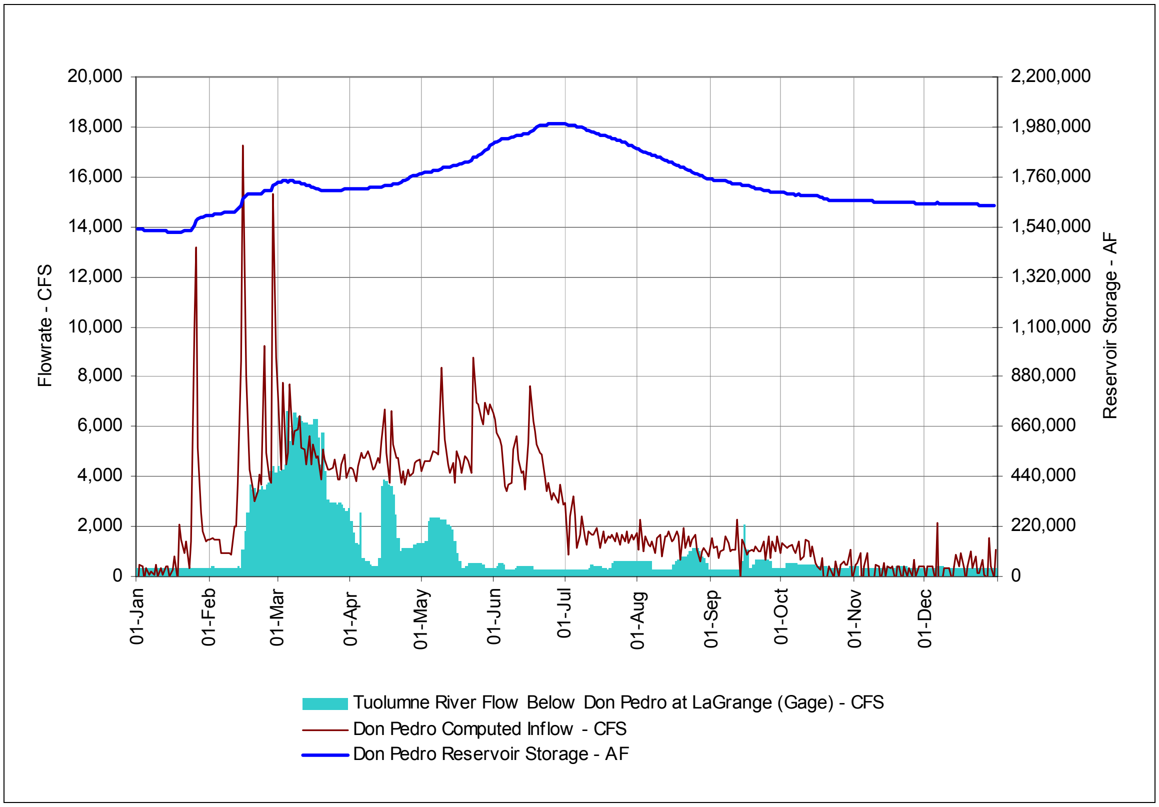
The results presented above are described in terms of average monthly flows because the HH/LSM is a monthly time-step model. TID's actual operational decisions may occur in smaller time steps, perhaps daily or weekly, depending on meteorological and operational circumstances. These within-month operational changes cannot be simulated with the HH/LSM, nor can the model be used to estimate the effects of the WSIP on peak flows in the river, because the peaks may only last for a few hours or days.

Insight into the effects of the WSIP on peak flows below La Grange Dam can be obtained by examining operational data. **Figure 5.3.1-13** shows actual data for 2000, an above-normal year; the greatest effects on peak flows would occur in wet and above-normal years. The figure shows storage in Don Pedro Reservoir falling slightly in the first half of January and then increasing to a maximum of about 2 million acre-feet at the end of June, as first rainfall runoff and then snowmelt enters the reservoir. Through January and the first half of February, TID added to storage in the reservoir and released only the minimum required to the Tuolumne River below La Grange Dam. In mid-February, faced with increasing quantities of rainfall runoff, the operators began to release water to the Tuolumne River in excess of the minimum required in order to maintain the required flood control storage reservation. Releases in excess of the minimum continued though March, April, and the first half of May. Beginning in April, the required flood control reservation decreased, enabling TID to add more water to storage. In mid-May, the operators reduced releases to the river, which remained at or close to the minimum for the remainder of the year. Measured flow in the Tuolumne River below La Grange Dam shows a number of step increases and decreases in flow from mid-February to mid-May lasting several days, as operators sought to balance reservoir inflow, gains in storage, and releases to the river in response to changing conditions.

If the WSIP had been in place in 1999, and water demand was at 2030 levels, storage during December in Don Pedro Reservoir (its seasonal low point) would have been about 1,600,000 acre-feet, similar to but less than under the existing condition. Needing to capture a slightly higher proportion of runoff with the WSIP than under the existing condition, operators would likely delay releases of water to the lower Tuolumne River in excess of minimum requirements by a few days. After the initial delay, the releases to the river with the WSIP would follow the same pattern as under the existing condition and would be of a similar magnitude.

The pattern and magnitude of releases from La Grange Dam to the Tuolumne River with the WSIP in any particular year would depend on meteorological and operational circumstances, as they do under the existing condition. Under the existing condition, there would be no releases from the dam to the river in excess of the minimum required release in 31 years of the 82-year hydrologic record. With the WSIP, there would be no releases above the minimum required in 33 years of the hydrologic record. In years when a release above the minimum required is made, the WSIP would delay the release of water and reduce the total volume of releases to the river in the winter and spring compared to the existing condition.

Releases from Don Pedro Reservoir and La Grange Dam follow a different pattern than releases from Hetchy Hetchy Reservoir. Hetch Hetchy Reservoir typically receives most of its water from



SOURCE: SFPUC, HH/LSM (see Appendix H).

SFPUC Water System Improvement Program ▪ 203287

Figure 5.3.1-13
Don Pedro Reservoir Storage and Inflow, Calendar Year 2000

snowmelt between early May and late July. Don Pedro Reservoir receives runoff over a longer period from both winter rainstorms and snowmelt. Furthermore, unlike Hetch Hetchy Reservoir, Don Pedro Reservoir is used to reduce downstream flooding. As a consequence, management of Don Pedro Reservoir is complex, and releases from the reservoir often occur in a series of pulses rather than in single episode as typically occurs at Hetch Hetchy Reservoir. In years when several pulse releases above the minimum required are made, the WSIP might eliminate one or more of the pulse releases and would delay others by several days or weeks.

After an unusual series of dry years, when Don Pedro Reservoir is drawn down substantially farther with the WSIP than under the existing condition, winter and spring releases above the minimum required would occasionally be eliminated or almost eliminated. This circumstance is illustrated by the sequence of hydrologic conditions that occurred between 1986 and 1993. Although the WSIP would commonly reduce winter and spring flow in the river below La Grange Dam, it would not affect very infrequent large peak flows produced primarily by rainstorms.

Impact Conclusions

The WSIP would not alter stream flow in the Tuolumne River below La Grange Dam such that it would be substantially outside the range experienced under the existing condition, nor would the flow alterations result in adverse hydrologic effects or be sufficient to change the character of the river. Large, infrequent peak flows under the existing condition and with the WSIP would be similar in magnitude. Minimum flows are the subject of an agreement with the FERC and would the same with the WSIP as under the existing condition.

Overall, the effects of the WSIP on flow along the Tuolumne River below La Grange Dam would be *less than significant*, and no mitigation measures would be required.

[Additional discussion on impacts on flow in the lower Tuolumne River was prepared in response to comments on the Draft PEIR. Please refer to Section 14.7, Master Response on Lower Tuolumne River Issues (Vol. 7, Chapter 14).]

Impact 5.3.1-5: Effects on flow along the San Joaquin River and the Sacramento–San Joaquin Delta.

The Tuolumne River joins the San Joaquin River about 50 miles downstream of La Grange Dam. The reductions in flow in the Tuolumne River below La Grange Dam attributable to the WSIP are shown in Table 5.3.1-6. The WSIP would reduce flows in the Tuolumne River between La Grange Dam and its confluence with the San Joaquin River, and in the San Joaquin River from the confluence to the Delta. Most of the reductions in flow would occur from January through June in wet or above-normal years, when flow in the San Joaquin River is at its seasonal maximum. The greatest reductions would occur in years following extended droughts when storage in Don Pedro Reservoir is being replenished. For example, under hydrologic conditions that prevailed in February 1936, average monthly flow in the San Joaquin River between the Tuolumne and Stanislaus River confluences would be reduced from about 10,000 cfs to 7,500 cfs under the WSIP compared to existing conditions. Similarly, under June 1993 conditions, average monthly flows would be reduced from about 7,000 cfs to 3,500 cfs. Flow reductions of these magnitudes would be rare events occurring four or five times in the 82-year period of hydrologic record.

The SWRCB has established flow objectives for the San Joaquin River at Vernalis, just upstream of the Sacramento–San Joaquin Delta. Almost all of the time, the reductions in San Joaquin River flow attributable to the WSIP would not be sufficient to cause flow in the river at Vernalis to fall below the objective. Very infrequently, following protracted droughts, reductions in San Joaquin River flow attributable to the WSIP would be sufficient to cause flow in the river at Vernalis to fall below the objective. Under these circumstances, the USBR, the agency responsible for compliance with objectives for the San Joaquin River, would be expected to increase releases from New Melones Reservoir on the Stanislaus River to meet the flow objectives at Vernalis. Thus, the WSIP would not alter flow in the San Joaquin River below its confluence with the Tuolumne River such that it would be substantially outside the range experienced under existing conditions nor result in a violation of flow objectives.

The reductions in flow in the Tuolumne River below La Grange Dam attributable to the WSIP would also reduce inflow to the Sacramento–San Joaquin Delta. The SWRCB has established objectives for Delta outflow as measured at Chipps Island, just upstream of Suisun Bay. Almost all of the time, the reductions in Delta inflow attributable to the WSIP would not be sufficient to cause Delta outflow to fall below the objective. Very infrequently, following protracted droughts, reductions in Delta inflow attributable to the WSIP would be sufficient to cause Delta outflow to fall below the objective. Under these circumstances, the USBR and DWR, the respective operators of the Central Valley Project and State Water Project, would be expected to decrease their diversions so that the Delta outflow objectives were met. Thus, the WSIP would not alter flow in the Sacramento–San Joaquin Delta such that it would be substantially outside the range experienced under the existing condition.

Overall, the effects of the WSIP on flow along San Joaquin River and in the Delta would be *less than significant*, and no mitigation measures would be required. Additional information on the effects of the WSIP on flows in the San Joaquin River and the Delta is provided in Section 5.3.4.

[Additional discussion on effects of WSIP on the San Joaquin River and Delta was prepared in response to comments on the Draft PEIR. Please refer to Section 14.8, Master Response on Delta and San Joaquin River Issues (Vol. 7, Chapter 14).]

5.3.2 Geomorphology

Channel morphology, or river form, reflects the interactions among watershed geology, flow, the supply of sediment and large woody debris, tectonic uplift and subsidence, and glacial advances and retreats. River channels are in a state of dynamic equilibrium with their watersheds. Although they may change each year, particularly in response to high flows, their characteristics remain stable in the medium term, provided conditions in the watershed also remain stable. When conditions in a watershed change, the dynamic equilibrium is disturbed, and river form will adjust to the new watershed condition (Knighton, 1984).

Over the last century, flow in the Tuolumne River between Hetch Hetchy Reservoir and Don Pedro Reservoir and below La Grange Dam has been progressively reduced by dam operations and the diversion of water for hydropower generation, flood control, and municipal and agricultural water supply. The WSIP would cause further changes in river flow over the next 25 years, as described in Section 5.3.1. Thus, WSIP-induced changes in river flow have the potential to further affect river channel characteristics.

5.3.2.1 Setting

The Tuolumne River drains a 1,960-square-mile watershed on the western slope of the Sierra Nevada range and is the largest of three major tributaries to the San Joaquin River. The river originates in Yosemite National Park and flows southwest to its confluence with the San Joaquin River, approximately 10 miles west of the city of Modesto. Deep canyons, granite river channels, and forested, mountainous terrain characterize the watershed between its crest and La Grange Dam. Near the town of La Grange, the river exits the Sierra Nevada foothills and flows through a gently sloping alluvial valley that is incised into Pleistocene alluvial fans.

Upper Tuolumne River and Tributaries

Upstream of Don Pedro Reservoir, the Tuolumne River and its tributaries flow through steep narrow valleys that confine the river channel. In most of this reach, the river channel is steep and alternates between bedrock chutes,[1] boulder cascades, and pools. Except in the Poopenaut Valley (a 2.5-mile reach below O'Shaughnessy Dam) and downstream of the Clavey River confluence, alluvial deposits are limited to small or medium-sized patches associated with flow obstructions (such as boulders and bedrock outcrops). For the first 2.5 miles below O'Shaughnessy Dam, the Tuolumne River flows through a U-shaped glaciated valley. The river channel is V-shaped and sinuous in the approximately 10 miles of river from the Poopenaut Valley to Early Intake. While the average channel gradient in this reach of the river is steep (averaging 2 percent), subreach-scale variation in channel gradient and valley confinement provides very diverse channel morphology. Channel morphology in this reach ranges from the low-gradient, sand-bedded channel and broad wetland meadow of the Poopenaut Valley to the steep, bedrock-confined channel found in most of the rest of the Tuolumne River (McBain & Trush and RMC, 2006).

1 A chute in this context is an inclined trough or channel feature such as a waterfall or rapid.

From Early Intake, the river flows about 10 miles to its confluence with the South Fork of the Tuolumne River. The river is confined in a deeply incised, V-shaped canyon with steep, competent side slopes. Channel gradient in this reach also averages about 2 percent, but is as steep as 4 percent in one section. For most of its length, the channel consists of a series of pools separated by steep cascades over boulders. Alluvial bars and side-channels are present throughout the reach where the valley widens or where bedrock constraints reduce channel gradient.

From the South Fork confluence to the upper end of Don Pedro Reservoir, the average channel gradient decreases to less than 1 percent. In the upper section of this reach, from the confluence with the South Fork to the confluence with the Clavey River, the river channel consists of boulder cascades separated by medium-length pools. Downstream of the Clavey River confluence, the channel gradient decreases, and the channel becomes semi-alluvial. Large boulder bars are common.

Cherry Creek is a tributary to the Tuolumne River. From Cherry Dam, Cherry Creek flows about 12 miles to its confluence with the Tuolumne River (1.3 miles downstream of Early Intake). For most of this length, Cherry Creek is confined within a narrow bedrock canyon, and channel gradient is steep (5 percent). The bed consists primarily of boulders and bedrock, although a large volume of sand is stored in pools. Immediately downstream of the dam, however, the channel alternates between low-gradient, gravel-bedded reaches separated by steep, bedrock chutes. In the gravel-bedded reaches of the upper five-mile reach between the dam and the confluence with Eleanor Creek, riparian and upland vegetation has encroached onto formerly active alluvial bars since completion of Cherry Dam.

Eleanor Creek flows into Cherry Creek seven miles upstream of the Tuolumne River and extends 3.5 miles from Eleanor Dam to Cherry Creek. For most of its length, Eleanor Creek flows through a steep bedrock canyon, and the channel is a series of pools and falls. The average channel gradient is 6 percent.

A common perception is that bedrock channel morphology is static compared to alluvial channels and therefore relatively insensitive to flow and sediment supply changes (e.g., Montgomery and Buffington, 1997). Bedrock channels, however, are often highly dynamic depositional environments; though principally erosional, they also exhibit abundant depositional features. Large, geomorphically derived hydraulic controls, such as width constrictions or expansions and resistant bedrock outcrops, remain stable over decades or centuries and define an overall limit for coarse sediment deposition in each segment of the bedrock channel. These geomorphic controls induce coarse depositional features that in turn perform as smaller hydraulic controls to induce finer and more transitory secondary depositional features. The occurrence of smaller hydraulic controls within larger hydraulic controls gives rise to a complex, nested depositional channel morphology that provides diverse aquatic and riparian habitats (McBain and Trush, 2004).

Short channel segments where channel gradient decreases and/or valley width increases may support unique and/or more diverse aquatic and riparian communities. These atypical channel segments exhibit prominent depositional features, such as alluvial bars, side channels, and limited floodplains. While these alluvial subreaches and patches constitute a small portion of the channel in this reach, they provide important establishment sites for riparian vegetation, habitat for aquatic flora and fauna and native amphibians, and low-velocity rearing habitat for juvenile fish.

Sediment is supplied to bedrock rivers primarily through “mass wasting.” Hill-slope mass wasting, such as rock falls and bedrock shearing from canyon walls, episodically delivers coarse sediment of sufficient volume and/or caliber to create large depositional features in the channel or to function as large-scale hydraulic controls capable of generating other prominent depositional features. Bedrock rivers have a huge potential transport capacity for coarse sediment, but a small storage capacity for coarse and fine sediment. Hydraulic complexity and channel form, expressed as nested hydraulic controls in a variable flow regime, exert the greatest control on storage capacity. The annual coarse bedload[2] transported may fluctuate dramatically without significantly affecting the volume of coarse sediment stored in a channel segment. Although storage capacity is low, the ecological implications for maintaining these limited depositional features can be great.

In bedrock rivers, diverse erosional and depositional features are created and maintained by a broad range of floods. For example, sand patches are scoured and deposited during small floods, while boulder ribs are mobilized only during very large, infrequent floods. Flow thresholds that mobilize depositional features in bedrock rivers are not well understood. Recent, though limited, observations of the Clavey River (a tributary to the Tuolumne River) suggest that:

- Common small floods that occur every one to three years scour and deposit sand at pools and bars
- Moderate-sized floods that occur every 12 to 17 years move gravel and cobbles, reshape side channels, and may move large woody debris
- Very large floods that occur every 70 to 100 years erode large bars, remove and create side channels, and move large boulders over short distances

Tuolumne River from La Grange Dam to the San Joaquin River

Near the town of La Grange, the Tuolumne River exits the Sierra Nevada foothills and flows through a gently sloping alluvial valley incised into Pleistocene alluvial fans. The valley walls confine the river corridor to as narrow as 500 feet near Waterford, about 20 miles downstream of La Grange, whereas the river reaches downstream of Modesto are virtually unconfined. In some locations, bedrock outcrops control the gradient of the river; in others, the bedrock is up to 50 feet below the riverbed.

Within the alluvial valley, the river can be divided into two geomorphic units defined by channel slope and bed composition: the gravel-bedded reach, which extends about 28 miles from La Grange Dam to below Geer Road, and the sand-bedded reach, which extends about 24 miles from below Geer Road to the confluence with the San Joaquin River. The gravel-bedded reach has moderate slopes (0.03–0.15 percent), and extensive alteration of the channel and floodplain

2 Refers to the amount of cobbles, gravel, and sand transported along the stream bottom (as opposed to suspended in the stream flow).

has occurred as a result of past gold dredging operations and past and current aggregate mining. Channel gradient decreases to less than 0.03 percent in the sand-bedded reach, and the channel is characterized by a meandering, alternate bar morphology. Under current conditions, coarse sediment sources are limited to tributaries downstream of La Grange Dam and to bed and bank erosion, so little coarse sediment enters the lower river. Most of the sediment that is currently contributed to the channel downstream of the dam consists of sand and finer-sized particles. While dams have eliminated upstream sediment supply, gold dredging and aggregate mining have removed sediment stored in the river channel and floodplain. Since sediment supply to the lower river has been cut off by upstream dams, the river cannot recover from past in-channel dredging and mining.

Operation of Don Pedro Reservoir has reduced the magnitude of peak flow in the lower river, and the reduction in peak flows has altered channel characteristics below La Grange Dam. Flood releases from the reservoir are dictated by three factors:

- Maximum releases through the dam outlet works (14,000 cfs)
- U.S. Army Corps of Engineers flood control rules, which limit flows to 9,000 cfs, as measured at the Modesto gauge (which includes inflows from Dry Creek)
- Maximum release capacity through the powerhouse turbines (5,500 cfs)

A number of agencies and nonprofit groups, including the SFPUC, TID, MID, U.S. Fish and Wildlife Service (USFWS), National Marine Fisheries Service (NMFS), California Department of Fish and Game (CDFG), Friends of the Tuolumne, and the Tuolumne River Preservation Trust, are cooperating in efforts to restore the lower Tuolumne River corridor. In 2000, the Tuolumne River Technical Advisory Committee completed the *Habitat Restoration Plan for the Lower Tuolumne River Corridor* (McBain & Trush, 2000). The goal of the plan is to improve the river's value as fish and wildlife habitat. The plan recommends several measures to improve ecological function in the lower river, including increased frequency and magnitude of high flows, channel reconstruction, and coarse and fine sediment management. Recommended increases in flood flows, which would be achieved through revisions to operating criteria during flood control release periods, would increase the magnitude of bankfull[3] flows to more effectively move sediment. Of the 14 channel restoration projects identified in the plan, two have been constructed, two will be constructed in 2007, and three have complete designs and are in various stages of funding and implementation planning. Peak flows below La Grange Dam are usually in the range of 5,000 to 5,500 cfs as a result of reservoir releases for power generation purposes. Consequently, all of these restoration projects are designed to function based on a bankfull flow and two-year flood of 5,000 cfs (McBain *et al*., 2004).

3 A bankfull channel conveys commonly occurring flows, with larger flows spilling over the banks and onto the floodplain.

5.3.2.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to geomorphology, but generally considers that implementation of the proposed program would have a significant impact if it were to:

- Substantially change the topography such that ecological, hydrologic or aesthetic functions are adversely affected, or substantially change any unique geologic or physical features of the site or area

- Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of the stream or river, in a manner that would result in substantial erosion or siltation or adversely affect the ecological, hydrologic or aesthetic functions of the site or area

Although the "substantial change in topography" criterion is typically applied to upland areas, it is considered applicable to stream channel/bank topography in this instance because of the sensitivity of the resources that depend on the topography of those features (i.e., riparian vegetation and fisheries).

Approach to Analysis

This impact section presents a discussion of the potential changes in sediment transport and geomorphology that could result from WSIP-related changes in stream flow, reservoir storage, and reservoir water levels, as described in Section 5.3.1. A qualitative assessment of potential effects was conducted based on generalized channel bed/bank characteristics and a consideration of the program-induced changes in stream flow. No modeling or field measurements have been performed to estimate program-generated changes in sediment transport in the Tuolumne River system.

As indicated in Section 5.3.1, the WSIP would have no effect on flow in Cherry Creek or Eleanor Creek. Consequently, the impact analysis focuses on the Tuolumne River between Hetch Hetchy Reservoir and the confluence with the San Joaquin River, a reach of the river that would be affected by WSIP-induced changes in stream flow.

Impact Summary

Table 5.3.2-1 presents a summary of the impacts on sediment transport and geomorphology in the Tuolumne River system and downstream water bodies that could result from implementation of the proposed water supply and system operations.

TABLE 5.3.2-1
SUMMARY OF IMPACTS –
GEOMORPHOLOGY OF THE TUOLUMNE RIVER SYSTEM AND DOWNSTREAM WATERBODIES

Impact	Significance Determination
Impact 5.3.2-1: Effects on sediment transport and channel characteristics between O'Shaughnessy Dam and Don Pedro Reservoir	LS
Impact 5.3.2-2: Effects on sediment transport and channel characteristics below La Grange Dam	LS

LS = Less than Significant impact, no mitigation required

Impact Discussion

Impact 5.3.2-1: Effects on sediment transport and channel characteristics between O'Shaughnessy Dam and Don Pedro Reservoir.

Sediment transport and channel characteristics are primarily influenced by peak flows rather than by smaller common flows. As noted above, studies of the Clavey River indicate that peak flows that occur every one to three years produce enough energy to move sand; peak flows that occur every 12 to 17 years produce enough energy move gravel and cobbles; and peak flows that occur every 70 to 100 years produce enough energy to move boulders. Although the relationship between peak flows and the transport of sand, gravel, and boulders for the Clavey River cannot be directly applied to the main stem of the Tuolumne River, it provides an indication of the frequency of peak flows that mobilize depositional features in steep, mountain streams.

As discussed in Section 5.3.1 and illustrated in Figure 5.3.1-9, the WSIP would have little effect on the very large and infrequent floods in the Tuolumne River between O'Shaughnessy Dam and Don Pedro Reservoir that are capable of moving boulders and altering the characteristics of the bedrock channels. When the volume of runoff from the watershed above Hetch Hetchy Reservoir is great, the reservoir fills rapidly, after which all flow in excess of the capacity of the reservoir and Mountain Tunnel is released to the river. Under these conditions, the WSIP would extend the reservoir refill period and delay releases from the reservoir slightly (for a few days), after which releases to the river would follow the same pattern as they do under the existing condition. Because the WSIP would not affect the frequency or magnitude of large and infrequent floods, it would have a less-than-significant effect on the bedrock channel characteristics of the Tuolumne River below O'Shaughnessy Dam, and no mitigation measures would be required.

Flow in the Tuolumne River between O'Shaughnessy Dam and Early Intake consists predominantly of controlled releases from Hetch Hetchy Reservoir, except during large storms or snowmelt runoff. Under certain conditions (e.g., in normal hydrologic years that follow extended droughts), the WSIP could reduce the magnitude and duration of bankfull peak flows that are released from the reservoir every one to three years. As shown Figure 5.3.1-9, reductions in peak flows of this type occur infrequently in the 82-year hydrologic record. Thus, the WSIP could affect the rate and amount of sediment deposition and erosion in side channels and in the vicinity of the few streamside meadows that exist in this reach of the river. However, because the changes in peak flow would occur infrequently, they would not be expected to result in a substantial change in erosion or siltation rates. The impact would be *less than significant*, and mitigation measures would not be required.

[Additional discussion on impacts on geomorphology in the upper Tuolumne River was prepared in response to comments on the Draft PEIR. Please refer to Section 14.6, Master Response on Upper Tuolumne River Issues Issues (Vol. 7, Chapter 14).]

Impact 5.3.2-2: Effects on sediment transport and channel characteristics below La Grange Dam.

As noted above, the bankfull peak flows that occur every one to three years are the primary channel-forming events in the reach of the Tuolumne River below La Grange Dam, although larger floods are also important. The WSIP would have little effect on very large and infrequent floods within the Tuolumne River below La Grange Dam, such as the flood that occurred in 1997, but could affect the magnitude of the bankfull peak flows.

The WSIP would increase the drawdown of Don Pedro Reservoir by a small amount each year and by a considerable amount in an extended drought. To refill the reservoir in the winter and spring, TID and MID would capture a larger proportion of runoff than it does under the existing condition. In some years, when runoff is great compared to the storage deficit, the WSIP might extend the reservoir refill period and delay releases from Don Pedro Reservoir by several days, after which releases from the reservoir would follow the same pattern as they do under the existing condition. Under these conditions, the WSIP would have little or no effect on channel geomorphology. Occasionally, refilling the reservoir would require most or all runoff in excess of the minimum required fish release, and flows below La Grange Dam would be substantially reduced compared to the existing condition. In these years, sediment transport in the river below La Grange Dam would be reduced. However, because WSIP-induced changes in peak flow would occur infrequently, they would not be expected to result in a substantial change in erosion rates, siltation rates, or channel form. The impact would be *less than significant*, and mitigation measures would not be required.

[Additional discussion on impacts on geomorphology in the lower Tuolumne River was prepared in response to comments on the Draft PEIR. Please refer to Section 14.7, Master Response on Lower Tuolumne River Issues (Vol. 7, Chapter 14).]

5.3.3 Surface Water Quality

The following setting section describes surface water quality in streams and reservoirs in the Tuolumne watershed and downstream water bodies that could be affected by the WSIP. The impact section (Section 5.3.3.2) provides a description of the changes in water quality in streams and reservoirs that would result from WSIP-induced changes in stream flow and reservoir water levels.

5.3.3.1 Setting

The Tuolumne River flows from the crest of the Sierra Nevada westward to its confluence with the San Joaquin River. The San Joaquin River flows north to the Sacramento–San Joaquin Delta. Water from the Delta discharges to the San Francisco Bay Estuary and the Pacific Ocean. The Tuolumne River system and downstream water bodies are shown in Figure 5.1-1. Beneficial uses of the Tuolumne River, as designated in the *Water Quality Control Plan for the Sacramento and San Joaquin River Basins*, include the following:

- Source to (New) Don Pedro Reservoir: Municipal and Domestic Supply (MUN); Agricultural Supply (AGR); Hydropower Generation (POW); Water Contact Recreation (REC-1); Non-water Contact Recreation (REC-2); Warm Freshwater Habitat (WARM); Cold Freshwater Habitat (COLD); and Wildlife Habitat (WILD)
- New Don Pedro Reservoir: MUN (Potential); POW; REC-1; REC-2; WARM; COLD; and WILD
- New Don Pedro Dam to San Joaquin River: MUN (Potential); AGR; REC-1; REC-2; WARM; COLD; Migration of Aquatic Organisms (MIGR); Spawning, Reproduction, and/or Early Development (SPWN); and WILD

The WSIP would affect flow in the Tuolumne River, the San Joaquin River, and the Sacramento–San Joaquin Delta as well as water levels in Hetch Hetchy Reservoir and Don Pedro Reservoir, as described in Section 5.3.1. WSIP-induced changes in flow and water levels could affect water quality in these streams and reservoirs. The WSIP would have minor effects on flow in Eleanor and Cherry Creeks and on water levels in Lake Eleanor and Lake Lloyd, but the changes would be too small to affect water quality.

The water supply and system operations components of the WSIP would not involve the discharge of pollutants into water bodies and therefore would have a limited potential to affect water quality. WSIP-related changes in water quality, such as changes in water temperature or dissolved oxygen, would stem from changes in stream flow and changes in water levels in reservoirs. Accordingly, the water quality data presented in this section are limited to those water quality characteristics that could be altered by elements of the proposed program or that are needed to provide a general understanding of potentially affected water bodies.

Tuolumne River

Water quality in the upper Tuolumne River basin is excellent. The Tuolumne River drainage above Hetch Hetchy Reservoir lies entirely within the less developed parts of Yosemite National

Park. The combination of a high-altitude granitic drainage basin and minimal human influences results in river water that is cold, clear, and free of contaminants. Water quality in Hetch Hetchy Reservoir is also excellent. Plant nutrients such as nitrogen and phosphorus are typically near or below detection limits, and dissolved oxygen concentrations are typically at or near saturation. Total dissolved solids concentrations are less than 10 milligrams per liter (mg/L), and average total organic carbon concentrations are less than 2 mg/L. The SFPUC samples water quality at various depths in Hetch Hetchy Reservoir. As shown in **Table 5.3.3-1**, monthly water temperatures at a depth of 140 feet below the water surface for the period from 1997 to the present ranged between 6.5 and 13.8 degrees Celsius (°C). This depth, which is approximately the middle of the water column, is representative of water released to the Tuolumne River.

[a] Flow Index is the year's total runoff as a percentage of the long-term average.

SOURCES: SFPUC (raw data); Merritt-Smith Consultants (data reduction).

Water quality in the reach of the Tuolumne River between Hetch Hetchy and Don Pedro Reservoirs is very good, but its dissolved mineral and plant nutrient content increases somewhat in a downstream direction. MID samples water from the outlet of Modesto Reservoir on the Modesto Canal. The samples are reasonably representative of water quality in the Tuolumne River at La Grange Dam. Total dissolved solids have been measured twice daily since 1997. These data show total dissolved solids concentrations that range from 15 to 26 mg/L, with an average of about 20 mg/L.

Below Don Pedro Reservoir, Tuolumne River water quality deteriorates somewhat as a result of agricultural irrigation return flow, urban and agricultural runoff, and recreation in and around the river and in Don Pedro Reservoir itself. In the warmer months, water temperature increases in a downstream direction as the river leaves the foothills of the Sierra Nevada and flows on to the floor of the San Joaquin Valley. Total dissolved solids content and turbidity also increase in a downstream direction.

Water temperature at several stations on the Tuolumne River downstream of La Grange Dam has been recorded for many years, but most intensively and reliably in the last decade in the course of a 2005 TID/MID study. La Grange Dam is located at river mile (RM) 52.2; that is, it is 52.2 miles upstream of the Tuolumne River's confluence with the San Joaquin River. Daily average water temperature at RM 51.8, about one-half mile below La Grange Dam, was usually in the range of 9 to 14 °C between 1996 and 2004. Daily average temperature at RM 36.7, about 15 miles below La Grange Dam, was usually in the range of 9 to 26 °C, and at RM 3.4, about 50 miles below La Grange Dam, was usually in the range of 9 to 29 °C. Daily average wintertime water temperature is similar for the entire river reach from La Grange Dam to the confluence with the San Joaquin River. The maximum temperatures experienced in the summer and fall from 1996 to 2004 at several locations are shown in **Table 5.3.3-2**. Seasonal variation at RM 43.4, about nine miles below La Grange Dam is shown in **Figure 5.3.3-1**.

TABLE 5.3.3-2
MAXIMUM SUMMER–FALL WATER TEMPERATURES IN THE TUOLUMNE RIVER FROM LA GRANGE DAM TO MODESTO[a]
1996–2004

Year	Water Year Type	Maximum Water Temperature (Summer–Fall) (°C rounded to nearest 0.5)				
		RM 49	RM 43.4	RM 36.7	RM 23.6	RM 3.4
1996	AN-W	18.5	**21**	**25**	NA	**29**
1997	AN-W	16	**20**	**23**	**26**	**28**
1998	W	14	16	17	**21**	**23**
1999	BN-AN	16	18	**23**	**27**	**29**
2000	BN-AN	NA	19	**23**	**27**	**28**
2001	D	**22**	**28**	**30**	**31**	NA
2002	D	**20**	**26**	**30**	**30**	**31**
2003	BN	16	19	**23**	**26**	**30**
2004	D	18	**24**	**27**	**30**	NA

[a] La Grange Dam is located approximately at RM 49 and Modesto at RM 3.4.

W = wet; AN = above normal; BN = below normal; D = dry; C = critically dry; RM = river mile
Temperatures ≥20 °C are shown in **bold** type.

The TID/MID study describes some general trends in water temperature:

- In all year types from 1996 to 2004, releases from Don Pedro Reservoir varied seasonally from a low of about 8 °C to a high of about 16 °C, with low temperatures occurring during the spring snowmelt and the highest temperatures occurring in late summer.
- In the reaches below Don Pedro Reservoir and La Grange Dam (RM 51.8 to RM 36.7), there is a clear relationship between hydrologic year type (and thus flow) and river temperatures during the summer and fall. This probably reflects the influence of surface-area-to-volume relationships. The effect becomes increasingly pronounced from upstream to downstream due to high summer temperatures in the San Joaquin Valley (Table 5.3.3-2). Even in wet years, peak summer temperatures in the reach downstream of RM 23.6 are above 20 °C. In all but the summer of 1998 following the extremely wet 1997/1998 floods, peak water temperatures exceed 20 °C up to RM 36.7.
- In downstream reaches of the river (RM 23.6 and below), the period of average daily temperatures in excess of 21 to 23 °C is frequently two to four months long.

The water temperature data from TID/MID(2005) are generally consistent with those reported in a 1996 FERC study. The FERC report notes that water temperature in the river is probably affected by the lack of riparian shade, and that leakage of water from diversion reservoirs and upwelling of groundwater probably provide some pockets of cool water in the summer.

Some water quality characteristics in the Tuolumne River are affected by reservoir operations and by changes in river flow attributable to water supply and hydropower generation activities. Primary among them is water temperature, which in turn may affect dissolved oxygen content. Water temperature in flowing streams depends on the water source, air temperature, flow, surface area, and exposure to solar radiation. Reductions in stream flow when air temperature is high usually

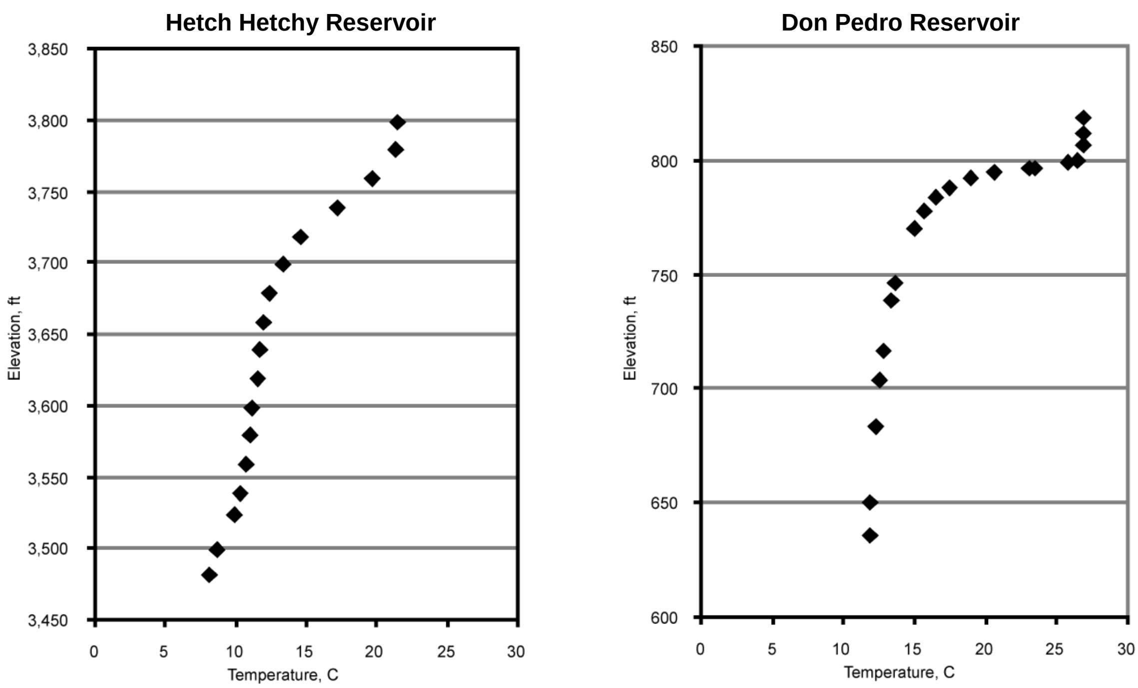
SFPUC Water System Improvement Program . 203287

Figure 5.3.3-1
Tuolumne River Water Temperature at River Mile 43.4

result in increases in water temperature. Storage of water in reservoirs may increase or decrease water temperatures. Hetch Hetchy and Don Pedro Reservoirs fill with cool water in the winter and spring. During the summer, water near the surface is heated by solar radiation, but because the reservoirs are deep they retain a large volume of cool water nearer the bottom. The boundary between the warmer surface waters and cooler waters below is referred to as the thermocline. The portions of the reservoir above and below the thermocline are referred to respectively as the epilimnion and the hypolimnion. The thermocline is quite distinct in most deep reservoirs in the Sierra Nevada and is typically at a depth of 25 to 50 feet below the water surface. **Figure 5.3.3-2** shows typical August temperature profiles for Hetch Hetchy and Don Pedro Reservoirs in August. Typical summertime water temperatures in the epilimnion and hypolimnion at Hetch Hetchy Reservoir are 20 °C and 10 °C, respectively. Corresponding values for Don Pedro Reservoir are 27 °C and 12 °C.



SFPUC Water System Improvement Program ▪ 203287

Figure 5.3.3-2
Typical Summertime Water Temperature Gradient in Hetch Hetchy and Don Pedro Reservoirs

Water is typically released to streams from outlets near the bottom of reservoirs. If water is released from a reservoir in the summer from below the thermocline, it is typically cooler than stream water would be if the reservoir did not exist. When reservoirs are drawn down in the late summer and fall, the thermocline moves downward, closer to the reservoir outlet. Releases from reservoirs at such times may be a mixture of cool bottom water and warmer water from nearer the surface, with a consequent increase in water temperature in the stream below the reservoir.

San Joaquin River

Water quality in the San Joaquin River at Vernalis is shown in **Table 5.3.3-3**. Vernalis is located just upstream of the Sacramento–San Joaquin Delta and about 10 miles downstream of the San Joaquin River's confluence with the Tuolumne River. The total dissolved solids and total organic carbon concentrations in the San Joaquin River are high for natural waters and are considerably higher than for Tuolumne River water. The total dissolved solids concentration (a measure of dissolved minerals) averages 380 mg/L, and the total organic carbon concentration (a measure of dissolved and particulate organic matter) averages 3.6 mg/L. The total dissolved solids concentration in San Joaquin River water at Patterson, about 10 miles upstream from the San Joaquin River and Tuolumne River confluence, averages more than 600 mg/L. The improvement in San Joaquin River water quality between Patterson and Vernalis is attributable to mixing with higher quality water from the Tuolumne and Stanislaus Rivers.

The primary causes of degraded water quality in the San Joaquin River are the unsolved agricultural drainage problem in the San Joaquin Valley, urban wastewater and stormwater discharges, discharges from wildlife refuges, and flow depletion in some months of some years. Inadequate drainage and accumulating salts have been persistent problems in parts of the San Joaquin Valley for more than a century. Farmers in arid areas must apply irrigation water to their crops in excess of crop needs to flush salts out of the root zone. In parts of the valley, this practice has caused shallow groundwater levels to rise close to the ground surface. To prevent land from becoming unproductive, farmers install tile drains under their fields in an effort to lower groundwater levels and remove salt from the soil. The tile drains convey saline water to perimeter ditches, which are typically routed to the nearest natural stream channel. In the San Joaquin Valley, the natural channels are tributary to the San Joaquin River or Tulare Lake. In the 1960s and 1970s, the USBR attempted to solve the drainage problem in the San Joaquin Valley by constructing an agricultural drainage system for the valley that routed drainage water away from the San Joaquin River. The project was only partially built and failed to solve the problem (U.S. Department of the Interior/California Resources Agency, 1990).

Sacramento–San Joaquin Delta

Water quality in the Delta is governed by the Delta's complex hydrodynamics. Freshwater enters the Delta from its tributary rivers and, with the tides, saline water enters the Delta from Suisun Bay, the northern reach of the San Francisco Bay Estuary. When freshwater flow through the Delta is great, saline water is repelled and the waters of the Delta exhibit little salinity. When freshwater flow is small, tidal flow enables saline water to penetrate into the Delta. Under these circumstances, water quality in some parts of the Delta becomes brackish and unsuitable (or less suitable) for use as a source of potable and irrigation water. The reversal of flow in the lower San Joaquin River and many south Delta channels as a result of water diversion by the State Water Project and Central Valley Project increases the tendency for saline water to penetrate into the Delta.

Table 5.3.3-4 shows water quality characteristics at selected locations in the Delta. In general, water quality in the Delta declines in a southerly and westerly direction. This is illustrated by the pattern of chloride concentrations. For Sacramento River water entering the Delta from the north, the chloride content is low. Chloride, a constituent of seawater, enters the Delta from the west. The chloride concentration at the State Water Project's Banks Pumping Plant is higher than in the Sacramento River because low-chloride Sacramento River water mixes with saline water entering from Suisun Bay. Water quality at the Banks Pumping Plant, one of the two large pumping plants in the south Delta, is shown in **Table 5.3.3-5**.

The water quality parameters in Delta waters that are of greatest concern to municipal water supply agencies are total dissolved solids (salinity), bromide, and total organic carbon content. Elevated salinity levels in drinking water supplies may make it unpalatable. Farmers are also concerned about salinity because elevated levels may make water unsuitable for irrigating certain salt-sensitive crops.

Organic carbon compounds are present in water in the form of microscopic plants and animals and the products of bacterial degradation of plant and animal material. Total organic carbon levels rise in the Delta in the winter and spring primarily as a result of the drainage of peat soils on the Delta islands. Organic carbon reacts with chemicals used to disinfect drinking water to form trihalomethanes and other disinfection byproducts. Trihalomethanes are known to cause cancer in humans and are regulated under the Safe Drinking Water Act. Bromine also reacts with organic matter and disinfection agents to form trihalomethanes and other brominated disinfection byproducts. Saline water from San Francisco Bay is the main source of bromine in the Delta.

Diminution of flow and flow reversal in the lower San Joaquin River as a result of water diversions by the State Water Project and the Central Valley Project are harmful to migrating salmon. In 1990, DWR began installing temporary barriers in several waterways in the south Delta to improve conditions for migrating salmon. Temporary barriers have been placed across

the Grant Line Canal, Middle River, and Old River. The purpose of the barriers is to control water levels for irrigators, improve water quality, and direct more water down the lower San Joaquin River for downstream migrating juvenile salmon in the spring and upstream migrating adults in the fall. It is expected that permanent operable barriers will replace the temporary barriers in the next few years.

Beneficial Uses and Water Quality Objectives

Water quality is regulated in California pursuant to the federal Clean Water Act and California's Porter-Cologne Water Quality Control Act of 1969. Responding to public concern in California, state legislators enacted a law designed to curb water pollution several years before passage of the Clean Water Act. The Porter-Cologne Act established regional water quality control boards and gave them defined responsibilities for water quality management.

The Porter-Cologne Act requires the regional water quality control boards to prepare regional WQCPs, often referred to as basin plans. The WQCPs must identify present and future beneficial uses of California's waters and establish water quality objectives to protect them. California's beneficial use designations and water quality objectives are the functional equivalent of the federal ambient water quality standards. After passage of the Federal Water Pollution Control Act Amendments in 1972, later known as the Clean Water Act, California's water quality objectives served as federal water quality standards, following review and approval by the U.S. Environmental Protection Agency (U.S. EPA).

WQCPs are adopted and amended by the regional water quality control boards and are subject to CEQA review. WQCPs, and amendments to WQCPs, do not become effective until approved by the SWRCB. Adoption or revision of surface water objectives/standards is subject to the approval of the U.S. EPA. The regional WQCPs complement statewide WQCPs adopted by the SWRCB, such as the WQCP for temperature control and the WQCP for ocean waters.

Two WQCPs govern management of surface and ground waters that could be affected by the WSIP. The Central Valley WQCP covers the Sacramento and San Joaquin River basins, including an area bounded on the east by the crests of the Sierra Nevada and Cascade Range and on the west by the Coast Ranges and Klamath Mountains. The San Francisco Bay/Delta WQCP covers those portions of Alameda, Contra Costa, Marin, Napa, San Mateo, San Francisco, Santa Clara, Solano, and Sonoma Counties that drain to the San Francisco Bay Estuary, including the Delta.

Each WQCP identifies existing and potential beneficial uses of surface waters and establishes water quality objectives within its part of California. Surface waters in the WQCP areas are in compliance with objectives, except for those waters contained in the SWRCB's Section 303(d) list of impaired water bodies.

Section 303(d) of the Clean Water Act requires that states periodically prepare a list of surface water bodies that do not meet ambient water quality standards after conventional water pollution control measures have been applied. The states must then establish the total maximum daily loads of pollutants that can be discharged to the water body without violating ambient water quality standards. Pollutant discharges must be cut back until they are in compliance with the total maximum daily loads.

Tuolumne River

Water quality objectives for the San Joaquin River Basin, including the Tuolumne River from the town of Waterford to La Grange Dam, are shown in **Table 5.3.3-6**. The only numerical water quality objective for the Tuolumne River is the objective for dissolved oxygen, which applies to

TABLE 5.3.3-6
PERTINENT WATER QUALITY OBJECTIVES FOR THE SAN JOAQUIN RIVER BASIN

Parameter	Water Body	Beneficial Use	Water Quality Objective
Dissolved Oxygen	San Joaquin River (Turner Cut to Stockton)	Chinook Salmon	6.0 mg/L (September 1 to November 30) and 5.0 mg/L (December 1 to August 30)
	Other Delta Waters	WARM COLD SPWN	5.0 mg/L 7.0 mg/L 7.0 mg/L
	Tuolumne River (Waterford to La Grange)		8.0 mg/L (or >95% saturation) (October 15 to June 15)
Salinity	San Joaquin River (Antioch Water Works)	MUN IND	Chloride: Maximum mean daily >150 mg/L Number of days per year <150 mg/L: Wet – 240 (66%) Above Normal – 190 (52%) Below Normal – 175 (48%) Dry – 165 (45%) Critical – 155 (42%)
	San Joaquin River (at Vernalis)	AGR	Electrical conductivity (maximum 30-day average): 0.7 (April 1 to August 31) 1.0 (September 1 to March 31)
Temperature	San Joaquin River (at Vernalis)	Chinook Salmon	April 1 to June 30 September 1 to November 3 Average daily water temperature may not be elevated by controllable factors above 68 °F.
	All	COLD WARM	Maximum 5 °F increase, as specified in Central Valley RWQCB objectives

most of the river below La Grange Dam between October 15 and June 15. The objective is intended to protect spawning salmonids and their eggs.

Impaired water bodies on the Tuolumne River are shown in **Table 5.3.3-7**. Don Pedro Reservoir is listed under Section 303(d) for mercury. The elevated mercury concentrations are a result of past gold mining in the Tuolumne River watershed. The reach of the river below Don Pedro Reservoir is listed for pesticides and unknown toxicity.

San Joaquin River

Water quality objectives for the San Joaquin River are shown in Table 5.3.3-6. The objectives include dissolved oxygen and water temperature objectives designed to protect migrating Chinook salmon and salinity objectives designed to protect municipal, industrial, and agricultural water supplies. As shown in Table 5.3.3-7, the San Joaquin River is listed as impaired under Section 303(d) for mercury, boron, various pesticides, salinity, and unknown toxicity.

Sacramento–San Joaquin Delta

As noted above, the Sacramento–San Joaquin Delta lies at the heart of California’s natural and manmade water systems. The Delta’s physical complexity and competing interests for water

make management of the Delta difficult. Water quality and flow objectives for the Delta have been the subject of much controversy and have frequently been revised. Some issues remain unresolved, including the degree to which parties that divert water upstream of the Delta are responsible for meeting Delta objectives. Resolution of these issues could affect all upstream diverters, including the SFPUC, TID, and MID.

The San Francisco Region WQCP, published in the early 1970s, designated beneficial uses and water quality objectives for both San Francisco Bay and the Delta. In 1978, a WQCP for the Sacramento–San Joaquin Delta and Suisun Marsh was published. In 1991, a WQCP for salinity in the San Francisco Bay/Sacramento–San Joaquin Delta Estuary (Bay-Delta estuary) was published. When the Monterey Agreement was signed in December 1994, the beneficial uses and water quality objectives contained in the 1978 and 1991 WQCPs were in effect. In May 1995, as the first elements of the Monterey Amendment were being implemented, the SWRCB adopted a new WQCP for San Francisco Bay and the Delta that superseded both the 1978 and 1991 plans (SWRCB, 1995).

The SWRCB is responsible for issuing and administering water-rights permits in California. In 1978, the SWRCB adopted Water Rights Decision 1485 (D-1485), which established minimum flows in the Delta and limited exports of water by the State Water Project and Central Valley Project. The purpose of D-1485 was to ensure compliance with then-current water quality objectives. D-1485 superseded all earlier water-rights decisions for State Water Project and Central Valley Project operations in the Delta. Various interests filed lawsuits challenging D-1485. In 1986, a ruling known as the Racanelli Decision affirmed the SWRCB's broad authority and obligation to establish water quality objectives and set water-rights permit terms that provide reasonable protection to the beneficial uses of Delta waters (DWR, 1998). In 1987, the SWRCB began hearings to adopt new Delta objectives and a new water-rights decision.

Although the SWRCB adopted new water quality and flow objectives in 1995 as part of the 1995 Bay-Delta WQCP, D-1485 remained in effect until 1999.

Water Quality and Flow Objectives. The WQCP for San Francisco Bay and the Delta, published in 1995, included water quality and flow objectives for the Delta. A draft EIR on the WQCP was published in 1997 (SWRCB, 1997). In the EIR, the SWRCB acknowledged that the flow objectives can only be achieved by limiting diversions of water in the Sacramento and San Joaquin River watersheds and within the Delta itself. The EIR noted that the SWRCB intended to implement the objectives, to the extent feasible, through amendments to the permits of water-rights holders in the Central Valley. However, the EIR also noted that some of the objectives cannot reasonably be achieved through changes to water-rights permits exclusively. Water quality and the health of aquatic resources in the Delta and San Francisco Bay are dependent on many factors outside the regulatory authority of the SWRCB. These factors include salt buildup in the San Joaquin Valley, introduction of non-native aquatic species, legal and illegal fishing, and degradation of upstream spawning habitat for fish that migrate through the Delta.

In the years following publication of the WQCP, most of the objectives of the WQCP were implemented through biological opinions issued by the USFWS and the NMFS pursuant to the Federal Endangered Species Act and through D-1485 and SWRCB Order WR 98-9. Under the biological opinions, D-1485, and WR 98-9, responsibility for meeting most of the objectives was assigned to the State Water Project and the Central Valley Project (SWRCB, 1999).

The SWRCB established separate Delta water quality objectives for municipal and industrial, agricultural, and fish and wildlife beneficial uses. The objectives for municipal and industrial beneficial uses require that certain chloride levels be maintained at certain locations in the Delta during certain hydrologic year types. The objectives for agricultural beneficial uses require that certain electrical conductivity levels be maintained at certain locations in the Delta during certain months of the year. The objectives for fish and wildlife beneficial uses require that certain electrical conductivity levels be maintained at certain locations in the Delta during certain months of the year. They also require that certain minimum levels of Delta outflow and maximum levels of export by the State Water Project and Central Valley Project be maintained during certain hydrologic year types.

5.3.3.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to surface water quality, but generally considers that implementation of the proposed program would have a significant impact if it were to:

- Substantially impair a water body's ability to support beneficial uses designated by the State Water Resources Control Board or Regional Water Quality Control Board
- Otherwise substantially degrade water quality

Approach to Analysis

This section describes the impacts of the WSIP on surface water quality in the Tuolumne River watershed. The changes in surface water quality would result from WSIP-induced changes in stream flow and reservoir water levels. The effects of the WSIP on stream flow and reservoir water levels are described in Section 5.3.1. In general, effects are found to be significant if they would frequently exceed water quality objectives. Very infrequent exceedances of water quality objectives would not be considered significant here because the exceedances would not substantially impair designated beneficial uses or substantially degrade water quality.

Changes in flow in rivers and streams and changes in reservoir storage and water levels attributable to WSIP implementation were estimated using the HH/LSM. An overview of the model is presented in Section 5.1. Detailed information on the model and the assumptions that underlie it is provided in Appendix H. A second model, VR_Temp, was used to assess the effects of the WSIP on water temperature in the Tuolumne River below La Grange Dam. It is also described in Appendix H.

Beth Neilson at Utah State University and Dr. Steve Chapra at Tufts University developed VR_Temp for application to the Virgin River in Utah. VR_Temp is a one-dimensional, surface heat balance and kinematic flow routing model developed based on the derivations found in Chapra (1997). The model is able to estimate maximum daily water temperatures and was constructed to allow different input time steps for meteorological data as well as point and distributed inflow sources. The model allows a single stream or river segment to be divided into computational cells or elements; stream networks are not modeled and tributaries are treated as a time-series input. VR_Temp was adapted for use on the Tuolumne River by Mike Deas for Merritt-Smith Consultants.

Impact Summary

Table 5.3.3-8 presents a summary of the impacts on surface water quality in the Tuolumne River system and downstream water bodies that could result from implementation of the proposed water supply and system operations.

TABLE 5.3.3-8
SUMMARY OF IMPACTS – SURFACE WATER QUALITY
IN THE TUOLUMNE RIVER SYSTEM AND DOWNSTREAM WATER BODIES

Impact	Significance Determination
Impact 5.3.3-1: Effects on water quality in Hetch Hetchy Reservoir and along the Tuolumne River below O'Shaughnessy Dam	LS
Impact 5.3.3-2: Effects on water quality in Don Pedro Reservoir and along the Tuolumne River below La Grange Dam	LS
Impact 5.3.3-3: Effects on water quality along the San Joaquin River and the Sacramento–San Joaquin Delta	LS

LS = Less than Significant impact, no mitigation required

Impact Discussion

Impact 5.3.3-1: Effects on water quality in Hetch Hetchy Reservoir and along the Tuolumne River below O'Shaughnessy Dam.

The primary water quality parameters of concern in Hetch Hetchy Reservoir and the Tuolumne River below the reservoir are water temperature and dissolved oxygen. Most fish species that inhabit the reservoir and the Tuolumne River below O'Shaughnessy Dam are adapted to cool temperatures and well-oxygenated water. Water entering Hetch Hetchy Reservoir in the spring is cold and well oxygenated. Rising air temperatures and solar radiation in the summer heat the surface waters of the reservoir, but deeper water (25 to 50 feet below the surface) remains cold. The oxygen content of deeper waters declines somewhat through the summer as a result of biochemical reactions, but oxygen depletion is limited by the lack of plant nutrients in Hetch Hetchy water. The reductions in storage and water levels in Hetch Hetchy Reservoir attributable to the proposed program under average (or even average dry) conditions would be too small to have much effect on water temperature or dissolved oxygen content. Because the WSIP would have little effect on reservoir water quality, it would have little effect on the quality of water released from the reservoir to the Tuolumne River below the reservoir.

However, reductions in storage and water levels could have a greater effect on reservoir water quality and the quality of water released to the Tuolumne River during extremely dry periods. As noted above and shown diagrammatically in Figure 5.3.3-2, deep reservoirs in the Sierra Nevada stratify in the summer. Normally, water released from Hetch Hetchy Reservoir to the Tuolumne River is drawn from the cool pool of water below the thermocline. If the reservoir is drawn down sufficiently, releases to the river could exhaust the pool of cool water, and warmer water from above the thermocline would be released.

Conditions that would result during droughts similar to those that occurred in 1923–1935, 1986–1993, and 1976–1977 were examined using the HH/LSM with the proposed program and under existing conditions. In a drought similar to the 1986–1993 drought, the water level in Hetch

Hetchy Reservoir would never be drawn down sufficiently to affect water temperature in the Tuolumne River below the reservoir. In a drought similar to the 1923–1935 drought, the water level in Hetch Hetchy Reservoir would be drawn down to very low levels in January through April of the tenth year of the drought. However, in these months the reservoir is not stratified and so the drawdown would have little or no effect on downstream water temperatures.

In a drought similar to the 1976–1977 drought, the water level in Hetch Hetchy Reservoir would be drawn down to very low levels in October through January of the second and third years of the drought with the WSIP, as shown in Figure 5.3.1-9. In October and November, the reservoir would normally be stratified; that is, water above the thermocline, which would be at a depth of about 60 to 80 feet, would be 10 or 12 °C warmer than water below the thermocline. The drawdown in September and October would destratify the reservoir and would result in an increase in the temperature of water released to the Tuolumne River, from about 8 °C to perhaps 14 to 18 °C. This phenomenon would occur in a drought similar to the 1976–1977 drought under the existing condition as well as with the proposed program. However, as shown in Figure 5.3.1-9, the drawdown in Hetch Hetchy Reservoir with the WSIP would be greater than under the existing condition, and thus the adverse water quality effects would likely last longer by several days or weeks.

The dissolved oxygen content of water released from Hetch Hetchy Reservoir varies depending on water temperature and the depth from which it is drawn. Most of the time, the water drawn from the reservoir is well oxygenated. Any water with depleted oxygen levels is rapidly reoxygenated as a result of its turbulent release to the Tuolumne River. The WSIP would have little or no effect on dissolved oxygen levels in water released to river.

Water quality in the Tuolumne River would occasionally be affected by WSIP-induced changes in the temperature of releases from Hetch Hetchy Reservoir, as described above. It could also be affected by WSIP-induced changes in stream flow in the Tuolumne River below Hetch Hetchy Reservoir. However, the effects of the two phenomena would not coincide because the former would occur in early fall and the latter in the late spring and early summer.

The proposed program would have little or no effect on flow below Hetch Hetchy Reservoir in most summer, fall, and winter months, as described previously, and consequently would have little or no effect on water temperature. Water temperature would only be affected if the WSIP resulted in a substantial reduction in flow at a time when air temperatures and solar radiation are sufficient to heat the diminished flowing stream. **Table 5.3.3-9** shows the five months in the 964-month hydrologic record during which the WSIP would reduce flows in the river substantially; as the table indicates, the proposed program would reduce flow by 50 percent or more compared to the existing condition and would reduce flows to below 200 cfs. All five occurrences would be in the month of May.

Even in the fairly extreme conditions shown in Table 5.3.3-9, it is questionable whether water temperatures in the Tuolumne River below Hetch Hetchy Reservoir would become elevated compared to the existing condition. In May, average daily air temperatures are moderate and accumulated snow is melting. Snowmelt runoff into the Tuolumne River, both directly and from

TABLE 5.3.3-9
AVERAGE FLOWS FOR CONDITIONS WHERE WATER TEMPERATURES COULD BE ADVERSELY AFFECTED (TUOLUMNE RIVER BELOW HETCH HETCHY)
(cubic feet per second)

Date	Existing Condition	Proposed Program	Difference
May 1962	777	100	-677
May 1978	857	100	-757
May 1981	413	144	-169
May 1992	530	50	-470
May 1999	383	164	-219

SOURCE: SFPUC, HH/LSM (see Appendix H).

tributaries (including Cherry Creek and the Clavey River) between Hetch Hetchy Reservoir and Don Pedro Reservoir would minimize any temperature increases resulting from WSIP-induced reductions in flow.

In general, the WSIP would have very little effect on water quality in Hetch Hetchy Reservoir or the Tuolumne River below the reservoir. WSIP-induced reductions in flow in the Tuolumne River below the reservoir would occur primarily in May and would not be expected to result in sufficient changes in water temperature to affect the river's ability to support its designated beneficial uses, including support of a coldwater fishery. On very rare occasions under existing conditions and during extreme droughts (once in the 82-year hydrologic record), warm water is released from Hetch Hetchy Reservoir to the Tuolumne River. At such times, the water quality objective that limits increases in water temperature to 5 degrees Fahrenheit (°F) to protect coldwater fish would likely be exceeded. With the WSIP, the release of warm water would continue to be a rare occurrence (once in the 82-year hydrologic record), but the period during which warm water would be released from Hetch Hetchy Reservoir, and the water quality objective exceeded, would be extended by several days or weeks.

Exceedances of the water quality objective that limits temperature changes have probably occurred very infrequently under the existing condition (modeling indicates that it may have occurred once in the 82-year period of hydrologic record). In the future with the WSIP, very infrequent exceedances of the water quality objective would continue to occur, but could last longer by several days or weeks than under the existing condition. Infrequent exceedances of the standard would not substantially affect the Tuolumne River's ability to support its designated beneficial uses, including support of a coldwater fishery. This is because, during times when an exceedance of the objective occurred, water temperatures would still remain within an acceptable range for coldwater fish (see Section 5.3.6). Thus, the impact of the WSIP on water quality in Hetch Hetchy Reservoir and the Tuolumne River would be *less than significant*, and no mitigation measures would be required.

[Additional discussion on impacts on water quality in the upper Tuolumne River was prepared in response to comments on the Draft PEIR. Please refer to Section 14.6, Master Response on Upper Tuolumne River Issues Issues (Vol. 7, Chapter 14).]

Impact 5.3.3-2: Effects on water quality in Don Pedro Reservoir and along the Tuolumne River below La Grange Dam.

The primary water quality parameter of concern in Don Pedro Reservoir is water temperature. Like Hetch Hetchy Reservoir, Don Pedro Reservoir stratifies in the summer months. If the WSIP caused the reservoir to be greatly drawn down, then it would adversely affect water temperature in the Tuolumne River below La Grange Dam. Reservoir drawdown would be at its greatest during extended dry periods.

Conditions that would result in Don Pedro Reservoir during droughts similar to those that occurred in 1923–1935, 1986–1993, and 1976–1977 were examined using the HH/LSM. As indicated in Figure 5.3.1-12, although Don Pedro Reservoir would be drawn down greatly in each of the droughts, storage in the reservoir would never decrease much below 500,000 acre-feet. **Table 5.3.3-10** compares storage in Don Pedro Reservoir in the 1923–1935 and 1986–1993 droughts with the proposed program and under existing conditions. It also shows the elevation of the thermocline and the volume of the cool water pool under both conditions. Although the WSIP would lower the elevation of the thermocline when storage in the reservoir is at a minimum, the thermocline would still be considerably above the elevation of the outlet from Don Pedro

TABLE 5.3.3-10
COMPARISON OF STORAGE, COOL WATER POOL VOLUMES, AND DEPTH TO THERMOCLINE FOR DON PEDRO RESERVOIR UNDER EXISTING CONDITIONS AND WITH THE WSIP

Drought Conditions	Minimum Storage (acre-feet)		Cool Water Pool (acre-feet)		Thermocline Elevation (feet msl)	
	Existing	WSIP	Existing	WSIP	Existing	WSIP
1923–1935	680,066	623,932	360,000	320,000	614	604
1986–1994	823,654	695,955	450,000	370,000	636	616

SOURCE: Merritt-Smith Consultants (raw data).

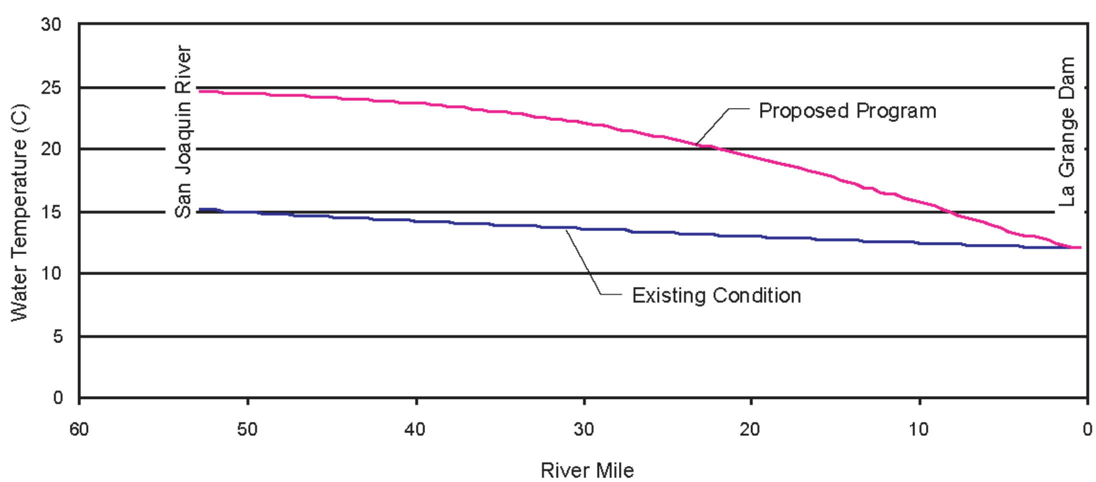
Reservoir. The outlet is an 18.5-foot-diameter tunnel with a crest elevation of 543.5 feet above mean sea level (msl). Releases from the reservoir with the WSIP in place would still be from the cool water pool below the thermocline. Thus, the changes in water level in Don Pedro Reservoir attributable to the proposed program would not increase the temperature of water released to the Tuolumne River below La Grange Dam.

Although water temperature in the Tuolumne River would not be affected by WSIP-induced changes in releases from Don Pedro Reservoir, it could be affected by WSIP-induced changes in stream flow. The proposed program would have little effect on flow below Don Pedro Reservoir in most summer, fall, and winter months, but it could cause reductions in flow of up to 95 percent compared to the existing condition under certain circumstances. For example, under hydrologic conditions similar to those that occurred in June 1999, the release to the Tuolumne River under the existing condition would be 523 cfs; with the WSIP it would be 250 cfs, a reduction of 52 percent.

Most of the large-percentage reductions in flow in the Tuolumne River below La Grange Dam would occur in April, May, and June following dry periods, when Don Pedro Reservoir would be drawn down. Reductions in flow in the late spring and early summer as a result of the proposed program could affect water temperatures under certain circumstances. These circumstances might include reductions in flow of 50 percent or more and flows of less than 400 cfs that result from WSIP-induced flow reductions. The results of the simulation of flows below La Grange Dam using 82 years of hydrologic data were examined to determine how frequently these circumstances occur. The analysis indicates that there are only three months over the 984-month hydrologic record when the circumstances would occur, and thus the condition has the potential to occur very infrequently.

The VR_Temp model was used to examine the effects on water temperature of WSIP-induced reductions in flow below La Grange Dam. Two conditions were simulated: the June 1993 and June 1999 events. The June 1993 event is an extreme event with over a 90 percent reduction in flow. Such a reduction only occurs once in the 82-year hydrologic record, as shown in Figure 5.3.1-12. The June 1999 event is less extreme than the June 1993 event, but it would still be rare. It involves a reduction in flow of 50 percent.

Water released from La Grange Dam in June is considerably cooler than the average daily air temperature. As water flows downstream, its temperature increases. The smaller the thermal mass of the water, the faster its temperature increases. **Figure 5.3.3-3** shows estimated mean daily water temperature in the Tuolumne River between La Grange Dam and the confluence with the San Joaquin River under June 1993 conditions with the proposed program and under existing conditions. Water temperature rises more rapidly with the proposed program than under existing conditions. Mean daily temperature in the Tuolumne River just upstream of the confluence with the San Joaquin River would be about 10 °C higher with the WSIP than under current conditions.



SFPUC Water System Improvement Program ▪ 203287

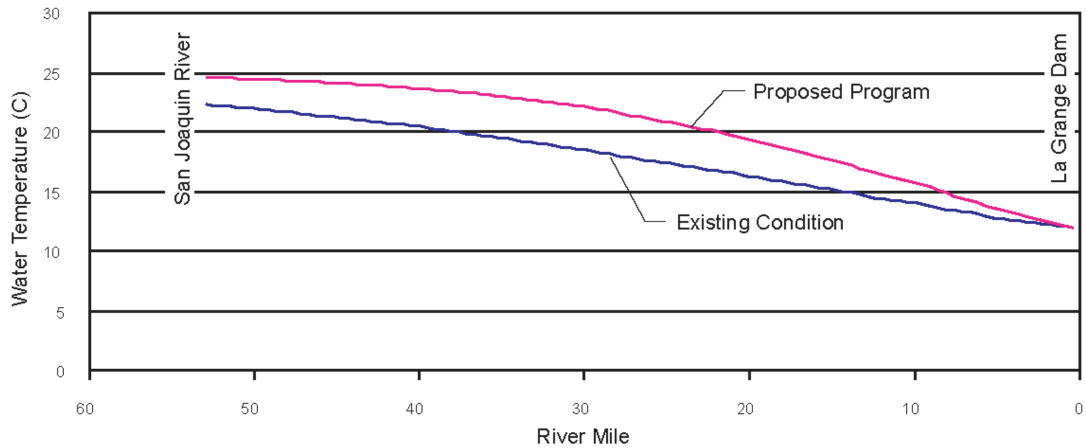
Figure 5.3.3-3
Longitudinal Profile of Simulated Mean Daily Water Temperature from La Grange Dam to the San Joaquin River, June 1993

Figure 5.3.3-4 shows similar information for June 1999 conditions. In this case, the temperature increase produced by the WSIP at the confluence with the San Joaquin River would be about 2°C.



SFPUC Water System Improvement Program ▪ 203287

SOURCE: Merritt-Smith Consultants (raw data)

Figure 5.3.3-4
Longitudinal Profile of Simulated Mean Daily Water Temperature from La Grange Dam to the San Joaquin River, June 1999

Almost all of the time, WSIP-induced flow reductions in the Tuolumne River below La Grange Dam would have no effect on water temperature. On infrequent occasions, 12 months in the 82-year period of hydrologic record, WSIP-induced flow reductions would cause mean daily temperature increases in the Tuolumne River of 1 or 2 °C. On very rare occasions, one month in the 82-year period of hydrologic record, WSIP-induced flow reductions would cause mean daily temperature increases of 10 °C.

Water quality objectives for the Tuolumne River require that water temperatures not be increased by more than 5 °F (2.8 °C). The WSIP would comply with this objective almost all of the time. On rare occasions, estimated at three or four months in the 82-year period of hydrologic record, there would be exceedances of the objective, but these rare exceedances would not impair the river's ability to support the designated beneficial uses that the objective is designed to protect, including coldwater fisheries. Consequently, this impact would be *less than significant*, and no mitigation measures would be required.

[Additional discussion on impacts on water quality in the lower Tuolumne River was prepared in response to comments on the Draft PEIR. Please refer to Section 14.7, Master Response on Lower Tuolumne River Issues (Vol. 7, Chapter 14).]

Impact 5.3.3-3: Effects on water quality along the San Joaquin River and the Sacramento–San Joaquin Delta.

The Tuolumne River joins the San Joaquin River about 50 miles downstream of La Grange Dam. The reductions in flow in the Tuolumne River below La Grange Dam attributable to the WSIP (as shown in Table 5.3.1-6) would reduce flows in the Tuolumne River between La Grange Dam and its confluence with the San Joaquin River, and in the San Joaquin River from the confluence to the Delta. There is a potential for reductions in flow to affect water quality. However, most of the reductions in flow would occur from February through June in wet or above-normal years when flow in the San Joaquin River is at its seasonal maximum. As a consequence, most of the time, WSIP-induced changes in flow would have little effect on water quality in the San Joaquin River.

The SWRCB has established water quality objectives for the San Joaquin River at Vernalis, just upstream of the Sacramento–San Joaquin Delta. The objectives are expressed in term of electroconductivity, a measure of salinity. The salinity of river water at Vernalis becomes elevated when flow in the river is insufficient to repel saltwater entering from Suisun Bay. Almost all of the time, the reductions in San Joaquin River flow attributable to the WSIP would not be sufficient to cause salinity in the river at Vernalis to rise above the objective. Very infrequently, following protracted droughts, reductions in San Joaquin River flow attributable to the WSIP could be sufficient to cause salinity in the river at Vernalis to rise above the objective. Under these circumstances, the USBR, the agency responsible for compliance with objectives for the San Joaquin River, would increase releases from New Melones Reservoir on the Stanislaus River to meet the water quality objectives at Vernalis. Thus, the WSIP would not alter water quality in the San Joaquin River below its confluence with the Tuolumne River such that it would be substantially outside the range experienced under the existing condition. The impact would be *less than significant*, and no mitigation measures would be required.

The reductions in flow in the Tuolumne River below La Grange Dam attributable to the WSIP would also reduce inflow to the Sacramento–San Joaquin Delta. The changes in Delta inflow as a result of the WSIP would be too small to have much effect on water quality in the Delta, particularly as the changes would occur when flow through the Delta is at its seasonal maximum. The impact would be *less than significant*, and no mitigation measures would be required.

5.3.4 Surface Water Supplies

The following setting section describes downstream water users whose water supply could be affected by the WSIP. The impact section (Section 5.3.4.2) provides a description of the changes in water availability and quality for downstream users resulting from WSIP-induced changes in stream flow.

5.3.4.1 Setting

The Tuolumne River flows from the crest of the Sierra Nevada westward to its confluence with the San Joaquin River. The San Joaquin River flows north to the Sacramento–San Joaquin Delta. Water from the Delta discharges to the San Francisco Bay Estuary and the Pacific Ocean. Because the WSIP would result in increased diversions of water from the Tuolumne River at Hetch Hetchy Reservoir, high in the Tuolumne River watershed, flow in the Tuolumne and San Joaquin Rivers and inflow to the Sacramento–San Joaquin Delta would be decreased in some months of some hydrologic year types. The changes in flow attributable to the WSIP are described in Section 5.3.1.

A number of water agencies and other diverters obtain their water supplies from the Tuolumne and San Joaquin Rivers and from the Delta. The water supplies of these agencies and other diverters could potentially be affected by the WSIP. Water agencies and others divert water from the rivers and the Delta in accordance with riparian water rights, pre-1914 appropriative water rights, and appropriative water-rights permits granted by the SWRCB.

In California, two doctrines govern surface water rights, the riparian doctrine and the doctrine of prior appropriation. A riparian water right is the right to use water for a reasonable and beneficial purpose as a result of the ownership of property that abuts a natural waterway. An appropriative water right is the right to use a specific quantity of water for a reasonable purpose at a specific location. The historical principle underlying the appropriation doctrine is "first-in-time, first-in-right." An entity that first appropriates and uses water for a reasonable beneficial purpose has a right that is superior to the rights of later appropriators. When water is short and insufficient to meet the needs of all holders of appropriative water rights, the rights of senior water-rights holders must be satisfied before those of junior water-rights holders.

Prior to 1914, an entity followed certain procedures to obtain an appropriative water right but did not need to obtain a permit from the State of California. A change in state law in 1914 provided that all water within the state is the property of the people of the state and made it a requirement that appropriators obtain a permit to divert surface water. San Francisco holds pre-1914 rights to divert water from the Tuolumne River. The SWRCB does not regulate pre-1914 water rights.

Two of California's largest water storage and conveyance projects, the federal Central Valley Project and the State Water Project, divert water from the Delta. The USBR, which operates the Central Valley Project, and the DWR, which operates the State Water Project, hold post-1914 appropriative rights to divert water from the Delta. These rights are junior to San Francisco's Tuolumne River water rights.

Because of the size of the diversions made by the Central Valley Project and State Water Project, the nature of their authorizing legislation, and the priority of their water rights, the SWRCB assigned unique responsibilities to the USBR and DWR for compliance with Delta water quality and flow objectives. The USBR and DWR must operate the Central Valley Project and State Water Project in a manner that maintains compliance with Delta objectives. They are not permitted to fully exercise their water rights in the Delta if to do so would cause a violation of Delta water quality or flow objectives.

San Joaquin River and Sacramento–San Joaquin Delta

The San Joaquin River rises in the Sierra Nevada and drains an area of 13,500 square miles. After reaching the floor of the San Joaquin Valley near Fresno, the river flows westward towards the community of Mendota, then northwest for about 100 miles to the Sacramento–San Joaquin Delta. Some reaches of the river upstream and downstream of Mendota are dry, except when flood releases are made from Millerton Reservoir. The river begins to flow again generally downstream of the Mariposa Bypass as it gains water from agricultural irrigation, wildlife area management return flows, and tributaries. Major tributaries that join the San Joaquin River upstream of its confluence with the Delta include the Merced, Tuolumne, and Stanislaus Rivers. The San Joaquin River watershed is shown in Figure 5.3.1-7.

State Water Project

The State Water Project is California's second-largest water project; it operates Oroville Reservoir, with a capacity of about 3.5 million acre-feet, on the Feather River. Water from Oroville Reservoir is released to the Feather River and flows downstream to the Sacramento River and the Delta. Water is diverted from the south Delta at the State Water Project's Banks Pumping Plant and conveyed southward in the California Aqueduct to the State Water Project's contractors and to San Luis Reservoir, a joint-use facility of the Central Valley and State Water Projects. On average, the State Water Project delivers 2.4 million acre-feet each year for municipal and agricultural use, almost all of which is diverted from the Delta at the Banks Pumping Plant.

Central Valley Project

The Central Valley Project is California's largest water project. On average, the Central Valley Project delivers 5.6 million acre-feet of water each year for agricultural, wildlife management, and municipal use.

North of the Delta, the Central Valley Project operates reservoirs on the Sacramento, Trinity, and American Rivers. Shasta Reservoir, on the upper Sacramento River, has a capacity of 4.5 million acre-feet. Claire Engle Lake is located on the Trinity River, which flows to the Klamath River and to the Pacific Ocean near the California/Oregon border. Claire Engle Lake has a capacity of 2.4 million acre-feet. Water from the lake is diverted through a tunnel to the Sacramento River, where it combines with releases from Shasta Reservoir. Folsom Reservoir is located on the American River and has a capacity of 1 million acre-feet. Releases from all three reservoirs flow downstream to the Delta.

Water is diverted from the south Delta at the Central Valley Project's Tracy Pumping Plant and conveyed southward to Central Valley Project contractors on the western side of the San Joaquin Valley via the Delta-Mendota Canal and for delivery to San Luis Reservoir. The Central Valley Project's diversions at the Tracy Pumping Plant average about 1.7 million acre-feet per year. Smaller amounts of Central Valley Project water are diverted at the State Water Project's Banks Pumping Plant and conveyed southward in the California Aqueduct. The USBR supplies water to Central Valley Project contractors on the eastern side of the San Joaquin Valley from Millerton Reservoir on the San Joaquin River and several other reservoirs on tributaries of the San Joaquin River, including New Melones Reservoir on the Stanislaus River.

Flow and Water Quality Objectives for the San Joaquin River and the Delta

The SWRCB has established numerous flow and water quality objectives for the San Joaquin River at Vernalis and for the Sacramento–San Joaquin Delta. These objectives are prescribed in Decision 1641. Illustrative of these objectives are the flow and quality objectives for the San Joaquin River at Vernalis shown in **Table 5.3.4-1**. Outflow requirements from the Delta could be the specific flow objectives or the required flow to maintain salinity objectives at certain locations in the Delta. Specific flow objectives at Chipps Island are shown in **Table 5.3.4-2**.

TABLE 5.3.4-1
FLOW AND WATER QUALITY OBJECTIVES FOR SAN JOAQUIN RIVER AT VERNALIS

Year Type	Dates	Minimum Monthly Average Flow (cfs)[a]
Wet, above normal	February – April 14	2,130 or 3,420
Below normal, dry	February 1 – April 14	1,420 or 2,280
Critical	February 1 – April 14	710 or 1,140
Wet	April 15 – May 15	7,330 or 8,620
Above normal	April 15 – May 15	5,730 or 7,020
Below normal	April 15 – May 15	4,620 or 5,480
Dry	April 15 – May 15	4,020 or 4,880
Critical	April 15 – May 15	3,110 or 3,540
Wet, above normal	May 16 – June 30	2,130 or 3,420
Below normal, dry	May 16 – June 30	1,420 or 2,280
Critical	May 16 – June 30	710 or 1,140
All	October	1,000
All Years	April – August	0.7 mmhos/cm[b]
All Years	September – March	1.0 mmhos/cm[b]

[a] The higher flow objective applies when the 2 parts per thousand isohaline is required to be at or west of Chipps Island. An isohaline is a line drawn through places that have equal values of water salinity. The April 15–May 15 flow objective is currently replaced by the protocols of the San Joaquin River Agreement and the Vernalis Adaptive Management Program, which provides flows during this period ranging between 3,200 cfs and 7,000 cfs.
[b] The water quality objective is to be met on a 30-day running average of mean daily water electroconductivity, which provides a measure of water salinity. The units of electroconductivity are millisiemens per centimeter.

SOURCE: SWRCB, 1995.

TABLE 5.3.4-2
FLOW OBJECTIVES FOR SACRAMENTO–SAN JOAQUIN DELTA

Year Type	Dates	Minimum Monthly Delta Outflow (cfs)[a]
All	January	4,500[b]
All	February – June	7,100[c]
Wet, above normal	July	8,000
Below normal	July	6,500
Dry	July	5,000
Critical	July	4,000
Wet, above normal, below normal	August	4,000
Dry	August	3,500
Critical	August	3,000
All	September	3,000
Wet, above normal, below normal, dry	October	4,000
Critical	October	3,000
Wet, above normal, below normal, dry	November – December	4,500
Critical	November – December	3,500

[a] Flow as determined by the Net Delta Outflow Index. For the May–January objectives, if the value is less than or equal to 5,000 cfs, the 7-day running average shall not be less than 1,000 cfs below the value; if the value is greater than 5,000 cfs, the 7-day running average shall not be less than 80 percent of the value.
[b] The objective is increased to 6,000 cfs if the best available estimate of unimpaired Delta inflow for December is greater than 800,000 acre-feet.
[c] The minimum Delta outflow required may be reduced under certain conditions described in the San Francisco Bay–Delta Water Quality Control Plan.

5.3.4.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to water supplies, but generally considers that implementation of the proposed program would have a significant water supply impact if it were to:

- Result in substantial adverse changes in operations or substantial decreases in water deliveries for water users, as measured by significant changes in reservoir storage, timing or rate of river flows, or water quality
- Violate any water quality standards or otherwise substantially degrade water quality

Approach to Analysis

Changes in flow in rivers and streams and changes in reservoir storage and water levels in the Tuolumne River watershed attributable to the WSIP were estimated using the HH/LSM. An overview of the model is presented in Section 5.1. The HH/LSM simulates water deliveries, reservoir storage, and releases to rivers under different conditions using hydrologic data from the period 1920 to 2002. Detailed information on the model and the assumptions that underlie it is provided in Appendix H. Changes in stream flow were then used to estimate the effects on water availability and water quality for downstream users.

Impact Summary

Table 5.3.4-3 presents a summary of the impacts on the water supply of downstream users that could result from implementation of the proposed program.

TABLE 5.3.4-3
SUMMARY OF IMPACTS – SURFACE WATER SUPPLIES OF DOWNSTREAM USERS

Impact	Significance Determination
Impact 5.3.4-1: Effects on Tuolumne River, San Joaquin River, and Stanislaus River water users	LS
Impact 5.3.4-2: Effects on Delta water users	LS

LS = Less than Significant impact, no mitigation required

Impact Discussion

Impact 5.3.4-1: Effects on Tuolumne River, San Joaquin River, and Stanislaus River water users.

Like the CCSF, TID and MID hold pre-1914 rights to Tuolumne River water. When the federal government passed the Raker Act in 1913, it granted the CCSF the rights-of-way and public lands necessary to construct the Hetch Hetchy system. The Raker Act includes various conditions, one of which is that the CCSF must recognize TID's and MID's prior rights to water from the Tuolumne River. In the same year the Raker Act was passed, the CCSF reached agreement with TID and MID on the amount of water needed to satisfy their prior water rights. All of the SFPUC's existing water supply facilities are operated in compliance with the provisions of the Raker Act and would continue to be operated in compliance with the act after the WSIP has been implemented. Consequently, the WSIP would have no adverse effect on the availability of Tuolumne River water to TID and MID or on the quality of water available to them.

Changes in flow in the Tuolumne River below La Grange Dam attributable to the WSIP would affect flows in the San Joaquin River from its confluence with the Tuolumne River to the Delta. The Delta standards include flow and quality objectives for the San Joaquin River at Vernalis, just upstream of the point where the San Joaquin River flows into the Delta. Very infrequently, following protracted droughts, reductions in San Joaquin River flow attributable to the WSIP could make it necessary for the USBR, the agency responsible for compliance with water quality and flow objectives for the San Joaquin River, to increase releases from New Melones Reservoir to meet the objectives at Vernalis.

As described in Section 5.3.1, under existing conditions in the majority of years classified as below-normal or drier, almost all of the winter and spring runoff from the watershed upstream of Don Pedro Reservoir on the Tuolumne River is captured in the reservoir. Only the minimum required releases to the Tuolumne River below La Grange Dam are made. The WSIP would have no effect on flow in the Tuolumne River below La Grange Dam or the San Joaquin River in months when only the minimum flows are currently released. In years when the reservoir fills, usually wet or above-normal years, excess water is released in some months to the Tuolumne River. In the future with the WSIP, TID and MID would draw Don Pedro Reservoir down farther in most years than they would under the existing condition, and consequently a greater proportion of spring runoff would be needed to refill the reservoir. As a result, the volume of excess water released to the Tuolumne River would be reduced in all wet years, most above-normal years, and occasional below-normal and dry years.

Table 5.3.4-4 shows the change in modeled releases from La Grange Dam attributable to the WSIP for the 82-year hydrologic simulation, by year type and descending order of wetness. The magnitudes of modeled releases with and without the WSIP are shown in Table 5.3.1-6. Flow in the Tuolumne River below La Grange Dam and flow in the San Joaquin River below its confluence with the Tuolumne River would reflect the changes. As shown in the table, most of the changes in releases and the greatest changes in releases would occur in wet and above-normal years following a series of dry years. Many of the changes are small in magnitude compared to the required minimum stream flow releases shown in Table 5.3.1-3. Furthermore, most of the changes in releases would occur from February through June of the affected years, with an occasional occurrence during other months. When they occur, the changes in average monthly flows are usually in the hundreds of cubic feet per second (an average monthly flow of 100 cfs is equal to a monthly volume of about 6,000 acre-feet). Occasionally, changes are in the range of 1,000 cfs to a little over 3,000 cfs. The greatest changes would potentially occur infrequently during wetter years following protracted droughts.

The changes in flow described above would affect the Tuolumne River below La Grange Dam and the San Joaquin River below its confluence with the Tuolumne River. **Table 5.3.4-5** shows measured flows in the San Joaquin River at Vernalis for the period 1969 through 2002, arranged by descending order of wetness. As can be seen by the record, average monthly flows in the San Joaquin River vary seasonally and by year type. During wet years in February through June (the period when WSIP effects would mostly occur), flows generally range from a low of 5,000 cfs to over 40,000 cfs. During the summer, flows can diminish to as low as 1,500 cfs. During above-normal years in February through March (the period when WSIP effects mostly occur within this year type), flows are generally in excess of 7,000 cfs. A comparison between Tables 5.3.4-4 and 5.3.4-5 indicates that, although flows would be reduced with the WSIP, they would still exceed the flow objectives during wet and above-normal hydrologic conditions. Typically, during wet and above-normal years, there is sufficient tributary flow in the San Joaquin River basin to meet water quality objectives at Vernalis. Under these conditions, the USBR does not need to release water from New Melones Reservoir on the Stanislaus River to meet flow or water quality objectives at Vernalis.

As noted above, if the WSIP caused flow in the San Joaquin River at Vernalis to fall below the flow objective or caused water quality at Vernalis to fall below objectives, the USBR would have to increase releases from New Melones Reservoir or other San Joaquin Valley Central Valley Project facilities to compensate. During wet and above-normal years, when most of the effects of the WSIP would be felt, flow and water quality objectives at Vernalis would be met and the USBR would not have to release extra water from the reservoir. Thus, the WSIP would have no

TABLE 5.3.4-4

effect on the availability of Stanislaus River water to the USBR and the water supply agencies that receive water from New Melones Reservoir, except possibly on rare occasions following protracted droughts.

As indicated in Table 5.3.4-4, in many years and during certain seasons, the WSIP would not alter flow in the Tuolumne River below La Grange Dam and would, in turn, have no effect on flow in the San Joaquin River. Thus, under these conditions, the WSIP would have no effect on water availability or quality at the intakes of water agencies and diverters that use San Joaquin River water. In some wet and above-normal years, the WSIP would have an effect on flow in the San Joaquin River between the confluence with the Tuolumne River and the confluence with the Delta. Because the changes in San Joaquin River flow would be small in most wet and above-normal years, and because the changes would occur in periods when flow in the river is at its seasonal maximum, the effects of the flow changes on water quality would also be small. Water quality is at its seasonal best during the period when the WSIP-induced changes in flow would occur, and thus the quality of water at water agencies' and irrigators' diversion points would not change appreciably. All water quality objectives would be met, and specifically by releases from New Melones Reservoir or other San Joaquin Valley Central Valley Project facilities, if such action were necessary.

The WSIP would have a less-than-significant impact on water quality and the availability of water at water agencies' and irrigators' diversion points on the Tuolumne, Stanislaus, and San Joaquin Rivers. Therefore, WSIP impacts on Tuolumne, Stanislaus, and San Joaquin River water users would be *less than significant*, and no mitigation measures would be required.

Impacts 5.3.4-2: Effects on Delta water users.

Changes in flow in the Tuolumne River below La Grange Dam attributable to the WSIP would affect Sacramento–San Joaquin Delta inflow. The Delta standards include flow objectives for Delta outflow, and outflow at times is required for maintenance of water quality objectives within the Delta. Reductions in Delta inflow attributable to the WSIP could make it necessary for the DWR and USBR, the agencies responsible for compliance with objectives for the Delta, to increase reservoir releases and/or decrease diversions at the Banks and Tracy Pumping Plants to meet the objectives. At other times, the DWR and USBR could be limited in their export capacity by an objective that relates allowable export to Delta inflow.

Table 5.3.4-4 shows the changes in releases from La Grange Dam attributable to the WSIP. The changes would be reflected downstream as a change in Delta inflow. As shown in the table, most of the changes in releases and the greatest changes in releases would occur in wet and above-normal years. Furthermore, most of the changes in releases would occur from February through June of the affected years, with an occasional occurrence during other months. When they occur, the changes in average monthly flows are usually in the hundreds of cubic feet per second.

Occasionally, changes are in the range of 1,000 cfs to a little over 3,000 cfs. The greatest changes would potentially occur infrequently during wetter years following protracted droughts.

The WSIP would increase the SFPUC's diversions from the Tuolumne River almost every year, which would result in a decrease in inflow to Don Pedro Reservoir almost every year. During protracted droughts, WSIP-induced reductions in storage in Don Pedro Reservoir would accumulate for several years. When the drought ends, a large volume of water would be needed to refill or partially refill Don Pedro Reservoir. Much or all of the winter and spring runoff would be retained in Don Pedro Reservoir, and only minimum required releases would be made below La Grange Dam. Under these fairly rare conditions, WSIP-induced reductions in flow in the Tuolumne River below La Grange and in the San Joaquin River compared to the existing condition would be in the range 1,000 to 3,000 cfs.

Delta inflow varies widely from year-to-year and depends on hydrologic conditions and the magnitude of diversions upstream of the Delta. Delta outflow depends on hydrologic conditions, the magnitude of diversions upstream of the Delta, and the magnitude of diversions within the Delta, including diversions by the State Water Project and Central Valley Project.

Certain objectives for Delta outflow are shown in Table 5.3.4-2. The table is not an exhaustive compilation of all requirements for flow, nor does it specify the amount of flow needed to meet water quality objectives for the Delta.

Compliance with Delta outflow objectives is the responsibility of the DWR and the USBR and is achieved by releasing water from reservoirs upstream of the Delta or by limiting pumping at the Banks and Tracy Pumping Plants. When Delta inflow exceeds the sum of the Delta outflow objectives and the water needs of the State Water Project, Central Valley Project, and other diverters, the Delta is regarded as in "excess conditions." When the Delta is in excess conditions, there are no limits on pumping as a result of the export limits that are a part of D-1641. Exports are limited to 35 percent of Delta inflow from February through June and to 65 percent of Delta inflow from July through January. When Delta inflow is generally equal to the sum of the Delta outflow objectives and the water needs of the State Water Project, Central Valley Project, and other diverters, the Delta is regarded as in "balanced conditions."

The Delta is typically in excess conditions from December through May and balanced conditions from June through November. However, Delta inflow can vary by a factor of 10 or more, so there is considerable year-to-year variability in the periods of excess and balanced conditions.

The WSIP would typically reduce Delta inflow in wet and above-normal years when the Delta is in excess conditions and Delta outflow is so great that the export limits do not limit pumping by the State Water Project and Central Valley Project. Under these conditions, the WSIP would reduce Delta inflow and outflow by the same amount, but would have no effect on the State Water Project's and Central Valley Project's ability to pump water from the Delta. There could be rare occasions when the WSIP would reduce Delta inflow during excess conditions but when the export limits do affect pumping by the State Water Project and Central Valley Project. Under these conditions, the WSIP would reduce Delta outflow and could potentially reduce pumping by the State Water Project and Central Valley Project by 35 percent of the WSIP-induced reduction in Delta inflow. However, the State Water Project and Central Valley Project may choose to comply with the export limits by releasing more water from upstream reservoirs rather than by limiting pumping.

In the winter and spring of wet and above-normal years, when the effects of the WSIP on Delta inflow would be felt, Delta outflow would typically be in the range of 13,000 to 63,000 cfs. In almost all cases, the reduction in Delta ouflow attributable to the WSIP would be less than 500 cfs, a small proportion of total outflow. In very rare circumstances, during a wetter year that follows a multi-year drought period (six or more years), the WSIP-induced reduction in Delta inflow would be greater than 500 cfs, in the range 1,000 to 3,000 cfs.

When the Delta is in balanced conditions, the DWR and USBR must balance reservoir releases and pumping at the Banks and Tracy Pumping Plants in order to meet the Delta objectives. There could be occasions between June and September during some wet and above-normal years when WSIP-induced reductions in Delta inflow would occur during balanced conditions in the Delta. Under these rare circumstances, the State Water Project and Central Valley Project would have to increase releases from upstream reservoirs or curtail pumping in order to meet flow objectives for the Delta.

WSIP-induced decreases in Delta inflow would not lead to violations of Delta objectives. The State Water Project and Central Valley Project, the parties responsible for compliance with Delta standards, would react to changes in Delta inflow and ensure that the standards were met. WSIP-induced decreases in Delta inflow would not necessarily lead to reductions in water deliveries by the State Water Project and Central Valley Project. Table 5.3.4-4 shows the reductions in flow below La Grange Dam attributable to the WSIP, which would also be reflected as WSIP-induced reductions in Delta inflow. The inflow difference that would occur when the Delta is in balanced conditions and when pumping might be curtailed to comply with export limits would typically amount to an annual volume of 20,000 acre-feet, a small fraction of the average annual Delta inflow of about 21 million acre-feet. A WSIP-induced reduction in Delta inflow would likely be compensated for by releases from upstream reservoirs. In any particular year, the Delta inflow difference attributable to the WSIP would contribute to an increase in risk to water deliveries in a subsequent year, and would only be realized in a series of dry years.

Given the very small magnitude and low frequency of potential effects on Delta flows, the impact of the WSIP on water availability and quality at water agencies' and other diverters' diversion points in the Delta would be *less than significant*, and no mitigation measures would be required.

[Additional discussion on Delta water users was prepared in response to comments on the Draft PEIR. Please refer to Section 14.8, Master Response on Delta and San Joaquin River Issues (Vol. 7, Chapter 14).]

5.3.5 Groundwater

The following setting section identifies groundwater bodies in the Tuolumne River watershed that could be affected by the WSIP; they include those that are hydraulically connected to the Tuolumne River and its tributaries. The impact section (Section 5.3.5.2) provides a description of the changes in groundwater levels and quality that would result from WSIP-induced changes in stream flow.

5.3.5.1 Setting

The Tuolumne River flows from the crest of the Sierra Nevada westward to its confluence with the San Joaquin River. The San Joaquin River flows north to the Sacramento–San Joaquin Delta. The Tuolumne River system and downstream water bodies are shown in Figure 5.3.1-1. Unless otherwise designated by the California Regional Water Quality Control Board, all groundwaters in the Central Valley region are considered to be suitable or potentially suitable, at a minimum, for municipal and domestic supply, agricultural supply, industrial service supply, and industrial process supply.

From Hetch Hetchy Reservoir to Don Pedro Reservoir, the Tuolumne River flows through a deep canyon in mountainous terrain. The hydrogeologic units underlying the river exhibit low permeability. There are no large groundwater bodies along this reach of the river. Below Don Pedro Reservoir, the Tuolumne River flows through the Sierra Nevada foothills and on to the floor of the San Joaquin Valley. Permeable hydrogeologic units of the San Joaquin Valley Groundwater Basin underlie the foothills and valley floor.

This section is focused on the effects of WSIP-induced flow and water quality changes on groundwater bodies along the reach of the Tuolumne River between La Grange Dam and the confluence with the San Joaquin River. As described in Section 5.3.1, the proposed program would alter flows and water quality in the Tuolumne River and, to a lesser extent, in the San Joaquin River and Delta. Because a dynamic balance exists between rivers and the groundwater basins they flow through, changes in river flow can affect groundwater levels and quality. The San Joaquin Valley Groundwater Basin is bounded on the west by the Coast Ranges, on the south by the San Emigdio and Tehachapi Mountains, on the east by the Sierra Nevada, and on the north by the Delta and Sacramento Valley. Within this basin, the Modesto Groundwater Subbasin lies between the Stanislaus River to the north, the Tuolumne River to the south, the San Joaquin River to the west, and the Sierra Nevada to the east. The Turlock Groundwater Subbasin shares the east and west boundaries with the Modesto Groundwater Subbasin, with the Tuolumne River forming the northern boundary and the Merced River forming the southern boundary (USGS, 2004).

Modesto Groundwater Subbasin

The Modesto Subbasin covers approximately 385 square miles, with lands primarily in the Modesto Irrigation District (MID), Oakdale Irrigation District, and the city of Modesto. The aquifer system is complex; primary hydrogeologic units include both consolidated and unconsolidated sedimentary deposits. The consolidated deposits lie in the eastern portion of the subbasin and include the Ione, Valley Springs, and Mehrten Formations; of these three, the Mehrten Formation is a high-yielding aquifer. Unconsolidated deposits include continental and alluvium deposits and are the main water-yielding units; Corcoran Clay separates older and younger alluvium, with generally unconfined conditions above and confined conditions below.[1] Groundwater recharge is primarily from deep percolation of applied irrigation water, canal seepage from irrigation facilities, seepage from Modesto Reservoir, and precipitation. The primary groundwater discharge is from extensive pumping for agricultural and municipal uses. Groundwater flow is primarily to the southwest; on average, water levels within the subbasin declined nearly 15 feet from 1970 through 2000 (DWR, 2003).

In general, groundwater quality is suitable for most urban and agricultural uses but is subject to some impairment. Total dissolved solids levels typically range from 200 to 500 milligrams per liter, with substantially higher levels along the east side of the subbasin (DWR, 2003). Other water quality impairment results from elevated levels of radionuclides, pesticides (especially dibromochloropropane, or DBCP), volatile organic compounds, hardness, chlorides, boron, nitrate, iron, and manganese. Localized areas of contamination from gasoline and solvents are also present (Stanislaus and Tuolumne Rivers Groundwater Basin Association, 2005).

Groundwater wells provide approximately 60 percent Modesto's municipal water supply; the remainder is provided by treated surface water from the Tuolumne River. As of 2000, the City operated 118 municipal wells, although several wells had been taken out of service due to water quality concerns (City of Modesto, 2000). The City has calculated its municipal safe yield from the groundwater basin to be 50,000 acre-feet per year.

Turlock Groundwater Subbasin

The Turlock Subbasin covers an area of about 542 square miles and includes lands in the city of Turlock, the Turlock Irrigation District (TID), the Ballico-Cortez Water District, the Eastside Water District, and a small portion of the MID. In general, the characteristics of the Turlock Subbasin are similar to those in the Modesto Subbasin. On average, water levels in the subbasin declined nearly 7 feet between 1970 and 2000 (DWR, 2003).

The City of Turlock obtains its drinking water from the lower confined aquifer, beneath the Corcoran Clay, and presently meets all municipal demands from groundwater wells. The City plans to develop additional sources of supply in the future, which could include using recycled wastewater, withdrawing water from the shallow unconfined aquifer for sub-potable uses, constructing new wells, and purchasing treated water from TID for potable uses (City of Turlock, 2005).

Tuolumne River/Groundwater Interaction

Based on groundwater-level monitoring data, the Tuolumne River is generally a "gaining" river[2] for most of its length between La Grange Dam and its confluence with the San Joaquin River. However, this situation is reversed for an approximately five-mile-long reach near central

1 The permeable materials that surround an unconfined aquifer allow the water table to fluctuate in response to recharge (precipitation in the wet season) and discharge (evapotranspiration in the dry season). A confined aquifer lies below impermeable materials and, as a result, is not recharged directly from above.

2 A gaining river receives water from the groundwater.

Modesto, where a pumping depression has formed; and this reach is considered a "losing" reach[3] (Stanislaus and Tuolumne Rivers Groundwater Basin Association, 2005). The gaining and losing reaches likely change depending upon the season and hydrologic year type.

Beneficial Uses and Water Quality Objectives

The Central Valley Regional Water Quality Control Board, which has regulatory authority over water bodies in the Central Valley watershed, has prepared the *Water Quality Control Plan* (Basin Plan) to implement plans, policies, and other provisions for water quality management. The Basin Plan establishes beneficial uses for the groundwater basin; these include Municipal and Domestic Supply (MUN), Agricultural Supply (AGR), Industrial Service Supply (IND), and Industrial Process Supply (PRO) (SWRCB, 1995).

5.3.5.2 Impacts

Significance Criteria

The City and County of San Francisco has not formally adopted significance standards for impacts related to groundwater, but generally considers that implementation of the proposed program would have a significant groundwater impact if it were to:

- Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of preexisting nearby wells would drop to a level that would not support existing land uses or planned uses for which permits have been granted)
- Substantially impair a water body's ability to support beneficial uses designated by the State Water Resources Control Board or Regional Water Quality Control Board
- Otherwise substantially degrade water quality

Approach to Analysis

Information on potentially affected groundwater bodies was obtained from published sources and through interviews with individuals who are knowledgeable about the hydrogeology of the area or involved with groundwater management in the potentially affected area. Impact assessments were performed by reviewing WSIP-induced changes in stream flow and examining their potential to affect groundwater levels or quality.

Impact Summary

Table 5.3.5-1 presents a summary of the impacts on groundwater bodies in the Tuolumne River watershed that could result from implementation of the proposed water supply and system operations.

[3] A losing river reach loses water to the groundwater.

TABLE 5.3.5-1
SUMMARY OF IMPACTS – GROUNDWATER BODIES IN THE TUOLUMNE RIVER WATERSHED

Impact	Significance Determination
Impact 5.3.5-1: Alteration of stream flows along the Tuolumne River, which could affect local groundwater recharge and groundwater levels	LS
Impact 5.3.5-2: Alteration of stream flows along the Tuolumne River, which could affect local groundwater quality	LS

LS = Less than Significant impact, no mitigation required

Impact Discussion

Impact 5.3.5-1: Alteration of stream flows along the Tuolumne River, which could affect local groundwater recharge and groundwater levels.

At present, the reach of the Tuolumne River below La Grange Dam generally gains flow for most of its length, except for the reach in the vicinity of Modesto, where a groundwater pumping depression exists, causing the river to lose flow. The proposed program would result in lowered stream flows in the Tuolumne River in the winter and spring, as compared to existing conditions and described in Section 5.3.1. This means that there could be a slight increase in groundwater discharge to the river in the areas where the river is gaining flow, due to the slight drop in surface water level. Correspondingly, there would be a slight reduction in the loss of stream flow to the groundwater basin in the vicinity of Modesto, where a pumping depression exists. This effect would be minor, and effects on groundwater levels would be limited to the shallow, unconfined aquifer in the vicinity of the river, which is not used as a source of municipal water supply. In addition, these effects could largely cancel each other out, as discharge of groundwater to the river would be increased in some reaches, and percolation to shallow groundwater would be increased in another. The WSIP would have little or no effect on groundwater levels and would not affect the production rate of existing wells in the vicinity. Overall, considering the scale of water resource development in the area, the withdrawals for agricultural and municipal supply, and variations in the hydrologic cycle, the effects of the WSIP on groundwater levels and groundwater recharge would be *less than significant*, and no mitigation measures would be required.

Impact 5.3.5-2: Alteration of stream flows along the Tuolumne River, which could affect local groundwater quality.

As described above, any effects on groundwater would be slight and would be limited to the shallow, unconfined aquifer in the vicinity of the bed of the Tuolumne River; this aquifer is not used as a source of municipal water supply, but rather for agricultural or other sub-potable uses. As such, any effects on groundwater quality are expected to be minimal, and no adverse effects on any identified beneficial uses of the groundwater basin would occur. The effects of the WSIP on local groundwater quality in groundwater bodies adjacent to the Tuolumne River below La Grange Dam would be *less than significant*, and no mitigation measures would be required.

5.3.6 Fisheries

The following setting section describes the fisheries resources in the Tuolumne River watershed that could be affected by the WSIP. The impact section (Section 5.3.6-2) provides a description of the changes in fisheries resources that would result from WSIP-induced changes in stream flow and reservoir water levels.

5.3.6.1 Setting

The Tuolumne River flows from the crest of the Sierra Nevada westward to its confluence with the San Joaquin River. The San Joaquin River flows north to the Sacramento–San Joaquin Delta. Water from the Delta discharges to the San Francisco Bay Estuary and the Pacific Ocean. The Tuolumne River system and downstream water bodies are shown in Figure 5.3.1-1 in Section 5.3.1, Stream Flow and Reservoir Water Levels.

Because the WSIP would affect flows in the Tuolumne River (as discussed in Section 5.3.1), this section examines potential effects on the aquatic resources in the Tuolumne River between Hetch Hetchy Reservoir and the San Joaquin River, the San Joaquin River itself, and the Sacramento–San Joaquin Delta. This analysis examined the aquatic habitats of the three tributary streams (Cherry, Eleanor, and Moccasin Creeks) as well as water storage in several reservoirs (Hetch Hetchy Reservoir, Lake Lloyd, Lake Eleanor, and Don Pedro Reservoir) that feed the Tuolumne River; hydrologic and operational modeling indicates that the WSIP would not affect Moccasin or Eleanor Creeks, and that the effects on Cherry Creek would be minimal to none.

The headwaters of the Tuolumne River are at an elevation of approximately 13,000 feet above mean sea level. As the river moves downstream from the headwaters, it flows westerly across the Tuolumne Meadows in Yosemite National Park and into Hetch Hetchy Valley. The upper Tuolumne River in the reach downstream of Hetch Hetchy Reservoir is a high-elevation, relatively steep-gradient river located on the western slope of the southern Sierra Nevada mountains.

Tuolumne River Between Hetch Hetchy and Don Pedro Reservoirs

General Description of Aquatic Habitat

In 1923, the Hetch Hetchy Valley was dammed by O'Shaughnessy Dam, which created Hetch Hetchy Reservoir. Downstream of O'Shaughnessy Dam, the Tuolumne River is characterized by a series of pools, cascades, riffles,[1] and pocket water (USFWS, 1992a). The river passes through an extremely deep gorge downstream of Poopenaut Valley and flows to the upper reaches of Don Pedro Reservoir.

Flow in the Tuolumne River is regulated, to a large extent, by operations of Hetch Hetchy Reservoir and minimum stream flow releases from O'Shaughnessy Dam. The hydrology of the river downstream of Hetch Hetchy Reservoir is characterized by relatively stable releases

[1] A stretch of choppy water caused by stones or other objects in a river or stream.

between the fall and spring, followed by a substantial increase in flow during the late spring and summer months (May–July) in response to snowmelt runoff. The SFPUC makes minimum releases from Hetch Hetchy Reservoir to support resident fisheries downstream of O'Shaughnessy Dam (see Table 5.3.1-2, Section 5.3.1). The SFPUC has initiated a fishery monitoring program within the river to assess potential effects of project operations on habitat quality and availability for resident trout and other fish species that over time will provide additional site-specific information on the effects of seasonal and interannual variation in stream flows on fishery populations inhabiting the river (Hanson, 2007).

Flows in the Tuolumne River downstream of its confluence with Cherry Creek are manipulated during the summer months to provide sufficient flow for whitewater rafting. The SFPUC releases pulses of water from Lake Lloyd via Holm Powerhouse to support rafting for several hours on most summer days. Short-duration increases and decreases in flows associated with whitewater rafting influence habitat conditions for resident trout and may affect the vulnerability of trout and other fish to stranding and habitat displacement as flows quickly change within the reach. Because the releases for whitewater rafting would be the same with and without the proposed program, this section does not evaluate the effects of flow fluctuations on habitat selection, habitat quality, growth, and survival, or associated effects on the macroinvertebrate community that trout rely on as a primary food resource.

Resident Fish and their Habitat

The Tuolumne River downstream of Hetch Hetchy Reservoir supports a resident community of fish, including rainbow trout, brown trout, California roach, sculpin, and suckers (USFWS, 1992b). The USFWS (1990; cited in USFWS, 1992b) conducted fishery surveys within the river and estimated that approximately 7,000 adult rainbow and brown trout inhabited the 12.1-mile reach between O'Shaughnessy Dam and Early Intake. Field observations within the river made at various times between October 20, 1987 and June 14, 1990 have confirmed successful reproduction, rearing, and maintenance of adult populations of both rainbow and brown trout.

The USFWS (1992b) documented the preliminary results of an instream flow field study designed to provide information on the relationship between habitat and instream flows for various life-history stages of rainbow and brown trout. Rainbow trout spawning within the Tuolumne River downstream of Hetch Hetchy Reservoir occurs primarily between mid-February and mid-June, with juvenile emergence occurring from about mid-March to early July. Juvenile and adult rearing occurs within the river throughout the year. Brown trout spawning occurs primarily in November and December, with juvenile emergence between April and September followed by juvenile and adult rearing throughout the year. In developing release recommendations, the USWFS considered the seasonal timing of spawning activity and other life-history stages within the river as well as the effects of seasonal water temperatures on habitat suitability for trout.

As part of the stream flow study, the USFWS identified 12 habitat types within the river reach extending from O'Shaughnessy Dam downstream to Early Intake, which included deep pools, shallow pools, pocket waters, cascades, cascades/deep pools, cascades/pocket waters, chutes, riffles, runs, glides, side channels, and backwaters. Among the habitat types, deep pools, shallow pools, pocket waters, runs, riffles, and cascades/pocket water represented 93.9 percent of the total habitat surveyed. Steep-gradient, high-velocity cascades, chute habitats, and a combination of cascades/deep pool habitats represented 4.6 percent of the river reach surveyed. Low-gradient glides, side channels, and backwater habitats represented 1.5 percent of the river habitat area. The results of habitat typing are characteristic of high-gradient, high-elevation Sierra streams and rivers that support populations of trout and other resident species. Among the habitat types observed within the river, deep pools, runs and riffles, and pocket waters are typically the most suitable for resident trout, and these habitat types were present in a majority of the reaches surveyed. The stream flow study did not identify physical habitat as a major limiting factor, although seasonal water temperatures were identified as a factor affecting both brown and rainbow trout within the river.

The quality and suitability of habitat for resident trout depend on various environmental factors, including seasonal stream flow, stream gradient, stream cover, habitat diversity and complexity, water depths, water velocities, and water quality. Trout are coldwater fishes; therefore, seasonal water temperatures within many stream and river systems in California affect habitat suitability. Optimum water temperatures for juvenile and adult trout growth are typically 13 to 21 °C. Trout experience increasing levels of stress, reduced growth rates, increased susceptibility to disease, and, under severe conditions, mortality within the temperature range of 21 to 28 °C. Water temperatures in excess of 28 °C are unsuitable for trout. Incubating trout eggs are more sensitive to elevated water temperatures than either juvenile or adult trout; suitable temperatures for trout egg incubation are approximately 8 and 18 °C, with mortality increasing rapidly at higher temperatures.

Water temperatures within the Tuolumne River between Hetch Hetchy and Don Pedro Reservoirs during the summer months (June–July) have been observed to exceed the maximum daily temperatures of 21 °C, although nighttime temperatures during the summer months are lower. Winter water temperatures are typically low and may be limiting successful egg incubation and hatching for brown trout, which spawn during the winter. The recommended instream flows developed by the USFWS (1992b) therefore included consideration of both physical habitat and seasonal water temperatures.

Tuolumne River Tributaries and Lakes: Hetch Hetchy Reservoir to Don Pedro Reservoir

The rivers, lakes, and reservoirs within the Sierra Nevada provide habitat for a diverse assemblage of native and introduced fish species. Moyle et al. (1996) report that 40 species of native fish inhabit the range, of which 22 are reported for the Sacramento–San Joaquin drainage. The abundance, species composition, and geographic distribution of fish within the watersheds have been influenced by a number of factors. The construction and operation of water impoundments designed for water supply, flood protection, and hydroelectric power generation have affected hydrologic conditions within many of these watersheds as well as modified fishery habitat and limited migration and movement of fish from one part of the watershed to another. The introduction of non-native species, many of which were planted in watersheds to support recreational fisheries, has resulted in substantial changes to the fishery communities. The production and planting of fish, such as various species of trout, to support local recreational fisheries has also affected the aquatic communities within many areas of the upper Tuolumne River watershed and elsewhere within the range. Inventories of fish species inhabiting the water bodies between Hetch Hetchy and Don Pedro Reservoirs have been fairly limited in recent years; the fish surveys that were conducted have been primarily limited to direct visual observations (Knapp and MSI, 1996). Fish species found in the Tuolumne River watershed above La Grange Dam are listed in **Table 5.3.6-1**.

Hetch Hetchy Reservoir, Lake Lloyd, and Lake Eleanor

Although a variety of fish inhabit the Tuolumne River upstream of and within Hetch Hetchy Reservoir, various species of trout that support local recreational fisheries have received the greatest attention. Rainbow trout, brown trout, and eastern brook trout have been reported to inhabit Hetch Hetchy Reservoir (Johnston, 1985). Resident trout within the upper watershed and reservoir include fish planted from hatchery production to support local recreational fisheries. The condition of the trout populations upstream of Hetch Hetchy Reservoir prior to the completion of O'Shaughnessy Dam is unknown, except that the populations are thought to have included both hatchery plantings and native stocks (Snyder, 1993). It is unclear whether or not anadromous[2] salmon or steelhead historically migrated upstream through the Hetch Hetchy reach of the river prior to the construction of the dam, since a number of natural impediments and barriers to passage exist within the watershed that are thought to have prevented access to upstream habitats (Snyder, 1993).

Similarly, it is unclear whether rainbow trout were native to the Hetch Hetchy Reservoir area prior to the construction of O'Shaughnessy Dam. While historical literature suggests that rainbow trout are native, other sources indicate that trout planting during the 19th century resulted in a population that would otherwise not exist (Moyle, 1976). It is also possible that impediments to passage may have prevented the migration of steelhead/rainbow trout upstream to the Hetch Hetchy Reservoir site on the Tuolumne River but that such impediments were not present on the Merced River, thus enabling rainbow trout to establish themselves in Yosemite (Moyle, 1999; cited in Cherrigan, 1999). Waterfalls just below the Hetch Hetchy Reservoir site would have prevented the upstream migration, and other sources have noted that this reach of the Tuolumne River was fishless (Muir, 1902).

Lake Eleanor, which was completed in 1917, is located on Eleanor Creek and is hydraulically connected to Lake Lloyd. Surveys of the lake conducted by the CDFG in the 1960s and 1970s indicated the presence of suckers, brown trout, rainbow trout, and sunfish, among other species. The fish population within Lake Eleanor probably parallels that at Cherry Lake due to its hydraulic connection (CDFG, 2006b), although recent published data on fisheries at these reservoirs are limited (Knapp and MSI, 1996).

2 Anadromous fish species migrate from the ocean to spawn in freshwater streams and rivers.

TABLE 5.3.6-1
FISH SPECIES KNOWN TO INHABIT TUOLUMNE RIVER TRIBUTARIES, HETCH HETCHY AND DON PEDRO RESERVOIRS, LAKE LLOYD, AND LAKE ELEANOR[a]

			Reservoirs				Tributaries (Upper Tuolumne River)		
Common Name	**Scientific Name**	**Native (N) Introduced (I)**	**Don Pedro Reservoir**	**Hetch Hetchy Reservoir**	**Lake Lloyd**	**Lake Eleanor**	**Cherry Creek**	**Moccasin Creek**	**Eleanor Creek**

Kokanee salmon	*Oncorhynchus nerka*	I	x		x	x			
Channel catfish	*Ictalurus punctatus*	I	x						

NOTE: Fish populations in the interconnected Lake Lloyd and Lake Eleanor are known to be the same (CDFG, 2006b).

a This table is principally based on unpublished CDFG data.
b It is not clear whether the California-native steelhead/rainbow trout was introduced to the area or planted early on to establish a fish population.
c Among the fish species present in the watershed, only golden trout has been identified by the CDFG as a species of special concern.
d Don Pedro Reservoir is regularly planted with hatchery-reared Chinook salmon.

SOURCES: Bacher, 1999; CDFG, 2006a, 2006b; USDA, 2007.

Lake Lloyd is located on Cherry Creek. The principal fish species found in Lake Lloyd include rainbow trout, brown trout, and brook trout (CDFG, 1987; Dirksen and Reeves, 1990; DWR, 1993). Golden shiner, green sunfish, and an abundance of Sacramento sucker also inhabit the lake. Salmon are probably not present in Lake Lloyd today—previous populations of salmon were a product of hatchery planting that occurred until the 1970s to support local recreational fisheries in the lake. Salmon were documented in the lake during gillnet surveys conducted by the CDFG in the 1960s and 1970s (CDFG, unpubl. data; CDFG, 2006b).

Eleanor and Cherry Creeks

Cherry Creek, a tributary to the main stem Tuolumne River about one mile below Early Intake, has a fishery population comprised mostly of rainbow trout (CDFG, 2006a). It has been hypothesized that Cherry Creek may have provided habitat for historical populations of steelhead and/or spring-run Chinook salmon. Major dams and reservoirs downstream within the Tuolumne River currently prevent anadromous fish such as steelhead and salmon from accessing the upper parts of the watershed. Sacramento sucker, riffle sculpin, and California roach have been observed during stream surveys between Early Intake and Preston Falls and have been observed within Cherry Creek as well, particularly in the reaches closest to the confluence of the Tuolumne River where water temperatures become warmer (CDFG, 2006a).

Eleanor Creek fish populations are mostly comprised of brown trout and rainbow trout (CDFG, 2006a). The creek is not stocked, although a hatchery was operated on Frog Creek until the 1950s. The trout raised in the hatchery originated from Lake Eleanor (CDFG, 2006a). Suckers, sculpin, and roach may also be present in Eleanor Creek and would be expected to occur in greater abundance farther downstream towards the confluence of Cherry Creek, where water temperatures become slightly warmer.

Moccasin Creek

Moccasin Creek, a tributary located downstream from the confluence of the Tuolumne River and Cherry Creek, has a fishery community consisting of California roach, Sacramento sucker, sculpin, and rainbow trout (CDFG, unpubl. data). Moccasin Creek is stocked with hatchery-reared rainbow trout on a weekly basis during trout season to support a local recreational fishery, and is considered a popular angling location (CDFG, 2006a). Each year this hatchery raises more than 1 million catchable rainbow trout, which are then planted in 40 heavily fished lakes and streams in the region. This hatchery also produces more than 1 million trout fingerlings for aerial planting in alpine lakes (Moyle et al., 1996).

Don Pedro Reservoir

The principal fish species in Don Pedro Reservoir are game fish, including trout (e.g., rainbow, brown, and brook trout), catfish, bluegill, crappie, sunfish, coho salmon, king and kokanee salmon, and largemouth and smallmouth bass (CDFG, 1987; Dirksen and Reeves, 1990; DWR, 1993). The salmon fishery population supports a local recreational fishery within the reservoir based on annual stocking conducted by the CDFG. Salmon species such as kokanee salmon (landlocked sockeye salmon) have proven sustainable through ecosystem management, including successful reproduction by the reservoir population. Threadfin shad and plankton also exist in abundant quantities in the lake. No special-status species are known to inhabit the reservoir (TID, 2005).

Species Life Histories

Steelhead/Rainbow Trout (*Oncorhynchus mykiss*).[3] Anadromous trout populations can convert to the resident form when drought events or the damming of rivers block their access to the ocean. Conversely, resident trout populations can become anadromous if ocean access becomes available. It is typical for both life-history patterns to occur in the same stream, and anadromous parents can produce offspring of both varieties. It has been speculated that a food-availability-related trigger determines whether a particular fish will emigrate to the ocean or remain in the stream; according to this hypothesis, if there is abundant food in the stream and a fish is growing at a rapid rate, it may remain in the stream. If food is limited and growth is slow, the fish will have a tendency to emigrate. A variety of biological and environmental factors, in addition to food supply, affect the migratory patterns and life history of steelhead/rainbow trout within a river.

This dual life-history pattern of steelhead and rainbow trout makes the species more adaptable to changing environmental conditions. At the southernmost limits of steelhead distribution, this adaptability is particularly important due to the unstable, variable climatic and hydrologic conditions.

Most steelhead spawn from December through April in small streams and tributaries where cool, well-oxygenated water is available year-round. The female selects a site with gravel substrate where there is good flow through the gravel. She digs a nest, called a redd, and deposits eggs, which the male then fertilizes. These eggs are covered by gravel and cobbles when the female excavates another redd slightly upstream.

The length of time it takes for eggs to hatch is heavily dependent on water temperature. In hatcheries with carefully controlled conditions, steelhead eggs hatch after 30 days at a temperature of 11 °C. The optimal temperature for egg incubation is between 7 and 10 °C. Eggs hatch sooner in warmer water, but the young fish are smaller and generally have lower survival rates. If the temperature goes too high, eggs will not hatch at all. After hatching, the developing steelhead (called “alevins”) remain in the gravel for another four to six weeks. During this time, they obtain nutrients from a yolk sack attached to their body. When they emerge from the gravel, they are called fry, and are able to catch their own food.

Newly emerged fry move to shallow, protected areas of the stream (usually in the stream margins). They establish and defend feeding areas. Most juveniles can be found in riffles, although larger ones will move to pools or deep runs.

Resident rainbow trout support one of the most popular recreational fisheries within lakes and streams in the higher elevation areas of California. Because of the popularity of this species, the

---

[3] Rainbow trout and steelhead are the same species of trout (*Oncorhynchus mykiss*). Rainbow trout spend their whole life in freshwater; steelhead spend much of their life in the ocean but return to freshwater to spawn.

CDFG produces juvenile, sub-catchable, and catchable rainbow trout in hatcheries and plants them in lakes, reservoirs, and streams, primarily during the spring, summer, and fall. Rainbow trout are also able to successfully reproduce in many of the streams and lakes where water temperatures and other environmental conditions are suitable.

German Brown Trout (*Salmo trutta*). Brown trout live in cold or cool streams, rivers, lakes, and impoundments and are known to be more tolerant of siltation and higher water temperatures than a species such as brook trout. They are also somewhat tolerant of acidity and are adaptable to stream changes.

Brown trout prefer temperatures similar to those preferred by rainbow trout, with upper tolerance limits of about 24 to 27 °C. Lower critical levels for trout are not as well known and tend to vary based on acclimation, exemplified by studies showing that hatchery-reared salmon tend to prefer warmer temperatures, perhaps due to hatchery conditions.

Brown trout spawn in the fall and early winter, a little later than brook trout, when water temperatures are in the mid- to high 40s. Eggs are deposited in a stream gravel depression that the female prepares with swimming actions of her fins and body. Large females produce 4,000 to 12,000 eggs. Several males may accompany the female during spawning. The eggs hatch the following spring, with no parental attention. Brown trout eat aquatic and terrestrial insects, crayfish and other crustaceans, and especially fish. The big ones may also eat small mammals (like mice), salamanders, frogs, and turtles. Large brown trout feed mainly at night, especially during the summer. Their life span in the wild can be 10 to 12 years. Brown trout support a popular recreational fishery.

Eastern Brook Trout (*Salvelinus fontinalis*). Brook trout, an introduced species in California, originated from northeastern America (Knapp and MSI, 1996). Brook trout range in size from 5 to 8 inches in length and usually spawn between September and December. The females lay eggs in the gravel of coldwater streams, such as in the mountains. After hatching, young brook trout feed on zooplankton, while adult fish feed mainly on insects and aquatic invertebrates. Adults also tend to eat small frogs, fish, and snails. Brook trout generally do not live past the age of four. Brook trout are a popular recreational species.

Golden trout (*Oncorhynchus aguabonita*). Wild naturally reproducing populations of golden trout inhabit the Sierran streams. Golden trout are also raised in hatcheries, and most fish are released in selected water bodies during the spring. Some fish are kept in the hatcheries for broodstock. Anglers fishing for golden trout typically use bait such as worms small spinner baits and flies.

Largemouth Bass (*Micropterus Salmoides*). Largemouth bass (commonly known by anglers as black bass) eat minnows, carp, and practically any other available fish species including their own. Young largemouth fall prey to larger bass, crappie, bluegill, and other predatory fish. Both largemouth and smallmouth bass are parasitized by the bass tapeworm, black spot, and yellow grub, none of which pose a threat to human health.

Largemouth bass live in shallow water habitats among reeds, water lilies, and other vegetation; they are adapted to warm waters of 27 to 28 °C and are seldom found deeper than 20 feet. They prefer clear waters with no noticeable current and do not tolerate excessive turbidity and siltation. In winter they dwell on or near the lake bottom, but stay fairly active throughout the season.

Like smallmouth bass, largemouth bass spawn in late spring or early summer. The male constructs a nest on rocky or gravelly bottoms, although occasionally the eggs are deposited on leaves and rootlets of submerged vegetation. The eggs, which are smaller than those of the smallmouth bass, hatch in three to four days. The fry rise up out of the nest in five to eight days and form a tight school. This school feeds over the nest and later the nursery area while the male stands guard. The school breaks up about a month after hatching, when the fry are about an inch long. Largemouth bass support an active recreational fishery in lakes and reservoirs.

Smallmouth Bass (*Micropterus dolomieu*). Smallmouth bass prefer deep, cool water lakes, cool streams, and gravel substrate habitat. Smallmouth bass spawn in spring; when water temperatures approach 16 °C, males move into spawning areas. Nests are usually located near the shore in lakes, or downstream from boulders or some other obstruction that offers protection against strong currents in streams. Hatching time is typically about 10 days if water temperatures are around 10 °C, but fish can hatch in two to three days if temperatures are warmer. Males guard the eggs for about a month, until fry begin to disperse. Like largemouth bass, fry begin to feed on zooplankton, switching to insect larvae and finally fish and crayfish as they grow.

Golden Shiner (*Notemigonus crysoleucas*). Golden shiners are a deep-bodied minnow species with a distinctive golden-olive/silvery color. Their fins may appear from golden brown to orange-reddish in hue. Older fish have a more golden color than their younger, silvery counterpart. This species has a distinctive scaleless strip on its underside between the pelvic fin and the bottom. Golden shiners are common in medium to large bodies of slow-moving or standing water, including reservoirs, and require good water quality and aquatic vegetation to thrive. They prefer quiet, clear water over sand-, gravel-, or organic-debris-covered bottoms. They spawn over a variety of materials, including sand, gravel, vegetation, and other objects. Anglers do not target golden shiners, although shiners are considered effective bait for a wide variety of species and are easy to keep alive. Golden shiners are collected with a dip net or seine.

Kokanee Salmon (*Oncorhynchus nerka*). Also known as sockeye, these fishes are unique in that they require a lake to rear in as fry, which means that the river system they choose to spawn in must have a lake. They can adapt to a range of water velocities and substrates. Juveniles rear for one or two years in a lake, although they are also found in the inlet and outlet streams of the lake. The fry are often preyed on by resident lake fish, and because they use freshwater year-round, the fry are susceptible to low water quality. Sockeye salmon feed on zooplankton within the lake. Because of the popularity of sockeye salmon as a recreational sport species in cooler mountain lakes and reservoirs, the CDFG plants hatchery-produced young sockeye salmon in a number of Sierran lakes each year. In many of the lakes, sockeye salmon are not able to successfully reproduce, so some populations are supported by annual juvenile plantings from the hatcheries.

Green Sunfish (*Lepomis cyanellus*). Native to the eastern United States, these fishes inhabit quiet pools and backwaters of sluggish streams, lakes, and ponds. Green sunfish spawn in spring and summer, hatching in about two days. They deposit their eggs in a single or colonial nest made by the male, often on fine gravel or sandy silt in shallow water near cover. They prefer warm streams and slow-moving to sedentary waters, ponds, and shallow weedy margins of lakes. They can usually be found in the vicinity of weed beds (Moyle, 1976).

Threadfin Shad (***Dorosoma petenense***)**.** This non-native fish species occurs mainly in freshwater in large rivers, reservoirs, lakes, and swamps, although it is also found in estuarine waters. Threadfin shad are typically found within the top 5 feet of the water column and spawn at approximately 7 °C. This species breeds in the spring and autumn in freshwater, near or over plants or other objects, and their eggs adhere to aquatic vegetation. Anglers also use threadfin shad as baitfish (Moyle, 1976).

California Roach (*Lavinia symmetricus*). Considered a minnow, this species prefers lower elevation streams, particularly sections that dwindle to seasonal pools. Roaches are usually the most abundant fish in the middle-elevation zones of local creeks. California roaches feed on invertebrates and filamentous (threadlike) algae (Moyle, 1976).

Riffle Sculpin (*Cottus gulosus*). This species spawns mostly in small streams with sandy to rocky bottoms. Riffle sculpin tend to inhabit sand and gravel riffles of headwaters and creeks and are also found in sand-gravel runs and backwaters of small to large rivers. They demonstrate resiliency and can withstand substantial changes in habitat. Within California, riffle sculpin are an abundant species (Moyle, 1976).

Sacramento Sucker (*Catostomus occidentalis*). Sacramento suckers prefer tributary streams with gravel or cobble. Foothill streams usually have two subpopulations: a resident one and one that migrates into the creek to spawn in the spring then returns to the river, although some may strand in low-water years. Suckers use their specialized mouths to scrape aquatic insects from the substratum. Spawning typically occurs in waters with temperatures ranging from approximately 6 to 10 °C in February to June, although the species is tolerant of a wide range of temperature conditions.

Bluegill (***Lepomis macrochirus***)**.** Originally introduced into California waters in 1908, bluegill have become a favorite of many anglers, and populations exist in mountain lakes as high as 5,000 feet. They breed in large colonies in which big, dark-colored males vigorously defend nests, embryos, and young against predators and other males. One problem for nesting males of this species is that small males often hang out near the nests and sneak or streak in to spawn (Moyle, 1976). Bluegill support a popular sport fishery, particularly in low- to mid-elevation lakes and reservoirs.

Coho Salmon (*Oncorhynchus kisutch*). Coho salmon, commonly known as silver salmon, occur naturally only in the Pacific Ocean and its tributary drainage, although it can also be found in some freshwater areas, including the Great Lakes. Adult coho salmon are usually 18 to 24 inches long and weigh 8 to 12 pounds. Adults in the ocean are steel blue to slightly green in color, with silver sides, white bellies, and small black spots on the back. Historically, coho salmon (along with other species) was a staple in the diet of several Native American tribes, which would also trade it with tribes farther inland. Coho salmon produced in hatcheries have been planted as juveniles in a number of coldwater lakes and reservoirs to support local recreational fisheries.

Black Crappie (*Pomoxis nigromaculatus*). Spawning varies according to latitude. In the northern states this species usually spawns in May and June. In the South, spawning takes place earlier in the year, beginning as early as March. Favorable spawning temperatures range from 18 to 20 ºC. The male sweeps out a nest in sand or fine gravel and guards the nest and defends the young until they start to feed.

Channel Catfish (*Ictalurus punctatus*). Channel catfish are freshwater fish, native to the central and eastern United States and southern Canada. In California, they were planted in Stockton in about 1874. These fish are readily distinguished by their scaleless bodies; broad, flat heads; sharp, heavy pectoral and dorsal spines; and long, whisker-like barbels[4] around the mouth. They are mostly nocturnal and use their barbels to locate food in the dark recesses of deep water. They prefer water temperatures of about 21 °C. Although this catfish does well in many muddy, dirt-bottom lakes, it prefers a clear, warm-water lake with a sandy bottom.

Lake Trout (*Salvelinus namaycush*). Lake trout prefer deep, coldwater lakes. They spawn in the fall, but the time varies among lakes and depends on such factors as latitude, weather, and the size and topography of the lake. Spawning most often occurs over a large boulder or rubble lake bottom at depths of less than 40 feet, and sometimes as shallow as 1 foot for inland lakes. Spawning takes place at night when the trout scatter their eggs over a rocky lake bottom; the eggs remain among the rocks for weeks and hatch the following spring. Lake trout support an active recreational fishery in a number of lakes and reservoirs.

King (Chinook) Salmon (*Oncorhynchus tshawytscha*). Fall-run Chinook salmon are anadromous, with spawning and juvenile rearing occurring within freshwater rivers and streams and juvenile and adult rearing occurring within coastal marine waters; however, Chinook salmon that are landlocked and/or hatchery-reared are not anadromous and not capable of natural reproduction. (Anglers commonly refer to landlocked, hatchery-reared salmon as king salmon). Native, non-hatchery-reared adult fall-run Chinook salmon migrate from the coastal marine waters upstream through San Francisco Bay, Suisun Bay, and the central Delta during late summer and early fall (approximately late July through early December). Adult fall-run Chinook salmon then migrate upstream to areas characterized by suitable spawning conditions, which include the availability of clean spawning gravels, cold water (considered to be less than 13 °C, and relatively high water velocities. Fall-run Chinook salmon spawning is similar to that described for other Chinook salmon, including the creation of redds where eggs are deposited and incubate. Fall-run Chinook salmon spawning occurs between October and December, with the greatest spawning activity typically in November and early December.

[4] A long, thin, fleshy growth projecting from the mouths or nostrils of some fishes.

The lower Tuolumne River supports a population of anadromous fall-run Chinook salmon. These fish support an active recreational fishery within both ocean and inland waters. Juvenile Chinook salmon produced in fish hatcheries are also planted in mid- to high-elevation lakes and reservoirs to support recreational fisheries.

Tuolumne River Below Don Pedro Reservoir

Aquatic Habitat

Aquatic habitats in the Tuolumne River downstream of La Grange Dam are influenced by a number of factors, many of them related to former gold mining and gravel mining. From La Grange Dam to RM 25, a distance of about 25 miles, the river flows through the Sierra foothills into the alluvial San Joaquin Valley. In the first 10 miles downstream of the dam, the channel is constrained by extensive fields of dredge tailings that include large cobbles to finer sediments. These tailings, which extend to Roberts Ferry (approximately RM 40), restrict river meander and access to alluvial sediments, thus reducing the delivery of gravel to the river. Some sections of the river are armored by cobbles, and replenishment of smaller gravels is necessary. Riparian vegetation in this reach is also limited by the dredge tailings. In some reaches upstream of Roberts Ferry, the interaction of modified flow regimes and areas of dredge tailings has altered channel characteristics and flow regimes, creating areas of lake-cascade habitat instead of the pool-riffle habitat typical of the pre-mining channels.

Downstream of Roberts Ferry, the lower gradient river meanders through low hills and valleys bordered by grazing land, tree crops, and irrigated row crops. In this reach, the river passes through several large gravel-mining pits, in part due to failure of the levees separating the river from these pits during the floods of 1997 (TID/MID, 2005). At approximately RM 25, the river is generally channelized and flows through sandy loam soils. In this lower reach, the channel is characterized by slow-velocity run habitat with a sandy-silty bottom and no riffles; the area is not suitable for salmonid spawning, and no spawning was observed during the 1996–2005 survey period.

Substantial habitat restoration has occurred in the lower Tuolumne River under the FERC Settlement Agreement (FSA) (see Chapter 2 for a description of the agreement). In 2000 the Tuolumne River Technical Advisory Committee completed a report titled “Habitat Restoration Plan for the Lower Tuolumne River Corridor” that provides guidance on the priorities and design of habitat enhancement projects to benefit salmon and other aquatic resources (McBain and Trush 2000). The plan identifies several measures to improve the ecological functions of the lower river including increasing the frequency of periodic high flows, channel reconstruction, and gravel and sediment management. A total of 14 channel restoration projects have been identified in the plan. Two of the projects have been completed and two additional projects will be constructed in 2007. Other planned restoration actions under the FSA include:

- Additional riffle cleaning to remove fine sediments from potential salmon spawning habitats
- Construction of a sedimentation basin on Gasburg Creek upstream of La Grange Dam

- Placement of up to 300,000 cubic yards of screened aggregate in the reach between La Grange Dam and Roberts Ferry
- Rehabilitation of pool-riffle habitats in areas now characterized as lake-cascade habitat

The effectiveness of recent riparian restoration has not been fully evaluated, in part because the restoration at such sites as the pool downstream of Fox Grove County Park is relatively immature.

Chinook Salmon

General Description. Chinook salmon are present in the major San Joaquin River tributaries, including the Tuolumne River, which supports a fall run of Chinook salmon. Based on a literature review for the 1996 FERC report, adults begin to arrive in the Tuolumne River in October, and the spawning run continues into January; spawning occurs primarily in October through January but can extend into March. Most egg incubation occurs from October through March but can extend into May. Juveniles begin to emerge from spawning gravels in December. The period of juvenile rearing ranges from January through June (FERC, 1996).

There is no fish hatchery on the Tuolumne River, but Tuolumne River Chinook salmon stocks have been influenced by fish straying from other Central Valley hatcheries and by releases of large quantities of hatchery juveniles and smolts in the river for smolt survival tests. Tuolumne River Chinook salmon are probably not a unique stock (FERC, 1996). Recovery of coded-wire-tagged fish indicates that Chinook salmon stocked in the Tuolumne River are contributing to the ocean commercial and recreational fishery and to adults returning to the river to spawn.

The general trends in the life history of Tuolumne River Chinook salmon are subject to substantial variation, probably depending on flow and water temperature (FERC, 1996), ocean rearing conditions, recreational and commercial harvest, and other factors. The extent of this variation is shown in the *2005 Ten Year Summary Report for the Don Pedro Project* (TID/MID, 2005). From 1998 to 2002, sampling of juveniles using rotary screw traps was extended to cover the period from late January through as late as June 30. This sampling found that the peak period of juvenile migration at the lower rotary screw traps varied by year:

Year	Period of Peak Juvenile Catch in Rotary Screw Traps at River Mile 5
1998	February 15 – March 15
1999	January 25 – February 15
2000	February 15 – March 1
2001	February 15 – March 18
2002	April 15 – May 10

Variable juvenile migration times may reflect variability in spawning and incubation times and/or variation in the duration of juvenile rearing based on flow and temperature conditions. In 2000 and 2001, juveniles were captured at RM 5 over a period of more than three months. In other years, juvenile emigration appears to have occurred over a shorter period of time. At various life-history stages, Chinook salmon may therefore be found in the Tuolumne River from October through May, although there is also some potential for a small number of juveniles to oversummer in cooler reaches of the river (FERC, 1996). In 1994, the USFWS (FERC, 1996) evaluated habitat availability by life-history stage and determined that:

- For spawning, habitat was optimized at flows of about 150 to 350 cfs, which optimized depth over spawning riffles.
- For juvenile rearing, habitat was optimized at low flows (50 to 150 cfs), which optimized low-velocity habitat.
- For egg rearing, habitat was optimized at flows from about 100 cfs to 800 cfs, which defined the optimal amount of riffle and run habitat and minimized the conversion of runs to pools.

Population Trends. TID/MID (2005) summarizes 1971–2004 population trends for adult Chinook salmon in the Tuolumne River and notes that the return of adult salmon to the river follows the general pattern observed in other major San Joaquin River tributaries:

- From 1971 through 2004, the estimated number of adult salmon returning to the Tuolumne River ranged from a low of 77 fish to a high of 40,332 fish (see **Table 5.3.6-2**).
- During the period of record, there were two periods when the CDFG carcass counts built up to peaks of over 5,000 carcasses, with intervening periods where runs declined to below 100 carcasses.
- Estimates of adult escapement based on carcass counts begin to build during years characterized by higher precipitation and flow (and the associated somewhat cooler water temperatures), and to decline with the onset of drought conditions and warmer water temperatures.
- Tagged carcasses (hatchery fish) accounted for 6.4 to 65 percent of the total carcass count, with an average of about 38 percent of carcasses carrying hatchery tags.
- The percentage of females ranged from 25 to 67 percent, with an average of 51 percent. Females made up less that 35 percent of the total carcass count in only 4 of 33 years (all of which were dominated by two-year-old fish).
- Based on redd (salmon nests) counts from 1981 to 2003, spawning is concentrated in the reaches between RM 34 and La Grange Dam (RM 52.2), with the density of redds greatest between RM 47 and La Grange Dam. In this reach, the average redds per mile was about 85, while in the reaches downstream, average redd count over the 24-year period of record was 18.5 redds per mile.
- Reach 2, from RM 47.4 to 50.5 (3.1 miles), contributed from 17 to 42 percent of the total run during 1981 to 2003, while the longer Reach 3 (RM 42.0 to 47.4; 5.4 miles) contributed from 13 to 36 percent of the total run during the same period.
- There was virtually no spawning activity below Fox Grove (RM 24.1), except in 1988 and 1989 when 30 redds were counted in this downstream reach.

TABLE 5.3.6-2
TUOLUMNE RIVER SPAWNING SURVEY SUMMARY

Year	Carcass Count	% Female	Estimated Run
1971	2,283	58	21,885
1972	537	52	5,100
1973	351	59	1,989
1974	90	55	1,150
1975	130	60	1,600
1976	336	51	1,700
1977	45	62	450
1978	116	67	1,300
1979	305	51	1,184
1980	248	61	559
1981	5,819	44	14,253
1982	2,135	60	7,126
1983	1,280	25	14,836
1984	3,841	34	13,689
1985	11,651	56	40,322
1986	2,463	48	7,288
1987	5,280	31	14,751
1988	3,011	60	6,349
1989	625	52	1,274
1990	37	32	96
1991	30	45	77
1992	55	43	132
1993	187	61	431
1994	215	50	513
1995	461	54	928
1996	1,301	35	4,362
1997	1,520	59	7,548
1998	2,712	51	8,967
1999	3,980	46	7,730
2000	6,884	63	17,873
2001	5,400	54	9,222
2002	4,702	54	7,125
2003	1,489	60	2,961
2004	1,224		1,900

SOURCE: TID/MID, 2005.

The TID/MID (2005) data are generally consistent with data from FERC (1996) in that they indicate a majority of spawning occurs in the 15-mile reach below La Grange Dam. Although the nine-year data set from 1996 through 2004 is too small to be the basis for long-term trend analysis, it is noteworthy that the dry years from 2001 to 2005 do not show the dramatic declines in carcass counts and estimated runs that characterized previous dry periods—possibly a function of the minimum release provisions of the FSA, ocean rearing conditions, or other factors.

Spawning. The distribution of Chinook salmon spawning and rearing is strongly influenced by the availability of spawning gravels, with spawning often concentrated in areas at the head of riffles where subsurface flows increase water flows and oxygen through the gravel (FERC, 1996).

Chinook salmon spawning takes place in a variety of habitats that vary in terms of depth, velocity, and substrate (Healey, 1991; cited in FERC, 1996). Spawning can occur within substrates ranging from fine to coarse gravel, as well as over a wide range of water temperatures; however, optimum spawning temperatures are probably in the 8 to 16 °C range. In the Tuolumne River, this temperature range occurs most consistently in the 15-mile reach below La Grange Dam. The distribution and quality of spawning habitat changes in response to flow, as evidenced by major shifts in the distribution of spawning gravels during the 1997 flood, which involved flood-control releases of over 50,000 cfs. TID/MID (2005) compared the estimated area of riffles in the reaches of the river below La Grange Dam for the years 1988 and 2000. In the three upper reaches of the river, the total area of riffle habitat decreased by over four acres (a loss of 15 percent), much of which was attributed to scour during the 1997 floods. However, the general distribution of riffle habitat was not substantially altered. The area of lost riffle habitat was replaced in 2002 and 2003 when the CDFG placed approximately 27,000 cubic yards of gravel in the reach below La Grange Dam. Further riffle restoration activities are projected to restore approximately 70 to 100 additional acres of riffle habitats.

Restoration activities, such as construction of pool-riffle habitats, incidentally reduce the total area of wetted channel, thus reducing the total area of juvenile rearing habitat while likely increasing food production (insects and other macroinvertebrates) and usable rearing floodplain habitat during higher flows (TID/MID, 2005). Post-restoration monitoring of spawning and juvenile rearing suggests that, based on redd counts, spawning has doubled on reconstructed riffle areas.

Juvenile Rearing. When juveniles emerge from the gravel they initially prefer pool habitats, with the distribution in pools affected by fish size (and thus dominance relationships). Habitat selection appears to be determined by food availability and other habitat characteristics, and dominant juveniles tend to select rearing locations at the head of pools where feeding is optimized (Chapman and Bjornn, 1969; cited in FERC, 1996). Larger juveniles can adapt to greater depth and higher velocity flow, and thus juveniles may move into riffle habitats as they grow. Juveniles can rear successfully over a wide range of temperatures, depending on food availability. Optimal rearing temperatures are generally considered to be 12 to 18 °C, but juveniles can thrive at warmer temperatures when food supplies are abundant enough to offset the increased metabolic rates associated with rearing in warmer water. Optimal temperatures are generally found in the 25 miles immediately downstream of La Grange Dam, but in very wet years may extend to the confluence with the San Joaquin River, at least into the late spring (TID/MID, 2005).

From 1986 to 2004, juvenile rearing was evaluated at 12 Tuolumne River seining locations, from the Old La Grange Bridge (RM 50.5) to the Shiloh Bridge (RM 3.4), with some sites monitored for only a portion of the 19-year period. The TID/MID data do not show any clear trend in the number of juveniles captured by seine netting before and after implementation of the FSA, although densities (fish per unit of seined volume) were marginally higher following FSA implementation. The 1986–1995 studies and 1996–2004 FSA monitoring data show expected trends in juvenile rearing and behavior:

- Young juveniles (fry typically less than approximately 45 millimeters) make up a majority of juveniles captured in January and February, with larger juveniles in excess of 65 millimeters (fingerlings and smolts) beginning to dominate captures by April.
- There are moderately strong relationships between the peak salmon juvenile density and average January 15 to March 15 salmon juvenile density and the estimated number of female spawners.

The seining data suggest a relatively stable egg-to-juvenile survival rate over a wide range of returning adult salmon abundances. The calculated relationship would be stronger if data from the very dry year of 1994 (pre-FSA) and the very wet year of 1997 were omitted from the analysis, which may indicate that egg-to-juvenile survival rates are not generally affected by variable flow. The survival of incubation eggs and juveniles is sensitive to very high flows that scour and erode spawning redds, as occurred in 1997.

The timing of juvenile movement downstream (based on rotary-screw-trap operations at lower screw traps) varied considerably from year to year; TID/MID noted that high variability in trap results makes it difficult to estimate juvenile production, and production estimates from the 1995–2004 monitoring vary by two orders of magnitude. Some preliminary mark-recapture studies of juvenile survival by river reach suggest that survival is substantially higher in the upstream spawning areas than it is in the lower reaches. Predation[5] by adult striped bass and other fish has been identified as one of the factors affecting juvenile survival within the river.

TID/MID also addressed the potential for juvenile stranding as a result of flow fluctuations, an issue of some importance since one goal of restoration is to increase areas of floodplain that may be accessed for rearing. The post-FSA stranding surveys indicated that stranding was a complex phenomenon, probably related to:

- Salmon density
- Flow reduction and the minimum flow in the fluctuation cycle, which determines the amount of potential stranding area exposed
- Salmon use of particular low-lying locations
- Slope and substrate of the channel

However, monitoring in 2005 found little post-FSA stranding and noted that restoration areas have been designed to minimize the potential for stranding (primarily by manipulating the slope of the accessible floodplain).

[Additional discussion on Chinook salmon in the lower Tuolumne River was prepared in response to comments on the Draft PEIR. Please refer to Section 14.7, Master Response on Lower Tuolumne River Issues (Vol. 7, Chapter 14).]

5 The act of preying on another animal or animals.

Steelhead/Rainbow Trout

Steelhead/rainbow trout oversummer in natal streams and require relatively cooler water temperatures than Chinook salmon. Water temperatures in the lower Tuolumne River are in the 25 to 30 °C range for an extended period of time during the summer in many locations (TID/MID, 2005) and are unsuitable for steelhead. Only in the reach immediately downstream of La Grange Reservoir are water temperatures suitable for steelhead rearing. Temperatures in the San Joaquin River during the spring and summer are consistently higher than temperatures farther upstream in the Tuolumne River (see Figure 5.3.1-4) (TID/MID, 2005) and may preclude successful out-migration of juveniles. FERC (1996) concluded that no significant populations of steelhead/rainbow trout are present in the lower Tuolumne River system.

The results of rainbow trout surveys from 1982 to 2004 show rainbow trout were not found below RM 38 during this period (TID/MID, 2005). In addition, only 10 of the fish identified in this extended period of snorkel survey were in excess of 400 millimeters in length, suggesting that large anadromous steelhead probably occur in the system very infrequently. A vast majority of rainbow trout observed during snorkel surveys were found above RM 45. Nevertheless, post-1995 monitoring suggests that the range of rainbow trout in the Tuolumne River has been moderately extended downstream as a result of the FSA flow regimes. Prior to 1998, rainbow trout had not been found below RM 47. Following implementation of the FSA flow regimes, the species was found with greater frequency downstream in the reach from RM 47 to RM 38, even in the dry 2001–2004 period.

[Additional discussion on steelhead in the lower Tuolumne River was prepared in response to comments on the Draft PEIR. Please refer to Section 14.7, Master Response on Lower Tuolumne River Issues (Vol. 7, Chapter 14).]

Other Fish Species

The lower Tuolumne River supports a number of native and non-native fish species, as shown in **Table 5.3.6-3**. From the perspective of salmon management, the most important are largemouth and smallmouth bass and striped bass due to the potential for predation, particularly on outmigrating juveniles (Orr, 1997; Cohen and Moyle, 2004).

Largemouth and Smallmouth Bass. Non-native largemouth and smallmouth bass have colonized the lower Tuolumne River, taking advantage of the low-velocity, and pond-like habitats of the river that are particularly found below RM 25. In these reaches, bass are present in relatively high abundance and feed actively during the spring out-migration of juvenile Chinook salmon. Both the low flow and high water temperatures in this reach stress juvenile salmon and enhance predation by the bass. Typical of centrarchids, smallmouth and largemouth bass are thick-bodied fish that rely on an ambush strategy for foraging. Their swimming speed over distance is low, and their ability to sustain speed is limited by their metabolism and body configuration.

TID/MID (2005) monitored largemouth and smallmouth bass in the Tuolumne River system from 1996 to 2004 and concluded:

- The population was depleted during the 1997 floods, but recovered slowly until 2003 when it reached its previous level.
- Largemouth bass are more abundant than smallmouth bass.

TABLE 5.3.6-3
NON-SALMONID SPECIES PRESENT IN THE LOWER TUOLUMNE RIVER

RST=rotary screw traps.

SOURCE: TID/MID, 2005.

- The restoration of pool-pond area downstream of Fox Grove County Park did not reduce largemouth bass density and may have increased smallmouth bass density at the site.
- Habitat modeling indicated that velocity is the key factor limiting bass habitat.
- Habitat modeling indicated that a flow of 300 cfs or higher would create limiting velocities for bass in the reach downstream of Fox Grove County Park after restoration, compared to a limiting velocity of 2,000 cfs for pre-project conditions.

Bass density could thus be reduced by recontouring the channel to enhance riffle and run habitats, combined with manipulation of flow to increase velocities. Restoration that increases the area of riffle habitat would therefore be expected to benefit out-migrating juvenile salmon.

Other Species. Based on surveys conducted from 1981 to 2004, including the TID/MID surveys conducted from 1996 to 2004 (Table 5.3.6-3), the lower Tuolumne River supports a relatively complex assemblage of fish, only 14 of 38 being native to the region. The non-natives were introduced for a variety of commercial and sport purposes, beginning in 1871 with the introduction of American shad and continuing into the 1970s with the introduction of the inland silversides as a mosquito-control fish. A majority of the introduced species are warmwater fish that thrive in the lower reaches of the rivers and in the Sacramento–San Joaquin Delta.

As the table indicates, many of the introduced fish species are more widely distributed in the lower Tuolumne River than some of the native species. TID/MID (2005) notes that warmwater introduced species were particularly well distributed in the lower 31 miles of the river, and that native species were dominant only in the short reach upstream of RM 50. The distribution of species responded to flow, with native fish whose life history involves use of riffles for spawning becoming more abundant in the year following a high-flow year.

San Joaquin River and Sacramento–San Joaquin Delta

General Ecological Description

The Sacramento–San Joaquin Delta is a 600-square-mile area of channels and islands at the confluence of the Sacramento and San Joaquin Rivers. Freshwater draining from a 41,300-square-mile watershed enters the Delta from the Sacramento and San Joaquin Rivers and several smaller rivers. Some of the water is diverted from the Delta channels for municipal and agricultural purposes. The remainder flows through the Delta to the San Francisco Bay Estuary.

The Delta is a tidal region. Every 12.4 hours, the tides cause water to move in and out of the Delta. Most of the time, tides cause a five- to eight-mile back-and-forth movement of water in the western part of the Delta. The movement of freshwater through the Delta is superimposed on the tidal flows. Typical freshwater flows are much smaller than tidal flows, usually in the range of 5 to 15 percent of the tidal flows (see Section 5.3.1).

The Bay-Delta estuary is a complex estuarine ecosystem (i.e., a transition zone between inland sources of freshwater and saltwater from the ocean). Along the salinity gradient extending from the Golden Gate upstream into the Delta, the species composition of the aquatic community changes dramatically, although the basic functional relationships among organisms (e.g., predator/prey, etc.) remain similar throughout the system. The primary energy input to the system is solar radiation, which is used, along with nutrients, by the primary producers (phytoplankton, vascular plants, and macroalgae) to convert inorganic carbon to organic matter through photosynthesis. Zooplankton (e.g., copepods, cladocerans, and mysid shrimp) prey on the phytoplankton. The vascular plants and macroalgae are grazed on and also produce detritus, which is decomposed by microbes and consumed by detritivores (e.g., polychaete worms, amphipods, cladocerans, and a diverse group of other fish and macroinvertebrates). The primary consumers are in turn preyed on by secondary consumers, consisting mainly of invertebrates (e.g., polychaete worms, snails, copepods, mysid shrimp, bay shrimp, and crabs) and fishes (northern anchovy, Pacific herring, topsmelt, white croaker, flatfish, gobies, sculpin, shad, juvenile Chinook salmon, and a variety of other resident and migratory fish species). These species in turn are preyed on by top consumers such as fish (striped bass, catfish, sturgeon, halibut, sharks, and rays), marine mammals, birds, and man. The role of a species in the food web may be different at different lifestages, or a species may utilize various levels of the food web simultaneously.

Fishery sampling within the Bay-Delta estuary has shown that 55 fish species inhabit the estuary (Baxter et al., 1999), of which approximately one-half are non-native, introduced species. Many of the fish species inhabiting the estuary, such as striped bass and American shad, were purposefully introduced to provide recreational and commercial fishing opportunities. A number of the fish species have been introduced accidentally to the estuary through movement among connecting waterways (e.g., threadfin shad and inland silversides). In recent years, a number of fish and macroinvertebrate species have been accidentally introduced into the estuary, primarily from the Orient, through ballast water discharges from commercial cargo ships (e.g., yellowfin and chameleon gobies). In addition, an estimated 100 macroinvertebrates have also been introduced, primarily through ballast water discharge, into the estuary (Carlton, 1979). These introductions of non-native fish and macroinvertebrates have contributed to a substantial change in the species composition, predator/prey interactions, and competitive interactions affecting the population dynamics of native species. Many of the introduced fish and macroinvertebrates have colonized and inhabit the lower San Joaquin River and Delta.

The lower San Joaquin River and Delta provide habitat to a diverse assemblage of resident and migratory estuarine organisms. The biological environment is a complex community of plants and animals inhabiting the saltwater, estuarine (brackish water), and freshwater habitats within the Bay-Delta estuary. This section provides a brief summary of information available on the aquatic plants, phytoplankton, zooplankton, bottom-dwelling macroinvertebrates, and common fish populations inhabiting the Bay-Delta estuary.

Fish

Fish species may utilize the estuary for any or all of their life-history stages. They may have planktonic, bottom-dwelling, and open-water life histories. The majority of fish species inhabiting the estuary have planktonic larval stages; as plankton they feed on zooplankton and in some cases phytoplankton. Many of these species forage on plankton during the larval and early juvenile lifestages, and then as juveniles and adults become more selective predators and feed on large invertebrates and fish. Bottom-dwelling fish such as sturgeon, flatfish, gobies, sculpin, and croaker are planktivorous as larvae but begin to feed on invertebrates as juveniles. Many smaller fish, including smelt, silversides, northern anchovy, and Pacific herring, are planktivorous throughout their lives.

Some estuarine fish do not rely on plankton as a major food source at any lifestage. Live-bearing surfperch, for example, predominantly feed on invertebrates such as mollusks, crustaceans, and polychaetes throughout their life. Sturgeon and sharks feed on invertebrates by shoveling through the substrate, and also feed on fish and large invertebrates in the water column. Many freshwater fish prey primarily on bottom-dwelling and drifting insect larvae and crustaceans, because zooplankton abundance is low in the swifter flowing freshwater sloughs and rivers.

The abundance and species composition of fish inhabiting the estuary vary in response to salinity gradients (Baxter et al., 1999). The most abundant fish inhabiting the high-salinity areas of the Central Bay include the schooling, bottom-dwelling forage fish such as northern anchovy, Pacific herring, topsmelt, jacksmelt, and true smelt (whitebait, surf smelt, and night smelt). Other members of the Central Bay fish community include flatfish, rockfish, surfperch, gobies, and sharks. In the low-salinity areas of Suisun Bay and the Delta, the most abundant fish include striped bass, prickly sculpin, staghorn sculpin, threadfin shad, yellowfin goby, and starry flounder. Anadromous fish species such as Chinook salmon, steelhead, American shad, striped bass, and sturgeon utilize the entire estuarine system as a migration corridor and foraging habitat.

Factors affecting the abundance and geographic distribution of fish within the estuary include water velocities, substrate, salinity gradients, water temperature, and food availability. Many of the fish species that inhabit the estuary reside in coastal marine waters and enter the estuary on a seasonal basis for foraging or reproduction. The seasonal cycles of fish abundance vary in response to migration patterns, reproductive cycles, foraging patterns, and environmental conditions occurring within both the estuary and coastal marine waters.

The fish community inhabiting the estuary is diverse and dynamic. The abundance of species can fluctuate substantially within and among years (Baxter et al., 1999) in response to both population dynamics and environmental conditions. Life-history strategies and habitat requirements also vary substantially among species within the fish community. Information on the fish community in the Delta is available from monitoring conducted by the CDFG and USFWS in addition to fish salvage monitoring at the State Water Project and Central Valley Project export facilities in the south Delta. The following sections briefly describe the species composition of the fish community in the lower San Joaquin River and Delta in the vicinity of the WSIP facilities. Information is also presented on habitat types that occur within the estuary, and habitat functions that affect species composition and habitat use. Information on habitat functions and analysis of the available fishery information was used to assess the potential adverse impacts of proposed program operations (e.g., changes in Delta hydrology) on the fish community inhabiting the lower San Joaquin River and Delta.

In recent years, the bottom-dwelling fish community, including delta and longfin smelt and other species, has experienced a significant decline in abundance. State and federal resource agencies are currently evaluating various factors that could be contributing to the decline. Hypotheses include the effects of losses at water diversions, changes in Delta hydrology, the effects of pollutants on survival, and the effects of introduced species on the Delta food web. The importance of these factors in the decline in fish abundance has not been determined.

Among the seasonal inhabitants, many species use the Bay-Delta estuary as a spawning area and/or juvenile nursery habitat on either an obligatory or nonobligatory basis (Baxter et al., 1999). For obligate species, reproduction and rearing of juveniles occurs almost exclusively within a bay or estuarine environment. Nonobligate species may or may not inhabit the estuary during any given year. The occurrence of nonobligate species varies substantially from one year to the next within the Bay-Delta estuary. These species are typically found in the more marine areas of the estuary and are not generally abundant upstream within Suisun Bay or the marsh. Opportunistic species use the Bay-Delta estuary as an extension of their habitat based on the suitability of environmental conditions. Many species that inhabit coastal marine waters, such as northern anchovy, may opportunistically move into the estuary when conditions are favorable for reproduction, juvenile rearing, and foraging. Several freshwater or low-saline species, such as white catfish and threadfin shad, may opportunistically use habitats within Suisun Bay, San Pablo Bay, or Central Bay during periods of high freshwater outflow from the river systems that results in lower salinity and more suitable habitat conditions for these species farther downstream within the system (Baxter et al., 1999).

Anadromous species such as Chinook salmon and steelhead spawn within freshwater portions of rivers and creeks tributary to the Bay-Delta estuary, including the Tuolumne River. Juvenile rearing habitat for these species is also present primarily within the freshwater or low-saline portions of the system. Juvenile Chinook salmon and steelhead emigrate from freshwater habitat and move downstream through the estuary, which is used primarily as a migratory corridor and short-term foraging habitat as the fish move into coastal waters for rearing. Adult Chinook salmon and steelhead subsequently migrate back upstream to spawn, again using the Bay-Delta estuary as a migratory corridor. Other anadromous species such as striped bass may inhabit freshwater, estuarine, and marine waters over an extended period of time as both juveniles and adults.

The open waters of the lower San Joaquin River and Delta serve as a migratory route for several species of anadromous fish whose adults migrate to the freshwater reaches of the tributary rivers to spawn and whose juveniles migrate downstream to return to the ocean. These fish include steelhead, Chinook salmon, white and green sturgeon, and striped bass. In addition, the main channel and adjacent areas support populations of resident species, including Sacramento pikeminnow, white catfish, and threadfin shad.

Regulatory Setting

Special-Status Species

A variety of special-status fish species, several of which have been listed for protection under the Federal and/or California Endangered Species Acts, are present in the Delta and the San Joaquin and Tuolumne Rivers. Special-status fish species that occur in the lower San Joaquin River and Delta include steelhead, green sturgeon, delta smelt, Chinook salmon, Sacramento splittail, and longfin smelt. Several special-status species use the Delta as a migratory corridor. The winter-run Chinook salmon is federally and state-listed as endangered. The spring-run Chinook salmon is federally and state-listed as threatened. The fall/late-fall-run Central Valley Chinook salmon is a federal candidate species and California species of special concern. The Distinct Population Segment of Central Valley steelhead is federally listed as threatened. Fall/late-fall-run Central Valley Chinook salmon use the lower San Joaquin River as a migratory corridor and spawn in the Tuolumne River below La Grange Dam. In addition, delta smelt, a federally and state-listed threatened species, and Sacramento splittail, a California species of special concern and formerly a federal threatened species, have been documented within the lower San Joaquin River and Delta (USFWS, 2003). The NMFS recently listed green sturgeon as a threatened species. Although the distribution of green sturgeon in the lower San Joaquin River is poorly understood, the species is known to reside within the Delta.

Essential Fish Habitat

The Pacific Fisheries Management Council has designated Central San Francisco Bay, Suisun Bay, and the Delta as Essential Fish Habitat (EFH) to protect and enhance habitat for coastal marine fish and macroinvertebrate species that support commercial fisheries. The major rivers tributary to the Delta, including the San Joaquin and Tuolumne Rivers, have also been identified as EFH for Pacific salmon. The amended Magnuson-Stevens Fishery Conservation and Management Act, also known as the Sustainable Fisheries Act (Public Law 104-297), requires all federal agencies to consult with the Secretary of Commerce on activities or proposed activities authorized, funded, or undertaken by that agency that may adversely affect EFH of commercially managed marine and anadromous fish species (Office of Habitat Conservation, 1999). The EFH provisions of the Sustainable Fisheries Act are designed to protect fishery habitat from being lost due to disturbance and degradation. The act requires that EFH must be identified for all species that are federally managed by the Pacific Fisheries Management Council.

5.3.6.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to fisheries, but generally considers that implementation of the proposed program would have a significant fisheries impact if it were to:

- Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG, NMFS, or USFWS
- Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites
- Have the potential to degrade the quality of the environment, substantially reduce the habitat of a fish or wildlife species, cause a fish or wildlife population to drop below

self-sustaining levels, threaten to eliminate a plant or animal community, substantially reduce the number or restrict the range of an endangered, rare or threatened species

Approach to Analysis

The effects of the WSIP on river flow and reservoir water levels were determined using the HH/LSM. An overview of the model is presented in Section 5.1; detailed information on the model and the assumptions that underlie it is provided in Appendix H. The effects of the WSIP on stream flow and reservoir water levels are evaluated in Section 5.3.1 and were used as the basis for assessing the WSIP's effects on fisheries and aquatic resources. In addition, the effects on water temperature due to WSIP-induced changes in flow in the Tuolumne River below La Grange Dam were determined using a temperature model and are described in Section 5.3.3.
A professional fish biologist assessed the effects of flow, reservoir level, and water temperature changes on aquatic life.

Impact Summary

Table 5.3.6-4 presents a summary of the impacts on fisheries in the Tuolumne River system and downstream water bodies that could result from implementation of the proposed water supply and system operations.

TABLE 5.3.6-4
SUMMARY OF IMPACTS –
FISHERIES IN TUOLUMNE RIVER SYSTEM AND DOWNSTREAM WATER BODIES

Impact	Significance Determination
Impact 5.3.6-1: Effects on fishery resources in Hetch Hetchy Reservoir	LS
Impact 5.3.6-2: Effects on fishery resources along the Tuolumne River between Hetch Hetchy Reservoir and Don Pedro Reservoir	LS
Impact 5.3.6-3: Effects on fishery resources in Don Pedro Reservoir	LS
Impact 5.3.6-4: Effects on fishery resources along the Tuolumne River below La Grange Dam	PSM
Impact 5.3.6-5: Effects on fishery resources along the San Joaquin River	LS

LS = Less than Significant impact, no mitigation required
PSM = Potentially Significant impact, can be mitigated to less than significant

Impact Discussion

Impact 5.3.6-1: Effects on fishery resources in Hetch Hetchy Reservoir.

Hetch Hetchy Reservoir provides habitat for resident fish, including trout. Rainbow, brown, and eastern brook trout support a popular recreational fishery. Operational modeling (presented in Section 5.3.1) indicates that increased water demand under the WSIP would result in a general reduction in water storage elevations in Hetch Hetchy Reservoir of 1 to 10 feet in most months, and to a larger degree in some months of a severe drought. Hetch Hetchy Reservoir typically undergoes a substantial change in storage volume throughout the year, with a general declining trend during the fall and winter followed by a substantial increase in storage during the spring and summer in response to snowmelt runoff (Figure 5.3.1-8). The fish community inhabiting the reservoir typically experiences a wide range of habitat conditions under both existing and proposed future operations. Given the range of natural variation in seasonal storage within the reservoir under existing conditions and the incremental changes predicted to occur under the WSIP, impacts on resident fish habitat within the reservoir under future conditions would be *less than significant*, and no mitigation is required.

Impact 5.3.6-2: Effects on fishery resources along the Tuolumne River between Hetch Hetchy Reservoir and Don Pedro Reservoir.

The Setting section describes the aquatic habitat and fishery resources in the Tuolumne River below Hetch Hetchy Reservoir; the resident fish species present in the river include rainbow trout, brown trout, California roach, sculpin, and suckers. Instream habitat conditions for resident trout and other fish species inhabiting the Tuolumne River downstream of Hetch Hetchy Reservoir are supported through the maintenance of minimum stream flows. The minimum flow requirements below Hetch Hetchy are described in Section 5.3.1.1 and shown in Table 5.3.1-2. The SFPUC operates all facilities such that these release requirements are met.

Hydrologic modeling (see Section 5.3.1) shows that WSIP operations would have little or no effect on average monthly flow in most summer, fall, and winter months in all hydrologic year types. In these months, the required fishery release would be made under the existing condition and with the WSIP. With the WSIP, the number of months in which only the required fishery release would be made would increase slightly. The modeling analysis indicates that, under the existing condition, the minimum flow release would be made 85.1 percent of the time (837 months in the 984-month hydrologic record), while under the WSIP the minimum flow release would be made 85.4 percent of the time (in 6 more months, or 843 months in the 984-month hydrologic record). Minimum release requirements would be maintained under all conditions. The WSIP would have a less-than-significant effect on river flows and, in turn, on fisheries in these months.

In spring months (April, May, and June), however, operation of the regional water system under the WSIP would reduce average monthly flows between 4 and 30 percent as the SFPUC refills Hetch Hetchy Reservoir with snowmelt. The greatest percentage reduction would occur in normal, below-normal, and dry years because, in these year types, a greater proportion of the snowmelt currently released by the SFPUC to the river would be needed to refill the reservoir. Actual flow reductions in any single spring month during the different hydrologic year types would vary widely. As discussed previously, the modeling tool used for this analysis reports information in a monthly time-step; it cannot provide weekly or daily information about flow releases. In reality, the flow reduction would not occur evenly over a month, but instead would be the result of SFPUC reservoir operators delaying the start of spring flow releases from Hetch Hetchy Reservoir by a few days in an effort to gauge and balance reservoir refill with releases of excess snowmelt. After the initial delay of releases from the reservoir under WSIP operations, and once the SFPUC determined that adequate reservoir refill would be achieved by July, the SFPUC would resume releases for the remainder of the spring and early summer, following a similar pattern of frequency and magnitude as under existing conditions.

Many of the resident fish spawn during the spring months, but the delayed rise in flow would not be expected to have a significant effect on rainbow trout and other resident fish during the spring spawning season. The delay in spring flow releases under the WSIP would typically be on the order of days and would be within the natural interannual variation that has occurred in the past. Resident rainbow trout, and other fish species, have evolved and adapted to short-duration variation in environmental conditions. The short-duration delay in increasing stream flows above the minimum flows would be a less than significant impact on habitat conditions and the biological response of resident trout and other fish species. Adverse impacts on fishery habitat quality and availability for resident rainbow trout related to the minor delay in increased flows would be less than significant.

With respect to potential water quality and temperature effects on fisheries (as discussed in Section 5.3.3), the WSIP would have no effect or a less-than-significant effect on temperature and dissolved oxygen in Hetch Hetchy Reservoir and downstream on the Tuolumne River in most months and year types. During some extremely dry periods under both existing conditions and with the WSIP, reductions in storage in Hetch Hetchy Reservoir might result in the release of warmer water from the reservoir at times when the reservoir is stratified (warmer water at the top and colder water below). Analysis of the droughts that occurred in 1923–1935, 1976–1977, and 1986–1993 indicates that this situation could occur in a drought similar to the 1976–1977 drought, but did not occur in the two other extended drought scenarios.

Under conditions similar to those of the 1976–1977 drought, with reduced water in storage during the dry period, water released downstream to the river in September and October could eventually come from the warmer water layer on the surface of the reservoir, which could be 10 to 12 °C warmer than the colder water initially released from the lower level of the reservoir. Release of this warmer water could increase the temperature in the river from about 8 °C to perhaps 14 to 18 °C. This situation would occur in a drought similar to the 1976–1977 drought under existing conditions as well as with the WSIP. However, since reservoir drawdown in Hetch Hetchy Reservoir would be greater with the WSIP than under existing conditions, the adverse water quality effects would be similar to those under the existing condition but would last longer under the WSIP.

This potential temperature effect would result in a less-than-significant impact on the fisheries in this reach of the river for several reasons. First, it would occur very infrequently; review of the historical hydrology indicates that this situation would not occur in all drought periods but only those, such as the 1976–1977 drought, where reservoir drawdown reaches levels low enough in September and October (when the reservoir would be stratified) to result in the release of the warmer surface water. Over the modeled 82-year hydrologic record this condition occurred only once. Although this temperature increase would exceed the 5 °F limit for temperature change specified in the Central Valley RWQCB objectives for coldwater fishery beneficial uses, the resulting temperatures of 14 to 18 °C would not exceed the suitable temperature range for juvenile and adult trout (13 to 21 °C). The rainbow trout fishery would be the most sensitive to the temperature increase. Also, this temperature effect would not occur during the spawning months of the year (a sensitive stage in the fishery life cycle), but rather during the adult and juvenile rearing period. This very infrequent temperature effect would not result in a significant impact on fishery populations.

Potential impacts to resident fish population inhabiting the river are *less than significant*, and no mitigation is required.

Impact 5.3.6-3: Effects on fishery resources in Don Pedro Reservoir.

Don Pedro Reservoir supports a diverse assemblage of resident fish (Table 5.3.6-1), including rainbow, brown, and brook trout, largemouth and smallmouth bass, sunfish, shad, and several species of fish such as Chinook salmon, coho salmon, and kokanee that are reared in hatcheries and planted in the reservoir to support recreational fisheries. Operational modeling (presented in Section 5.3.1) indicates that reservoir storage under the WSIP would be reduced year-round (Figure 5.3.1-11). As a result of increased deliveries under the WSIP, inflows to Don Pedro Reservoir would be reduced, causing a reduction in storage elevations within the reservoir of 1 to 10 feet in most months, and to a larger degree in some months of a severe drought. Don Pedro Reservoir typically undergoes a substantial change in storage volume throughout the year, with a general increasing trend during the fall, winter, and early summer followed by a substantial decline in storage during the late summer and early fall (Figure 5.3.1-11). The typical variation in reservoir conditions within a year is substantially greater than the change expected to occur under WSIP operations. The fish community inhabiting the reservoir typically experiences a wide range of habitat conditions under both existing and proposed future operations. Given the range of natural variation in seasonal storage within the reservoir under existing conditions and the incremental changes predicted to occur under the WSIP, impacts on resident fish habitat within the reservoir under future conditions would be *less than significant*, and no mitigation is required.

Impact 5.3.6-4: Effects on fishery resources along the Tuolumne River below La Grange Dam.

Changes in reservoir operations, coldwater pool availability, and instream flow releases have the potential to affect the quality and availability of habitat for resident and anadromous fish species. Chinook salmon is the species of most concern in this reach of the river. On the Tuolumne River downstream of La Grange Dam, fall-run Chinook salmon use the river for migration, spawning, egg incubation, and juvenile rearing. Steelhead, which is a federally listed threatened species, may inhabit the river in low abundance. These two are the more sensitive fish species in this reach of the river and thus are the focus of this impact analysis; impacts on these species are representative of potential effects on the other species present in this reach. Potential mechanisms for adverse effects on fishery habitat include:

- Reductions in adult salmon attraction and migration flows
- Reductions in stream flows resulting in dewatering of incubating eggs
- Reductions in stream flows resulting in reductions in physical habitat for juvenile rearing
- Reductions in reservoir storage volume and coldwater pool availability resulting in elevated downstream water temperatures
- Reductions in stream flows and/or increases in seasonal water temperatures affecting juvenile emigration

The potential for each of these mechanisms to adversely affect fishery habitat as a result of proposed operations was assessed based on the reservoir storage information and monthly instream flows presented in Section 5.3.1 and the water quality/temperature effects assessment presented in Section 5.3.3.

The potential flow changes on the lower Tuolumne River under the WSIP, as discussed in Section 5.3.1, can be summarized as follows. Under existing conditions, in most below-normal or drier years, almost all of the winter and spring runoff from the watershed upstream of Don Pedro is captured in the reservoir. In years when the reservoir fills, usually wet or above-normal years, excess water is released to the Tuolumne River. In the future with the WSIP, Don Pedro Reservoir would be drawn down farther in most years than it would under the existing condition. Consequently, TID would have to capture a greater proportion of spring runoff to refill the reservoir with the WSIP. As a result, the volume of water released to the Tuolumne River would be reduced compared to the existing condition. The flow reductions that would occur under WSIP operations would primarily take place during the December to June period, when TID fills Don Pedro Reservoir.

The WSIP would have little or no effect on average monthly flow in the lower river in most summer, fall, and winter months in all hydrologic year types. The WSIP would have no effect on average monthly flow in any months of critically dry years or in most summer months of dry, below-normal, and above-normal years (see Table 5.3.1-6). Only the required fishery releases are made in these months under the existing condition, and this would remain the case under the WSIP. The WSIP would result in reductions in average monthly flow in the Tuolumne River below La Grange Dam in the November through June period in non-critically dry years. As shown in Table 5.3.1-6, reductions in flow would occur in some months of all year types except for critically dry years. Looking at monthly flows averaged by year type, the greatest average monthly reduction would be a 25 percent flow reduction in June of an above-normal year. The analysis of the 82-year hydrologic record indicates that reductions of 30 percent or more could occur in some months of 18 years out of 82, or about once in every four springs on average. A maximum flow reduction ranging from 80 to 95 percent was projected to occur once in the 82-year hydrologic simulation.

As discussed previously, the modeling tool used for this analysis reports information on a monthly time-step. As a result, while the model describes the nature and magnitude of monthly flow changes that could occur under the WSIP compared to existing conditions, it does not show the specific daily or weekly changes in reservoir operations made by the operators. The predicted flow changes would not occur uniformly over an entire month. The flow reductions on the lower Tuolumne River under the WSIP would result from Don Pedro Reservoir operators adjusting the timing and duration of reservoir releases by a matter of days as they balance reservoir refill objectives with flood control and fishery release requirements.

Adult fall-run Chinook salmon migrate upstream from September through December. Minimum instream flows in the Tuolumne River were established as part of the FSA to provide suitable habitat conditions for adult Chinook salmon migrating upstream. Minimum instream flows would continue to be maintained under the WSIP. Although flows in the lower river would be reduced in some months, the remaining flows are suitable for adult migration. Flow reductions under the WSIP would have a less-than-significant effect on adult migration.

Chinook salmon spawning and egg incubation typically occurs from approximately mid-October through March. If there were a substantial reduction in flows during egg incubation, the redds could be dewatered, resulting in mortality. During the spawning season, average monthly flows generally show an increasing trend throughout the egg incubation period under both existing conditions and with the WSIP. Although the WSIP would reduce flow relative to existing conditions, the flow reductions would not be expected to result in an increased risk of redd dewatering. Since flows during the egg incubation period are increasing under both existing and future WSIP conditions, it is expected (based on the monthly average flow estimates) that impacts on egg incubation, hatching, and fry emergence would be minor. Instream flows under existing conditions are managed on a daily basis to reduce the risk of redd dewatering. It is assumed they would be managed in the same way with the WSIP. Thus, it flow reductions under the WSIP are not anticipated to have a significant effect on incubating eggs.

Juvenile Chinook salmon rearing occurs in the lower Tuolumne River from January through May. WSIP-induced changes in river flow that are projected to occur during the juvenile Chinook salmon rearing are typically less than 10 percent of the existing baseline flows (Table 5.3.1-6), with some exceptions where a higher-percentage flow reduction could occur. Instream flow studies have been conducted on the lower river to identify the relationship between stream flow and juvenile salmon rearing habitat (USFWS, 1994). The results of these analyses were used to identify minimum instream flow requirements. The minimum instream flows would be maintained under both existing and proposed operations. In some years, the projected flow reductions would not substantially reduce rearing habitat (based on an examination of the predicted changes in stream flow during the juvenile rearing period and the flow/habitat relationships for the river), and the WSIP would have a less-than-significant effect on the salmon fishery. However, in some years, when the flow reductions are more substantial, the WSIP changes would adversely affect juvenile fall-run Chinook salmon rearing habitat.

Fall-run Chinook salmon juvenile out-migration occurs during February and March (fry) and April and May (smolts). The predicted stream flows under existing and proposed operations during the juvenile emigration period show that stream flow reductions are typically less than 10 percent when compared to the existing baseline flows. As noted above, minimum stream flow requirements identified for the river would continue to be met under both existing and proposed operations. Based on the magnitude of the stream flow changes, it is not expected that flow reductions under the WSIP would result in significant adverse impacts on juvenile fall-run Chinook salmon migration.

The largest percentage reductions in Tuolumne River stream flow downstream of La Grange Dam under WSIP operations are expected to occur in June (Table 5.3.1-6). Flow reductions in June would likely result in seasonally elevated water temperatures and a corresponding reduction in the linear extent of suitable habitat for steelhead/rainbow trout rearing. Steelhead/rainbow trout rear within the river system throughout the year. Seasonally elevated water temperatures affect habitat suitability during summer months. Although steelhead are not abundant in the Tuolumne River, these changes in stream flow and water temperature could affect habitat quality and availability for summer rearing. Changes in flow in June of average wet years (-7 percent) would have a minor effect on steelhead/rainbow trout because river flow under both existing and proposed conditions would be in excess of 1,000 cfs. The average monthly flow reduction in June of above-normal hydrologic years (-25 percent) represents a change in flow from 408 cfs under existing conditions to 306 cfs with the WSIP. A reduction in average monthly flow in June of approximately 102 cfs would cause a moderate change in habitat conditions, potentially affecting oversummering steelhead/rainbow trout as well as reducing physical habitat within the river for other aquatic species.

As discussed in Section 5.3.3 regarding water quality and temperature, the proposed program would not result in changes in reservoir storage that would adversely affect the extent of the coldwater pool available for release to the lower river. Based on the results of these analyses, it was concluded that the WSIP would not affect seasonal temperatures in water released to the river from Don Pedro Reservoir. Almost all of the time, WSIP-induced flow reductions in the Tuolumne River below La Grange Dam would have no effect on water temperature. As described in Section 5.3.3, on infrequent occasions, WSIP-induced flow reductions could cause temperature increases in early summer (June) in the Tuolumne River downstream near the confluence with the San Joaquin River. Water released from La Grange Dam in June is considerably cooler than the average daily air temperature. As water flows downstream, its temperature increases. Water temperature modeling projected that mean daily temperature increases of 1 or 2 °C could occur infrequently in the Tuolumne River downstream near the confluence with the San Joaquin River (see Section 5.3.3). On very rare occasions, WSIP-induced flow reductions would cause mean daily temperature increases of 10 °C downstream near the San Joaquin River confluence. This occurred in only one month in the modeled simulation of WSIP operations over the 82-year hydrologic record.

Overall, the flow reductions coupled with the projected infrequent water temperature increases that could result under the WSIP would have an adverse impact on habitat conditions for juvenile salmonids. The flow reductions would reduce available habitat in the entire reach of the river used by juvenile salmonids below La Grange Dam. The elevated temperatures, although infrequent, would truncate the length of the river reach suitable for juvenile salmonids. These adverse effects on flows and temperature in the river under the WSIP would not substantially alter or degrade salmonid habitat in most years or jeopardize the continuation of the salmonid populations in the lower Tuolumne River. However, WSIP effects on flow and temperature would infrequently contribute to potentially significant effects on the fishery resources. The *Habitat Restoration Plan for the Lower Tuolumne River Corridor* (McBain and Trush, 2000) establishes goals for fishery habitat restoration, and the NMFS and others have identified goals for fishery enhancement on the lower river. The WSIP's small but incremental contribution to adverse effects on the lower river would make planned restoration of habitat and fishery resources more difficult. As a result, the impact of the WSIP on these fishery resources in the lower Tuolumne River would be *potentially significant*. Implementation of Measure 5.3.6-4a, Avoidance of Flow Changes By Reducing Demand for Don Pedro Reservoir Water, would reduce this impact to less than significant. This measure involves some uncertainty because its implementation depends on the SFPUC reaching agreement with MID/TID and possibly other water agencies. If this measures proves to be infeasible, the SFPUC will implement Measure 5.3.6-4b, Fishery Habitat Enhancement, to enhance fishery habitat in the lower Tuolumne River. Implementation of Measure 5.3.6-4a or 5.3.6-4b would reduce these adverse impacts to a *less-than-significant* level.

[Additional discussion on Mitigation Measures 5.3.6-4a and 5.3.6-4b was prepared in response to comments on the Draft PEIR. Please refer to Section 14.7, Master Response on Lower Tuolumne River Issues (Vol. 7, Chapter 14).]

Impact 5.3.6-5: Effects on fishery resources along the San Joaquin River.

The lower San Joaquin River provides habitat for a diverse assemblage of fish, including catfish, largemouth bass, striped bass, shad, and many others. The lower river also serves as the migratory corridor for the upstream passage of adult salmon and steelhead and the downstream passage of juveniles. Although water quality (e.g., electrical conductivity, dissolved oxygen, etc.) and other factors affect habitat for these species within the San Joaquin River, seasonal flow and water temperatures have been identified as important environmental parameters affecting the health and survival of migrating salmonids.

For the San Joaquin River and its tributaries, a relationship has been established between spring flow and the subsequent survival and contribution of adults to the salmon population (USFWS, 1994). A reduction in river flow during the spring rearing and juvenile emigration period would result in an incremental contribution to reduced juvenile survival and a small incremental contribution to the cumulative reduction in juvenile survival and subsequent adult population abundance. Increased water temperatures, particularly during the late spring juvenile salmonid migration period (April–May), would also be expected to adversely affect juvenile salmon survival.

Hydrologic modeling has shown that the WSIP would affect habitat conditions within the lower San Joaquin River as a result of changes in Don Pedro Reservoir storage. This potential adverse effect of WSIP operations on fishery habitat within the lower river would be greatest during the summer months (e.g., June, July, etc.) at the end of a prolonged drought, when the reservoir storage volume would be lowest and water temperatures greatest. Inflow to the lower San Joaquin River from the Tuolumne River would not be less than the minimum stream flow specified in the FERC license for the Don Pedro Project. As a result of this minimum flow requirement, the WSIP would not have a significant impact on flows, particularly during drought conditions.

WSIP operations (as discussed above) would reduce inflow to the reservoir and, as a result, increase the seasonal (summer) temperatures in water released from the reservoir, which would also affect water temperature within the lower San Joaquin River. Under low-flow summer conditions, particularly during a drought, water temperatures increase rapidly with distance downstream of a dam and reach thermal equilibrium with ambient air temperatures. As discussed in Measure 5.3.6-4a, the SFPUC would attempt to enter into a water transfer agreement with MID/TID or other water provider that would reduce the potential for adverse impacts on habitat conditions within the Tuolumne River that would also extend downstream to the San Joaquin River. The effectiveness of increased storage in reducing water temperatures is greatest during the spring, but is reduced during the summer as air temperatures increase. As a result, water temperatures in the lower San Joaquin River could increase during the summer months in years following an extended drought, although these conditions are expected to occur infrequently. Increased water temperatures during the summer of an extended drought would not be expected to result in significant adverse impacts on salmon or steelhead migrating downstream within the San Joaquin River, since the migration would occur earlier in the year and ambient water temperatures within the river might already be elevated to a level that is highly stressful or potentially lethal to juvenile salmonids. To the extent that infrequent reductions in flow and corresponding increases in water temperature occur during the spring (April-June) WSIP operations would contribute to adverse impacts on habitat conditions for downstream migrating Chinook salmon and steelhead. However, this potential impact would occur so infrequently that it does not represent a significant impact to fishery resources. Other fish species inhabiting the river, such as largemouth bass and striped bass, are tolerant of elevated water temperatures and would not likely be affected. As a result, the impacts of WSIP operations on habitat conditions for fish within the lower San Joaquin River would be *less than significant,* and no mitigation would be required.

5.3.7 Terrestrial Biological Resources

The following setting section describes terrestrial biological resources in the Tuolumne River watershed that could be affected by the WSIP. The impact section (Section 5.3.7-2) provides a description of the changes in terrestrial biological resources that would result from WSIP-induced changes in stream flow and reservoir water levels.

5.3.7.1 Setting

Riparian and wetland habitats form an important element in the ecology of most landscapes, whether in the Sierra Nevada or the Central Valley. This analysis deals only with those species and communities that have an essential requirement for stream or meadow conditions and whose range includes the Tuolumne River. Approximately 17 percent of Sierran plant species, 21 percent of vertebrate species, and, by definition, all aquatic invertebrate species in streams are closely associated with or dependent on riparian or wet areas (Sierra Nevada Ecosystem Project, 1996a). While Tuolumne River water does reach the San Joaquin River and the Delta, at that distance it is subject to so many other inputs and impacts, and at such larger scales, that an assessment of the biological impacts due to the WSIP alone would be speculative. As a result, this discussion focuses on the Tuolumne River from Hetch Hetchy Reservoir downstream to the confluence with the San Joaquin River, and the Tuolumne's two major mountain tributaries, Cherry Creek and Eleanor Creek.

In Chapter 4, the term "key special-status species" is used to indicate those species (principally but not exclusively those listed under the California or Federal Endangered Species Acts) that would be subject to a significant impact at the programmatic level. For all proposed WSIP projects analyzed in Chapter 4, separate, project-level CEQA review would be performed. This chapter (Chapter 5) uses a slightly expanded set of groupings. The term "sensitive habitats" has the same definition throughout this PEIR, although in Chapter 5 the term refers mainly to riparian, wetland, and associated upland habitats that could be affected by WSIP-induced changes in reservoir water levels. Because the analysis in Chapter 5 must sometimes address project-level impacts of the WSIP and no further CEQA review would be performed, two additional categories were developed to ensure that no impact category is left unaddressed: "other species of concern," which is the broader suite of species appearing on the CDFG's Special Animals or Special Plants list (CDFG, 2007) or the California Native Plant Society's (CNPS) Lists 1 or 2 (CNPS, 2001). All other biological resources are included in the widest category, "common habitats and species." This latter category evaluates project-level impacts that are great enough in scale to potentially affect species and habitats of widespread distribution (e.g., annual grasslands).

The sections that follow describe the existing conditions for terrestrial riparian resources associated with the Tuolumne River portion of the Hetch Hetchy system. Section 4.6, Biological Resources, Figure 4.6-1 shows the habitat types found along the Tuolumne River within the WSIP program area. Habitat types are broader groupings than natural communities, but are useful when describing both wildlife and vegetation resources together.

Hetch Hetchy Reservoir, the Tuolumne River, and its Tributaries from O'Shaughnessy Dam to Don Pedro Reservoir

O'Shaughnessy Dam is located in a glacial valley dominated by walls of smooth, mostly unvegetated granite. Essentially no marsh or meadow habitat has formed around the perimeter of Hetch Hetchy Reservoir because of the steep granite slopes and annual fluctuations in reservoir water levels. The vegetation around the reservoir is generally mapped as foothill woodland and lower montane coniferous forest (NPS, 2007).

The Tuolumne River below O'Shaughnessy Dam flows through the transition from a glacially carved, U-shaped valley to a river-incised, V-shaped canyon. The stairstep morphology typical of formerly glaciated streams is evident for several miles below the reservoir; there are long reaches of low relief, sometimes with extensive gravel bars, punctuated by short, steeper sections with boulders and exposed bedrock channel. The Tuolumne River below O'Shaughnessy Dam represents the lowest-elevation evidence of glaciation found anywhere in the western Sierra (NPS, 2006). The stairstep morphology combined with exceptional water quality, a seasonal flood regime, and a largely undisturbed river corridor sustains systems that are remarkable in their size and diversity (NPS, 2006). Upslope from the narrow riparian zone, the Tuolumne River canyon has a largely unvegetated section of bare granite rock scoured during high flows following rain-on-snow precipitation events. The most recent of these events took place in 1982 and January 1997. The Tuolumne River below O'Shaughnessy Dam contains extensive sections of bedrock channel confined in a narrow canyon, with a riparian zone consisting of interrupted bands of white alder (*Alnus rhombifolia*) and dusky willow (*Salix melanopsis*) with very limited understory. The riparian strip is wider and contains more extensive stands along gravel bars found on the larger river bends. Alternating with the low-diversity bedrock channel portions of the river are areas of higher species diversity on alluvial fans and terraces where tributary streams with a natural hydrograph[1] empty into the river (McBain and Trush, 2007).

The Poopenaut Valley, about two miles below the dam, represents a low-elevation limit of glaciation. The substrate in the Poopenaut Valley is primarily decomposed granite with a high proportion of sand and gravel particles. The Poopenaut Valley supports stands of tule bulrush, wet and dry meadow, willow and woodland habitats, hanging ponds, and seasonal pools (NPS, 2006). The National Park Services considers the low-elevation meadow and wetland complex of the Poopenaut Valley to be an "outstandingly remarkable value" of the Tuolumne Wild and Scenic River (NPS, 2006). The presence of hanging ponds suggests that less-pervious, possibly fine-textured layers may be present in the valley alluvium.

Lake Lloyd is situated in a steep-sided valley and has little meadow development around its perimeter. Lake Eleanor is similarly situated, but contains some gradual slopes around the periphery that support seasonal wetland vegetation. These reservoirs are also bordered by foothill woodland and lower montane coniferous forest. Lake Lloyd and Lake Eleanor are similar in that their annual fluctuations expose a broad, essentially unvegetated strip below the maximum reservoir elevation.

---

1 The pattern of flow in a stream over time.

Cherry Creek is a steep, rapidly flowing tributary to the Tuolumne River. Cherry Creek has experienced riparian encroachment because of diversions at Lake Lloyd. Montane black cottonwood (*Populus trichocarpa*) forest with frequent Jeffrey pines (*Pinus jeffreyi*) now occupies most of the former stream channel. Eleanor Creek is a major tributary of Cherry Creek. It supports a narrow band of riparian habitat typical of mid- to high-elevation streams, with minimal riparian vegetation encroachment into the channel (McBain and Trush, 2007).

The Tuolumne River above Don Pedro Reservoir supports a diverse assemblage of Great Valley mixed riparian forest and scrub with species similar to those found in the riparian systems of the valley floor, although the habitat in this area is confined to rather narrow canyons.

Don Pedro Reservoir and Tuolumne River below La Grange Dam

Don Pedro Reservoir is situated in the lower Sierra Nevada foothills at an elevation of 900 to 1,000 feet. The surrounding area consists of foothill woodland typically dominated by gray pine (*Pinus sabiniana*) and blue oak (*Quercus douglasii*) with a grass understory. Due to the sloping terrain and large seasonal drawdown, very little wetland habitat is present on the margins of this reservoir.

This discussion of the current setting for the lower Tuolumne River draws heavily from the *Habitat Restoration Plan for the Lower Tuolumne River Corridor* (McBain and Trush, 2000). The restoration plan was developed after the 1995 FERC Settlement Agreement (FSA) to help the parties select and design restoration projects (see Chapter 2 for a description of the original FERC license for the New Don Pedro Project and the subsequent settlement agreement related to instream flows in the lower river).

The lower Tuolumne River extends for 52 river miles, from La Grange Dam to the confluence with the San Joaquin River. Its floodplain terraces extend up to several miles in width. Backwater channels and old oxbows are evidence of channel-forming processes that characterized historical, unimpaired flows. Prior to flow and sediment regulation, the stream flows of the Tuolumne River downstream of La Grange Dam within a given year and between years varied from 100 cfs in summer months to peak winter floods exceeding 100,000 cfs; these flows created variable and complex local channel morphologies and regularly occupied the full width of the floodplain.

Today, about 67 percent of the lower Tuolumne River water is diverted. Low flows are maintained at regulated levels, but the high flows have been greatly diminished and are dictated by flood control requirements. The lower Tuolumne River has experienced substantial encroachment from agriculture, grazing, and gravel mining

The previous alteration of physical and ecological characteristics of the lower Tuolumne River has changed the ability of the floodplain to support and sustain riparian habitat and ecological processes. The lower Tuolumne River is currently unable to mobilize its bed particles as a result of reduced flow magnitudes, among other factors. In most alluvial rivers with unimpaired flow regimes, floods with recurrence intervals of 1.5 to 2.5 years typically inundate floodplains. In the lower Tuolumne, the 1.5-year recurrence flood at the La Grange gaging station (RM 51.6) decreased from 8,600 cfs to 3,000 cfs following construction of Don Pedro Reservoir, with a consequent reduction in the frequency and amplitude of bed mobilization. McBain and Trush (2000) noted that the reduction in flows has prevented the formation of any distinct post-FSA floodplains.

Historically, willow scrub occupied the actively accumulating gravel beds and sandbars of river meanders. Broad riparian forests dominated by Fremont cottonwood (*Populus fremontii*) occupied the lower floodplain terraces. Backwater channels and oxbows (river meanders cut off from the main channel) supported a variety of seasonal and perennial wetlands dominated by shrubs, grasses, grasslike plants, and forbs. Valley oak (*Quercus lobata*) woodlands occupied the upper floodplain terraces (Conard et al., 1977).

The total historical acreage of riparian vegetation in the Tuolumne River corridor between La Grange Dam and the San Joaquin River has diminished from approximately 13,000 or more acres to less than 2,200 acres. Fremont cottonwood is commonly observed within the lower Tuolumne River corridor, but nearly all stands and individuals are old and dying, with little or no natural regeneration. Valley oaks are also found throughout the Tuolumne River corridor. Because valley oaks are not as dependent on fluvial processes for regeneration, their regeneration in the river corridor is more successful. McBain and Trush observed that where the floodplain has not experienced land use encroachment, relict riparian vegetation fragments of a much larger ecosystem are detectable.

McBain and Trush attributed the change of dominant tree species at the channel margins to the decrease in channel slope and transition from gravel-bedded to sand-bedded substrate. They concluded that, on the lower Tuolumne River, riparian regeneration (particularly Goodding's black willow (*Salix gooddingii*) and Fremont cottonwood) depends on a migrating channel that creates floodplain surfaces, flood inundation every 1.5 to 5 years, and gently receding flows following the spring snowmelt. The elimination of post-FSA floods exceeding 10,000 cfs has allowed narrow-leaf willow (*Salix exigua*), box elder (*Acer negundo* var. *californicum*), and white alder to establish and caused drier conditions on the former floodplains. As a result, the Fremont cottonwood and valley oak are beginning to die of old age.

Natural Communities, including Sensitive Natural Communities

Considering its length and elevational range, the Tuolumne River in the WSIP program area supports relatively few riparian natural communities. The California Natural Diversity Database (CNDDB) (CDFG, 2006a) lists all but the montane meadow community as sensitive. However, as indicated above, the National Park Service considers the low-elevation montane meadow in the Poopenaut Valley to be an outstandingly remarkable value of the Tuolumne Wild and Scenic River area (NPS, 2006). The natural communities along the Tuolumne River are briefly described below.

- **White alder riparian forest** is a streamside deciduous riparian forest strongly dominated by white alder with a shrubby, deciduous understory. A common associated tree species in the upper Tuolumne area is dusky willow. This natural community is associated with rapidly flowing, well-aerated perennial streams with coarse streambed sediments. White alder riparian forest is found extensively along most of the Tuolumne River below O'Shaughnessy Dam.

- **Montane meadow** is a dense herbaceous natural community dominated by sedges (*Carex* spp.) along with rushes (*Juncus* spp.), perennial grasses, and herbs. It is found on fine-textured, more or less permanently moist or wet soils. Unlike most natural communities identified by Holland (1986), montane meadow actually consists of many vegetation series dominated by a number of grass-like species associated with a wide range of elevations, soils, and hydrologic conditions. The Poopenaut Valley is considered to be an exceptional example of a low-elevation montane meadow.

- **Montane black cottonwood riparian forest** is a dense riparian forest dominated by black cottonwood with emergent Jeffrey pine. Shrub cover is fairly high, and herb cover is typically very high. Montane black cottonwood forest is found on high-flow streams below about 7,000 feet in the mid-Sierra Nevada. Small remnants of this natural community are found in the Poopenaut Valley. It is also found along Cherry Creek, where water diversions have resulted in substantial encroachment by Jeffrey pine.

- **Great Valley mixed riparian forest** is a tall, winter-deciduous, broadleaved riparian forest. Natural examples of this community include box elder, California black walnut (*Juglans hindsii* var. *californica*), California sycamore (*Platanus racemosa*), and several willow species (*Salix* spp.). The understory is a dense tangle of shade-tolerant shrubs, and California grape (*Vitis californica*) is also found in well-developed forests. Great Valley mixed riparian forest is found all along the lower Tuolumne River as well as the lower elevations of the river above Don Pedro Reservoir.

- **Great Valley cottonwood riparian forest** is similar to the preceding natural community. It is strongly dominated by Fremont cottonwood with some Goodding willow. This community is typically found on the largest streams in the Central Valley that provide ample subsurface irrigation even when the channel is dry. Great Valley cottonwood riparian forest is typically inundated yearly during spring, and cottonwood regeneration is dependent on freshly deposited, fine-textured alluvium and on the gradual ebbing of spring flows as the tiny cottonwood seedlings develop their root systems. Remnants of this community are still found along the lower Tuolumne River, although natural recruitment (i.e., growth of new vegetation) has essentially ceased.

- **Great Valley valley oak riparian forest** is a medium to tall, broadleaved, winter-deciduous, closed-canopy riparian forest dominated by valley oak. This community is found on the higher river terraces that receive periodic flooding and annual inputs of sediment. This community has become rare primarily through encroachment by agriculture, mining, and other human uses, although the cessation of flooding and sediment deposition has limited natural reproduction of the dominant species.

[Additional discussion on streamside meadows in the upper Tuolumne River watershed was prepared in response to comments on the Draft PEIR. Please refer to Section 14.6, Master Response on Upper Tuolumne River Issues (Vol. 7, Chapter 14).]

Key Special-Status Species and Other Species of Concern

Tables 5.3.7-1 and **5.3.7-2** present key special-status plant and animal species and other species of concern along the Tuolumne River that could be affected by the WSIP. Although the watershed as a whole supports a larger assemblage of species, the key special-status species and other species of concern considered here are limited to those that depend on riparian and river-associated habitats. Riparian, wet meadow, seep, or marsh plants were included if they appeared on CNDDB records for the 21 U.S. Geological Survey 7.5-minute quadrangles that encompass

Delta button-celery *Eryngium racemosum*	List 1B	Riparian scrub		Potential
Knotted rush *Juncus nodosus*	List 2	Meadows and seeps, marshes and swamps; lake margins and mesic sites	Potential	
Pansy monkeyflower *Mimulus pulchellus*	List 1B	Open sandy benches, wet meadows	Known, Poopenaut Valley	
Slender-stemmed monkeyflower *Mimulus filicaulis*	List 1B	Moist meadows, seeps in lower montane coniferous forest	Potential	
White beaked-rush *Rhynchospora alba*	List 2	Bogs, fens, marshes, swamps	Potential	
Brownish beaked rush *Rhynchospora capitellata*	List 2	Meadows, seeps, marsh, swamps, upper and lower montane coniferous forest	Potential	

[a] In this document, CNPS-listed species with no federal or state listing status are considered plant species of concern; no key special-status plants are known to occur in the Tuolumne project area.
[b] California Native Plant Society species codes are as follows:
List 1B: Rare and endangered.
List 2: Rare but not endangered.

SOURCES: CDFG, 2006b; CNPS, 2001.

the Tuolumne River from O'Shaughnessy Dam to the confluence with the San Joaquin River, Lake Lloyd, Cherry Creek, Lake Eleanor, and Eleanor Creek (CDFG, 2006b). The list of animals was compiled from the 2005 California Gap Analysis Project[2] species dependent on valley foothill riparian, montane riparian, and fresh emergent wetland habitat types. The list was then compared with CNDDB records for the 21 quadrangles encompassing the WSIP program area, and additional locality data were obtained by reviewing 2007 species occurrence records from the University of California Museum of Vertebrate Zoology. Figure 4.6-2 in Chapter 4 show the distribution of federally designated critical habitats for species listed under the Federal Endangered Species Act within the WSIP program area.

2 The Gap Analysis Project provides regional assessments of the conservation status of native vertebrate species and natural land cover types and facilitates the application of this information to land management activities. The Gap Analysis Project is conducted as state-level projects and is coordinated by the U.S. Geological Survey Biological Resources Division.

American badger *Taxidea taxus*	–/CSC	Lives in open country; forages on burrowing animals, roots, and berries	Potential	Potential

[a] Federal (USFWS) and state (CDFG) protection status codes are as follows:
FC: Federal candidate for listing
FE: Federal endangered
FT: Federal threatened
FD: Federal delisted
FPD: Federal proposed for delisting
CE: California endangered
CT: California threatened
CSC: California species of special concern
CP: California fully protected

* Indicates key special-status species, defined here to mean federal- or state-listed as endangered or threatened. All other species listed here are defined as species of concern.

SOURCES: CDFG, 2006a, 2006b.

Plants

High-elevation plants. No key special-status plants are known to occur in habitats associated with the Tuolumne River or its tributaries in the WSIP program area. Several plant species of concern occur in montane meadows and seeps, including the pansy monkeyflower (*Mimulus pulchellus*, a CNPS List 1B plant). This species grows at the margins of wet meadows and open sandy benches. Several populations of pansy monkeyflower have been reported in the Poopenaut Valley at the edges of the meadow vegetation (CDFG, 2006a). Several other species are known to be present in wet meadows, bogs, seeps, and moist meadows. They have not been reported from this portion of the Tuolumne River watershed, but suitable habitat could be present at the Poopenaut Valley. They include slender-stemmed monkeyflower (*Mimulus filicaulis*, CNPS List 1B), shore sedge (*Carex limosa*, CNPS List 2), knotted rush (*Juncus nodosus*, CNPS List 2), white beaked-rush (*Rhynchospora alba*, CNPS List 2), and brownish beaked rush (*Rhynchospora capitellata,* CNPS List 2) (CDFG, 2006a).

Mariposa clarkia (*Clarkia biloba ssp. australis,* CNPS List 1B) grows in chaparral and cismontane woodland, sometimes on the edge of riparian habitats, in the lower Sierra Nevada at elevations below 3,000 feet.

Don Pedro Reservoir and La Grange Dam to the San Joaquin River. Delta button-celery (*Eryngium racemosum*, CNPS List 1B) grows in riparian scrub in the lower elevations of the Central Valley. Suitable habitat is present in the lowest portions of the Tuolumne River near the confluence with the San Joaquin River, although the nearest known records are from the floodplains of the San Joaquin River several miles to the north and south of the confluence with the Tuolumne River.

Reptiles and Amphibians

Hetch Hetchy Reservoir to Don Pedro Reservoir. California red-legged frog (*Rana aurora draytonii,* federal threatened, California species of special concern) is known to occur in lowlands and foothills in or near permanent sources of water with dense, shrubby, or emergent vegetation. This species has been reported from Woods Creek, a tributary to Don Pedro Reservoir in Tuolumne County, and it may once have ranged into the vicinity of the Tuolumne River (CDFG, 2006b). Foothill yellow-legged frog (*Rana boylii,* California species of special concern) is found in small permanent streams above about 660 feet in the mid-Sierra (Jennings and Hayes, 1994). Suitable habitat could be present along the Tuolumne River and its tributaries. Western pond turtle (*Clemmys marmorata,* California species of special concern) is a thoroughly aquatic turtle that inhabits permanent ponds, rivers, and even ditches. The CNDDB (CDFG, 2006b) has a record of this species at O'Shaughnessy Dam.

Mountain yellow-legged frog (*Rana muscosa*, California species of special concern) is associated with sunny, high-elevation streams that often have vegetation and sloping banks. There are no CNDDB records from the Tuolumne River watershed below O'Shaughnessy Dam. Habitat in the Poopenaut Valley and along Cherry Creek and Eleanor Creek could be suitable for this species. Although these areas are lower than the currently documented known elevation limit for this species, museum records indicate that this species historically had a lower elevational range (Jennings and Hayes, 1994). The nearest known localities for mountain yellow-legged frog are Crane Flat, Tamarack Flat, and Lake Vernon in Yosemite National Park (Museum of Vertebrate Zoology, 2007).

Don Pedro Reservoir and La Grange Dam to the San Joaquin River. California tiger salamander (*Ambystoma californiense*, federal threatened, California species of special concern) inhabits long-standing or permanent ponds and uplands that contain burrows during the dry season. It is limited to the valley floor and nearby terraces, and a number of historical records document its presence on the valley floor and floodplain of the Tuolumne River in eastern Stanislaus County. California red-legged frog could occur in suitable habitat throughout this portion of the WSIP program area, although it is more likely to be present on the terraces and foothills rather than the valley floor. Western pond turtle could occur anywhere along the Tuolumne River and at Don Pedro Reservoir; there are several recent records from several locations in the WSIP program area. Western spadefoot toad (*Spea hammondii*, California species of special concern) is typically found in association with vernal pools, but may have occurred in seasonal wetlands on floodplains as well. It is known primarily from the valley floor within the program area.

Birds

Entire Tuolumne River WSIP program area. Cooper's hawk (*Accipiter cooperi*, California species of special concern) inhabits open woodland and riparian forest, where it preys on songbirds and small mammals. Sharp-shinned hawk (*Accipiter striatus*, California species of special concern) is found in more dense forest than is Cooper's hawk, where it feeds primarily on small birds. Golden eagle (*Aquila chrysaetos*, California species of special concern) nests on cliffs and in large trees. It is likely to forage over large areas of the program area, except for the valley floor. Bald eagle (*Haliaeetus leucocephalus*, federal delisted, California endangered) nests on cliffs and in large trees, and forages on and near lakes. Suitable habitat is present at Don Pedro Reservoir, and one pair recently nested at Lake Lloyd.

Northern harrier (*Circus cyaneus*, California species of special concern) nests and forages in wet meadows over a wide elevational range that apparently includes all of the program area. Short-eared owl (*Asio flammeus*, California species of special concern) nests and forages in open or marshy ground. It apparently is resident in the higher Sierra Nevada and winters at low elevations in the Central Valley. Long-eared owl (*Asio otus*, California species of special concern) nests in dense trees and forages in open country. Its distributional range includes all of California. Yellow warbler (*Dendroica petechia brewsteri*, California species of special concern) nests in dense riparian vegetation and is found in suitable habitat throughout California. Prairie falcon (*Falco mexicanus*, California species of special concern) usually nests on cliffs and forages in open country, but could also nest in tall riparian trees. American peregrine falcon (*Falco peregrinus anatum*, federal delisted, California endangered) nests on cliffs and outcrops and forages in open country, often near meadows or marshes where small birds are abundant. There are no CNDDB records of species occurrence in the program area, but suitable habitat may be present.

Hetch Hetchy Reservoir to Don Pedro Reservoir. Northern goshawk (*Accipiter gentilis,* California species of special concern) is found in dense forest, where it forages on flying squirrels, birds, ducks, and even hares. Its elevational range may be higher than the WSIP program area, as there are no CNDDB records of species occurrence in the program area. California spotted owl (*Strix occidentalis occidentalis*, California species of special concern) inhabits thickly wooded forests, including riparian forests where it forages on small mammals such as squirrels. Great gray owl (*Strix nebulosa*, California endangered) nests in dense forest and forages in forest openings or meadows. There are several recent records indicating its occurrence in Yosemite National Park down to Pine Mountain Lake. Suitable habitat may be present within the program area. Vaux's swift (C*haetura vauxi*, California species of special concern) nests in hollow trees and forages near water. Although there are no CNDDB records of species occurrence near the program area, habitat appears suitable along much of the mountainous portion of the Tuolumne River. Black swift (*Cypseloides niger,* California species of special concern) nests on cliffs near water and forages for insects. It is reported to occur along the Tuolumne River between Tuolumne Meadows and Hetch Hetchy Reservoir (NPS, 2006). Willow flycatcher (*Empidonax trailii*, California endangered) nests and forages in dense riparian thickets and meadows in mountainous areas. Purple martin (*Progne subis*, California species of special concern) is found in mountain forests, especially near water. Suitable habitat is present in this portion of the Tuolumne River.

Don Pedro Reservoir and from La Grange Dam to the San Joaquin River. Double-crested cormorant (*Phalacrocorax auritus*, California species of special concern) nests in rookeries on cliffs and along lake margins, and forages for fish. Its wintering range includes the Central Valley. White-faced ibis (*Plegadis chihi,* California species of special concern) and greater sandhill crane (*Grus canadensis tabida,* California threatened) winters in the Central Valley, foraging in shallow water along the floodplains of the major rivers. White-tailed kite (*Elanus leucuru*s, California species of special concern) nests in trees and forages over open country. It is found mainly in the lower elevations of the program area. California black rail (*Laterallus jamaicensis coturniculus*, California threatened) is a marsh-dwelling species known primarily to occur in salt marsh, but is occasionally found inland in low-elevation marshes. Long-billed curlew (*Numenius americanus*, California species of special concern) winters in the Central Valley and forages in grassland and marshes, including floodplains. Burrowing owl (*Athene cunicularia,* California species of concern) nests in burrows that are created by digging mammals. Sometimes these burrows are located on streambanks, edges of canals, or other areas near riparian habitats. Burrowing owls are found in low-elevation areas such as the Central Valley.

Yellow-breasted chat (*Icteria virens*, California species of special concern) nests low in dense riparian vegetation, breeding in low elevations in California. Tricolored blackbird (*Agelaius tricolor,* California species of special concern) nests and forages near marshes with emergent vegetation. It is found on the valley floor, and the CNDDB has several records of breeding colonies in or near the program area. Ferruginous hawk (*Buteo regalis*, California species of special concern) winters in the Central Valley. Swainson's hawk (*Buteo swainsoni*, California threatened) nests in tall trees and forages in grassland and farmland, primarily in the Central Valley. Some known locations for this species are along the Tuolumne River. Osprey (*Pandion* *haliaetus*, California species of special concern) nests in flat-topped trees and snags near water and feeds on fish (primarily in lakes). There are no known records of this species along the Tuolumne River, although it may have once occurred there. Merlin (*Falco columbarius,* California species of special concern) is a winter visitor to the Central Valley.

Loggerhead shrike (*Lanius ludovicianus,* California species of special concern) nests in riparian woodland and forages over open grasslands, meadows, and marshes. It is resident in the Central Valley and would be expected to occur near the Tuolumne River. Bank swallow (*Riparia riparia,* California threatened) nests in banks along large rivers and forages over open water. Although this species may have once been present along the Tuolumne River, there are no current records for this species within the program area.

Mammals

Entire Tuolumne River WSIP program area. American badger (*Taxidea taxus,* California species of special concern) may be found in riparian habitats and open country throughout the program area. Several species of bats (all California species of special concern) could occur within the program area, generally roosting in riparian trees. Pallid bat (*Antrozous pallidus*) and Pacific western big-eared bat (*Corynorhinus* (*=Plecotus*) *townsendii*) roost in trees and forage over open grasslands.

Hetch Hetchy Reservoir to Don Pedro Reservoir. Sierra Nevada snowshoe hare (*Lepus americanus tahoensis*, California species of special concern), Sierra Nevada mountain beaver (*Aplodontia rufa californica*, California species of special concern), and Sierra Nevada red fox (*Vulpes vulpes necator,* California species of special concern) inhabit riparian and forest habitats higher in elevation than the program area. American marten (*Martes americanus*, California species of special concern) and Pacific fisher (*Martes pennanti pacifica,* California species of special concern) live and forage in dense forest at mid- to high elevations in the Sierra Nevada.

Spotted bat (*Euderma maculatum*, California species of special concern) and western mastiff bat (*Eumops perotis*, California species of special concern) primarily nest on cliffs and forage in openings, sometimes near water. These species are reported to occur near the Tuolumne River between Tuolumne Meadows and Hetch Hetchy Reservoir (NPS, 2006) and may also be present along the Tuolumne River below O'Shaughnessy Dam.

Don Pedro Reservoir and from La Grange Dam to the San Joaquin River. All of the bat species except spotted bat and western mastiff bat could occur in this portion of the Tuolumne River. In addition, American badger is likely to occur throughout this portion of the Tuolumne River.

5.3.7.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to terrestrial biological resources, but generally considers that implementation of the proposed program would have a significant biological impact if it were to:

- Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS
- Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations or by the CDFG or USFWS
- Have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including but not limited to marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means
- Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites
- Have the potential to degrade the quality of the environment, substantially reduce the habitat of a fish or wildlife species, cause a fish or wildlife population to drop below self-sustaining levels, threaten to eliminate a plant or animal community, or substantially reduce the number or restrict the range of an endangered, rare or threatened species
- Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance
- Conflict with the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, or state habitat conservation plan, including the *Tuolumne Wild and Scenic River Management Plan* (USFS, 1986)

Approach to Analysis

The assessment of WSIP impacts on terrestrial biological resources is based primarily on the extent to which altered water system operations would change the existing habitat near reservoirs and creeks. This section reviews changes in hydrology (discussed in Section 5.3.1) and analyzes the related effects on riparian and wetland habitats, key special-status species, other species of concern, and common habitats and species. The discussion of riparian and wetland habitats addresses the second and third significance criteria listed above. “Key special-status species” include species that are formally listed as endangered or threatened under the California or Federal Endangered Species Acts, as well as a few other species (such as foothill yellow-legged frog and burrowing owl) that are afforded some degree of legal protection and have a high risk of local population decline or extirpation. The key special-status species discussion addresses the first significance criterion. “Other species of concern” and “common habitats and species” are more general categories relevant to the fourth and fifth significance criteria. Consistency with biological resources planning for the Tuolumne Wild and Scenic River (the last criterion) is discussed below under Impact 5.3.7-7.

River Hydrology and Riparian Ecology

At any point in a watershed, riparian ecological resources react primarily to two factors in the stream channel: geomorphic and hydrologic processes. Individual riparian species are adapted to a range of physical conditions along gradients of water table depth, soil moisture, and frequency and type of disturbance (Kondolf et al., 1996). Most riparian species depend on open sites created by flood flows for the recruitment of new individuals, and on minimum flows and the gradual return to base flows to provide subsurface soil moisture. Local climate, hydrology, geology, and geomorphology play an important role in determining the abundance, distribution, composition, and overall condition of the riparian habitat along a watercourse. The interrelationships between physical channel processes and riparian vegetation vary along the length of a stream and from river to river (Kondolf et al., 1996; McBain and Trush, 2007).

The effects of diversions on riparian ecology are complex. Reductions in stream flow generally lower species diversity and facilitate riparian encroachment into the active channel (Sierra Nevada Ecosystem Project, 1996b). Diversions and releases vary by site conditions and from year to year. Conditions may improve for one plant species and not another, and may vary from site to site along a reach of stream. Changes in riparian vegetation, in turn, affect the availability of food, cover, and structure for animal species that depend on the habitat. Moreover, causative factors tend to blur together with time: habitat structure and diversity represent an integration of influences spanning many decades. The adjustment to a substantially different flow regime requires many years, since some changes can affect the recruitment of long-lived plant species.

An assessment of impacts is complicated in an already stressed system, because some species may be at a critical stage in which further stress could cause the decline, reproductive failure, or local extirpation of mature individuals, even though they may appear robust and superficially able to adapt to change. Taking this into account, the analysis presented in this section is conservative, using reasonable worse case assumptions about the potential WSIP impacts to terrestrial biological resources that could result from program changes on reservoirs and streams.

Peak Flows

One of the most important influences on riparian structure and function is the magnitude and frequency of flood flows (also referred to as peak flows). Peak flows direct channel processes such as meandering, the formation of gravel bars, and sediment transport (Busch and Scott, 1995). Peak flows also play an important role in determining the period of saturation in the root zone during high water, which can result in a stratification of plant species along a fine topographic/soil moisture gradient up to the floodplain. Peak flows move and remove vegetation, creating open sites for the establishment of seedlings; some woody species that are uprooted or felled can later re-sprout. First, erosion of stream banks during floods carries away the vegetation. The removal or death of some plants during peak flows then creates opportunities for other plants to grow, ensuring regeneration and contributing to a structurally diverse canopy: sediment deposition can bury and damage some plants that may be able to re-sprout above the new surface, and can provide fresh substrate for other plants to thrive where competition had been reduced (Kattelmann and Embury, 1996).

Major flood events that recur only every few decades can have lasting effects on the channel form. In river systems such as the Tuolumne, very high periodic peak flows scour the channel and canyon walls for a considerable height. Many riparian species depend on such periodic disturbance for recruitment (Friedman and Lee, 2002). In meadow systems, peak flows serve a similar function, depositing sediment, facilitating channel migration, removing decadent vegetation, and creating open sites.

Diversions that reduce peak flows tend to reduce sediment transport and habitat complexity. Meandering and channel-forming processes are constrained. Without the scouring effects of high flows, riparian vegetation can encroach onto formerly active depositional surfaces (McBain and Trush, 2007). A reduction in open sand and gravel bars reduces the habitat for animal species such as foothill yellow-legged frog. Diminished cobble surface reduces the areas suitable for macroinvertebrate production, thus reducing the food supply for amphibians, bats, and many species of birds (McBain and Trush, 2007). In meadow systems, reduced peak flows reduce sediment deposition and limit the formation of openings and the removal of older vegetation.

Sustained High Flows

While peak flows are the most dramatic channel-forming events, sustained high spring flows mobilize sediment, and, as the flows recede, fresh sediment deposits are exposed. These regularly recurring high-flow events are the 1.5- to 2.5-year flows that define ordinary high water and facilitate sediment transport. Low flows and depth to groundwater determine the distribution of riparian vegetation according to ecological requirements. Channel width, meander wavelength, and rate of channel migration are all highly sensitive to discharge. Thus, a reduction in flows constrains the dynamic formation and movement of backchannel ponds, fresh sediment deposits, and other physical variation.

Meadow systems depend on sustained high flows to recharge groundwater, which determines the extent and composition of different sub-habitats such as wet meadows, dry meadows, and seasonal ponds. Wildlife respond to channel-forming processes and the microhabitats they create, and to the variety of structure and species diversity in the riparian vegetation. In addition, aquatic-dependent species such as frogs are directly affected by high flows during the breeding season, when tadpoles and eggs may be entrained and washed downstream.

Diversions that reduce high flows also reduce suitable sites for the recruitment of many riparian species, thus restricting their extent and abundance. The lack of dynamic deposition also allows upland vegetation to encroach into the riparian corridor and onto formerly active bar surfaces. An example of this phenomenon is Cherry Creek below Lake Lloyd, where encroachment has allowed Jeffrey pines to become established in the riparian zone. Reduced high flows also tend to reduce the available habitat and productivity of benthic macroinvertebrates, a food source for many riparian wildlife. Meadows affected by diversions tend to experience encroachment from upland vegetation.

The Hydrograph

The reproductive cycle of each riparian tree species is specifically tied to the timing of soil and moisture conditions that depend on the stream hydrograph (McBain and Trush, 2007). Many riparian tree species such as willows and cottonwood release large numbers of tiny seeds during a brief period in spring. These seeds are viable, or capable of germination, for only a few weeks. Their establishment depends on moist, bare soil for a period of several weeks or months while the seedling's root system develops to the depth of sustained groundwater. Each species of tree, shrub, and herb has evolved adaptations to ensure a place in the range of soil, moisture, and light conditions found in the highly dynamic riparian habitat.

Diversions that delay the highest spring flows can reduce or eliminate the required germination conditions for species adapted to early seed dispersal and germination events. A reduction in flows on the "receding limb" of the hydrograph can cause exposed sediment bars to dry out before seedlings establish their root system, thus resulting in mortality. Although very high flows can be detrimental for amphibians or other wildlife that may be swept away, a reduction in spring high flows can reduce the available extent and duration of breeding habitat.

Abrupt Changes in the Hydrograph

In a natural stream, water recedes gradually from high flows. Under a diversion scenario, these changes in flow can be much more abrupt. Especially when the flows are diminished rapidly, seedlings can become desiccated and die, and amphibian and invertebrate larvae can become stranded and die (McBain and Trush, 2007). The pattern and timing of stream releases is especially important for aquatic-dependent wildlife. Rapid increases in flow during managed releases can result in scouring and entrainment.

Terrestrial wildlife are also affected by an altered hydrograph resulting from diversions. Many animal species depend on specific plant species or vegetation structure for the completion of their life cycle; for example, willow flycatcher requires low, dense shrubby vegetation for nesting, and yellow-billed cuckoo requires large quantities of insect larvae as forage. Many insect species also have specific relationships with plant species to complete their life cycle; for example, Valley elderberry longhorn beetle requires blue elderberry shrubs of a particular stem diameter in which to lay its eggs. Alteration of the species composition, extent, or structure of the riparian habitat has direct impacts on some species, and indirect impacts on other species that depend on these species. In return, the riparian vegetation itself may be altered if the habitat is insufficient to sustain animal populations of pollinators, seed dispersers, or insectivores that keep the system in balance.

Minimum Flows

Minimum flows are a determining factor in maintaining groundwater levels. Some riparian species, such as alders, require year-round flowing water, while most others depend on groundwater, the extent of which depends to a large degree on sustained minimum flows. While the pattern of the hydrograph governs recruitment of riparian vegetation, minimum flows can determine the survival of established vegetation. Minimum flows also determine the extent and duration of surface water habitat for aquatic-phase vertebrate and invertebrate species. Similarly, these effects are also important for maintaining the extent and diversity of meadow habitats.

Diversions that substantially reduce minimum flows can cause encroachment by upland vegetation, reduction in the extent of riparian vegetation, and an overall reduction in species diversity and stand structure. Over time, constrained physical conditions reduce the micro-habitats required for the establishment of different riparian species, with an eventual reduction in riparian plant species diversity and structure. Reduced summertime flows also tend to result in higher stream temperatures. Although increased temperature does not affect riparian vegetation, it can adversely effect vertebrate and invertebrate populations, which tend to be more sensitive to water temperature. Since these effects reduce the food base and extent of riparian habitat, they also tend to result in a reduction in the species diversity and abundance of vertebrate riparian wildlife.

Sustained minimum flows deepen the stream channel, further limiting channel migration. In addition, these flows alter growing conditions, favoring plant species that require permanently flowing water for germination, establishment, and growth, such as white alder and willow. If minimum flow releases convert a seasonal stream into a perennial stream, a narrow band of water-dependent species may form along the stream.

Reservoirs

Seasonal wetlands, perennial freshwater marsh, and riparian habitats around reservoirs depend on the season, duration, and elevational range of prevailing water levels. The lower-elevation ecological range of terrestrial plants is limited by inundation, and the upper range is constrained by the limits of water availability. The more consistent the water level from year to year and throughout a season, the more favorable the conditions are for perennial freshwater marsh and a resulting overall high species diversity for both animals and plants.

The more the pattern of water levels approximates a natural regime (i.e., highest levels in spring, with a gradual reduction through the summer and fall), the greater the diversity of habitats and species. Some plant species are limited by sustained inundation when the reservoir is maintained at its highest levels, and some plants are limited by drought when the reservoir is maintained at its lowest levels. Conversely, highly variable water levels decrease plant species diversity, and annual, weedy species become more prevalent. When a reservoir is operated at a higher or lower water level, habitats respond by migrating to the appropriate elevation. Similarly, the structure and composition of riparian and wetland habitats also respond to the timing and duration of maximum and minimum reservoir elevations. Reservoir operations often expose compact, bare, gravelly soil below the sustained high water line. This area generally supports only a sparse cover of weedy annual plants, and the habitat has little value for wildlife.

While the scientific literature presents numerous approaches to assessing and predicting potential effects on riparian ecosystems resulting from water diversions and other hydrologic manipulations (e.g., Kondolf et al., 1996), many of the suggested methods amount to extensive interdisciplinary research projects.[3] The implementation of such studies is beyond the typical scope of an impact analysis under CEQA. Therefore, the following assessment, based on a review of the scientific literature, is a conservative presumption of effects on the riparian vegetation of the Tuolumne River that might be expected to occur as a result of the WSIP.

Impact Summary

Table 5.3.7-3 presents a summary of the impacts on terrestrial biological resources in the Tuolumne River system and downstream water bodies that could result from implementation of the proposed water supply and system operations.

TABLE 5.3.7-3
SUMMARY OF IMPACTS –
TERRESTRIAL BIOLOGICAL RESOURCES IN THE TUOLUMNE RIVER WATERSHED

Impacts on Terrestrial Biological Resources	Sensitive Habitats	Key Special-Status Species	Other Species of Concern	Common Habitats and Species
Impact 5.3.7-1: Impacts on riparian habitat and related biological resources in Hetch Hetchy Reservoir and along the bedrock channel portions of the Tuolumne River from O'Shaughnessy Dam to Don Pedro Reservoir	LS	LS	LS	LS
Impact 5.3.7-2: Impacts on alluvial features that support meadow and riparian habitat along the Tuolumne River from O'Shaughnessy Dam to Don Pedro Reservoir	PSM	PSM	PSM	PSM
Impact 5.3.7-3: Impacts on biological resources in Lake Eleanor and along Eleanor Creek	LS	LS	LS	LS
Impact 5.3.7-4: Impacts on biological resources in Lake Lloyd and along Cherry Creek	LS	LS	LS	LS
Impact 5.3.7-5: Impacts on biological resources in Don Pedro Reservoir	LS	LS	LS	LS
Impact 5.3.7-6: Impacts on biological resources along the Tuolumne River below La Grange Dam	PSM	PSM	PSM	PSM
Impact 5.3.7-7: Conflicts with the provisions of adopted conservation plans or other approved biological resources plans for the Tuolumne Wild and Scenic River	LS			

LS = Less than Significant impact, no mitigation required
PSM= Potentially Significant impact, can be mitigated to less than significant

[3] For example, in a baseline analysis and long-term monitoring study conducted along Bishop Creek, California, the authors conclude: "Collection of data over the next thirty years will result in an evaluation of the effects of streamflow alteration on the riparian ecosystem on a time scale more suitable for ecological interpretation" (Nachlinger et al., 1989).

Impact Discussion

Impact 5.3.7-1: Impacts on riparian habitat and related biological resources in Hetch Hetchy Reservoir and along the bedrock channel portions of the Tuolumne River from O'Shaughnessy Dam to Don Pedro Reservoir.

Sensitive Habitats

The WSIP would not affect the maximum elevation of Hetch Hetchy Reservoir, and little wetland habitat has developed around the periphery of the reservoir because of the granite substrate and existing large annual fluctuations in storage. Although annual fluctuations in reservoir storage would be greater under the WSIP, the impact on riparian and wetland habitats around and above Hetch Hetchy Reservoir would be less than significant.

Under the WSIP, the delay in snowmelt releases to the Tuolumne River below O'Shaughnessy Dam could incrementally reduce the extent and frequency of germination events, seedling survivorship, plant growth rates, and species diversity in riparian habitats. In the bedrock channel portions of the river, encroachment of riparian vegetation into the channel would be minimal. Riparian tree structure is already limited, and channel incision in the bedrock channel would be insignificant.

Studies supported by the SFPUC are currently underway to assess the physical and ecological conditions in the upper river. Given the dynamic hydrology, steep banks, and rocky substrate, there are few sensitive receptors for impact, since tree structure and channel incision are resistant to change. The effects of the WSIP in the confined bedrock channel portions of the upper river area would be relatively small and therefore difficult to quantify. As a result, this impact would be less than significant for the bedrock channel portions of the Tuolumne River and Hetch Hetchy Reservoir.

Thus, the effects of the WSIP on sensitive habitats would be *less than significant*, and no mitigation measures would be required.

Key Special-Status Species

No key special-status species are reported to occur at Hetch Hetchy Reservoir. The Tuolumne River between O'Shaughnessy Dam and Don Pedro Reservoir supports or has historically supported foothill yellow-legged frog and may support California red-legged frog. It contains only marginal habitat for willow flycatcher (see also Impact 5.3.7-2). Since changes in the structure and diversity of the riparian habitat at the reservoir and in the bedrock channel portion of the river would be less than significant, this impact would also be *less than significant*. No mitigation measures would be required.

Other Species of Concern

Species of concern potentially using Hetch Hetchy Reservoir and the bedrock channel reaches of this section of the Tuolumne River include Cooper's hawk, sharp-shinned hawk, California spotted owl, great gray owl, Vaux's swift, black swift, purple martin, yellow warbler, and several bat species, including spotted bat and mastiff bat. Since the changes in the structure and diversity of the riparian habitat at the reservoir and in the bedrock channel portion of the river are expected to be less than significant, this impact would also be *less than significant*. No mitigation measures would be required.

Common Habitats and Species

Impacts of the WSIP on common habitats and species around Hetch Hetchy Reservoir and in the bedrock channel portion of the Tuolumne River below O'Shaughnessy Dam would be minimal and *less than significant;* no mitigation measures would be required.

Impact Conclusions

Overall, implementation of the proposed WSIP water supply and system operations would result in *less than significant* impacts on terrestrial biological resources in this portion of the WSIP program area. No mitigation measures would be required.

Impact 5.3.7-2: Impacts on alluvial features that support meadow and riparian habitat along the Tuolumne River from O'Shaughnessy Dam to Don Pedro Reservoir.

Sensitive Habitats

The alluvial area supporting the largest wetland complex in this section of the Tuolumne River is the Poopenaut Valley, although smaller alluvial areas downstream, where larger tributaries empty into the Tuolumne River, also support riparian and/or wetland habitats. A delay in snowmelt releases, reduction in flows, and the resulting reduction in meadow groundwater recharge under the WSIP could contribute to a reduction in wetland habitats and encroachment of upland vegetation. All habitats could experience a reduction in their extent as well as in germination events and stand diversity. All wetland and riparian habitats in the Poopenaut Valley are considered sensitive, including seasonal wetlands, wet meadows, hanging ponds, tule bulrush stands, dry meadows, and willow communities. Similarly, the extent and diversity of sensitive wetland and riparian areas on alluvial features farther downstream along the Tuolumne River would be affected by a reduction in the quantity and timing of releases from O'Shaughnessy Dam. This impact would be *potentially significant*.

Key Special-Status Species

Key special-status species potentially using meadows and riparian habitats on alluvial deposits in this portion of the Tuolumne River include foothill yellow-legged frog and potentially California red-legged frog in the lower section of this portion of the Tuolumne River. Potential habitat may be present for willow flycatcher in dense riparian scrub. A reduction in wetland and riparian habitat would reduce suitable breeding habitat for these species, populations of which are already critically reduced in the Sierra Nevada (Jennings and Hayes, 1994). This impact would be *potentially significant*.

Other Species of Concern

Pansy monkeyflower is present at the edges of wet meadows in the Poopenaut Valley. A reduction in wet meadow habitat and upland species encroachment could reduce suitable habitat for this species. Several other plant species of concern could occur in wetlands and riparian edges in this portion of the Tuolumne River (see Table 5.3.7-2). A reduction in the extent and diversity of wetland and riparian habitats could reduce suitable habitat for these plants. A number of animal species of concern depend on meadows and diverse riparian habitats. Mountain yellow-legged frog has not been documented in the Poopenaut Valley, but may have occurred there historically, and suitable habitat may still be present. Western pond turtle, Vaux's swift, black swift, spotted bat, and mastiff bat are known to occur in this reach of the Tuolumne River. Other species likely to be present are Cooper's hawk, sharp-shinned hawk, northern goshawk, northern harrier, California spotted owl, great gray owl, purple martin, willow flycatcher, Pacific fisher, and several bat species. Because of the potential for a reduction in habitat quality and extent, the impact on species of concern would be *potentially significant*.

Common Habitats and Species

The habitats that could be affected by the WSIP are all considered sensitive; no impacts on common habitats would occur. However, a large number of common animal species depend on meadows and larger riparian areas in the mid-elevation Sierra Nevada for food and cover. From a regional perspective, incremental impacts on meadow habitats could have a *potentially significant* impact on common wildlife species.

Impact Conclusions

Overall, implementation of the proposed WSIP water supply and system operations could result in potentially significant impacts on terrestrial biological resources due to potential effects on riparian habitat and species of concern. Implementation of Measure 5.3.7-2, Controlled Releases to Recharge Groundwater in Streamside Meadows and Other Alluvial Deposits, would manage releases from Hetch Hetchy reservoir to recharge riverside meadows, including the Poopenaut Valley. In combination with the groundwater and plant population monitoring being carried out in accordance with Provision 6 of the amended permit for the Canyon Power Project (March 1987) and further adjustment of controlled releases, timing, and magnitude in collaboration with the USFWS, it is expected that meadow conditions in the Poopenaut Valley will be maintained in the current state or improved. Therefore, controlled releases under Measure 5.3.7-2, if timed properly and of adequate volume, would be sufficient to fully mitigate these impacts to less-than-significant.

[Additional discussion on Mitigation Measure 5.3.7-2 was prepared in response to comments on the Draft PEIR. Please refer to Section 14.6, Master Response on Upper Tuolumne River Issues (Vol. 7, Chapter 14).]

Impact 5.3.7-3: Impacts on biological resources in Lake Eleanor and along Eleanor Creek.

Sensitive Habitats

Lake Eleanor supports limited wetland habitats. The WSIP would not change the level and pattern of reservoir storage in Lake Eleanor, except that increased transfers to Lake Lloyd could occur during extended droughts. This change under the WSIP could slightly reduce the extent and quality of potential suitable habitat for wetland species. Riparian habitats along Eleanor Creek would be unaffected because the quantity and timing of releases would be essentially the same as under existing conditions. Overall, impacts on sensitive riparian and wetland habitats due to the WSIP would be *less than significant*, and no mitigation measures would be required.

Key Special-Status Species

There are no records indicating the presence of key special-status species in Lake Eleanor and Eleanor Creek. However, habitat in Eleanor Creek appears to be suitable for foothill yellow-legged frog. Since habitat changes are predicted to be small, any potential effects on this species and its habitat would be *less than significant*, and no mitigation measures would be required.

Other Species of Concern

Species of concern potentially using the riparian habitats associated with Lake Eleanor and Eleanor Creek are similar to those for the Tuolumne River below O'Shaughnessy Dam. They include western pond turtle, mountain yellow-legged frog, Cooper's hawk, sharp-shinned hawk, California spotted owl, great gray owl, Vaux's swift, black swift, purple martin, willow flycatcher, and several bat species. Since WSIP-induced impacts on habitat are predicted to be very small, the impact on species of concern would also be *less than significant*, and no mitigation measures would be required.

Common Habitats and Species

Potential impacts of the WSIP on common habitats and species are expected to be *less than significant*, and no mitigation measures would be required.

Impact Conclusions

Overall, the impacts on terrestrial biological resources due to implementation of the proposed WSIP water supply and system operations would be *less than significant*, and no mitigation measures would be required.

Impact 5.3.7-4: Impacts on biological resources in Lake Lloyd and along Cherry Creek.

Sensitive Habitats

Lake Lloyd would experience a small decrease in average reservoir water levels under the WSIP, but this lake contains little wetland habitat. The WSIP would increase releases somewhat during dry years, which could benefit riparian habitats along Cherry Creek. Overall, impacts on sensitive riparian and wetland habitats would be *less than significant*, and no mitigation measures would be required.

Key Special-Status Species

There are no records indicating the presence of key special-status species in Lake Lloyd or Cherry Creek. However, habitat in Cherry Creek appears to be suitable for foothill yellow-legged frog. Since habitat changes are predicted to be small, any potential effects on this species and its habitat would be *less than significant*, and no mitigation measures would be required.

Other Species of Concern

Species of concern potentially using the riparian habitats associated with Lake Lloyd and Cherry Creek are similar to those for the Tuolumne River below O'Shaughnessy Dam. They include western pond turtle, mountain yellow-legged frog, Cooper's hawk, sharp-shinned hawk, western spotted owl, great gray owl, Vaux's swift, black swift, purple martin, willow flycatcher, and several bat species. Since WSIP-induced impacts on habitat are predicted to be very small, the impact on species of concern would also be *less than significant,* and no mitigation measures would be required.

Common Habitats and Species

Potential impacts of the WSIP on common habitats and species are expected to be *less than significant*, and no mitigation measures would be required.

Impact Conclusions

Overall, impacts on terrestrial biological resources due to implementation of the proposed WSIP water supply and system operations would be *less than significant*, and no mitigation measures would be required.

Impact 5.3.7-5: Impacts on biological resources in Don Pedro Reservoir.

Sensitive Habitats

Because riparian and wetland habitat at Don Pedro Reservoir is limited, the impact on sensitive habitats due to the increased drawdown under the WSIP would be *less than significant*, and no mitigation measures would be required.

Key Special-Status Species

Very limited potential habitat for California red-legged frog is present at Don Pedro Reservoir, and no other key special-status species are known to occur there. As a result, the impact on key special-status species at Don Pedro Reservoir would be *less than significant*, and no mitigation measures would be required.

Other Species of Concern

Western pond turtle could be affected by an incremental reduction in the quality and extent of habitat due to increased drawdown. An incremental but small reduction in habitat could occur for several bat species, bird species such as osprey, and bald eagle. Because of the very limited reduction in potentially suitable habitat for species of concern, this incremental impact would be *less than significant*, and no mitigation measures would be required.

Common Habitats and Species

The increased reservoir drawdown under the WSIP would not reduce any common habitats; therefore, the impact on common species would be *less than significant*, and no mitigation measures would be required.

Impact Conclusions

Overall, impacts on terrestrial biological resources at Don Pedro Reservoir due to implementation of the proposed WSIP water supply and system operations would be *less than significant*, and no mitigation measures would be required.

Impact 5.3.7-6: Impacts on biological resources along the Tuolumne River below La Grange Dam.

Sensitive Habitats

Slightly delayed spring releases as well as reductions in average peak flows and total flow in the Lower Tuolumne River (especially during and following an extended drought) would incrementally affect riparian communities through upland encroachment into the riparian habitat and riparian encroachment into the channel. Existing conditions have already eliminated conditions for Fremont cottonwood regeneration and reduced the species diversity and variety of riparian vegetation stand structure. The proposed flows under the WSIP could further reduce stand diversity and variation in structure and further reduce or eliminate suitable conditions for recruitment of some riparian species. The degree of potential impact on riparian habitat due to the WSIP is difficult to quantify. However, because it would result in an incremental adverse change in a severely stressed system, the impact of the WSIP is considered *potentially significant*.

Key Special-Status Species

The WSIP would incrementally reduce habitat for some species that depend on the riparian habitats in the lower Tuolumne River, such as California tiger salamander, Valley elderberry longhorn beetle, and Swainson’s hawk. Because of the known presence of key special-status species and the very limited amount of remaining suitable habitat along the Tuolumne River, this incremental impact would be *potentially significant.*

Other Species of Concern

Several species of concern could be affected by the incremental reduction in riparian habitat quality and extent under the WSIP. These species include western pond turtle, several bat species, and a wide variety of riparian- and marsh-associated bird species. Because of the known presence of species of concern and the very limited amount of remaining suitable habitat along the Tuolumne River, this incremental impact would be *potentially significant.*

Common Habitats and Species

Potential impacts of the WSIP on common habitats are expected to be less than significant. However, many common species depend on riparian habitats, and their populations would be incrementally affected by the alteration of habitat. As a result, this impact would be *potentially significant*.

Impact Conclusions

Overall, implementation of the proposed WSIP water supply and system operations would result in *potentially significant* impacts on terrestrial biological resources due to potential effects on riparian habitat, other species of concern, and common habitats and species. If feasible, implementation of Measure 5.3.6-4a, Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water, would result in reduced demand on Don Pedro Reservoir water. The result would offset the reduction in inflow to Don Pedro Reservoir attributable to the WSIP and the release pattern from La Grange Dam would be the same or similar to the existing condition. If fully implemented, this measure would reduce the potential impact of the WSIP on riparian resources to less than significant and no further mitigation would be required.

Due to some uncertainty regarding negotiations with MID/TID that would be necessary to implement Measure 5.3.6-4a, Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water, this measure may not be feasible. In the event that Measure 5.3.6-4a is deemed infeasible, implementation of Measure 5.3.7-6, Lower Tuolumne River Riparian Habitat Enhancement, which would require SFPUC to implement riparian habitat enhancement actions on the lower Tuolumne River, would reduce the impact of WSIP operations on riparian resources on the lower Tuolumne River to a less-than-significant level.

Impact 5.3.7-7: Conflicts with the provisions of adopted conservation plans or other approved biological resources plans for the Tuolumne Wild and Scenic River.

The U.S. Forest Service identified the Tuolumne River as a Wild and Scenic River and has developed a management plan for the 29 miles of the Tuolumne River downstream of the Yosemite National Park boundary to Don Pedro Reservoir (shown in Figure 5.2-1). The *Tuolumne Wild and Scenic River Management Plan* (Wild and Scenic Plan), approved in 1986 and administered by the U.S. Forest Service, calls for providing cover and forage habitat for fish and riparian-associated wildlife species by maintaining medium to high habitat quality according to the certain habitat quality criteria. Specific guidelines include maintaining and enhancing habitat for threatened, endangered, and sensitive indicator species, including peregrine falcon, bald eagle, mule deer, western gray squirrel, yellow warbler, and Sierra Nevada red fox and protecting streamside vegetation (USFS, 1986).

The Wild and Scenic Plan does not apply to the exercise of the CCSF’s water rights under the existing Raker Act grant, as stated in the Wild and Scenic Rivers Act (Section 3 [a] [53] Tuolumne, California) as follows: “Nothing in this section is intended or shall be construed to affect any rights, obligations, privileges, or benefits granted under any prior authority of law including chapter 4 of the Act of December 13, 1913, commonly referred to as the Raker Act (38 Stat. 242) and including any agreement or administrative ruling entered into or made effective before the enactment of this paragraph [September 28, 1984].” However, although SFPUC’s operations are exempt from the provisions of the Wild and Scenic Plan, WSIP impacts on biological resources, including those specifically addressed in the Wild and Scenic Plan, are evaluated in this PEIR under CEQA.

Potential WSIP impacts on sensitive habitats and associated species of concern along the reach of the Tuolumne River covered by the Wild and Scenic Plan are included in the analyses presented in Impacts 5.3.7-1 and 5.3.7-2. As noted under Impact 5.3.7-1, impacts on riparian habitat and related biological resources along the bedrock channel portions of this reach of the Tuolumne River would be less than significant. As described in Impact 5.3.7-2, the changes in streamflow associated with implementation of the WSIP could affect streamside vegetation on alluvial features that support meadow and riparian habitats along this reach of the river; however, for the reach of the Tuolumne River downstream of the Yosemite National Park boundary to Don Pedro Reservoir, there are no notable alluvial features that support meadow and riparian habitats. Furthermore, this reach of the river receives inflow from numerous side tributaries, including Cherry Creek, which would mask any WSIP-related changes in streamflow, and no noticeable changes on sensitive habitats and associated species of concern along the reach of the Tuolumne River covered by the Wild and Scenic Plan would be expected. Therefore, impacts related to the potential conflicts related to the provisions of the adopted Wild and Scenic Plan are considered *less than significant*.

The National Park Service (NPS) has identified the Tuolumne River, and specifically the Poopenaut Valley, as an outstandingly remarkable value of the Tuolumne Wild and Scenic River corridor in Yosemite National Park (NPS, 2006). The *Tuolumne Wild and Scenic River Draft Report, Outstandingly Remarkable Values* (NPS, 2006) calls for maintaining and enhancing riparian and meadow habitats within the Tuolumne River corridor. This report is part of the NPS’s ongoing development of the management plan for the designated wild and scenic reaches of the Tuolumne River within Yosemite Park, including the Poopenaut Valley. Since this plan is still under development and not yet adopted, no impact determination is made regarding conflicts with any of its provisions.

Impacts related to the potential conflicts related to the provisions of adopted conservation plans are therefore considered *less than significant*.

5.3.8 Recreational and Visual Resources

The following setting section describes recreational and visual resources in the Tuolumne River watershed that could be affected by the WSIP. The impact section (Section 5.3.8.2) provides a description of the changes in recreational opportunities and visual quality that would result from WSIP-induced changes in stream flow and reservoir water levels.

5.3.8.1 Setting

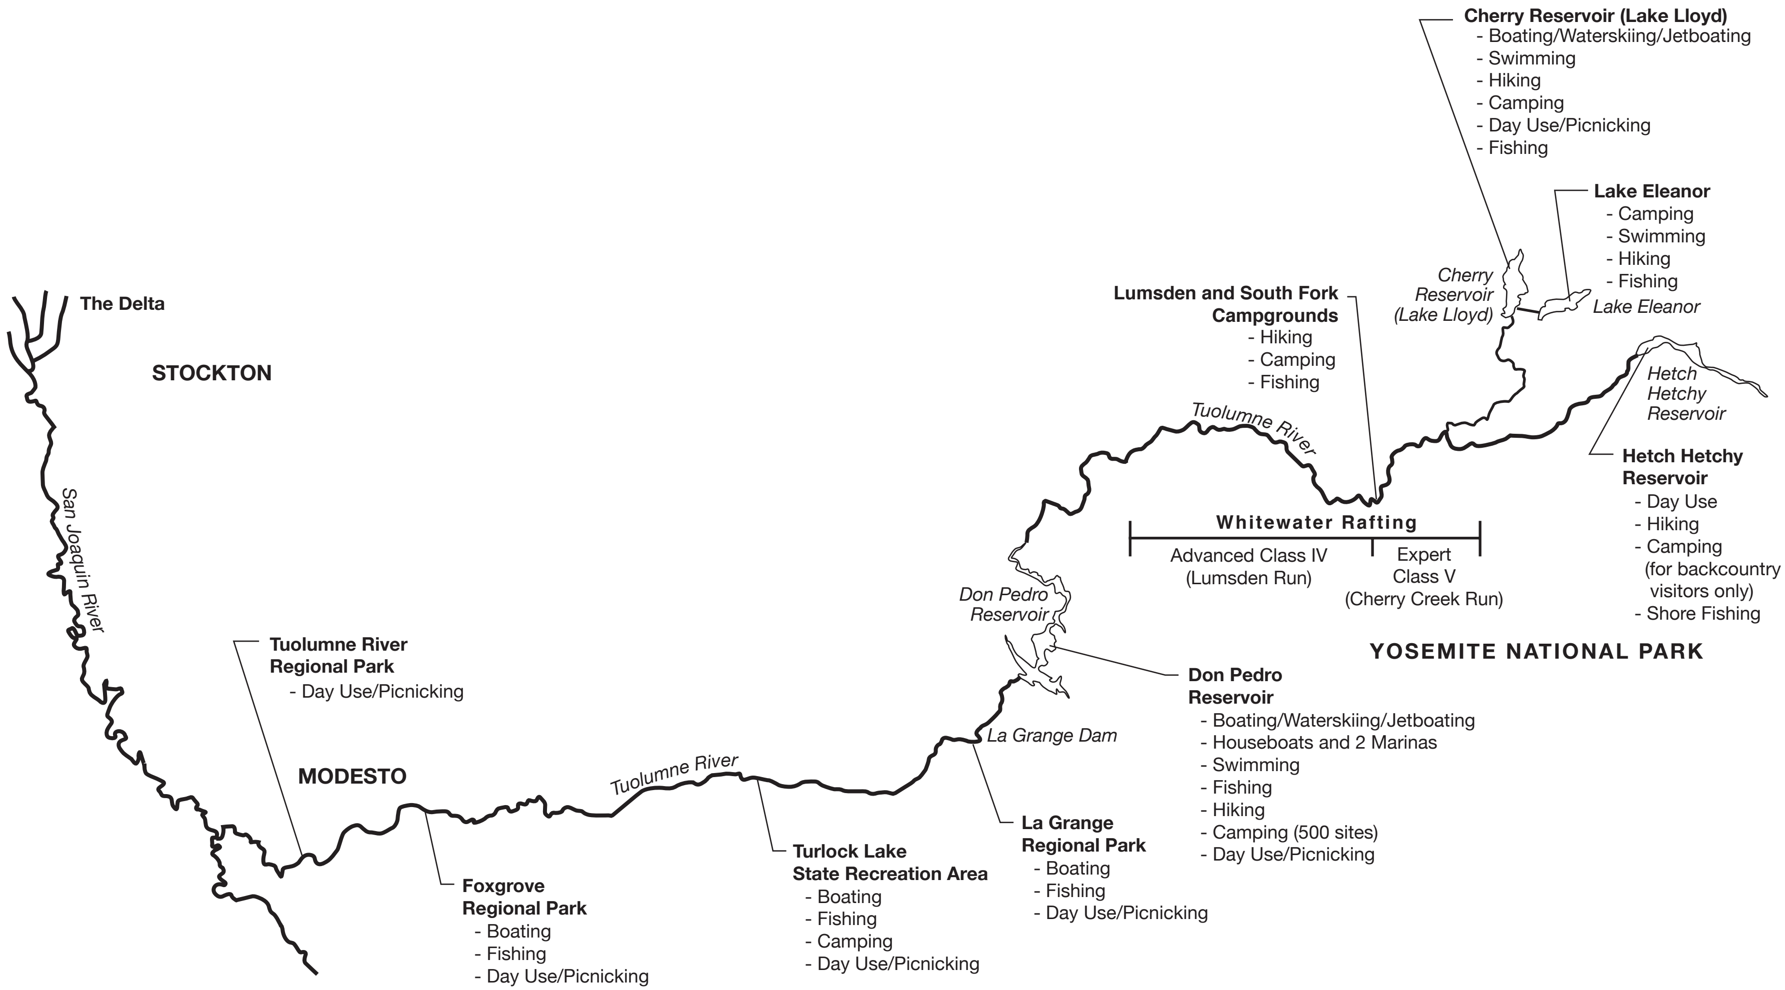
Recreational activities and facilities are dispersed throughout the Tuolumne River system (except for whitewater boating, which is limited to the upper reaches of the river above Don Pedro Reservoir). Water recreational activities in the Tuolumne River, other than whitewater rafting, include boating (often consisting of “flatwater” river kayaking or rafting), fishing, and swimming. Boating recreation is generally limited to sections of the river with suitable river access (e.g., boat ramps for hard-bottomed boats). Both fishing and swimming within the Tuolumne River is regulated. Swimming is generally discouraged due to the often hazardous currents.

Off-water river-related recreation consists of hiking, picnicking, and camping. Hiking occurs throughout the Tuolumne River system in several forms, including both vigorous trail walking and more casual sightseeing or nature viewing. Picnicking is a common activity at nearly all of the region’s recreation sites, but overnight camping along the river is mainly limited to developed campsites. Recreational resources are identified by location in order to delineate the specific impacts of the WSIP within the Tuolumne River system (see **Figure 5.3.8-1**).

Yosemite National Park and the Hetch Hetchy Watershed

Hetch Hetchy Reservoir

Hetch Hetchy Reservoir and the associated watershed lands lie mainly in Yosemite National Park. The park encompasses approximately 1,170 square miles, and about half of this area lies within Tuolumne County (the remainder is in Mariposa and Merced Counties). Yosemite receives about 4 million visitors a year and offers a wide variety of recreational activities, including camping, hiking, mountain climbing, fishing, and river rafting. The headwaters of the Tuolumne River lie within the park. The Hetch Hetchy Reservoir watershed encompasses the 459 square miles that make up the Tuolumne River watershed. There are numerous recreational facilities and activities in the watershed above Hetch Hetchy Reservoir at Tuolumne Meadows and the Glen Aulin High Sierra Camp. Tuolumne Meadows attracts by far the greatest amount of recreational use in the watershed at its large developed campground, visitor center, trailheads, and Tuolumne Meadows Lodge. Glen Aulin High Sierra Camp also generates substantial recreational use. There is also considerable backcountry visitation within the Hetch Hetchy watershed above the reservoir. Between 1990 and 2005, annual overnight use was approximately 40,000 user nights in the backcountry wilderness of the Hetch Hetchy watershed (NPS, 2006c). However, since no program-related changes would occur upstream of the reservoir, wilderness users who only visit the Hetch Hetchy watershed backcountry (i.e., do not hike along the reservoir or downstream along the Tuolumne River) would not be affected by the WSIP.



SOURCE: ESA + Orion

SFPUC Water System Improvement Program . 203287

Figure 5.3.8-1
Principal Recreational Resources
Tuolumne River System

Hetch Hetchy Reservoir sits in a dramatic valley of steep, glacier-eroded mountains. Dispersed and scrubby vegetation is predominantly clustered around the flatter portions and fissures of the surrounding mountainsides. Due to the steep slopes, most of the surrounding rock faces are bare granite rock. Around the lakeside, scoured whiter rings (referred to as the “bathtub ring”) are periodically visible when the water level falls. While no recreational activities are permitted on the Hetch Hetchy Reservoir due to water quality restrictions, hiking is permitted within the watershed area, overnight backpacking is allowed with a wilderness permit, and visitors with a valid California fishing license, who comply with the rainbow trout catch-and-release policy, are allowed to fish from the reservoir shoreline. Considerable day use of the reservoir occurs from early May to early October, except during the hottest periods of late July and August when visitation typically decreases. A walk-in campsite operates at Hetch Hetchy for backpackers hiking in and out of the backcounty. Swimming in the off-reservoir streams is currently permitted, but the National Park Service is in the process of promulgating a regulation that would prohibit body contact in the tributaries within one mile of the reservoir in accordance with the sanitary provisions of the Raker Act. The road to Hetch Hetchy is generally open year-round during daylight hours, except on occasion during the winter and spring when it is closed due to extreme weather conditions (NPS, 2007).[1]

Only limited and partial past visitation data for the Hetch Hetchy entrance gate and backcounty use are available. Annual visitation frequently fluctuates considerably between years, often due to weather conditions. Over the last five years, visitation has generally averaged approximately 14,300 vehicles annually; in 2005, the number of vehicles using the entrance increased to nearly 22,000, likely due to the increased media attention on the reservoir. Based on an assumption of 2.5 visitors per vehicle, average visitation through the Hetch Hetchy entrance was approximately 35,750 visitors annually between 2000 and 2005. In comparison, visitation between 1990 and 1995 was approximately 50 percent higher, averaging 21,056 vehicles per year between April and early November. According to National Park Service staff, the majority of day-use visitors to Hetch Hetchy Reservoir and Tuolumne River trails use this entrance.

Statistics on wilderness permits for backcounty use fluctuate greatly and are considered less reliable measurements of visitor use, since not all visitors using the backcountry obtain permits. Nonetheless, based on the available wilderness permit data for 2003 to 2005, approximately 2,345 backcountry visitor permits were issued from the Hetch Hetchy location. It is estimated that these backcountry visitors stayed an average of 2.3 nights in the area (NPS, 2006a), accounting for about 5,400 user nights. Since these permits were obtained from the Hetch Hetchy location, it is presumed that the majority of these permits were likely used to hike and camp in the Hetch Hetchy area.

While a small number of other backcountry users may have obtained their permits from other park wilderness offices or from U.S. Forest Service (USFS) locations, this number, according to park staff, would represent a very small proportion of backcountry users along the Tuolumne River below Hetch Hetchy Reservoir or around the reservoir itself.

1 Due to safety concerns, access to the O’Shaughnessy Dam parking lot is limited to 8:00 a.m. to sunset, and no overnight parking is permitted.

Lake Eleanor

Lake Eleanor, another SFPUC system reservoir, also lies within Yosemite National Park. Lake Eleanor has a 79-square-mile watershed along Eleanor Creek. The lake measures three miles long and one mile wide and is situated at an elevation of 4,660 feet. Activities at and around the lake include camping, fishing, swimming, nonmotorized boating, and hiking. Trailheads connect this area to the Emigrant Wilderness, Hetch Hetchy Reservoir, and the rest of Yosemite National Park. No visitor counts are available specifically for Lake Eleanor; however, due to its lack of direct road access, Lake Eleanor is a far less popular recreational destination than Hetch Hetchy Reservoir, which better accommodates day use (NPS, 2006b).

The visual setting for Lake Eleanor is characterized by open vistas of mixed conifer forest covering most of the gradually sloped surrounding mountains. These hills and low mountains are less dramatic than those around Hetch Hetchy Reservoir, but are generally more forested.

Poopenaut Valley

All of the Tuolumne River within the Poopenaut Valley downstream to the western park boundary is classified as Wild, apart for the first mile below the O'Shaughnessy Dam (which is classified as Scenic). While there is limited hiking and other recreational access to the Wild section of the river, the *Tuolumne Wild and Scenic River Study Final EIS and Study Report* (U.S. DOI and USDA, 1979) found this segment of the river to have numerous "outstandingly remarkable values," including Scenic, Recreation, Geological, Wildlife, Historic, and Scientific values. The Tuolumne River's outstanding scenic values in this segment are based on the stunning views of verdant meadows, a glacially carved bedrock valley, large river pools, dramatic canyon walls, and a constricted slot canyon below the Poopenaut Valley (NPS, 2006d). The river's outstanding recreational values are based its opportunities for recreation in a largely undisturbed, low-elevation riparian environment dominated by natural scenery and soundscapes. In addition, the recreational opportunities are considered unique for the Sierra Nevada as a result of the rarity of such low-elevation designated wilderness.

Stanislaus National Forest

The Stanislaus National Forest, which is managed by the USFS, encompasses almost 900,000 acres to the west of Yosemite National Park. It stretches through Tuolumne, Calaveras, and Alpine Counties in a wide band from the Mokelumne River on the north to the Merced River on the south. Recreational opportunities in the Stanislaus National Forest include river rafting, hiking, and fishing. A 29-mile stretch of the Tuolumne Wild and Scenic River (described below) lies within the Stanislaus National Forest (USFS, 2007a).

Lake Lloyd, another part of the SFPUC water system, is the largest lake in the Stanislaus National Forest. It has a 114-square-mile watershed along Cherry Creek, mainly in the Emigrant Wilderness, and numerous recreational activities are permitted (SFPUC, 2007). The lake is 3.8 miles long and one mile wide and lies at an elevation of 4,702 feet. The lake is impounded by an earthen dam that was constructed in 1954 (SFPUC, 2007). Fishing and boating are common activities, as are camping, hiking, swimming, waterskiing, and jet-boating. There are

46 campsites in the Cherry Valley Campground, and shoreline boat-in camping is popular. Fish species targeted by anglers include several species of trout (rainbow trout, eastern brook trout, and German brown trout) as well as some sockeye (kokanee) salmon (Fish Sniffer, 2006).

The visual setting for Lake Lloyd is similar to that of the neighboring Lake Eleanor, generally consisting of mixed conifer forest on the surrounding High Sierra mountains. The lake is open year-round; however, the access road to Lake Lloyd can experience closures in the winter (USFS, 2007b).

Upper Tuolumne River Corridor

In 1984, Congress designated the Tuolumne River as one of the nation's Wild and Scenic Rivers. The river provides an abundance of recreational opportunities, including fishing, hiking, and whitewater rafting. In total, 83 miles of the Tuolumne River have been classified as Wild (47 miles), Scenic (23 miles), or Recreation (13 miles) (NPS, 2006c), as shown in Figure 5.2-1. Most of the river corridor within the 29 miles of the Tuolumne Wild and Scenic River located outside of Yosemite National Park is classified as Wild. The one-mile stretch of river between Early Intake and Cherry Creek is classified as Recreational because a road parallels it, and the four miles of river starting about a mile above the Lumsden Bridge is recognized as Scenic.

Whitewater rafting is the primary water recreation activity in the Tuolumne River corridor above Don Pedro Reservoir and is discussed in the section below. Other water and off-water recreational resources are discussed separately following the whitewater recreation discussion.

Whitewater Recreational Resources

There are two whitewater boating runs in the Tuolumne River watershed. The Cherry Creek Run extends from just above the Cherry Creek/Tuolumne River confluence to Lumsden Campground, and the Lumsden Run extends from Lumsden Campground to the Wards Ferry Bridge, just upstream of Don Pedro Reservoir. Both runs are located within the jurisdiction of the Groveland Ranger District of the Stanislaus National Forest and managed under the 1986 USFS *Tuolumne Wild and Scenic River Management Plan*.

Cherry Creek Run

This nine-mile run begins at Holm Powerhouse on Cherry Creek and ends at Lumsden Campground on the Tuolumne River. The Cherry Creek Run is one of the most difficult whitewater boating runs on the West Coast, and is probably the most challenging run in the country that has regularly scheduled commercial boating trips. The Cherry Creek Run is suitable solely for expert boaters and can only be run during low summer flows. The run's excellent scenery, outstanding rapids, and relative proximity to the Bay Area and Sacramento make it California's most popular Class V (expert) run (Cassady, 1995). It is commonly considered to be the initiation run for boaters ready to transition from Class IV to Class V (Holbeck, 1998).

The run's gradient generally falls 110 feet per mile, although one section consists of a 200-foot descent over the course of one river mile. However, the rapids are generally formed from large, round granite boulders that are relatively forgiving for boaters and less likely to result in entrapment hazards than other comparable runs. The typical whitewater boating condition thresholds for the Cherry Creek Run are shown in **Table 5.3.8-1** and **Figure 5.3.8-2**.

TABLE 5.3.8-1
WHITEWATER RAFTING CONDITION THRESHOLDS FOR THE CHERRY CREEK RUN

River Flows	Rating	User Type
600–1,500 cfs	Class V	Expert
1,500–2,000 cfs	Class V+	Expert +
> 2,000 cfs	Unrunnable	NA

SFPUC Water System Improvement Program ▪ 203287

Figure 5.3.8-2
Whitewater Rafting Condition Thresholds for the Cherry Creek Run

The Cherry Creek Run is predominantly used by private kayakers in the mid- and late summer, when it is one of the few remaining suitable expert runs in the country. Earlier in the year, flows are generally above 2,000 cfs and the run is unsafe.

Lumsden Run

The lower 18-mile run on the main fork of the Tuolumne River extends from Lumsden Campground to Ward's Ferry Bridge. This stretch of the river is generally known as the Lumsden Run (Rosekrans et al., 2004). The Lumsden Run is a premier California whitewater boating run that is famous within the rafting and kayaking community. It is typically rated as a Class IV+ run and provides a high-quality experience for boaters. The Lumsden Run offers the opportunity for an overnight trip, which is rare in the central Sierra region. The run's beautiful scenery, wilderness solitude, and challenging rapids within easy driving distances from Sacramento and the Bay Area make it a popular whitewater boating location for both private and commercial boaters.

The run's gradient generally falls 40 feet per mile through difficult boulder slalom rapids. The typical whitewater boating conditions for the Lumsden Run are shown in **Table 5.3.8-2** and **Figure 5.3.8-3**.

TABLE 5.3.8-2
WHITEWATER RAFTING CONDITION THRESHOLDS FOR THE LUMSDEN RUN

River Flows	Rating	User Type
600–1,500 cfs	Class IV-	Advanced
1,500–4,000 cfs	Class IV	Advanced
4,000–8,000 cfs	Class IV+	Advanced
> 8,000 cfs	Class V	Expert

Current Operating Conditions

The 1995 FERC Settlement Agreement (see Chapter 2 for a description of the agreement) requires the SFPUC to consult, cooperate, and communicate with whitewater recreational interests regarding releases from the Hetch Hetchy system, but does not require the SFPUC to schedule releases for the purpose of maintaining or enhancing whitewater recreation. However, subject to the availability of water and hydropower needs, the SFPUC attempts to accommodate whitewater recreation in the Tuolumne River below its reservoirs by "shaping" releases from Holm Powerhouse on Cherry Creek, upstream of its confluence with the Tuolumne River. These "pulse" releases enable whitewater rafting during the summer season when flows are otherwise insufficient (see **Figure 5.3.8-4**).

The SFPUC meets annually with whitewater recreation representatives to develop, to the degree practicable, a schedule of releases for whitewater recreation. The schedule of these releases is developed in accordance with the duration of expected spills below the Hetch Hetchy systems' Tuolumne River watershed reservoirs and the projected availability of water in Lake Lloyd and

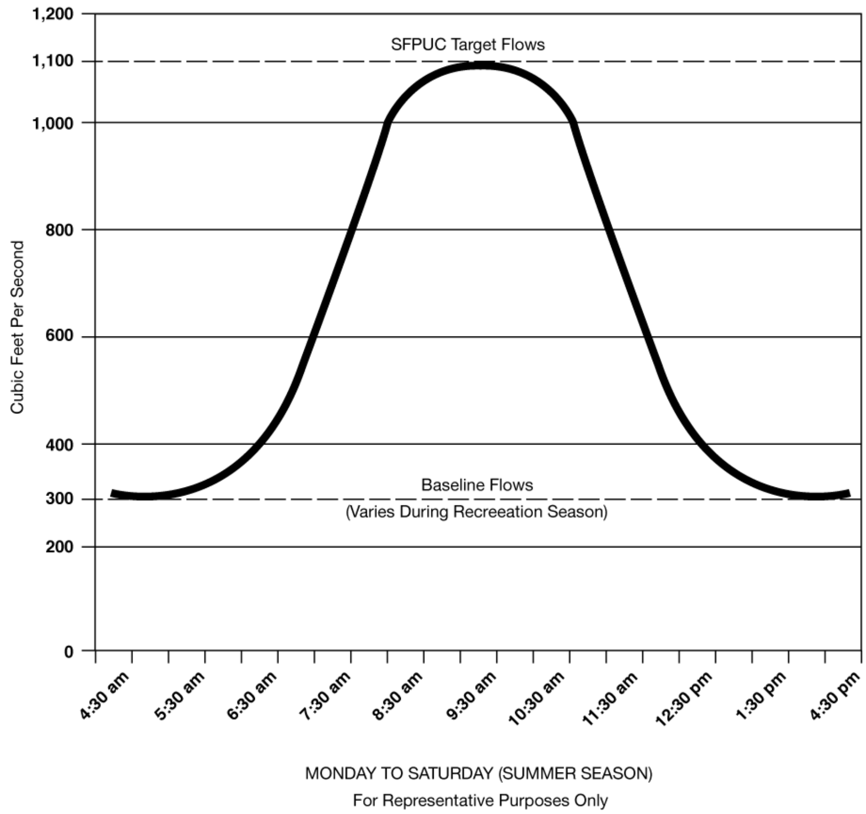
Figure 5.3.8-3
Whitewater Rafting Condition Thresholds for the Lumsden Run

Lake Eleanor beyond the amount necessary to maintain the SFPUC's water deliveries from its Tuolumne River reservoirs. The need to divert Cherry Creek water to Early Intake through the Lower Cherry Aqueduct for water supply use in the Bay Area in emergencies and extreme droughts as well as the expected price of energy and maintenance projects are also considered in establishing the schedule of releases for whitewater recreation.

The primary considerations in scheduling releases are the needs to maintain water supply, undertake maintenance, and deliver water in emergencies. The SFPUC maintains high levels of carryover storage in Lake Lloyd and Lake Eleanor because releases from these reservoirs can be used to meet TID's and MID's Raker Act water entitlements in the event that the SFPUC's storage in its water bank in Don Pedro Reservoir is exhausted. This enables continued water deliveries to Bay Area customers from Hetch Hetchy Reservoir. This operational strategy is consistent with the SFPUC's obligation to operate the Hetch Hetchy system for "water first."

The price of energy is also a consideration in establishing the annual schedule of boating releases. Once Hetch Hetchy Reservoir, Lake Lloyd, and Lake Eleanor have finished spilling spring and early summer runoff, which typically occurs by July 1, releases to streams are reduced to the minimum required flow. Flow in the Tuolumne River consists of the minimum releases from the



SFPUC Water System Improvement Program ▪ 203287

Figure 5.3.8-4
Example of a Pulse Release
for Whitewater Recreation

reservoirs, tributary flow, and releases from Holm, Kirkwood, and Moccasin Powerhouses. Hydropower generation at Kirkwood and Mocassin Powerhouses is limited to that which is incidental to water deliveries to the Bay Area. In a typical year, hydropower from the two powerhouses is insufficient to meet the SFPUC's peak municipal and retail power demand for several months beginning at the end of June, and the SFPUC must purchase power. When the SFPUC chooses to generate hydropower at the Holm Powerhouse, it must offer some electrical power to TID and MID at an agreed upon price for their municipal needs and agricultural pumping.

Energy prices are at their seasonal maximum during the summer and fall, because the cheapest source of energy (i.e., hydropower) is no longer plentiful. In addition, the price of energy rises during the day to a peak price around midday, when energy use is the highest. If the SFPUC were to operate solely to meet its own municipal and retail demand for energy or to maximize revenue from hydropower sales, it would generate hydropower during the midday period only. To deliver a pulse flow to Lumsden Campground for boaters by 9:30 a.m., the SFPUC must begin hydropower generation at Holm Powerhouse by 7:00 a.m. Were the SFPUC to operate solely in its own interest, it would not begin generation until late morning. Operating Holm Powerhouse early in the morning to produce boating flows represents both lost revenues as well as exposure to higher energy costs when the SFPUC must purchase energy to meet its needs in the middle of the day.

Scoping comments received in response to the Notice of Preparation for this PEIR (see Appendix A) included expressions of concern that the WSIP could further restrict the quality of whitewater rafting on the Tuolumne River by reducing water release hours or flows, or by shortening the length of the summer rafting season.

Since the 1995 FERC Settlement Agreement, representatives for the commercial boating community have met annually with SFPUC staff to collaborate in determining operating and flow management schedules that can better accommodate whitewater recreation downstream of Hetch Hetchy Reservoir and Lake Lloyd. While commercial users have generally adapted their trips and operations to conform to the flow conditions, reductions in water releases (typically resulting in an earlier ending to the whitewater recreation season) inevitably reduce the commercial operators' earnings. The highest demand for whitewater use of the Tuolumne River is during the Memorial to Labor Day season. In addition, there is also considerable and frequently unmet whitewater recreational demand for the early to mid-September shoulder season. In May and early June, the colder water and weather as well as the often higher river flows are less attractive to many whitewater boaters. Furthermore, later in the summer season many other rivers are no longer runnable. As a result, the late summer whitewater opportunities on the Tuolumne River are generally in greatest demand and offer users particularly high-quality whitewater recreation experiences (Welch, 2006).

A 1,100-cfs flow at Lumsden Campground is the minimum required for whitewater paddle boats and oar boats; a 900-cfs flow is the minimum required for kayaks, and a 1,500- to 2,000-cfs flow is considered optimal. The commercial outfitters prefer an eight-hour release, but a four-hour release allows them to launch one-, two- and three-day trips. One-day trips launch first and ride the pulse down to Wards Ferry; two-day trips launch next and run nine miles down river; and three-day trips launch last and ride five miles down river. Launches of two- and three-day trips from riverside campgrounds are staged to avoid congestion at rapids.

In recent years, the water releases to the river have generally been in a daily three- to four-hour pulse release timed to reach the upper reaches of the rafting runs in the mid-morning. According to representatives of the commercial users, three hours represents a minimum adequate duration for whitewater recreation, as launchings and all associated recreation must occur during the flow of released water down the river (Welch, 2006). If the duration of flow is insufficient, crowding can decrease the quality of the recreational experience for some users. A longer duration water release pulse would provide more opportunities for users to spread out their river use and take greater advantage of the off-river hiking and other recreational opportunities.

Due to the demand for power generated from the Lake Lloyd's water releases, the weekday water releases may be larger than the Saturday releases. Typically, no water releases occur on Sunday, and, as a result, the Tuolumne River is mostly unrunnable on Sunday. Many commercial operators have adapted their weekend trips to include an off-river hiking day on Sunday. However, the absence of a Sunday release has a greater impact on private users, who generally value weekend recreational opportunities for whitewater use of the river.

Whitewater Recreational Use

As shown in **Table 5.3.8-3**, whitewater use of the Tuolumne River varies considerably from year to year. Over the last 10 years, an average of 6,000 people per year boated on the river. In recent years, use has been limited by the water release schedules from Hetch Hetchy Reservoir and Lake Lloyd. In 2005, water releases were halted on August 21 so that maintenance could be performed on upstream dam facilities. According to commercial boaters, many additional river trips would otherwise have occurred on the Lumsden Run. In 2001, during the height of the California energy crisis, water releases were only delivered between July 2 and August 11. The shortened rafting season resulted in many trip cancellations during June and later in August and early September of that year.

[a] Drought conditions prevented whitewater recreation in 1997.

SOURCE: USFS Groveland Ranger District, 2006b.

The majority of Tuolumne River whitewater recreation occurs on the Lumsden Run; only 17 percent of whitewater users boated the Cherry Creek Run. Since many visitors take multiple day trips down the Lumsden Run, this run accounts for an even greater proportion of whitewater recreation user days. The length of stay for both private and commercial users on the Lumsden Run averages 1.8 days. Between 1995 and 2005, the total whitewater user days on the Tuolumne River averaged 9,930 per year, of which the Lumsden Run accounted for 90 percent of the user days.

The majority of whitewater river use on the Tuolumne is by rafters. Only limited statistics on kayak use are available, but the number of annual commercial kayak trips is very small (Welch, 2006). In 2005, total kayak use among private users was approximately 44 percent, which is equivalent to 17 percent of all boaters. Although late summer rafting use was reduced due to the cessation of water releases in late August 2005, this proportion of kayak use is considered generally representative of typical river use.

A USFS analysis of Tuolumne River whitewater recreation between 1980 and 2000 concluded that total boater use on the Lumsden Run appeared to be stable, although use fluctuated considerably from year to year. Private boater use on the Lumsden Run was found to be decreasing. Over the 20-year study period, boating use was found to be relatively evenly split between commercial and private users, although since 1992 commercial use has been consistently higher than private use (this trend continued through 2005) (Norman, 2001). Between 1998 and 2000, the analysis also found commercial use to be about 30 percent higher than private use. This trend has also generally continued in the subsequent years.

While the USFS determined there were no statistically significant trends in total use (as can be seen in Table 5.3.8-3), peak use levels (6,900 users or more) have been attained periodically over the last 20 years (1984–1986, 1992–1993, 1997, and 2000) that are far higher than the average use levels between 2001 and 2005. Over the last five years, total use of the Lumsden Run has averaged 4,180 users. While reductions in river flows and releases have contributed to lower use numbers, a reduction in Groveland ranger staff since 1999 has significantly reduced permit compliance monitoring at Meral's Pool. Therefore, actual private boater levels may be significantly higher than reported. USFS analysis for a comparable management situation in Georgia determined that additional non-permit use was about 25 percent of permit use levels (Norman, 2001).

For the Cherry Creek Run, private use was found to be steadily increasing, while commercial use remains limited and stable.

The USFS statistical analysis found no significant correlation between seasonal flow averages and the private or commercial use levels for either of the two runs. However, this analysis did not examine actual daily flow levels. On high-demand weekend days, flow levels could affect user demand. However, only limited monthly river use data are available from the USFS. **Table 5.3.8-4** shows the reported monthly private boater use on the Lumsden and Cherry Creek Runs.

SOURCE: USFS Groveland Ranger District, 2006b.

The USFS analysis determined that the highest private boater demand for whitewater recreational use of the Lumsden Run occurred in drier years earlier in the season (typically May through July), while in wet years, the highest demand occurred in the summer during the months of July and August. However, rather than reflecting user preferences, this finding may simply represent the availability of adequate water flows for recreational use of the river.

Commercial Rafting. Commercial rafting on the Tuolumne River began in the 1970s under permits issued by the Stanislaus National Forest. Commercial use of both the Cherry Creek and Lumsden Runs is allowed only through special-use permits issued by the USFS. There are seven commercial outfitters permitted to operate commercial rafting trips down the river. Total commercial use by these outfitters is limited to two commercial trips per day. Each of these trips is limited to a maximum of 26 passengers (each trip typically includes six guides, so there are 20 customers per commercial trip). The Groveland Ranger District is responsible for administration and oversight of the commercial operators. Although a few commercial trips are taken down Cherry Creek Run each year, the vast majority of commercial rafting occurs on the Lumsden Run (approximately 95 percent of passengers). Furthermore, since many of the commercial trips are multiday trips, an even greater proportion of the commercial operators' revenues are based on Lumsden rafting trips (USFS, 2007b).

Most of the rafting companies also operate trips on other rivers in California, although a few are small companies that primary rely on Tuolumne River trips for the majority of their business. Several of the Tuolumne operators are large rafting companies that offer river trips throughout the West and even internationally.

Commercial use has declined in recent years, in part due to the reduced water releases and flow conditions. Between 2001 and 2005, commercial use of the Tuolumne River averaged 2,640 boaters and 4,620 user days, which represents a decrease of approximately 15 percent from the 1995 to 2005 average commercial boating levels of 3,111 users (see Table 5.3.8-3).

Private Rafting. Rafters wishing to run the Lumsden and Cherry Creek Runs are required to obtain a private boater permit by telephone or in person from the USFS Groveland Ranger Station. Permits can be booked in advance and are limited to a maximum of 90 people launching per day for the Lumsden Run. There are currently no limits on private use of the Cherry Creek Run.

Private use has declined in recent years, in part due to the reduced water releases and flow conditions. Between 2001 and 2005, private boater use of the Tuolumne River averaged 2,485 passengers and 3,760 user days. During that period, private boater use of the Lumsden Run averaged 1,690 passengers and 2,960 user days. This recent decline in total private boaters is about 13 percent of the 1995 to 2005 average levels.

Other Water and Off-Water Recreational Resources

In addition to whitewater use, recreationists also hike, camp, and fish within the Tuolumne River above Don Pedro Reservoir. While a major proportion of whitewater users participate in these other recreational activities as part of their trip, many park visitors come solely to enjoy the area's non-whitewater resources. Due to its relatively remote location, many visitors camp overnight in the area as part of their trip. The majority of camping along this section of the Tuolumne River occurs at designated sites. There are three developed campgrounds along the National Forest portion of the Wild and Scenic Tuolumne River corridor. Camping is free, but the campgrounds are only open from April to October. Access to the three developed campgrounds is via a five-mile-long steep dirt road that is unsuited to trailers or motor homes. The Lumsden Bridge Campground offers the farthest upstream opportunity for developed camping. There are nine campsites, two vault toilets, grills, and tables for users at the campsite. The South Fork Campground, located near the confluence of the Tuolumne River and its south fork tributary, is approximately two miles below the Lumsden Bridge Campground site. The South Fork Campground has eight campsites, two vault toilets, grills, and tables for users. The Lumsden Campground is located a mile downstream of the South Fork Campground and consists of 11 campsites with grills and tables. There are also four vault toilets at the site.

Over a dozen undeveloped campsites are dispersed along the Tuolumne River below the Meral's Pool launch site. These sites are used by whitewater boaters as well as hikers in the area. However, hiking use along the river within most of the Tuolumne River valley is relatively limited, since there are no improved trails and the hiking conditions are difficult.

Below Hetch Hetchy Reservoir, the principal hiking trails along the Tuolumne River are the Preston Flat and Tuolumne River Canyon Trails. The Preston Flat Trail parallels the north side of the Tuolumne River upstream from the Early Intake. The trail is 4.5 miles long and is of average difficulty, with an elevation gain of 400 feet over its course. The trail generally runs near the riverside and is predominantly used by anglers to access the river. Most trail use occurs at the start of the trout season and during the late spring and early summer, when wildflowers are present and the weather is not too hot. However, even during the most popular periods, trail use is typically only about 30 to 40 visitors per day. While the canyon is generally sparsely forested, sections of the north side are moderately to densely vegetated, especially near the river's edge (USFS, 2006b).

The Tuolumne River Canyon Trail is considerably more strenuous and hiked less frequently. The trail starts a half mile from the Lumsden boat launch and follows the south side of the Tuolumne River down to its confluence with the Clavey Trail. The trail is six miles long and generally runs along the canyon sides several hundred feet above the riverbed. The steep slopes of the canyon are sparsely vegetated, although during the late spring and early summer wildflowers cover much of the hillsides.

The area's visual resources generally consist of a narrow and rocky riparian valley with limited vegetation. Much of the mostly steep-walled, V-shaped canyon is bare of vegetation. Some trees grow within the narrow floodplain on the river's edge. Along much of the river's course, a narrow band of trees stands along the riverside, while larger groupings of trees and other vegetation are occasionally present at the outer bends for river where adequate river sediment has accumulated. When the river contains sufficient flow, it provides an abundant variety of water forms, including rapids, cascades, waterfalls, and pools. When flow is sufficient, these water forms as well as the dramatic geological formations define the visual setting throughout most of the Tuolumne River's course.

Don Pedro Reservoir and Recreation Area

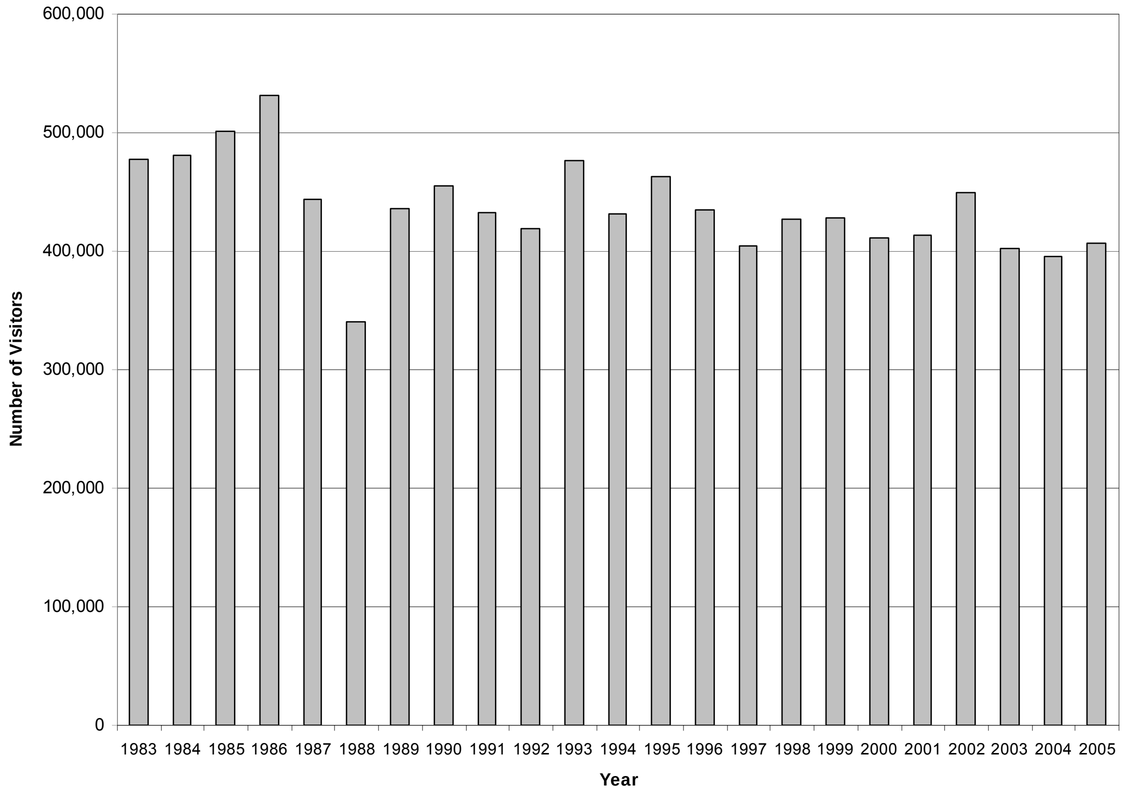
The Don Pedro Reservoir and Recreation Area is located on the Tuolumne River near the western border of Tuolumne County. The reservoir is primarily managed by the Don Pedro Lake Recreation Agency and TID. The Don Pedro Recreation Agency is an independent agency supervised by a board of directors made up of representatives from the TID, MID, and SFPUC. TID provides administrative support and day-to-day supervision. The reservoir provides 160 miles of shoreline and 13,000 surface acres of water at its maximum pool elevation of 830 feet above mean sea level (msl). Don Pedro Reservoir is the fifth largest reservoir in California.

Water recreation at Don Pedro Reservoir includes boating, swimming, waterskiing, jet skiing, windsurfing, sailing, house-boating, fishing, and boat-in camping. Boat launch facilities are located at the Fleming Meadows Recreation Area on the southern shoreline, Blue Oaks Recreation Area on the southwestern shoreline, and Moccasin Point Recreation Area on the northeastern arm of Moccasin Bay. Two full-service marinas (i.e., with docks, boat slips, mooring areas, and provisions) are located at the Flushing Meadows and Moccasin Point Recreation Areas. In addition, there are 257 privately owned houseboats and 20 rental houseboats on Don Pedro Reservoir (USBR, 1999).

Boating and waterskiing take place throughout the reservoir; swimming occurs mainly at the Fleming Meadows swimming lagoon, a two-acre pool separated from the main reservoir. The lagoon has a maximum depth of 6 feet and is surrounded by a sandy beach area. Anglers fish from the shore and boats, mainly for non-native bass, trout, salmon, crappie, bluegill, and catfish. The CDFG plants the lake with species such as brook trout from the San Joaquin River Hatchery, and sub-catchable rainbow and brown trout from the Moccasin Creek Hatchery, which is upstream from Don Pedro Reservoir on Moccasin Creek.

Off-water recreation at Don Pedro Reservoir includes picnicking, camping, and sightseeing. There are a total of 550 campsites at the Fleming Meadows, Blue Oaks, and Moccasin Point Recreation Areas (Don Pedro Recreation Agency, 2007). Don Pedro is by far the largest and most popular recreation destination along the Tuolumne River system. **Figure 5.3.8-5** shows visitation at Don Pedro Reservoir since 1983. Annual visitation at the reservoir is typically more than 400,000 visitors, and even exceeded half a million in 1985 and 1986. Between 1983 and 1999, average reservoir visitation averaged approximately 446,000 per year. However, visitation has declined slightly since that time, averaging approximately 413,800 since 2000. Don Pedro Reservoir attracts considerable visitation from the Bay Area and Sacramento, and many visitors stay for several days or a week at a time (Jackson, 2006).

Beach use at Don Pedro Reservoir generally begins to decline once its elevation falls below 790 feet msl (i.e., 40 feet below its maximum pool elevation of 830 feet msl). Use of the reservoir



SFPUC Water System Improvement Program / 203287 ■

SOURCE: Don Pedro Recreation Agency, 2006.

Figure 5.3.8-5
Don Pedro Reservoir Annual Visitation

declines moderately until the 750-foot level, below which use then begins to decrease more considerably. The Fleming Meadows boat ramp is out of operation when water levels fall below 600 feet msl (minimum pool). Between 710 feet and 600 feet msl, five of the reservoirs boat ramps are lost. The Moccasin Point boat ramp cannot be used below an elevation of 722 feet msl, and the Blue Oaks boat ramp cannot be used below 726 feet msl. The Fleming Meadows and Moccasin Point marina operations are limited when water levels fall below 600 and 630 feet msl, respectively. The swimming lagoon is used at all reservoir water surface elevations because it is separated from the main reservoir, and water is pumped from the reservoir into the lagoon to maintain water levels (USBR, 1997).

Don Pedro Reservoir's visual setting is characterized by its numerous long expanses of flatwater that stretch through a series of narrow valleys and inlets. The Sierra Nevada foothills surround the reservoir, rising gradually from its shoreline and giving wide and open views. The hillsides are largely covered by trees interspersed with grassland areas that remain unvegetated during the dry summer months. As the water level falls, an unvegetated ring around the entire reservoir is clearly visible.

Stanislaus County

The Tuolumne River continues through Stanislaus County for approximately 52 miles below Don Pedro Reservoir to the confluence with the San Joaquin River. This reach crosses mainly private open space and grazing lands, City of Modesto property, and several public parks. The principal recreational resources related to the Tuolumne River are described below.

Water recreation includes fishing, boating, rafting, and some swimming. These activities are dispersed along the river corridor and primarily depend on the availability of river access. No single public agency has comprehensively estimated recreational use along the river and, as a result, there is very limited recreation data for this reach of the river. Nonetheless, as with most recreational activities, summer is the peak season, and the majority of use occurs between Memorial Day and Labor Day. During the nonpeak season, winter and early spring use of the river is very limited.

The primary game fish in this stretch of the Tuolumne River are rainbow and brown trout, largemouth and smallmouth bass, striped bass, and Chinook salmon. The fishing season is from late April to mid-October; anglers are required to use barbless hooks and to release their trout catches, and are permitted to keep one salmon if it is caught in the lower reaches of the river. Between mid-October and the end of December, the CDFG increases enforcement of its fishing regulations at popular local fishing sites to protect the winter salmon run (CDFG, 2006a). The USBR has determined flow thresholds for boating recreation on the lower Tuolumne River. According to the USBR, the optimal flow range for boating activities is from 400 to 700 cfs. For swimming use, the optimal flows are between 200 and 600 cfs. Critical flows for power boating on the river occur below 500 cfs, and for canoeing and kayaking occur below 150 cfs (USBR, 1999).

La Grange Regional Park

La Grange Regional Park consists of 700 acres at 11 different sites, including an off-highway vehicle park, a Kiwanis Youth Camp, and the Joe Domecq Wilderness Area. The park has a boat ramp and a riverside picnic area as well as 225 acres of mostly undeveloped river plain areas along the Tuolumne River. Other park facilities include parking, restrooms, gravel beach area for swimming, trails and pathways, and handicapped access. Overnight camping is prohibited within the park. The majority of fishing and other river-related uses within the park take place at the Basso Bridge site, where there are approximately two acres of parkland on the river. Fishing at the river is prohibited between mid-October and the end of December to protect adult spawning salmon (Stanislaus County Department of Parks and Recreation, 2006). The visual setting of La Grange Regional Park is characterized by wide forested floodplain terraces, with some open space and turf areas. The river runs wide along major portions of its course downstream. Other parts of the park include less vegetated areas located on the dredge tailings from former gold mining operations (mostly on the northern side of the river).

Turlock Lake State Recreation Area

Turlock Lake State Recreation Area is located on the south side of the Tuolumne River, approximately 25 miles east of Modesto. Turlock Lake has 26 miles of shoreline and a surrounding area of 228 acres that is leased from TID. All of the park's 63 campsites are located in the northern area overlooking or near the Tuolumne River. Although no recreational vehicle hookups are provided, the campsites can accommodate 27-foot vehicles; each site is equipped with a grill, table, and food locker and is near to potable water, showers, and flush toilet facilities (California Department of Parks and Recreation, 2006). The park's annual visitation over the last few years has been approximately 69,000 visitors, of which more than three-quarters were day users.

There is about a mile of Tuolumne River shoreline within the park; however, the majority of the park's recreational facilities and opportunities are located lakeside. While park users can access the river, there is no beach area and most visitors instead recreate at the lake. Relatively few park visitors fish in the river due to CDFG regulations, which do not apply on the nearby Lake Turlock. The primary river-related recreation at the park occurs during the late summer, when park visitors occasionally "float" the river with inflatable rafts or inner tubes. In contrast, Turlock Lake offers a wide range of recreational opportunities, including camping, fishing, picnicking, swimming, boating, and water skiing. Lakeside recreational facilities consist of two formal picnic areas (each with nearby parking and toilet facilities), a boat launching ramp, and a swim area (although no lifeguards are on duty). As a result, the majority of the non-camping recreational use is lake-related.

The park's visual setting is similar to that of La Grange Regional Park, comprising a primarily open view of the flat, forested river floodplain within mostly undeveloped land. The river and its adjacent sloughs are forested by numerous native tree species, including interior live oak, cottonwood, and white alder. The broad riparian areas are also vegetated with underbrush that provides habitat for many birds and animals.

Fox Grove Regional Park

Fox Grove Regional Park encompasses approximately 64 acres along a one-mile river frontage, providing fishing access to the Tuolumne River. The park has a boat ramp, river access, barbecues, and picnic tables, and disabled access to the park is provided. The river runs deeper at Fox Grove than at the area's other popular river and fishing access site at Basso Bridge; as a result, flat-bottomed boat use is typically allowed at Fox Grove throughout the summer. Public access to the site is generally prohibited by the Stanislaus County Department of Parks and Recreation between mid-October and the end of December to protect the winter salmon run (Stanislaus County Department of Parks and Recreation, 2006). The visual setting at Fox Grove Regional Park is very similar to that at Turlock Lake State Recreation Area.

Tuolumne River Regional Park

The proposed Tuolumne River Regional Park lies along a seven-mile stretch of the Tuolumne River and encompasses approximately 500 acres of land (EDAW, 2005). Stanislaus County, the City of Modesto, and the City of Ceres have partnered to commence development of this project, and park plans are currently in environmental review. The majority of the parkland is located on the north side of the river, with the exception of Mancini Park and a series of small, riverfront parcels near the western end of the park.

Approximately 180 acres of the parkland has already been developed for recreational purposes, including open lawn areas within mature tree canopies as well as park amenities (e.g., park benches, picnic tables, trails, restrooms, and parking areas). The Dryden and Modesto Municipal Golf Courses are included as part of the city of Modesto's greenway areas for the park. The privately owned River Oaks Golf Course is also located along the southern bank of the river east of the Modesto Airport. However, recreational use of these golf courses is sport-focused and therefore non-river-related.

The eastern section of the park near the Modesto Airport is already developed for park use. The neighboring 50-acre Legion Park has mowed lawns, picnic tables, barbecue sites, and restrooms and is occasionally used for community special events such as the annual Cinco de Mayo celebration and Scottish Games. Mancini Park is located on the southern bank of the river and consists of 25 acres, including a children's play area, ball field, restrooms, and parking area. There is no river access from the park, and the remaining 320 acres are unimproved open space. The developed parkland areas include open space and turfed areas with scattered trees that provide shade. Sections of the park are heavily vegetated by trees and underbush that hide much of the nearby housing and other urban development. However, the majority of the undeveloped areas contain little vegetation, with much of the land consisting of denuded open or disked farmland (Tuolumne River Regional Park, 2007).

Future development of the park, proposed under the *Tuolumne River Regional Park Master Plan*, aims to restore a continuous riparian corridor along the river as well as develop a riverside bicycle and pedestrian trail. The plan also proposes to add river access at Legion Park and develop a regional sports complex in the Carpenter Road area (although this development is to be planned and approved separately from the master plan). The majority of the master plan's future park improvements would be located at the Gateway parcel site. These planned improvements include a river promenade trail and internal trail system, multi-use meadows suitable for community events and informal park activities, wetland areas for stormwater runoff, removal of Dennett Dam, a pedestrian bridge connection to the western parkland across Dry Creek, new parking, an "amphimeadow" (a grassy, outdoor amphitheater within a natural, meadow-like setting), and river access piers. Special events at the amphimeadow, construction of the river piers, and Dennet Dam removal are planned as subsequent projects to the master plan.

5.3.8.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to recreational and visual resources, but generally considers that implementation of the proposed program would have a significant impact if it were to:

Recreation

- Increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated (Secondary impacts of growth are evaluated in Chapter 7, Growth-Inducement Potential and Indirect Effects of Growth)
- Include recreational facilities or require the construction or expansion of recreational facilities that might have an adverse physical effect on the environment (Secondary impacts of growth are evaluated in Chapter 7)
- Physically degrade existing recreational resources

The first two criteria do not apply to the analysis of the proposed water supply and system operations component of the WSIP presented in this section of the PEIR, because these components of the proposed program would not increase the use of existing parks, nor would they require the construction or expansion of recreational facilities. Therefore, only the third criterion (potential physical degradation of existing recreational resources) is considered in the impact analysis below. The physical degradation of existing resources could occur if the WSIP were to:

- Remove or damage existing recreational resources
- Cause environmental impacts (such as air quality or noise effects) that would indirectly result in deterioration in the quality of the recreational experience
- Disrupt access to existing recreational facilities (which would divide a community from some of the established amenities used by its members)

While impeding a visitor's ability to participate in recreational activities does not in itself qualify as an environmental effect under CEQA, visitor use impacts can serve as indicators of physical changes to a recreational resource.

For visual resources, significant impacts could occur if the WSIP were to:

Visual Quality

- Have a substantial adverse effect on a scenic vista
- Substantially damage scenic resources, including but not limited to trees, rock outcroppings, and other features of the built or natural environment, that contribute to a scenic public setting
- Substantially degrade the existing visual character or quality of the site and its surroundings

Approach to Analysis

The analysis of impacts on recreation generally distinguishes between recreational activities associated with the rivers and reservoirs (e.g., swimming, boating, and fishing) and off-water recreation (e.g., hiking, picnicking, and camping). However, recreational activities are not separately identified, except for whitewater rafting, which is discussed separately and in greater detail due to the potential magnitude of impacts and the unique factors related to this recreational use of the Tuolumne River.

River-related recreational use within the Tuolumne River system predominantly occurs during the summer season between Memorial Day and Labor Day. In addition, there are relatively short shoulder seasons after mid-April and late October. During the off-season from November to mid-April, there is very limited river-related recreational use. Therefore, the primary focus of this impact analysis is on the summer season, when the majority of recreational activity occurs.

This analysis also considers potential visual impacts of the WSIP. Due to the Tuolumne River's limited accessibility and visibility, any visual or aesthetic changes to the river would predominantly affect recreation users; therefore, this analysis evaluates potential program-related changes in the quality of the visual experience for recreation users. The predominant visual effect that could occur at reservoirs under the WSIP involves the "bathtub ring" at reservoirs that are also used for recreational purposes. The bathtub ring refers to the exposed shoreline below the maximum water surface elevation, which is usually devoid of vegetation. This effect is a normal and unavoidable occurrence at reservoirs as water levels decline. Nonetheless, the WSIP would reduce reservoir water levels for longer periods and thus could diminish aesthetic values at program area reservoirs. The magnitude, incidence, and duration of future changes in the reservoirs' aesthetic values are qualitatively assessed as part of this analysis.

As noted above, the changes in river recreation that could result from the WSIP are consequences of changes in stream flow and reservoir water levels. These WSIP-induced changes in stream flow and reservoir water levels were estimated using the HH/LSM. An overview of the model is presented in Section 5.1. Detailed information on the model and the assumptions that underlie it is provided in Appendix H.

Impact Summary

Table 5.3.8-5 presents a summary of the impacts on recreational and visual resources in the Tuolumne River system that could result from implementation of the proposed water supply and system operations.

**TABLE 5.3.8-5
SUMMARY OF IMPACTS –
RECREATIONAL AND VISUAL RESOURCES IN THE TUOLUMNE RIVER SYSTEM**

Impact	Significance Determination
Impact 5.3.8-1: Effects on reservoir recreation due to changes in water system operations	LS
Impact 5.3.8-2: Effects on river recreation due to changes in water system operations	LS
Impact 5.3.8-3: Effects on the aesthetic values of the Tuolumne Wild and Scenic River	LS

LS = Less than Significant impact, no mitigation required

Impact Discussion

Impact 5.3.8-1: Effects on reservoir recreation due to changes in water system operations.

Lake Eleanor

The WSIP would have very little effect on water levels or water quality in Lake Eleanor, as described in Sections 5.3.1 and 5.3.3. Therefore, recreational impacts at Lake Eleanor would be less than significant.

Hetch Hetchy Reservoir

The WSIP would result in an average monthly lowering of reservoir water levels by an additional 1 to 10 feet over the course of the year compared to the existing condition. During the primary recreation season (between Memorial Day and Labor Day), the WSIP-related decrease in reservoir depth would be less than 5 feet from current levels except in critically dry years, when up to a 10-foot drop in reservoir levels would be expected. In average wet to normal hydrologic years, no change in reservoir levels would occur during the months of May through July; therefore, under these conditions, no recreational impact would result.

Off-water activities such as hiking and camping are the predominant recreational use at Hetch Hetchy Reservoir, since no swimming or boating is permitted. During the summer season for non-dry years, the drop in reservoir levels would increase the size of the “bathtub ring” visible to hikers by up to 4 feet; however, this increase would not likely be perceptible to most hikers, even in foreground views. Furthermore, during most of the year, Hetch Hetchy Reservoir would appear as it does a week or so earlier under current operating conditions. Between October and late December, visual conditions at the reservoir would be typical of those seen a month later under current conditions.

Only during the period between January and March would average reservoir levels at Hetch Hetchy fall lower than they normally do under the current operating conditions. On average, the maximum extra decrease in reservoir depth would be 10 feet in March, which would represent an approximate 15 percent increase to the reservoir’s current average 65-foot drawdown. This additional drawdown could be noticeable in foreground views; however, in views across the reservoir, the increase would likely be imperceptible to most hikers. This visual impact would only occur during the off-season, when visitation to the reservoir is low. Furthermore, the bathtub ring is a typical feature of an operating reservoir and would be a familiar sight for hikers at the reservoir. Therefore, recreational impacts at Hetch Hetchy Reservoir would be less than significant.

Lake Lloyd

The potential WSIP-related impacts on Lake Lloyd would be limited. During normal and below-normal hydrologic years, no changes in the reservoir’s current operations would occur, and no recreational impacts would result.

During wet or above-normal hydrologic years, future reservoir depths would generally be reduced by 1 or 2 feet; this reduction in the reservoir’s depth (less than 1 percent) would be imperceptible to recreational users. Furthermore, no reservoir level reductions would occur during the months of June through September, when the majority of the recreational use occurs. Therefore, no impacts on recreation would result.

During the summer season of critically dry hydrologic years, Lake Lloyd's depth would be expected to decrease by a maximum of 3 or 4 feet from current levels. However, this drop in reservoir levels (less than 2 percent) would be imperceptible to water and off-water recreational users. Furthermore, the conditions for fish species inhabiting the lake would not be affected by the WSIP. These non-native fish species are acclimated to the water-level fluctuations that occur in the reservoir, and thus impacts on the lake's recreational fishery are expected to be less than significant. Use of Lake Lloyd by other water recreationists for swimming or boating would also not be impaired. Therefore, recreational impacts at Lake Lloyd would be less than significant.

Don Pedro Recreation Area

With an average of more than 400,000 visitors a year, Don Pedro Reservoir is the most popular recreational resource in the Tuolumne River system that could be affected by the WSIP. The program's proposed increase in water withdrawals from the Tuolumne River would result in lower reservoir levels, varying on average up to 4 to 6 feet lower during above-normal or wet hydrologic years over the course of the year.

During below-normal, dry, and critically dry hydrologic years, water levels in Don Pedro Reservoir would be expected to fall up to 7 to 10 feet below current levels during the May to September recreational season. The reservoir's full depth is 530 feet (with a dead pool depth[2] of 230 feet below the maximum pool level). The average decrease in water levels from current levels would be less than 1 percent, and the decrease during dry years would be approximately 2.1 percent. Given the large annual fluctuation in the reservoir's depth both during the year and between years, these decreases in reservoir levels are likely to be barely perceptible to most recreational users. Water level changes are more likely to be noticed by on-water recreational users than by off-water recreationists at the reservoir.

Past recreational studies of Don Pedro Reservoir identified a threshold of 490 feet (i.e., a 40-foot decrease from the maximum elevation) below which recreational use of the beaches declined. However, only at levels below 450 feet (i.e., 80 feet below maximum pool) would recreational use decrease considerably. All of Don Pedro's recreational facilities nonetheless remain fully operational until the reservoir depth falls to 426 feet (i.e., 104 feet below maximum pool), at which point the Blue Oaks boat ramp is no longer operational, and 422 feet (i.e., 108 feet below maximum pool), at which point the Moccasin Point boat ramp is no longer operational (USBR, 1997). Critical thresholds are also reached when water levels decrease to the point that reservoir water levels recede from hiking trails, campsites, and picnic areas. A water-level decrease below the 426-foot threshold would impair use of the lake and limit reservoir access.

Under the proposed water withdrawal schedule (as shown in **Figure 5.3.8-6**), even at its lowest levels during the months of October and November, Don Pedro Reservoir would typically remain

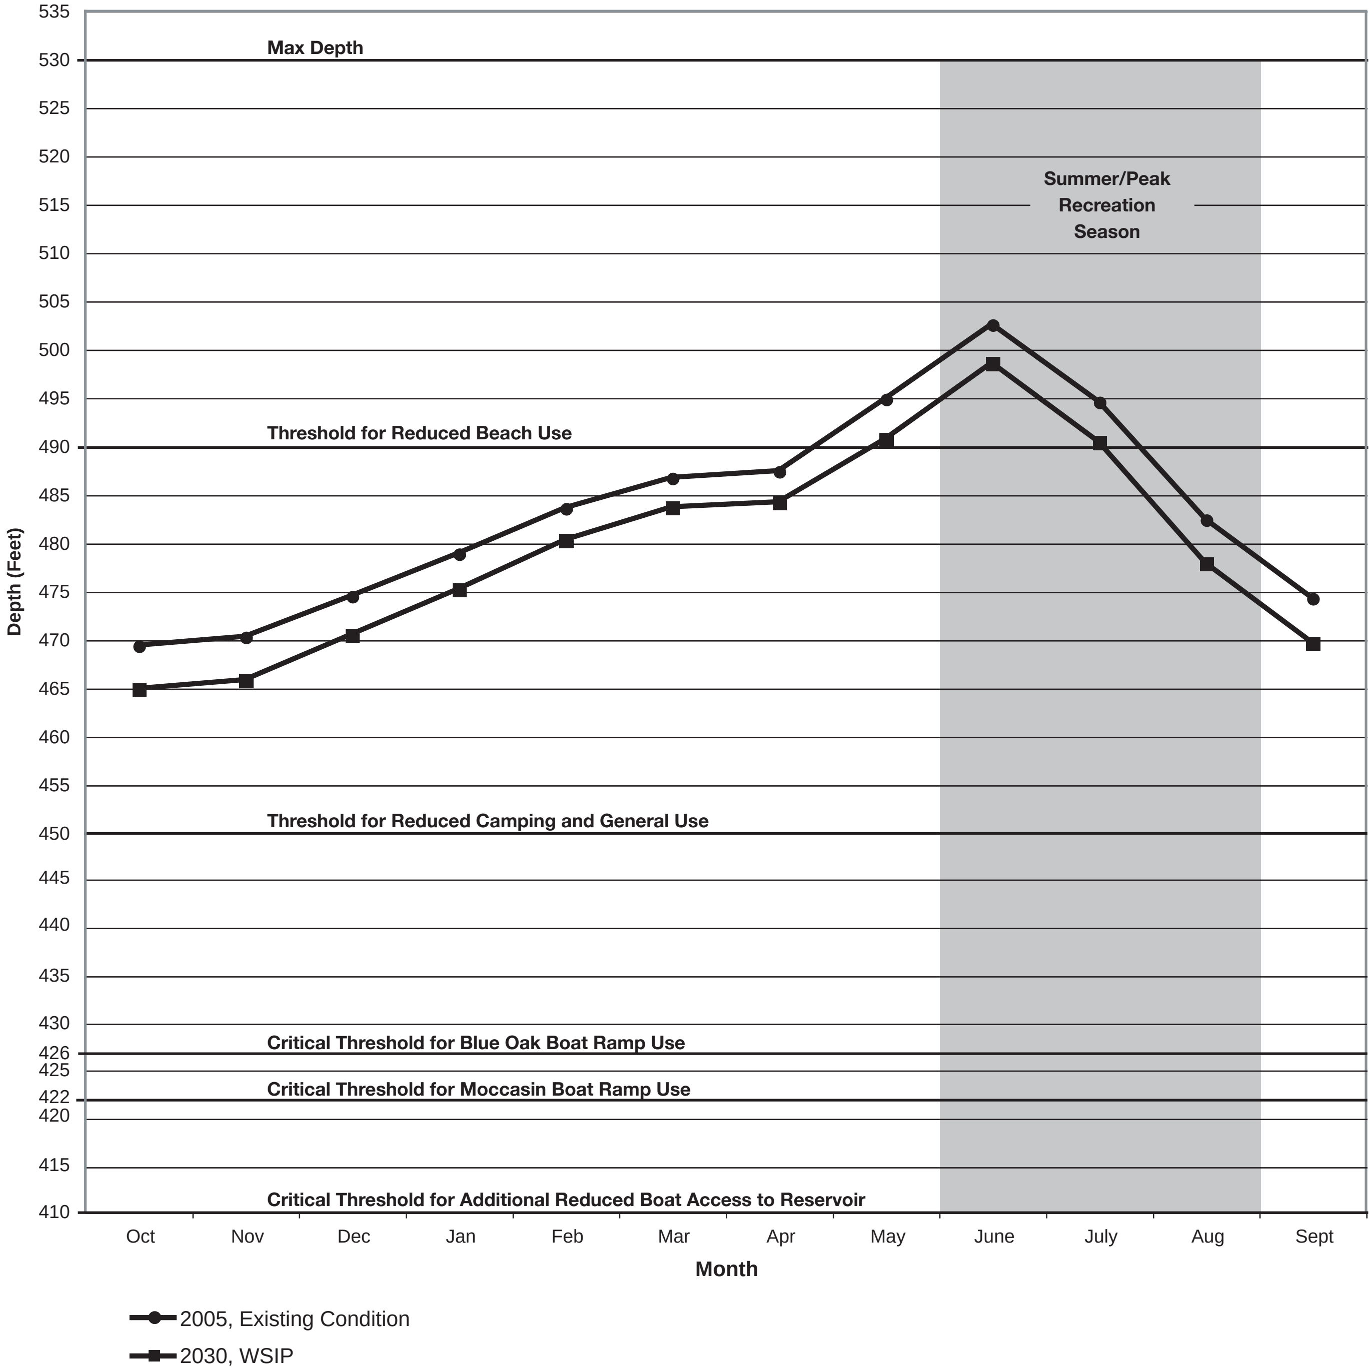
2 Dead pool is the depth beyond which the reservoir cannot be drained.

more than 15 feet above the 450-foot threshold, below which recreational use would begin to decline significantly. Average annual reservoir levels would be 490 feet or above during the summer months of June and July, when the majority of recreational use occurs; this level is more than 40 feet above the threshold for significant recreation impacts and 64 feet above facility-use impacts. In August, the reservoir's levels would typically fall an additional 4 feet with the WSIP, but would still be 488 feet—well above the 450 foot-threshold level. Because future reservoir levels in most years are expected to remain well above the threshold for adverse effects on recreational visitation, no significant impacts on recreational use at Don Pedro Reservoir are expected.

However, following a succession of dry years, the reduction in summer storage in Don Pedro Reservoir could increase the likelihood of adverse recreation impacts. Effects on Don Pedro's water levels associated with WSIP operational changes for the summer recreation season (i.e., June through August) were projected based on the available 82-year hydrologic record. Currently, out of 82 years, there were 13 months during the summer period (June through August) when water levels at Don Pedro Reservoir would have been below the 426-foot threshold (at which the Blue Oaks boat ramp becomes unusable). Under the proposed program, the incidence would increase to 24 summer months over the 82-year period. The 12-month increase represents an approximate doubling in the amount of time boat ramp facilities would be physically impaired (equivalent to 1 out of every 20 years). However, at reservoir depths below the 450-foot threshold, boat ramp use would be reduced but would continue to be possible. At 422 feet, the Moccasin Point ramp would not be usable. Another boat ramp access point would be unavailable at 410 feet. Currently, reservoir levels would fall below this threshold a projected 9 summer months out of 82 years. Under the WSIP, future Don Pedro levels would fall below this threshold for 13 summer months—an increase of 4 months.

Therefore, future operations under the WSIP are expected to reduce access to boating facilities. However, given the limited frequency of the impacts (which would occur only in extended drought periods) and the limited lost boating ramp use (since both marinas and most boat ramps would continue to function adequately), the impact on boating due to Don Pedro's increased vulnerability to drought effects would be less than significant.

Recreational fishing would not be affected by the WSIP, as the non-native fish populations in Don Pedro Reservoir can tolerate the changes in reservoir levels. Largemouth bass and bluegill, which are a popular catch for anglers, use the lakeshore as spawning ground during the springtime; however, effects on fishing as a result of the WSIP would be less than significant.



SFPUC Water System Improvement Program . 203287

SOURCE: ESA, 2006

Figure 5.3.8-6
Don Pedro Reservoir Annual Average Reservoir Depth and Recreational Uses

Off-water activities such as hiking and camping are more indirectly related to reservoir levels. The program-related drop in reservoir levels would increase the size of the bathtub ring visible to hikers, campers, and other reservoir users by up to 7 feet in foreground views (i.e., during the summer season of drier-than-average hydrologic years). This increase would likely be noticeable only to reservoir users who are very familiar with the reservoir. Furthermore, during most of the year, Don Pedro Reservoir would appear as it does two weeks or so earlier under current operating conditions. Between October and late December, visual conditions at the reservoir would be typical of those seen a month later under current conditions.

Only during the period between October and November would average reservoir levels at Don Pedro fall lower than they do under current operations. The visual impact associated with the bathtub ring would occur in the off-peak season only, when visitation to the reservoir is low. On average, the decrease in reservoir depth would be approximately 4 feet, which would represent a less than 10 percent increase in the reservoir's current average 45-foot drawdown over the year. This additional drawdown could be noticeable in foreground views; however, in views across the reservoir, the increase would not likely be very noticeable to most reservoir users. Furthermore, the bathtub ring is a typical feature of an operating reservoir and would be a familiar sight for frequent visitors to the reservoir. If fish were spawning along the reservoir shoreline during the spring, the increase in reservoir drawdown would have the potential to affect only a limited number of spawning grounds. Therefore, recreational impacts at Don Pedro Reservoir associated with WSIP operational changes would be less than significant.

Summary of Impacts

Overall, implementation of the proposed WSIP water supply and system operations would result in *less than significant* impacts on reservoir recreation.

Impact 5.3.8-2: Effects on river recreation due to changes in water system operations.

Diversion of additional water from the Tuolumne River as a result of the WSIP could affect the availability of water for whitewater rafting uses in the upper reaches of the river. It could also decrease stream flow in lower reaches of the river, thereby reducing opportunities for (and the quality of recreational experiences at) existing and planned parks and recreational facilities located at the river's edge, such as the Tuolumne River Parkway, a 500-acre parkway to be sited along a seven-mile stretch of the Tuolumne River in the Modesto area.

Whitewater Recreation

Hetch Hetchy Reservoir and Lake Lloyd are usually drawn down to their seasonal minimum in the spring. The SFPUC captures some of the late spring/early summer snowmelt runoff to refill the reservoirs and releases the rest to the Tuolumne River and Cherry Creek.

Flow in the Tuolumne River just below the confluence with Cherry Creek, and just downstream of the launching point for the Cherry Creek whitewater run, consists of releases and spills from

Hetch Hetchy Reservoir, Lake Lloyd, and Lake Eleanor; releases from Holm and Kirkwood Powerhouses; and tributary flow. Flow at this location is at its seasonal minimum in October. Flow typically increases through the winter and early spring and then increases sharply in the May and June with the snowmelt.

Hetchy Hetchy Reservoir would be drawn down farther in the spring with the WSIP than it is under the existing condition because diversions at Hetch Hetchy Reservoir would increase to meet 2030 water demand in the Bay Area. A greater proportion of the spring runoff would be needed to refill the reservoir than under the existing condition. As a result, with the WSIP, the onset of large releases from Hetch Hetchy Reservoir would be delayed by an average of one to two days (and up to eight days) and the total volume of releases would be reduced. After the large releases begin, releases during the rest of the year would be similar with the WSIP and under the existing condition.

Table 5.3.8-6 shows flows just below the Cherry Creek confluence under the existing condition and with the WSIP. The table slightly understates flow at this location because it does not include the small amount of inflow from tributaries between Hetch Hetchy Reservoir and Cherry Creek.

The WSIP would have very little effect on flow below the Cherry Creek confluence in wet and above-normal years. It would result in reductions in average monthly flow of up to 14 percent in May of normal, below-normal, and dry years. The reductions would manifest themselves as a delay in the onset of large snowmelt flows. This situation can best be illustrated with a simplified example. Under the existing condition, flow might be 1,000 cfs for the first five days in May and then 5,000 cfs for the remaining 26 days, for an average monthly flow of 4,354 cfs. With the WSIP, flow might be 1,000 cfs for the first 10 days of May and then 5,000 cfs for the remaining 21 days, for an average monthly flow of 3,709 cfs.

Currently, whitewater recreation on the upper river from mid-June through the summer is generally only possible due to SFPUC releases from Holm Powerhouse. For rafting flows, the SFPUC attempts to provide up to 1,100 cfs on the Tuolumne River at Lumsden for about four hours in the morning, from Monday through Saturday and on holiday weekends.

Tables 5.3.8-7 and **5.5.8-8** show flows in the Tuolumne River below the Cherry Creek confluence under the existing condition and with the WSIP for the 82-year hydrologic record. Although the flows shown in the tables understate actual flows at Lumsden Campground because they do not include tributary flows, they provide insight into the effects of the WSIP on whitewater rafting.

Under the existing condition and in May, the first month the weather is warm enough for whitewater rafting, flows below Cherry Creek would exceed 1,100 cfs in 74 years of the 82-year hydrologic record. A flow of 1,100 cfs in the Tuolumne River below Cherry Creek, and at least that at Lumsden Campground, would be suitable for rafting without a pulse release from Holm Powerhouse. With the WSIP and in May, flows below Cherry Creek would exceed 1,100 cfs in 72 years of the 82-year hydrologic record. Under the existing condition and in June, flows in the Tuolumne River below Cherry Creek would exceed 1,100 cfs in 64 years of the 82-year hydrologic

Note: The data represent the summation of releases to rivers/creeks from: Hetch Hetchy Reservoir, Lake Eleanor, Lake Lloyd, Holm Powerhouse, and Kirkwood Powerhouse. The flow data are incomplete and do not include accretions from the watersheds below the dams. These accretions would remain constant under all modeling scenarios. Actual Tuolumne River flow at the Cherry Creek confluence would be greater than the values presented.

Notes: The data represent the summation of releases to rivers/creeks from: Hetch Hetchy Reservoir, Lake Eleanor, Lake Lloyd, Holm Powerhouse, and Kirkwood Powerhouse. The flow data are incomplete and do not include accretions from the watersheds below the dams. These accretions would remain constant under all modeling scenarios. Actual Tuolumne River flow at the Cherry Creek confluence would be greater than the values presented. Year Types: Wet, AN – Above Normal, BN – Below Normal, Dry, and Critical

TABLE 5.3.8-8
FLOW IN THE TUOLUMNE RIVER IMMEDIATELY BELOW THE CHERRY CREEK CONFLUENCE WITH THE WSIP (cubic feet per second)

Notes: The data represent the summation of releases to rivers/creeks from: Hetch Hetchy Reservoir, Lake Eleanor, Lake Lloyd, Holm Powerhouse, and Kirkwood Powerhouse. The flow data are incomplete and do not include accretions from the watersheds below the dams. These accretions would remain constant under all modeling scenarios. Actual Tuolumne River flow at the Cherry Creek confluence would be greater than the values presented. Year Types: Wet, AN – Above Normal, BN – Below Normal, Dry, and Critical record. With the WSIP and in June, flows below Cherry Creek would also exceed 1,100 cfs in 64 years of the 82-year hydrologic record. Thus, during May and June, the high flow months, the WSIP would have very little effect on the number of days flow in the river is suitable for rafting and would have very little effect on the need for pulse releases from Holm Powerhouse.

Typically, inflow to the SFPUC's reservoirs in the Tuolumne River watershed is much diminished by mid-July, and large releases to the Tuolumne River have ended. Only the minimum required releases are made through the rest of the summer and early fall. Under the existing condition and in July, flows in the Tuolumne River below Cherry Creek would exceed 1,100 cfs in 28 years of the 82-year hydrologic record. With the WSIP and in July, flows below Cherry Creek would also exceed 1,100 cfs in 28 years of the 82-year hydrologic record. Under the existing condition and with the WSIP in August, flows below Cherry Creek would exceed 1,100 cfs in two years of the 82-year hydrologic record. Under the existing condition and with the WSIP in September, flows below Cherry Creek would never exceed 1,100 cfs in the 82-year hydrologic record. During many Julys, almost all Augusts, and all Septembers, releases from Holm Powerhouse would be needed to provide suitable flows for rafting under the existing condition and with the WSIP. There would be no appreciable increase in the amount of time releases would need to be made from Holm Powerhouse to provide rafting flows with the WSIP. Thus, the WSIP would have a less-than-significant effect on whitewater rafting in the Tuolumne River between the Cherry Creek confluence and Don Pedro Reservoir, and no mitigation measures would be necessary.

Comparison of the modeled controlled releases from Lake Lloyd, Lake Eleanor, and Holm Powerhouse for the existing condition and with the WSIP indicates that changes in the average monthly flow below Holm Powerhouse would occur in one or more months in 18 percent of the years in the 82-year hydrologic record. The WSIP would result in both increased and decreased flow rates; in some cases, flow would increase and decrease within the same year. These modeled changes primarily reflect slight changes in reservoir operations that may not occur during actual operations. The changes identified in the model occur rarely, and it is concluded that flow in Cherry Creek below Holm Powerhouse would be the same under either condition. Thus, the WSIP would have a less-than-significant effect on flows in the short section of the Cherry Creek Run between Holm Powerhouse and the confluence with the Tuolumne River, and no mitigation measures would be needed.

Other River Recreation Upstream of Don Pedro Reservoir

Non-rafting recreation on the Tuolumne River is limited. A majority of campers and hikers along the river are also on river rafting trips; therefore, any reductions in whitewater recreation would likely result in a related decrease in non-rafting recreational use.

However, as discussed in the Setting, some non-rafting visitors choose to recreate along the upper Tuolumne River despite the limited developed hiking trails and other recreational resources. The majority of recreational opportunities for these visitors are off-water activities, although a number of the visitors to this reach do partake in fishing. However, because no change in the flow releases for July through August are expected, no WSIP-related recreational impacts on river flow levels would occur during the peak recreational period.

Due to the considerable variance in the upper Tuolumne flow rates both seasonally and daily (as a result of the pulse releases), the relatively minor changes in river flow levels associated with the WSIP, predominantly in May and June, would be imperceptible to visitors. Therefore, impacts on non-rafting recreation along the upper Tuolumne River would be less than significant.

River Recreation Below La Grange Dam

Under existing conditions, most of the time (717 months in the 984-month hydrologic record) flow in the Tuolumne River below La Grange Dam consists of the minimum required instream flows. In average critically dry years, the releases made from La Grange Dam are those needed to sustain the minimum required instream flows. In other hydrologic year types, releases in excess of minimum flows are made primarily between November and June.

Don Pedro Reservoir would be drawn down farther in the spring with the WSIP than it is under the existing condition because diversions at Hetch Hetchy Reservoir would increase to meet 2030 water demand in the Bay Area and inflow to Don Pedro Reservoir would be reduced. A greater proportion of the winter and spring runoff would be needed to refill the reservoir than under the existing condition. As a result, with the WSIP, the onset of releases above from La Grange Dam above the minimum required would be delayed, and the total volume of releases would be reduced. After releases in excess of the minimum required begin, releases during the rest of the year would be similar with the WSIP and under the existing condition.

The effects of the WSIP on average monthly flows in the Tuolumne River below La Grange Dam in different year types are shown in Table 5.3.1-6. During the summer recreational season, when the majority of river-related recreation occurs, the WSIP would have no effect on releases from La Grange Dam in average below-normal, dry, and critically dry years. Therefore, the WSIP would have no effect on river recreation in these year types.

During average wet and above-normal years, the WSIP would reduce flow in some summer months by up to 25 percent. The greatest effect would be in June of average above-normal years, when a 25 percent reduction would occur. The next greatest proportional reduction in flow (7 percent) would occur in June of average wet years. Nonetheless, the resulting flow conditions with the WSIP in wet and above-normal years would still be appreciably higher than the typical flow conditions that now occur at that time of the year. The WSIP-induced decrease in flow in wet and above-normal years would not likely reduce accessibility or use of the area’s recreational resources.

Below Don Pedro Reservoir, recreational use of the Tuolumne River is limited. The river’s flow conditions, limited public access, as well as county and other agency regulations limit the type and level of river recreation. The Tuolumne County Recreation Department generally discourages swimming in the river at La Grange and Fox Grove Regional Parks due to dangerous undercurrents and the absence of lifeguard supervision. Although the CDFG annually restocks the river with fish, fishing in the Tuolumne River is regulated. Only barbless hooks and “catch and release” fishing is generally permitted, and no fishing is allowed during certain winter periods to protect the fall run of spawning adult Chinook salmon (CDFG, 2006b). Furthermore, the minimum instream flows for salmon and other fish populations would be maintained within the lower river to protect fishery habitat.

As discussed in the Setting, many local residents participate in off-water recreation in the parks along the Tuolumne River. However, this recreational use is generally independent of river flow conditions, which park visitors expect to vary considerably during the summer season. Future minimum flow conditions would be maintained under all circumstances during the summer season. Therefore, impacts river recreation along the Tuolumne River below La Grange Dam would be less than significant.

Summary of Impacts

Overall, implementation of the proposed WSIP water supply and system operations would result in *less than significant* impacts on river recreation.

Impact 5.3.8-3: Effects on the aesthetic values of the Tuolumne Wild and Scenic River.

Increasing the Hetch Hetchy system's reliance on Tuolumne River water sources could affect future stream flows within the Wild and Scenic sections of the Tuolumne River below O'Shaughnessy Dam, thereby degrading the river's visual resources. Such an impact, if it were to occur, could contravene policies of the *Tuolumne Wild and Scenic River Management Plan* (USFS, 1988) with respect to maintaining and improving the appearance of the stream and its water quality for aesthetic purposes. Reduction in the river's free-flowing condition could also diminish the management plan's policy to protect the river's outstandingly remarkable values.

Current flow conditions in the Tuolumne River vary considerably as a result of natural variations in rainfall and snowmelt in addition to the existing operation of the Hetch Hetchy system. Stream flow is only one of several qualities contributing to the river's scenic values. Other components of the river corridor's setting and scenery include geological and biological resources, which may be independent of and/or unaffected by WSIP changes in the water release schedule.

WSIP-induced changes in Tuolumne River flows would be greatest directly below O'Shaughnessy Dam. The effect of the WSIP would decrease in a downstream direction as more tributary flow and runoff enter the river, increasing river flow. As shown in Table 5.3.1-5, in most months of most hydrologic year types, flows in the Tuolumne River below O'Shaughnessy Dam with the WSIP and under the existing condition would be the same. In some months, usually in the spring, flows with the WSIP would be reduced compared to the existing condition. Average flows in May of all years would be 11 percent lower than under the existing condition. During average below-normal and dry years, the reduction in flows would be up to 30 percent in May. The WSIP would typically delay the initial spring release of water from Hetch Hetchy Reservoir by a few days, lengthening the period in which only the minimum required flow is released to the river by a few days. With the WSIP in place, flow in the Tuolumne River would remain within the range experienced under the existing condition. WSIP-related flow reductions would likely not be noticeable to most of the relatively few recreational users that hike along the Tuolumne River within the Wild sections of the Poopenaut Valley below the dam.

In addition, observers of the Tuolumne River's visual conditions are almost entirely recreational visitors. Although late-spring recreational use along the Wild and Scenic section of the river does occur, the greatest recreational use is during the summer season between Memorial Day and Labor Day. As a result, most recreationists would experience the Tuolumne River's Wild and Scenic visual resources during this period, when conditions would not be affected by the WSIP. In addition, a major proportion of the river users are whitewater rafters who also recreate on the river during the pulse flow releases, which would therefore reduce the period of time when visitors could observe any reductions to the Tuolumne's water flow conditions during non-pulse flows.

As a result, any future WSIP reductions in stream flow within the Tuolumne River would likely be imperceptible to or unobserved by most visitors. Therefore, impacts on the visual resources of the Tuolumne Wild and Scenic River would be *less than significant*, and no mitigation measures would be required.

5.3.9 Energy Resources

This section describes the potential effects of the WSIP water supply and systemwide operations on energy resources. The impact section (Section 5.3.9.2) provides a description of the changes in hydropower generation and energy consumption that would result from implementation of the proposed program. For a discussion of overall energy production and use by the WSIP, see Chapter 4, Section 4.15.

5.3.9.1 Setting

There are four major hydropower generation facilities on the Tuolumne River. Three, the Holm, Kirkwood, and Moccasin Powerhouses, are owned by the CCSF and operated by the SFPUC. The fourth, Don Pedro Power Plant, is owned by TID and MID and operated by TID. Hydropower facilities convert the energy of flowing or falling water into electrical power. Water released from a reservoir flows through a tunnel or pipeline to a powerhouse where it rotates one or more turbines. The spinning turbines drive electricity power generators.

Water is released from Lake Lloyd and flows to Holm Powerhouse though the Cherry Power Tunnel. Holm Powerhouse is equipped with two turbine and generator sets with a maximum generation capacity of 170 megawatts (MW). After passage through the turbines, water is released from Holm Powerhouse to Cherry Creek.

Water is diverted from Hetch Hetchy Reservoir and flows to Kirkwood Powerhouse through the Canyon Tunnel. Kirkwood Powerhouse is equipped with three turbine and generator sets with a maximum generation capacity of 126 MW. After passage through the turbines, most of the water from Kirkwood Powerhouse enters Mountain Tunnel, which conveys it to Priest Regulating Reservoir. The remainder is released to the Tuolumne River.

Water is released from Priest Regulating Reservoir and flows to Moccasin Powerhouse in the Moccasin Power Tunnel. Moccasin Powerhouse is equipped with two turbine and generator sets with a maximum generation capacity of 110 MW. After passage through Mocassin Powerhouse, water is discharged to Moccasin Reregulating Reservoir. Most of the water is diverted from the reregulating reservoir into Foothill Tunnel and conveyed to the Bay Area for water supply. Some water is discharged to Moccasin Creek, which discharges to Don Pedro Reservoir.

Water stored in Don Pedro Reservoir is conveyed through Don Pedro Dam in two tunnels to the Don Pedro Powerhouse, which is located at the base of the dam. The powerhouse is equipped with two turbine and generator sets with a capacity of 161 MW. After passage through the turbines, water is released from the powerhouse to the Tuolumne River.

The amount of hydropower generated at facilities on the Tuolumne River in any particular year depends on hydrologic conditions in that year and in preceding years. On average, and under current conditions, the hydropower facilities produce about 2.2 million megawatt-hours (MWh) (see Appendix H2-1).

The regulatory framework for energy use in the area served by the WSIP is described in Chapter 4, Section 4.15. It includes the National Energy Policy, the state's Energy Action Plan II and building energy efficiency standards, and San Francisco's Sustainability Plan, Electricity Resource Plan, and Climate Action Plan.

5.3.9.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to energy resources, but generally considers that implementation of the proposed program would have a significant energy resource impact if it were to:

- Encourage activities that result in the use of large amounts of fuel, water, or energy, or use these resources in a wasteful manner
- Reduce the production of renewable energy

Approach to Analysis

Changes in river flow, reservoir storage, and hydropower generation rates attributable to the WSIP were estimated using the Hetch Hetchy/Local Simulation Model. Detailed information on the model is provided in Appendix H.

Impact Summary

Table 5.3.9-1 presents a summary of the impacts on energy resources along the Tuolumne River that could result from implementation of the proposed water supply and system operations.

TABLE 5.3.9-1
SUMMARY OF IMPACTS – ENERGY RESOURCES ALONG THE TUOLUMNE RIVER SYSTEM

Impact	Significance Determination
Impact 5.3.9-1: Effects on hydropower generation at facilities along the Tuolumne River	B

B = Beneficial impact

Impact Discussion

Impact 5.3.9-1: Effects on hydropower generation at facilities along the Tuolumne River.

On average under current conditions, the SFPUC's hydropower facilities on the Tuolumne River generate 1,618,180 MWh of electricity each year. With the WSIP, this amount would rise to an average of 1,641,257 MWh, an increase of about 23,000 MWh or 1.4 percent. The increase in hydropower generation is attributable to the increase in diversion of water from Hetch Hetchy

Reservoir to meet water demand in the Bay Area. En route to the Bay Area, the water generates hydropower at the Kirkwood and Moccasin Powerhouses.

On average under current conditions, TID's and MID's facilities generate 590,180 MWh of electricity per year. With the WSIP, this amount would be reduced to an average of 576,046 MWh, a decrease of about 14,000 MWh or 2.4 percent. The decrease in hydropower generation is attributable to reduced inflow to Don Pedro Reservoir because of increased upstream diversion and a slightly lowered average water level in the reservoir.

Overall, the WSIP would increase hydropower generation on the Tuolumne River by an average of about 9,000 MWh, or 0.4 percent. Thus, the impact of the WSIP on the production of renewable energy from the Tuolumne River would be *beneficial*.

5.4 Alameda Creek Watershed Streams and Reservoirs

5.4 Alameda Creek Watershed Streams and Reservoirs

Section 5.4 Subsections

5.4.1 Stream Flow and Reservoir Water Levels

The following setting section describes the streams and reservoirs in the Alameda Creek watershed that could be affected by the WSIP. The impact section (Section 5.4.1.2) provides a description of the changes in stream flow and reservoir water levels that would result from implementation of the WSIP.

5.4.1.1 Setting

Watershed Overview

The Alameda Creek watershed covers an area of about 633 square miles in the East Bay, 30 miles southeast of San Francisco (**Figure 5.4.1-1**). Precipitation in the watershed is primarily in the form of rainfall, most of which falls in the November through March rainy season. Average annual precipitation ranges from about 20 to 25 inches per year; precipitation is heaviest in the west at higher elevations, and lowest in the eastern part of the watershed and at lower elevations.

There are two major drainage basins within the greater watershed: the Livermore Drainage Unit (shown as Arroyo Mocho and Arroyo de la Laguna in Figure 5.4.1-1) and the southern Alameda Creek watershed (also referred to as the Sunol Drainage Unit). The southern Alameda Creek watershed occupies about 175 square miles between Pleasanton to the north and Mount Hamilton to the south, spanning Alameda and Santa Clara Counties. Natural drainage is from the hills toward San Francisco Bay via Alameda Creek. The City and County of San Francisco (CCSF) owns 56 square miles (36,000 acres), or a little less than one-third, of the southern Alameda Creek watershed (shown in Chapter 2, Figure 2.2). The natural hydrology of the Alameda Creek watershed has been altered by water supply activities as well as by development and flood control.

Alameda Creek flows through a series of alluvial valleys linked by narrow bedrock-channel corridors. Alameda Creek is usually a perennial stream in the upper parts of the watershed, but in

Alameda Creek Drainage Area

the Sunol Valley and other alluvial flats, a high rate of infiltration and through-flow (water flowing through sediments) typically results in a dry creekbed during the summer months. The creek then resurfaces as pools in the confined bedrock canyons. Many of the tributaries that supply flows to the creek are historically intermittent and can be isolated from the main stem beginning in early to mid-summer (Gunther et al., 2000). The primary exception to this is Arroyo Hondo, which has year-round flow in many locations. In addition to fluctuations in stream flow caused by varying levels of surface water runoff, flows in Alameda Creek tributaries also vary greatly with rising and falling water tables in the area (Gunther et al., 2000). For the period from 1970 through 2003, Alameda Creek had an annual mean flow of 139 cubic feet per second (cfs), ranging from 31.5 cfs in the critically dry year of 1977 to 621 cfs in 1983. Mean flows are not indicative of daily flows, which can rise and fall dramatically depending on storm events. The highest peak flow (measured at the Niles gaging station) was 17,900 cfs on February 3, 1998. The total average annual runoff is 100,900 acre-feet (USGS, 2005a).

The SFPUC manages the Alameda Creek watershed portion of the regional system with the primary objective of conserving local watershed runoff for delivery to customers. Therefore, the Alameda reservoirs are managed to capture winter and early spring runoff in order to maximize storage and water delivery to customers during the winter months, while Hetch Hetchy runoff is stored for summer and fall delivery. This interconnectivity of the Alameda and Hetch Hetchy systems provides for substantial flexibility in operations, which are described in Chapter 2 and in this section.

The proposed WSIP system operations would affect the two SFPUC reservoirs in this watershed—Calaveras and San Antonio Reservoirs—as well as some reaches of Alameda Creek and its tributaries. These creeks and facilities are shown on **Figure 5.4.1-2**. Within the CCSF-owned watershed, Calaveras Creek and Arroyo Hondo drain directly to Calaveras Reservoir, and Alameda Creek flow is diverted into Calaveras Reservoir via the Alameda Creek Diversion Tunnel through operation of the Alameda Creek Diversion Dam (diversion dam). Farther downstream, San Antonio Creek drainage flows to San Antonio Reservoir, which is also used to store water from the Hetch Hetchy system and, periodically, water from Calaveras Reservoir. Downstream of its confluence with San Antonio Creek, Alameda Creek continues flowing through the Sunol Valley and then through Niles Canyon, eventually draining to San Francisco Bay. The drainage areas of each of these sub-watersheds of Alameda Creek are shown in **Table 5.4.1-1**.

Alameda Creek below the diversion dam conveys flows through the Sunol Valley, then to Niles Canyon and eventually to San Francisco Bay. As shown in Figures 5.4.1-1 and 5.4.1-2, tributaries include Calaveras Creek, which conveys releases from Calaveras Reservoir; Welch Creek, which flows into Alameda Creek near the Sunol Valley Water Treatment Plant (WTP); San Antonio Creek, which conveys releases from San Antonio Reservoir; Arroyo de la Laguna, which conveys flows from the Livermore Drainage Unit and Del Valle Drainage Unit; and Stoneybrook Creek, which enters Alameda Creek from the north within Niles Canyon.

San Antonio Reservoir	**24,645**	**38.5**

SOURCE: EDAW, 2007.

The reach of Alameda Creek through the Sunol Valley has a low gradient, with an elevation change of about 80 feet in five river miles. The creek channel is wide and braided in places; long sections have very shallow depths of water when flows are below about 75 cfs (Entrix, 2004). The Sunol Valley is broad but is bordered in parts by steep slopes (Center for Ecosystem Management and Restoration, 2002).

The reach of Alameda Creek through Niles Canyon, which starts downstream of the confluence with Arroyo de la Laguna, is constrained on both sides by steep canyon walls. There are several instream structures in this reach, including a culvert at the Stoneybrook Creek confluence and a U.S. Geological Survey (USGS) weir (Center for Ecosystem Management and Restoration, 2002). In 2006, the SFPUC completed removal of the Sunol and Niles Dams as part of an effort to restore creek flows and fish habitat along this reach of Alameda Creek; these facilities were historical parts of the regional water system that were built prior to construction of the Hetch Hetchy system.

After exiting Niles Canyon, Alameda Creek is contained within a flood control channel for 12 miles until it reaches San Francisco Bay. The Alameda County Water District (ACWD) manages this part of the creek for water supply, and the Alameda County Flood Control and Water Conservation District (ACFCWCD) maintains the channel for flood control purposes. Three large, inflatable rubber dams span the width of the channel and divert water to several hundred acres of ponds (former gravel quarries), where water percolates to recharge the underlying Niles Cone Groundwater Basin, a major source of water supply for the ACWD (ACWD, 2007). A flow control structure known as the BART weir (owned by the ACFCWCD and located where the BART and railroad tracks cross Alameda Creek in Fremont) provides structural protection of the footings of the BART and railroad bridge crossing and is a barrier to fish passage along this reach.

Mean annual precipitation over lower portions of the Alameda Creek drainage is about 20 inches.

Calaveras Reservoir and Creek

Calaveras Reservoir

Calaveras Reservoir was constructed between 1913 and 1925 with a storage capacity of 96,800 acre-feet, corresponding to a spillway elevation of 756 ft (USGS datum). Since December 2001, in response to safety concerns about the seismic stability of the dam and mandates from the California Department of Water Resources, Division of Safety of Dams (DSOD), the SFPUC has operated Calaveras Reservoir with the goal of holding the maximum water level at about 705 feet or below (USGS datum), which is approximately 37,800 acre-feet (roughly 40 percent of its maximum capacity). Because of heavy spring rains, Calaveras Reservoir has reached elevations of 720 to 736 feet for a few months during the springs of 2005, and 2006, as shown on **Figure 5.4.1-3**.

The natural drainage basin contributing to the Calaveras Reservoir drainage includes the Arroyo Hondo and Calaveras Creek Subbasins as well as local drainage areas along the west shore of the reservoir, with a total area of approximately 98 square miles. Stream flows within the Calaveras Reservoir drainage are highest during the winter and early spring rainy season and are minimal in summer and early fall. Calaveras Creek and Arroyo Hondo provide an average combined inflow to Calaveras Reservoir of about 36,000 acre-feet per year (afy) (nearly 12 billion gallons per year) (Bookman-Edmonston Engineering, Inc., 1995). Under pre-2002 conditions,[1] diversions from Alameda Creek added an average of approximately 6,000 afy (about 17 percent) to inflows into Calaveras Reservoir.

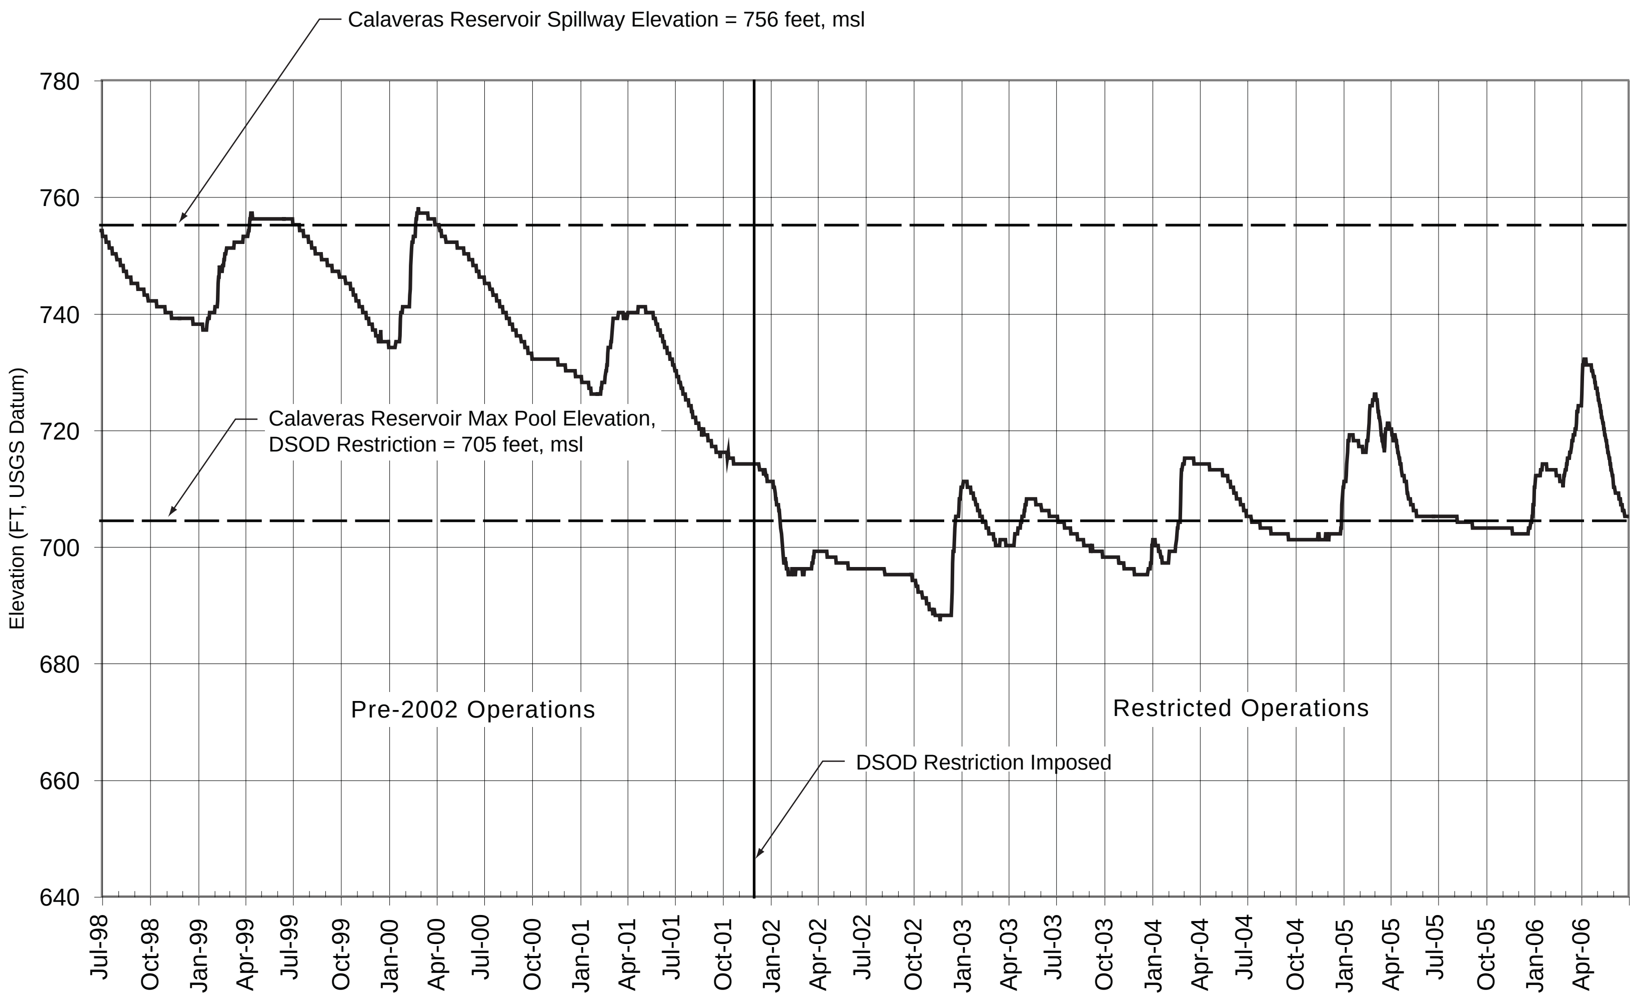
Water from the 35 square miles that drains into Alameda Creek upstream of the diversion dam can be diverted to Calaveras Reservoir through the Alameda Creek Diversion Tunnel. As shown in Figure 5.4.1-2, the diversion tunnel is situated about two miles upstream from the confluence with Calaveras Creek. At this overflow-type diversion, stream flow backs up behind an impoundment, flows into a short canal, and then enters the diversion tunnel if the diversion dam gates are open. During these conditions, flow in Alameda Creek in excess of the capacity of the diversion tunnel flows over the diversion dam and continues down Alameda Creek.

Much of the land surrounding Calaveras Reservoir is eroded or highly susceptible to erosion, and the subbasins of Calaveras Creek and Arroyo Hondo also contain eroded and steep soils. Above the diversion dam, slopes along Alameda Creek are eroded or severely eroded, with slope angles as high as about 45 percent (San Francisco Planning Department, 1999).

The SFPUC operates Calaveras Reservoir to meet the following objectives:

- Maximize storage within the reservoir to meet potential drought and water supply needs
- Maximize conservation of runoff on a long-term basis
- Meet short-term water supply operational requirements

1 Calaveras Reservoir operations before the 2001 DSOD restrictions are referred to throughout this document as "pre-2002 operations"; pre-2002 conditions are associated with pre-2002 operations.



SOURCE: SFPUC, HH/LSM (see Appendix H)

Figure 5.4.1-3
Calaveras Reservoir, Historical Water Levels, 1998 to 2006

Normal releases from Calaveras Reservoir are made through the intake tower. Under pre-2002 conditions, water could be withdrawn from three reservoir depths, corresponding to the elevations of the intake openings (adits) in the intake tower. However, the top adit is above the 705-foot restricted reservoir level; therefore, under current conditions, water can only be drawn from the lower two adits. Water from the tower's vertical conduit is conveyed through the 4.1-mile-long Calaveras Pipeline to the Sunol Valley WTP.

Water from Calaveras Reservoir is treated at the Sunol Valley WTP before entering the transmission system. Water flows from the reservoir to the treatment plant by gravity. The Sunol Valley WTP treats the water, which then travels by gravity to the transmission system at the Alameda Siphon No. 2. System operators have also transferred water from Calaveras Reservoir to San Antonio Reservoir as part of DSOD-restricted operations, in addition to making deliveries to the Sunol Valley WTP and releases via the cone valve.

Before December 2001, the reservoir would typically be operated to fill by the end of the rainy season in normal or wet years. The reservoir would be drawn down 15,000 to 20,000 acre-feet by early winter to ensure sufficient capacity to capture winter runoff. During a drought or water supply emergency, the reservoir would be drawn down farther to meet SFPUC water supply needs.

Following periods of heavy inflow, reservoir storage rises temporarily; at such times, the SFPUC employs "best efforts" to lower the level by releasing water to the regional system, and, if necessary, discharging excess inflow to Calaveras Creek. Average monthly storage in Calaveras Reservoir under restricted operations ranges from about 28,000 to 38,000 acre-feet in all conditions and months. As indicated in Figure 5.4.1-3, recent historical elevations in Calaveras Reservoir have varied from about 690 to 755 feet, with maximum post-2001 elevations of up to 736 feet. The SFPUC has also maintained a minimum water level elevation of 690 feet in accordance with a 1991 letter sent to the California Department of Fish and Game (CDFG) (SFPUC, 2005), as described in Chapter 2, Section 2.5.3.

In 1997, the CCSF and CDFG signed a Memorandum of Understanding (MOU) regarding releases of water from Calaveras Reservoir and maintenance of minimum storage levels from July through October to enhance fishery habitat, improve the coldwater fishery resources downstream of Calaveras Dam, and enhance warm-water fisheries in the lower reach of the creek. The SFPUC agreed to use best efforts to maintain at least 30,000 acre-feet in the reservoir (690-foot elevation) as well as to release up to 6,300 afy from Calaveras Reservoir. The MOU indicated possible year-round releases if target flows below the confluence of Alameda and Calaveras Creeks were not met. However, implementation of the 1997 MOU instream flow requirement below Calaveras Reservoir is currently on hold and hindered by the lack of sufficient cold-water storage in Calaveras Reservoir. (MOU flows are shown below in Table 5.4.1-9.)

Calaveras Creek Below Calaveras Dam

As part of system operations, the SFPUC can make releases from Calaveras Reservoir to Calaveras Creek, which then flow to Alameda Creek. Controlled emergency releases and other controlled releases (i.e., for fish studies) can be made through the dam outlet works, which can release up to about 1,100 cfs. Uncontrolled releases are conveyed to Calaveras Creek through the spillway structure. Spillway discharges could exceed 33,000 cfs if the reservoir were to fill to an elevation near the top of the dam.

Uncontrolled releases (spills) over the Calaveras Dam spillway have been infrequent. Recorded spills since 1938 have occurred in the following water years: 1941, 1945, 1952, 1956, 1958, 1965, 1967, 1969, and 1996–2000, as shown in **Table 5.4.1-2**.

SOURCE: SFPUC, 2006.

The spillway has not been used since the 2001 DSOD restrictions were placed on reservoir storage. Reservoir storage rises temporarily following periods of heavy inflow, and the SFPUC attempts to lower the reservoir level by releasing water to the Sunol Valley WTP and occasionally discharging water through the cone valve to Calaveras Creek. **Table 5.4.1-3** summarizes the releases made through the cone valve since the imposition of DSOD restrictions. As stated above, 1997 MOU fishery releases from Calaveras Reservoir are on hold due to the lack of sufficient cold-water storage in the reservoir.

Alameda Creek Above the Diversion Dam

Alameda Creek above the diversion dam has a reach length of about 14.9 miles, with an average slope of about 125 feet per mile. The average annual stream flow in Alameda Creek at the diversion dam has been estimated at 12,000 acre-feet (Bookman-Edmonston Engineering, Inc., 1995). As shown in **Table 5.4.1-4**, upper Alameda Creek is “flashy”; the creek has brief periods

TABLE 5.4.1-3

SOURCE: SFPUC, 2006.

of high flows interspersed with longer periods of low flows. Because the table shows daily means, it substantially understates the "flashiness" of the creek, where peak flows may occur for a few hours or less. As indicated on **Table 5.4.1-5**, measured peak flows at the diversion dam have exceeded 650 cfs on 48 days in the past 11 years, or an average of about four days per year. Despite the rarity of these flows, they constitute a substantial amount of stream flow volumes.

Alameda Creek Between the Diversion Dam and Calaveras Creek Confluence

Alameda Creek from the diversion dam to Calaveras Creek is 2.85 miles long with an average slope of 190 feet per mile. This reach has areas of boulders and pools with a segment of gorge carved through sandstone deposits, including the "Little Yosemite" area. Peak flows typically occur in the December through May rainy season. Minimal flows occur from July through October.

The diversion dam includes a dam/spillway, a sluice gate at the bottom of the dam that is used annually to wash out sediments that have accumulated behind the dam, as well as to pass flows when the tunnel gates are closed, a diversion sluiceway that directs water to the diversion gates, and a second sluice gate in the diversion sluiceway. The entire facility is remote (accessed via an unpaved road from the Sunol Regional Wilderness staging area) and, due to a lack of power availability, the gates must be manually operated. There is a gaging station in Alameda Creek immediately upstream of the diversion dam; the nearest Alameda Creek station below the diversion dam is immediately downstream of the creek's confluence with Calaveras Creek.

Prior to 2002, most of the flows were diverted to Calaveras Reservoir via the diversion tunnel. The maximum capacity of the diversion tunnel is about 650 cfs. Typical operation involves opening the diversion tunnel gates in early winter and leaving them open throughout the rainy season, except when Calaveras Reservoir is full. To avoid the need to spill water from Calaveras Reservoir when it is full, the SFPUC closes the gates at the diversion tunnel so that stream flow in Alameda Creek continues down its natural course. The diversion dam does not divert all flows when the diversion gates are open; due to through-flow as well as seepage through the dam and its sluice gates, flows of less than 1 cfs (and possibly somewhat higher) flow through the dam and down the creek.

Note: Flows in excess of 650 cfs are shaded; flows above 650 cfs flow past the diversion dam to the downstream reaches of Alameda Creek.

SOURCE: USGS, 2005b.

Diversions have substantially changed the hydrograph (i.e., a graph that shows the pattern of flows—both peak volumes and duration) of this reach of Alameda Creek. Pre- and post-diversion downstream flows in a typical above-normal-water-year storm are discussed below in Section 5.4.1.2, Impacts (see Figures 5.4.1-9, 5.4.1-10, and 5.4.1-11). Nearly all of the downstream flows below 650 cfs were diverted from the creek, and the peak flows were halved. The resulting hydrograph was that of a much smaller storm in a dry year. The effect of diversions on smaller storms (those with instantaneous flows of less than 650 cfs) was even more dramatic, with nearly all flows being removed from the creek downstream. The creek segment below the diversion dam essentially reverted to very low-flow conditions during these lesser storm events.

TABLE 5.4.1-5
NUMBER OF DAYS ALAMEDA CREEK EXCEEDED 650-CFS FLOW, MEASURED ABOVE THE DIVERSION DAM – 1997 TO 2007

Water Year	Hydrologic Year Type	Ranking	Number of Days with Flow Rates Exceeding 650 cfs

2006	N/A	N/A	4
2007	N/A	N/A	1

SOURCE: USGS, 2005b.

The SFPUC estimates that, prior to lowering Calaveras Reservoir water levels (pre-2002 conditions), about 8,000 afy had been diverted from Alameda Creek to Calaveras Reservoir in years with normal rainfall, with lesser diversions in dry and below-normal years. In wet years following drought periods, higher diversion quantities could occur, and in dry years, diversions could be much lower.

As a result of Calaveras Reservoir's restricted capacity, the SFPUC has had to significantly reduce its diversions through the Alameda Creek Diversion Dam compared to its 70-year historical operation. Since 2002, both the total quantities of diverted flows and the number of days of diversions have been substantially reduced. In addition, SFPUC records indicate that the diversion valves were only opened for about 35 days in 2002 (November 13 to December 18), about 80 days in 2003 (February 13 to May 2), and 25 days in 2004 (September 29 to October 24), and were not opened for over two years (between late October 2004 and early March 2007). As a result, most flows in Alameda Creek bypassed the diversion dam and continued on into this reach between 2002 and March 2007.

Alameda Creek Below the Calaveras Creek Confluence

Alameda Creek between Calaveras Creek and San Antonio Creek is about 3.3 miles long, with an average slope of 22 feet per mile. Except for the infrequent periods of releases and/or spills from Calaveras Reservoir (see Tables 5.4.1-2 and 5.4.1-3), flows in Alameda Creek below its confluence with Calaveras Creek are similar to, but slightly greater than, those described above for Alameda Creek at the diversion dam. Typical flows are discussed below in Section 5.4.1.2, Impacts.

San Antonio Reservoir

The James H. Turner Dam, which impounds San Antonio Reservoir, was constructed in 1965, approximately one mile upstream of San Antonio Creek's confluence with Alameda Creek and approximately 2.5 miles southeast of the town of Sunol. Above its toe, the dam is about 190 feet high and has a crest elevation of 468 feet (USGS datum).

The catchment area of the reservoir is about 40 square miles. The CCSF owns most of the drainage area north and northeast of San Antonio Reservoir (as shown in Chapter 2, Figure 2.2). These lands extend eastward to include the downstream portions of each of the major contributing creeks (Indian Creek, La Costa Creek, and Williams Gulch, shown in Figure 5.4.1-2) and are considered part of the primary watershed of the reservoir. The upstream portions of the tributaries, however, are outside of CCSF ownership and include large areas of eroded and erodible lands. Stream flows into San Antonio Reservoir are highest during the winter and spring rainy season and become insignificant in summer and early fall. Average annual stream flow into San Antonio Reservoir has been estimated at 7,200 acre-feet (Bookman-Edmonston Engineering, Inc., 1995).

As described above, San Antonio Reservoir normally receives inflow from the San Antonio Creek watershed and imported water from the Hetch Hetchy Aqueduct (as described in Chapter 2, Section 2.2.3). In addition, the reservoir has been used to store South Bay Aqueduct emergency water, groundwater (influenced by surface water) pumped from the infiltration galleries at the Sunol Water Temple, and Calaveras Reservoir surplus flows. The initial capacity of the reservoir was 50,300 acre-feet. Sedimentation since its construction has reduced its maximum capacity by about 2 percent, to roughly 49,500 acre-feet. Average monthly storage in San Antonio Reservoir does not vary substantially from month to month or year to year, ranging from about 39,000 to 50,300 acre-feet in all conditions and months. As shown in **Figure 5.4.1-4**, reservoir levels have ranged from about 440 to 468 feet. The average annual rainfall near San Antonio Reservoir is about 20 inches per year (San Francisco Planning Department, 1999).

Reservoir Operations

The SFPUC operates San Antonio Reservoir to receive and store dechlorinated water from the Hetch Hetchy Aqueduct as well as local watershed runoff. Hetch Hetchy water can be stored in San Antonio Reservoir by diverting it from the Alameda Siphons via the San Antonio Pump Station through the San Antonio Pipeline. Although not part of normal operations, surplus water from Calaveras Reservoir can flow by gravity through the Calaveras and San Antonio Pipelines to be stored in San Antonio Reservoir.

Water from San Antonio Reservoir is treated at the Sunol Valley WTP before entering the transmission system. San Antonio Reservoir water can flow to the Sunol Valley WTP by gravity when the water level in the reservoir is above 445 feet. Below this elevation, the water must be pumped via the San Antonio Pump Station. The Sunol Valley WTP treats the water before it reenters the system by gravity-flow through the Alameda Siphons.

As part of system operations, the SFPUC can make releases from San Antonio Reservoir to San Antonio Creek, which then flow to Alameda Creek. Controlled releases through the

Figure 5.4.1-4
San Antonio Reservoir, Historical Water Levels, 1998 to 2006

emergency discharge valve on Turner Dam and uncontrolled releases (spills over the spillway) are discharged to San Antonio Creek. Uncontrolled releases flow over the spillway structure, an 80-foot-long weir with a crest elevation of 468 feet. The SFPUC estimates the spillway capacity at 13,500 cfs for a reservoir water level of 480 feet.

San Antonio Creek Below San Antonio Reservoir

Modeled uncontrolled releases from San Antonio Reservoir to San Antonio Creek average about 1,000 afy, ranging from no releases in below-normal and dry years to about 3,200 acre-feet in very wet years. Actual dam operation makes adjustments to prevent spill such that less water is spilled than predicted by the model. Currently, there are no releases from June through December; the highest releases typically occur in February and March. For much of the year, this stream reach is dry. San Antonio Creek joins Alameda Creek in the lower reaches of the Sunol Valley in the vicinity of the quarries and upstream of Arroyo de la Laguna.

Alameda Creek Below the San Antonio Creek Confluence

The reach of Alameda Creek through the Sunol Valley (both upstream and downstream of the confluence with San Antonio Creek) has a low gradient, with an elevation change of about 80 feet in five river miles. The Sunol Valley is broad but is bordered in parts by steep slopes (Center for Ecosystem Management and Restoration, 2002). In the lower reaches of the Sunol Valley, Alameda Creek is bordered by numerous gravel quarries, and much of the flow in the creek is lost to groundwater.

Since October 1999, the USGS has monitored mean daily flows in Alameda Creek downstream of Welch Creek, at about the location of the Sunol WTP. Mean daily flows generally range from near zero during dry months to above 1,000 cfs in wet months. The highest mean daily flow recorded prior to lowering Calaveras Reservoir water levels was 1,070 cfs in late March. The highest mean daily flow since 2002 was 1,340 cfs in early April. During the month of May, flow rates are usually in the order of 50–100 cfs, decreasing to 20–50 cfs in June and 0–20 between July and November.

Peak flows in Alameda Creek at Welch Creek increased substantially after the closure of the diversion tunnel. In 2000 (a wet year), a peak flow rate of 2,910 cfs was recorded. If the tunnel intake had been closed, the flow would have been about 650 cfs greater.

5.4.1.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to stream flow, but generally considers that implementation of the proposed program would have a significant impact if it were to:

- Substantially alter stream flows such that they are outside the range of pre-WSIP conditions and result in substantial hydrologic changes

In addition to direct impacts resulting from changes in stream flows and reservoir levels, this PEIR also considers indirect impacts. These include impacts related to geomorphology, surface water quality, groundwater, fisheries, terrestrial biological resources, and recreational and visual resources. Each of these topics is discussed in its own section in this chapter. It should be noted that there might be cases in which significant indirect impacts could result from less-than-significant direct impacts.

Approach to Analysis

As discussed above in Section 5.4.1.1, DSOD-imposed restrictions on Calaveras Reservoir capacity substantially altered SFPUC operations and, as a result, changed the hydrologic conditions in Alameda Creek, Calaveras Creek, and Calaveras Reservoir (i.e., flow diversions from Alameda Creek have been reduced or halted and reservoir levels lowered). These hydrologic conditions will continue until the Calaveras Dam project (SV-2) is implemented, which would restore the original reservoir capacity. Therefore, these hydrologic conditions will have occurred for 10 years or more (from 2002 through approximately 2012, the target date for reservoir refill). Once the dam is rebuilt and the reservoir refilled, the SFPUC would reinitiate operations that are similar to those it implemented prior to the DSOD restrictions, and the hydrologic conditions in Alameda Creek and Calaveras Reservoir would return to those that existed prior to the DSOD restrictions; that is, the SFPUC would again divert substantial flow from Alameda Creek to the reservoir and would maintain the reservoir water levels near the maximum storage level.

The SFPUC operates the Alameda Creek Diversion Dam to divert water from Alameda Creek into Calaveras Reservoir when such water can be stored. The SFPUC closes the ACDD Tunnel when diversions are not needed. As a result of the 2001 DSOD restriction on Calaveras Reservoir, the SFPUC has had to reduce the volume of water stored in Calaveras and has therefore significantly reduced its diversions through the Alameda Creek Diversion Dam by closing the tunnel more frequently compared to its 70-year historic operation. Upon completion of the Calaveras Dam Replacement project (SV-2), the SFPUC would no longer have DSOD restrictions on storage level in Calaveras Reservoir. Compared to historical operations with full storage capacity at Calaveras, the SFPUC plans to maintain Calaveras Reservoir at a higher elevation over long periods of time, and as a result the diversion tunnel would be closed more often than historically and there would be more occasions when water bypasses the Alameda Creek Diversion Dam into Alameda Creek (see Appendix H2-2, Table 2.7-7).

For the purpose of impact analysis, CEQA Guidelines Section 15125(a)[2] considers the existing conditions baseline to be those conditions in existence at the time the environmental review is initiated, as marked by issuance of the notice of preparation (NOP). For the WSIP, the existing baseline used for the impact analysis reflects the range of hydrologic conditions that have resulted since the DSOD restrictions were imposed in December 2001 and continued through issuance of the NOP in 2005, and which are expected to continue until such time that a restored reservoir

[2] CEQA Guidelines Section 15125(a) states that an EIR must include a description of the physical environmental conditions in the vicinity of the project as they exist at the time the NOP is published, and that this environmental setting will normally constitute the baseline physical conditions by which the lead agency determines whether an impact is significant.

begins refilling. This PEIR does not use the historical range of hydrologic conditions that existed prior to the DSOD restriction as the basis of impact analysis of the WSIP impacts on stream flow.

The following section addresses the impacts of the WSIP on water levels in Calaveras and San Antonio Reservoirs and flow along Calaveras, Alameda, and San Antonio Creeks. In applying the above significance criteria, very infrequent changes in reservoir levels and/or flow are not generally considered to generate a significant effect. Changes in stream flow and changes in reservoir storage and water levels attributable to the WSIP were estimated using the Hetch Hetchy/Local Simulation Model (HH/LSM). An overview of the model is presented in Section 5.1.4. Detailed information on the model and its underlying assumptions is provided in Appendix H.

This section compares modeled existing (2005) hydrologic conditions (with Calaveras Reservoir operated at its restricted capacity and assuming current operational priorities) to modeled post-WSIP 2030 conditions. The WSIP 2030 conditions assume full implementation of all proposed WSIP facility improvement projects, including the Calaveras Dam (SV-2) and Alameda Creek Fishery (SV-1) projects, as well as implementation of fishery releases and downstream recapture of those releases. In some cases, patterns from actual flow data were used to supplement results from the modeled data in order to provide additional detail and context for assessing potential impacts. Stream reaches are discussed separately below, and their interrelationships are highlighted.

Impact Summary

Table 5.4.1-6 presents a summary of the impacts on stream flow in the Alameda Creek watershed that could result from implementation of the proposed water supply and system operations.

TABLE 5.4.1-6
SUMMARY OF IMPACTS – STREAM FLOW IN ALAMEDA CREEK WATERSHED

Impact	Significance Determination
Impact 5.4.1-1: Effects along Calaveras Creek below Calaveras Reservoir	LS
Impact 5.4.1-2: Effects on flow along Alameda Creek below the diversion dam	SU
Impact 5.4.1-3: Effects in San Antonio Reservoir and along San Antonio Creek	LS
Impact 5.4.1-4: Effects on flow along Alameda Creek below the confluence of San Antonio Creek	LS

LS = Less than Significant impact, no mitigation required
SU = Significant Unavoidable impact

Impact 5.4.1-1: Effects along Calaveras Creek below Calaveras Reservoir.

Calaveras Reservoir is currently operated to conserve local watershed runoff for integration into the SFPUC regional water supply; however, due to DSOD restrictions, the water level in Calaveras Reservoir has been considerably lower since the end of 2001 than in previous years.

Reservoir storage is constrained to approximately 37,800 acre-feet (except on a temporary basis), about 40 percent of its design capacity. Under the WSIP, Calaveras Reservoir would be restored to its full design capacity (approximately 96,800 acre-feet), which would allow the SFPUC to maximize the use of local watershed supplies. Furthermore, fishery releases from the proposed bypass flow structure at the Alameda Creek Diversion Dam and/or from the reservoir and flow recapture would be implemented under the WSIP in accordance with the 1997 MOU (compliance with the 1997 MOU is measured below the confluence of Alameda and Calaveras Creeks). The fishery releases from the diversion dam bypass flow structure to Alameda Creek and from Calaveras Reservoir to Calaveras Creek would be recaptured downstream and returned to the SFPUC water supply in compliance with the 1997 MOU.

Under existing and future modeled conditions, yearly Calaveras Reservoir storage operations are typically cyclical: the reservoir fills in the late winter/early spring and is depleted during the summer. During a drought, reservoir storage is further depleted by the slow, successive drawdown of reservoir storage that occurs due to required releases and the drafting of supplies to the Sunol Valley WTP that exceed runoff to the reservoir. The reservoir then refills after the drought, as the SFPUC strives to conserve local watershed runoff. Both the annual range and year-to-year range of variation in reservoir water levels would increase as the storage capacity of Calaveras Reservoir is restored.

Figure 5.4.1-5 illustrates the modeled chronological storage and stream releases from Calaveras Reservoir for both the existing condition and the WSIP using hydrologic data from the period 1920 to 2002. Releases to Calaveras Creek from Calaveras Reservoir represent both controlled releases through the cone valve and uncontrolled releases over the spillway. The graphs also show how peak flows in Calaveras Creek downstream of the dam tend to correspond to periods when Calaveras Reservoir is operating at or near capacity. This figure assumes the SFPUC would make fishery releases in compliance with the 1997 MOU from Calaveras Reservoir only and does not account for the proposed bypass flows from the diversion dam; this represents a worst-case condition for the range of fluctuation in Calaveras Reservoir water levels.

As illustrated in the graphs, the most notable change that would occur under WSIP operations is that Calaveras Reservoir would be operated at a higher water surface elevation than at present; as the graphs show, the brown line (2030 WSIP conditions) is consistently at a much higher level than the blue line (existing conditions) for the 82-year period. Reservoir storage and water levels also show greater variation than under existing conditions, as illustrated by the wider range of fluctuation of the brown line (2030 WSIP conditions) compared to the blue line (existing conditions). The graphs also show that the restored reservoir storage would reduce peak releases (and therefore flows) into Calaveras Creek downstream of the dam under all but the heaviest wet-year storms; the releases are represented by the blue line (existing conditions) and magenta line

(2030 WSIP conditions) along the bottom of each graph, with the magenta line generally lower than the blue line except in the wettest years. Under actual operations to date, storage in the reservoir under restricted conditions has at times exceeded the DSOD target; as a result, more water has been temporarily held in storage than the model indicates (see Figure 5.4.1-3) and fewer releases have actually occurred than predicted by the model. This is because the model

Average Monthly Storage Volume,
Calaveras Reservoir

imposes absolute rules, whereas under actual conditions, the SFPUC operators must adjust operations in response to many real-time factors.

Figure 5.4.1-6 presents the estimated change in average monthly reservoir water surface elevation under existing conditions and after implementation of the WSIP. This figure assumes the SFPUC would make fishery releases in compliance with the 1997 MOU from Calaveras Reservoir only and does not account for the proposed bypass flows from the diversion dam; this represents a worst-case condition for the range of fluctuation in Calaveras Reservoir water levels. The water level in Calaveras Reservoir would be higher year-round with the WSIP; the increase in average monthly storage would be mostly attributable to completion of the Calaveras Dam project (SV-2) and the removal of the DSOD storage limitations. During rainy months, the reservoir water level would be kept near the wintertime storage objective, or roughly 20 to 30 feet higher than under existing conditions. The average water surface elevation would be substantially greater than under current conditions, but only 6 to 12 feet higher than pre-2002 conditions (prior to the DSOD restrictions).

With implementation of the WSIP, the change in operation of Calaveras Reservoir storage would affect hydrologic conditions elsewhere in the watershed. As described below, the restored capacity of Calaveras Reservoir would affect the operation of the Alameda Creek Diversion Dam and Tunnel, and thus the inflow to Calaveras Reservoir and flow to Alameda Creek below the diversion dam. The proposed bypass structure at the Alameda Creek Diversion Dam and the restored storage capacity would also allow for implementation of the 1997 MOU-required releases from either the new bypass structure or Calaveras Reservoir in support of fisheries.

Compared to existing conditions, the WSIP would change the nature of releases from Calaveras Reservoir to Calaveras Creek. With implementation of the fishery releases from the new bypass flow structure at the diversion dam and from Calaveras Reservoir (up to 6,300 afy), there would at times be releases from the reservoir under the WSIP that are not made under existing conditions. These flows would be gaged and maintained below the confluence of Alameda and Calaveras Creeks. Contributing to these flows would be: (1) flows that spill past the Alameda Creek Diversion Dam, (2) unregulated runoff from accretions (inflow) between the diversion dam and the Calaveras Creek confluence, (3) unregulated runoff between Calaveras Dam and the confluence, (4) operational releases from Calaveras Reservoir for reservoir regulation purposes, and (5) operational releases from the Alameda Creek Diversion Dam to support fishery releases when there is available flow in Alameda Creek.

Figure 5.4.1-7 illustrates the modeled chronological releases of water below Calaveras Dam to Calaveras Creek for both existing conditions and with the WSIP; this figure assumes the SFPUC would make fishery releases in compliance with the 1997 MOU from Calaveras Reservoir only and does not account for the proposed bypass flows from the diversion dam. Operational releases from Calaveras Reservoir occur in about 50 percent of the years under the modeled existing condition and in about 35 percent of the years under the WSIP (with the exception of 1997 MOU releases, which would occur in all years), with most of these years being classified as above-normal or wet. **Table 5.4.1-7** shows the releases from the reservoir for various representative hydrologic year types and assumes the SFPUC would make fishery releases in compliance with the 1997 MOU from Calaveras Reservoir only and does not account for the proposed bypass flows from the diversion dam. As shown in the table, releases with the WSIP would be substantially diminished in the winter months of normal, above-normal, and wet years, with up to a 70 percent reduction. This reduction in the frequency and magnitude of releases would primarily result from removal of the DSOD storage constraint following construction of the Calaveras Dam project (SV-2). With greater operational capacity, more local runoff would be stored and used for water supply. During all months of below-normal and dry years and the majority of months in normal, above-normal, and wet years, the volume of releases would remain nearly the same or would be slightly diminished with the WSIP compared to existing conditions. However, in several scenarios, releases would be eliminated under WSIP operations.

With implementation of the WSIP, summer base flows (flows that occur in the absence of any recent rainfall) in Calaveras Creek below the dam would increase due to the required fishery releases below Calaveras Dam (shown in Table 5.4.1-5). The maximum supplemental release of 6,300 afy might not be needed in every year due to other flows reaching the confluence, including bypass flows at the Alameda Creek Diversion Dam.

Impact Conclusions

As indicated in the relevant tables and figures, the WSIP would substantially reduce average flows in Calaveras Creek below Calaveras Dam in the winter and early spring months of wet and above-normal precipitation years. The proposed program would also increase flows due to fishery releases in the summer months. As indicated on Figure 5.4.1-7, the changes in flow due to the WSIP would occur in years with above-normal rainfall only, and the reduced winter flows would still remain in the range of existing flows; therefore, the impact would be *less than significant*, and no mitigation measures would be required. The new summer instream releases in Calaveras Creek would constitute a beneficial flow impact.

Impact 5.4.1-2: Effects on flow along Alameda Creek below the diversion dam.

The diversion of flows from Alameda Creek at the diversion dam affects two reaches of the creek: the reach between the diversion dam and the confluence with Calaveras Creek and the reach below the confluence with Calaveras Creek. Both reaches are discussed in this impact analysis.

Between the Diversion Dam and the Calaveras Creek Confluence

The Alameda Creek Diversion Dam and Tunnel divert water from the upper Alameda Creek watershed to Calaveras Reservoir. Inflow at the diversion dam is diverted into the tunnel up to the maximum capacity of the tunnel, which is estimated at about 650 cfs. Inflow to the diversion dam that exceeds the tunnel capacity (or when the tunnel gates are closed) flows past the diversion dam and continues downstream in Alameda Creek. As described above, diversions from Alameda Creek to Calaveras Reservoir have been substantially reduced because of the DSOD restrictions on Calaveras Reservoir. Currently, as indicated on Figure 5.4.1-3, Calaveras Reservoir is often filled near, or above, the maximum permitted storage level with runoff from its natural drainage and, at these times, has no capacity to accept diversions from Alameda Creek. Therefore, while the DSOD restrictions on Calaveras Dam are in effect, the SFPUC is unable to capture most local watershed runoff from upper Alameda Creek, and post-2002 flows in Alameda Creek below the diversion dam have been substantially greater than they were prior to 2002.

Modeling of future operations under the WSIP indicates that diversions would primarily occur during the December through May rainy season. The greatest diverted/reduced stream flow quantities would occur from December through March. **Figure 5.4.1-8** shows the modeled chronological average monthly spill of water past the diversion dam for the period from 1920 to 2002. As illustrated in the figure, the number of occurrences and magnitude of flows continuing down Alameda Creek past the diversion dam would be reduced with the WSIP due to more

SFPUC Water System Improvement Program ▪ 203287

SOURCE: SFPUC, HH/LSM (see Appendix H).

Figure 5.4.1-8
Flows in Alameda Creek Below the Diversion Dam

frequent diversions to Calaveras Reservoir. Flows past the diversion dam would be reduced in wet, above normal, and normal year types, although when flow is available, the SFPUC would allow for minimum bypass flows consistent with the requirements of the 1997 CDFG MOU.

As described in Section 5.4.1.1, Setting, instantaneous gage data (15-minute readings) for the period from 1997 through 2007 indicate that flows greater than 650 cfs in Alameda Creek above the diversion dam have occurred an average of about four days per year (a total of 48 days over the 11-year period) and, in one-quarter of those years, did not occur at all. These instantaneous readings show that flows in excess of 650 cfs occur more frequently than is indicated by the daily mean flow data shown in Table 5.4.1-4. This is because many of the peak flows last for a few hours only and are obscured by 24-hour means. Daily means also underrepresent the actual volumes of water passing the diversion dam. As indicated in **Figures 5.4.1-9** and **5.4.1-10**, under the WSIP in a typical above-normal rainfall year, there would be only a few days per year when flows above the minimal seepage levels (approximately 1 cfs) would reach Alameda Creek below the diversion dam (the primary exceptions being when Calaveras Reservoir is full and diversions cease, and when large storms result in runoff substantially over 650 cfs). However, as indicated on these graphs, substantial volumes of water (sometimes over 1,000 cfs) would still flow down the creek during these peak events. The existing diversion dam facilities seep, and therefore, summer and fall base flows of less than about 1 cfs continue down the creek and these flows would be expected to continue down the creek under the WSIP via the new bypass facilities.

On a storm-by-storm basis, even when stream flows exceed 650 cfs, WSIP diversions would substantially reduce the flows and alter the hydrograph, leaving only brief periods of high flows in major storm events, as shown on Figures 5.4.1-5 and **5.4.1-11**. The graphs show that flows below 650 cfs (which make up several hours of the typical large storm) would be eliminated, and that flows above 650 cfs would be substantially reduced in all but the heaviest storms compared to existing conditions. Both duration and magnitude of flows in the creek downstream of the diversion dam would be substantially reduced during storm events such that, with the proposed program, flows from major storms would resemble those currently occurring during much smaller storm events, and smaller storms would not result in any flows at all.

Alameda Creek Below the Calaveras Creek Confluence

The total flow at the confluence of Alameda and Calaveras Creeks is the combination of total releases/spills from Calaveras Dam, flow spilled past the Alameda Creek Diversion Dam, and the unregulated runoff occurring between the confluence and the diversion dam and Calaveras Dam. However, because most of the flows from Arroyo Hondo and Calaveras Creek are retained in Calaveras Reservoir for water supply storage, the vast majority of Alameda Creek flows in this reach originate above the diversion dam (except when Calaveras spills or makes large releases). This is shown on **Figure 5.4.1-12**, which compares graphs of flows in Alameda Creek in an above-normal year, as gaged above the diversion dam, and below the Calaveras Creek confluence. The graphs indicate that, with the exception of one spike (which may be due to releases from Calaveras Reservoir or an erroneous gage reading), flows above the diversion dam were very similar to those measured just below the Calaveras confluence.

Table 5.4.1-8 presents modeled flow data for the Calaveras confluence in terms of the monthly average flow within year type. As shown in the table, there would be a substantial reduction (up

to 44 percent) in wintertime flow at the confluence during normal, above-normal and wet years. As with the upstream reach, peak flows would also be substantially reduced, primarily as a result of renewed upstream diversions. However, overall flows would be increased due to fishery releases.

Figure 5.4.1-13 illustrates the modeled chronological stream flows at the confluence for both the existing condition and with the WSIP. As shown in the figure, flow is low in many years under both existing and WSIP conditions, with rapid spikes in flow during and immediately following episodes of high rainfall. However, except in times of spills or winter releases from Calaveras Reservoir, winter and early spring flows in Alameda Creek at Calaveras Creek would be substantially reduced due to the reinstated large-scale diversions from Alameda Creek (described above). As shown in Figure 5.4.1-11, although the effects of reduced diversions would occasionally be damped by releases from Calaveras Reservoir, renewed diversions would continue to substantially reduce rainy season flows in Alameda Creek at and below its confluence with Calaveras Creek.

Under the WSIP, the SFPUC would augment flow below the confluence of Calaveras and Alameda Creeks by bypassing/releasing water from the Alameda Creek Diversion Dam and Calaveras Reservoir; as a result, there would be an increase in flow at the confluence in April to November of wet and above-normal rainfall years and in all instances of other years. The target flow rates in Alameda Creek are shown in **Table 5.4.1-9**. The proposed program includes facilities (as part of the Calaveras Dam project, SV-2) to provide the 1997 MOU-required releases. In addition, the SFPUC is developing alternative means of recapturing a portion of the water released downstream of the Sunol Valley WTP as part of the Alameda Creek Fishery project (SV-1).

Impact Conclusions

Implementation of the WSIP would increase diversions from Alameda Creek to Calaveras Reservoir, nearly eliminating the low and moderate (1 to 650 cfs) flows in Alameda Creek downstream of the diversion dam that currently occur when the diversion gates are closed, and substantially reducing many higher (greater than 650 cfs) flows. Under the WSIP, flows in Alameda Creek in the reach below the diversion dam to the Calaveras Creek confluence and in the reach below the confluence would be substantially reduced compared to the conditions in

Figure 5.4.1-13
Flow in Alameda Creek below the Calaveras Creek Confluence

existence since December 2001, when the DSOD imposed storage capacity restrictions on Calaveras Reservoir. This reduction of stream flows and alteration of the stream hydrograph is considered a substantial hydrologic effect and, as a result, this impact is *significant and unavoidable*. Measure 5.4.1-2, Diversion Tunnel Operation, requires the SFPUC to close the diversion dam and cease Alameda Creek diversions to Calaveras Reservoir as soon as possible each year, once the reservoir is at desired levels, such that the later-season storm flows not needed to refill Calaveras Reservoir are allowed to flow down Alameda Creek past the diversion dam to the lower reaches. Although this measure could help reduce the impact, it would not fully mitigate it; therefore, this impact would remain significant and unavoidable for the reaches of Alameda Creek below the diversion dam to its confluence with Calaveras Creek and below the confluence. However, after implementation of the WSIP, flow in this 2.85-mile reach of Alameda Creek would approximate conditions experienced between 1935 and 2001. In addition, in some years, flows in Alameda Creek below the diversion dam would be greater due to revised reservoir operations. The reestablishment of the diversions is necessary to achieve the SFPUC water supply objectives, and full mitigation could not be accomplished without foregoing the needed diversions.

This impact conclusion applies only to flow effects and not to the indirect impacts associated with these flow changes. Indirect effects are addressed in subsequent sections of this chapter; as discussed, these effects are either less than significant, or mitigation has been identified to reduce them to a less-than-significant level.

As a result of the 2001 DSOD restriction on Calaveras Reservoir, the SFPUC has had to reduce the volume of water stored in Calaveras and has therefore significantly reduced its diversions through the Alameda Creek Diversion Dam by closing the tunnel more frequently compared to its 70-year historic operation. Upon completion of the Calaveras Dam Replacement project (SV-2), the SFPUC would no longer have DSOD restrictions on storage levels in Calaveras Reservoir. Compared to historical operations with full storage capacity at Calaveras, the SFPUC plans to maintain Calaveras Reservoir at a higher elevation over longer periods of time, and as a result the Alameda Creek Diversion Tunnel would be closed more often than historically and there would be more occasions when water bypasses the diversion dam into Alameda Creek (see Appendix H2-2, Table 2.7-7). Therefore, in the reach below the confluence with Calaveras Creek, the increased dry-season releases that would occur under the WSIP in accordance with the 1997 MOU would be a beneficial effect.

Impact 5.4.1-3: Effects in San Antonio Reservoir and along San Antonio Creek.

The overall operation of San Antonio Reservoir with the WSIP would remain the same as under existing conditions. San Antonio Reservoir would continue to be operated to conserve local watershed runoff for integration into the SFPUC water supply and, when possible, would continue to store imported water from the Hetch Hetchy system to maximize carryover storage. As described below, the HH/LSM indicates small changes in reservoir releases; however, those changes are within the range of operator discretion, and actual operations may be closer to existing operations.

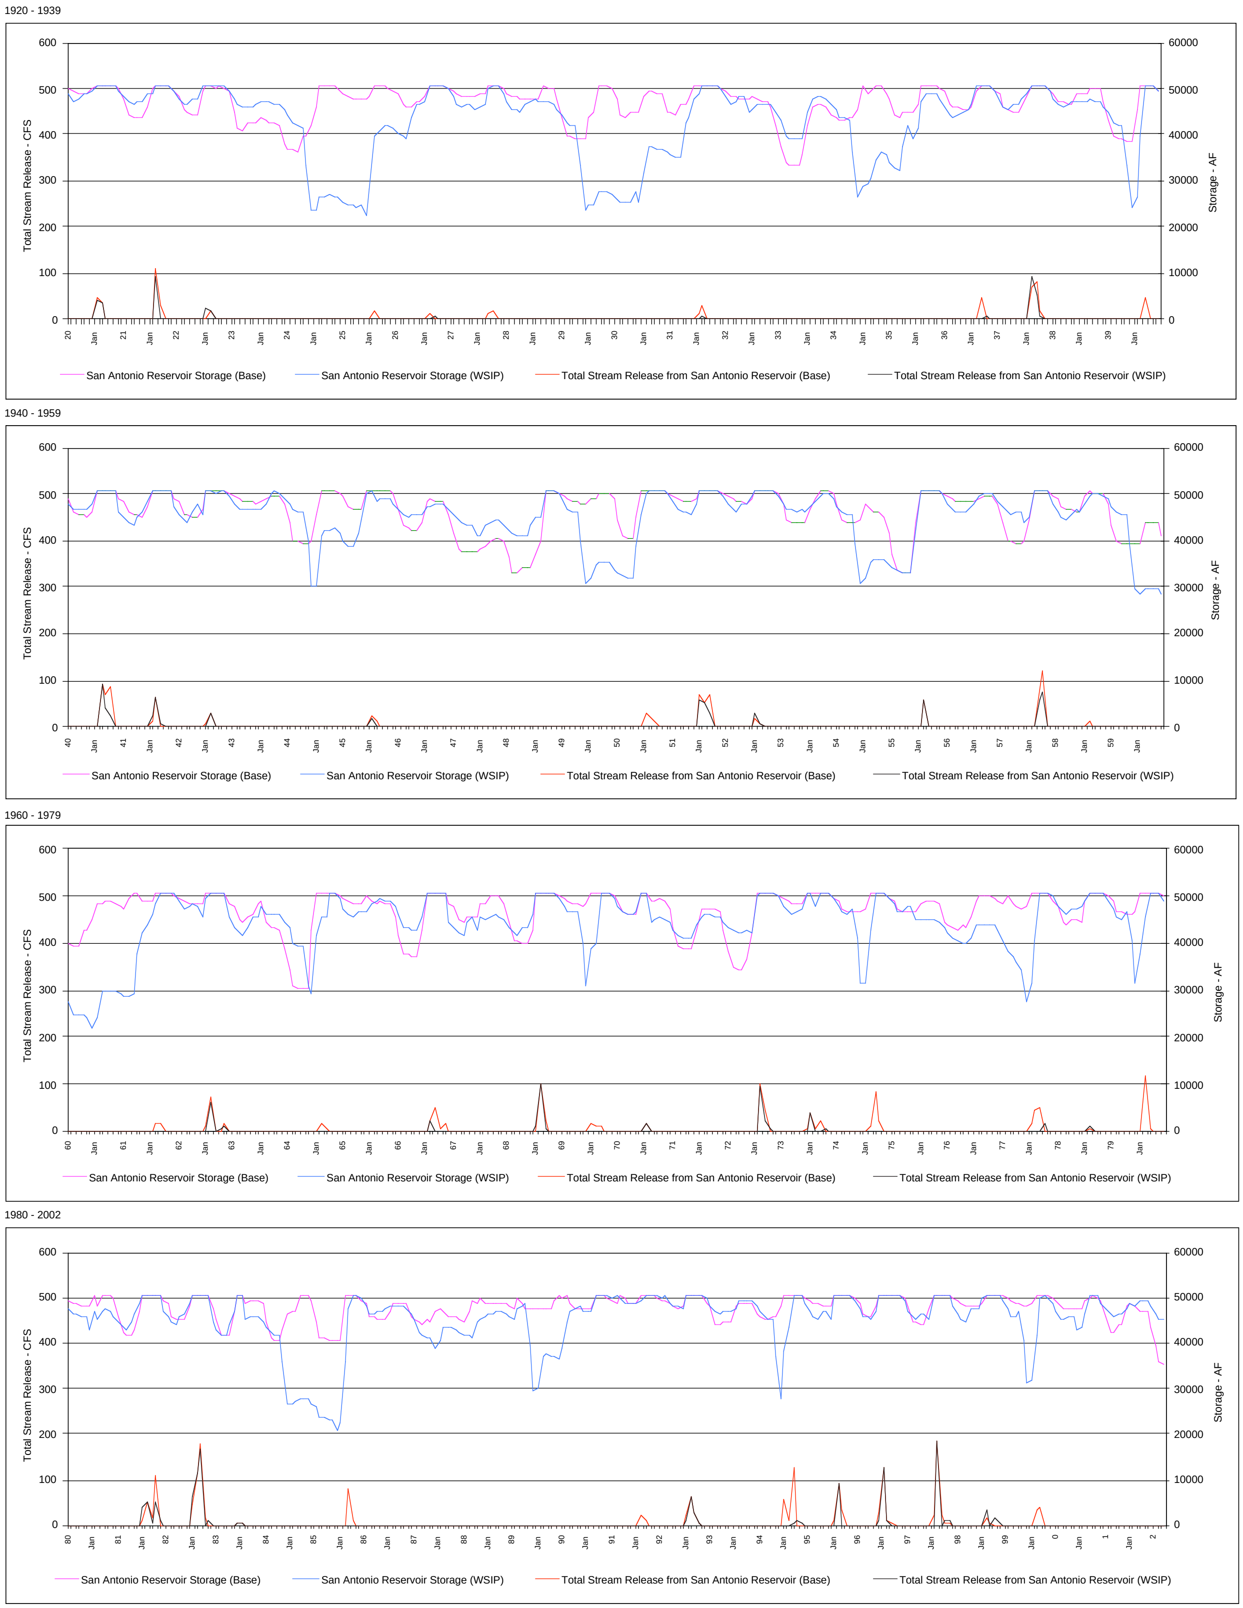
Figure 5.4.1-14 illustrates the modeled chronological operation of San Antonio Reservoir for both the existing condition and with the WSIP. The figure shows the reservoir's storage, inflow from the Hetch Hetchy system, and releases to San Antonio Creek for each condition.

WSIP operations involve keeping local reservoirs higher for delivery reliability and system maintenance purposes. This supply would be used to maintain the Sunol Valley WTP's minimum throughput of 20 mgd and to satisfy water demand in excess of Hetch Hetchy flows. Every fifth year storage levels would drop when planned maintenance for the Mountain Tunnel would reduce Hetch Hetchy flows to the Bay Area during the winter. During this period, San Antonio Reservoir would be drawn to replace the flows not provided from the Hetch Hetchy system. The reservoir would refill to typical operating levels within one to two years after the maintenance period.

The change in operation of San Antonio Reservoir storage would result in minor changes to other components of watershed hydrology. As described below, the increased storage in San Antonio Reservoir would affect the operation of diversions to the Sunol Valley WTP and imports from Hetch Hetchy. The increased storage capacity would also affect the release of spills from San Antonio Reservoir and subsequently the downstream flows in Alameda Creek.

As indicated in the table, the WSIP would have a minimal effect on flow in San Antonio Creek. The proposed program would result in minor increases and decreases in winter and spring flows in some above-normal years. Occasionally, the WSIP could result in spills to San Antonio Creek that would not occur under existing conditions.

Figure 5.4.1-15 illustrates the modeled chronological release of water below Turner Dam under the existing condition and with the WSIP. Releases from San Antonio Reservoir to San Antonio Creek have historically been rare and would continue to be rare with the WSIP. Releases past the dam are modeled to occur at about the same frequency with the WSIP—mostly in above-normal or wet years. It should be noted that under actual operations, these changes in modeled average monthly flows could take the form of a few days of larger releases.



Note: This figure is revised to reflect updated HH/LSM modeling (see Appendix O).

SFPUC Water System Improvement Program ▪ 203287

Figure 5.4.1-15
San Antonio Reservoir Releases to San Antonio Creek

Table 5.4.1-10 presents the modeled average monthly releases from San Antonio Reservoir under the existing condition and with the WSIP. The table also shows the difference in flow between the existing and WSIP conditions. Differences in releases could occur during the rainy season; the magnitude of the differences varies greatly compared to modeled existing flows, sometimes increasing and sometimes decreasing. Although the model predicts small releases in wet months, in reality the projected releases of less than an average monthly flow of 35 cfs (2,000 acre-feet) could likely be avoided through flexibility in actual day-to-day operations that cannot be represented by the HH/LSM (meaning that there would have been no flow released under those circumstances).

Impact Conclusions

Because the modeled flow changes in San Antonio Creek are within the current range and would be quite small, this impact would be *less than significant*, and no mitigation measures would be required.

Impact 5.4.1-4: Effects on flow along Alameda Creek below the confluence of San Antonio Creek.

The flow at the confluence of Alameda and San Antonio Creeks is a function of: (1) flows arriving at the confluence of Alameda and Calaveras Creeks, which are dependent on releases from Calaveras Dam, flow spilled past the Alameda Creek Diversion Dam, and the unregulated runoff occurring between the confluence and the diversion dam and Calaveras Dam, (2) unregulated runoff from the watershed between the two confluences, and (3) flow entering Alameda Creek from San Antonio Creek, which is regulated by releases from Turner Dam. In addition, the creek can seasonally either lose (dry season) or gain (rainy season) flows to and from the groundwater and nearby gravel pits. Depending on its design and location, the recapture facility to be constructed under the Alameda Creek Fishery project (SV-1) could also draw groundwater flows from the creek.

Figure 5.4.1-16 illustrates the modeled flow at the confluence during the various rainfall scenarios for the existing condition and with the WSIP. **Table 5.4.1-11** presents modeled flows at the confluence in terms of the average monthly flow within hydrologic year type. As shown in the figure and table, there would be a substantial (8 to 52 percent) reduction in flow volumes at the confluence during January, February, and March of normal or wetter years, depending on the rainfall distribution. The majority of this effect would occur due to the reduction in spills from Calaveras Reservoir and increased diversions from the Alameda Creek Diversion Dam during these periods. However, in April of normal years, the modeled data indicate a moderate increase in total flow volumes (about 14 percent), again due to the change in operation of Calaveras Reservoir, as described above.

Impact Conclusions

Flow in Alameda Creek below the confluence of San Antonio Creek would be altered as a result of the WSIP in winter months of normal or wetter years; however, the change in flows would be substantially dampened by inflows from other tributaries in the Sunol Valley and would not result in any adverse hydrologic effects. Therefore, impacts on Alameda Creek below the confluence of San Antonio Creek would be *less than significant*, and no mitigation measures would be required.

There would be no change in flows in most other months of normal or wetter years and in all months of drier years, because the fishery releases would be recaptured at a location upstream from the confluence of Alameda and San Antonio Creeks.

[Additional discussion on flow in lower Alameda Creek was prepared in response to comments on the Draft PEIR. Please refer to Section 14.9, Master Response on Alameda Creek Fishery Issues (Vol. 7, Chapter 14) and to Appendix N, Technical Memorandum—Estimation of Flow Changes in Lower Alameda Creek with Implementation of the WSIP (Vol. 8).]

5.4.2 Geomorphology

The following setting section describes the geomorphology of the streams in the Alameda Creek watershed that could be affected by the WSIP. The impact section (Section 5.4.2.2) provides a description of the changes in stream channel form and erosion that would result from WSIP-induced changes in stream flow, as described in Section 5.4.1.

5.4.2.1 Setting

Geomorphology and Sediment Transport

The SFPUC's Alameda watershed upstream of Niles Canyon is comprised of two general landform (geomorphic) regions: the "canyon areas" above the Sunol Valley WTP, and the Sunol Valley. The geomorphology of the canyon areas can be further divided into reservoirs and stream channels. The fluvial geomorphologic conditions[1] of each of these areas are summarized below.

The Sunol Valley has lower gradients than the canyon reaches, and the channel bed and banks are primarily comprised of sediments. There are several grade controls (where erosion is restricted by a solid feature such as a bedrock outcrop, weir, or dam) in the Sunol Valley and downstream; two of these, Sunol and Niles Dams, were recently lowered by the SFPUC to calculated pre-dam streambed elevations. A bedrock outcrop about 1,000 feet below the Sunol Dam site also controls channel morphology and stream downcutting (Weiss Associates, 2004).

An average of approximately 270,000 tons (160,000 cubic yards) of sediment is transported by Alameda Creek annually. At the Sunol dam site, these sediments are about one-quarter to one-third sand and two-thirds to three-quarters gravel. These sediments are transported by high flows in the creek; for example, it has been estimated that the 3.5-year flow in Alameda Creek at the Sunol Dam site (approximately 7,000 cfs) transports a volume of sediment equal to about 25 percent of the average annual sediment load in the creek (Weiss Associates, 2004). Sediment transport curves developed by Weiss Associates for Alameda Creek near Niles indicate minimal sediment transport with flows of less than 20 cfs, and an increase from 10 to 1,000 tons/day when stream flows increase from 100 to 1,000 cfs. At 2,000 cfs, sediment loads approach 10,000 tons/day. At Niles Canyon, there is virtually no bedload transport[2] with flows under 1,000 cfs, and 2,500 to 6,000 tons/day with flows of 10,000 cfs (Weiss Associates, 2004).

The ACFCWCD removes about 300,000 cubic yards of sediments from their flood control channel downstream of Niles Canyon every 10 years; this constitutes about 19 percent of the total creek sediment load. The remaining sediments deposit in parts of the flood control channel that are not subject to maintenance and/or are eventually transported to San Francisco Bay (Weiss Associates, 2004). It should be noted that these are long-term averages, and annual sediment loads could vary widely depending on runoff events and watershed conditions.

---

1 The term "fluvial geomorphologic conditions" refers to changes in the shape of the stream channels and associated erosional and depositional features (e.g., canyons, streambeds, stream banks, floodplains), and the hydrologic and geologic processes and conditions contributing to or affecting those changes.

2 Bedload refers to the amount of sediment, cobbles, gravel, and rocks transported along the stream bottom (as opposed to suspended in the stream flow).

Much of this sediment is generated in the Vallecitos, Arroyo Mocho, Arroyo Valle, and Arroyo de la Laguna watersheds, outside of the SFPUC watersheds. These watersheds include large alluvial valleys, where erosion due to natural channel meandering as well as land management practices can generate substantial sediment volumes. Although substantial sediment generation can occur from the steep slopes in the upper watersheds (upstream of Calaveras and San Antonio Dams), much of this sediment is trapped behind these dams.

The stream channel portions of the canyon areas include stretches of bedrock channels interspersed with lower gradient areas, such as the Calaveras Valley, where the channel bottom and sides are comprised primarily of sediments. Substantial quantities of sediment have accumulated in Calaveras and San Antonio Reservoirs. In the upstream reach of Alameda Creek, the SFPUC discharges approximately 900 cubic yards per year of sediment accumulated behind the Alameda Creek Diversion Dam via 50-cfs flow releases through the sluice gates. This indicates that, in the narrower, steeper reaches of the creek, smaller flows are adequate to transport accumulated suspended sediments. Such smaller flows may also affect the local geomorphic conditions of the small alluvial flats, banks, and terraces adjacent to the stream channels above Sunol Valley.

5.4.2.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to geomorphology, but generally considers that implementation of the proposed program would have a significant impact if it were to:

- Substantially change the topography such that ecological, hydrologic, or aesthetic functions are adversely affected, or substantially change any unique geologic or physical features of the site or area
- Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation or adversely affect the ecological, hydrologic, or aesthetic functions of the site or area

Although the “substantial change in topography” criterion is typically applied to upland areas, it is considered applicable to stream channel/bank topography in this instance because of the sensitivity of the resources that depend on the topography of those features (i.e., riparian vegetation and fisheries). For a stream channel, the relevant aspect of topography to be evaluated are those associated with channel form and the related movement and distribution of sediment.

Approach to Analysis

This impact section discusses projected changes in sediment transport and geomorphology, reservoir storage, and related reservoir water levels resulting from WSIP implementation. In addition to potential direct impacts, these sediment transport changes could cause indirect environmental impacts in areas for which the CEQA Guidelines Appendix G identifies significance criteria, including flooding potential, erosion, water quality, fisheries, aquatic and riparian resources and related special-status species, and recreation and visual resources. These potential impacts are addressed in the respective sections of this PEIR.

This assessment of potential effects is based on generalized channel bed/bank characteristics and consideration of proposed changes in stream flow that would result from the WSIP.

Impact Summary

Table 5.4.2-1 presents a summary of the impacts on sediment transport and geomorphology in the Alameda Creek watershed that could result from implementation of the proposed water supply and system operations.

TABLE 5.4.2-1
SUMMARY OF IMPACTS – GEOMORPHOLOGY OF THE ALAMEDA CREEK WATERSHED

Impact	Significance Determination
Impact 5.4.2-1: Effects on channel formation and sediment transport along Calaveras Creek	LS
Impact 5.4.2-2: Effects on channel formation and sediment transport along Alameda Creek downstream of the diversion dam and downstream of the San Antonio Creek confluence.	LS
Impact 5.4.2-3: Effects on channel formation and sediment transport along San Antonio Creek downstream of San Antonio Reservoir	LS

LS = Less than Significant impact, no mitigation required

Impact 5.4.2-1: Effects on channel formation and sediment transport along Calaveras Creek.

There are currently no uncontrolled releases (spills) from Calaveras Reservoir. With the WSIP, uncontrolled releases would occur during heavy rains, particularly later in the rainfall season when the reservoir is full. Therefore, the WSIP could result in increased erosion, sediment transport, and deposition downstream of Calaveras Dam during heavy rainfall events compared to existing conditions. However, these higher flows, and therefore sediment transport, are similar to the long-term conditions that formed the current channel. Therefore, impacts on channel formation and sediment transport along Calaveras Creek would be *less than significant*, and no mitigation measures would be required.

Impact 5.4.2-2: Effects on channel formation and sediment transport along Alameda Creek downstream of the diversion dam and downstream of the San Antonio Creek confluence.

Increased use of the diversion tunnel under the WSIP would reduce peak flows in Alameda Creek downstream of the diversion dam by up to 650 cfs compared to existing conditions; lesser flows (under 500 to 600 cfs) would also be diverted, which could reduce erosion, sediment transport, and deposition in the channel reach downstream of the diversion dam. However, substantial quantities of sediments would still be transported down the creek by high flows (over 650 cfs) during heavy rains. The annual sluicing of sediments accumulated behind the diversion dam would continue with the WSIP. Therefore, this impact would be *less than significant*, and no mitigation measures would be required.

Implementation of the WSIP would reduce flow in Alameda Creek downstream of the San Antonio Creek confluence in winter months of normal to wet years, ranging from a -18 percent decrease to a +13 percent increase in flow at the USGS Niles gage station. In the majority of winter months (December to March), flows at this location would decrease, but in April and May the flows would exhibit small to moderate increases. Although implementation of the WSIP would result in additional flow in Alameda Creek in summer months as part of the 1997 CDFG MOU releases, these additional flows would not mobilize significant amounts of sediment and could be recaptured at a location downstream of the Sunol Valley WTP. This net decrease in flow in Alameda Creek below the San Antonio Creek confluence when compared to the existing condition would likely result in a slight decrease in the amount of sediment transported in Niles Canyon and lower Alameda Creek and would therefore decrease sediment and debris loading on lower Alameda Creek facilities.

As noted in Impacts 5.4.2-1 and 5.4.2-3, flows and the resulting impacts on geomorphology upstream of the San Antonio Creek confluence are expected to be within the range of conditions that have been experienced since development of water supply and flood control facilities in the upper and lower Alameda Creek watershed. Therefore, implementation of the WSIP would not significantly alter bed or channel form or introduce substantial new sources of sediment.

As a result of this net decrease in sediment transport in Niles Canyon and the less-than-significant impacts in upper Alameda Creek, the impact related to geomorphologic characteristics and sediment transport along Alameda Creek downstream of the San Antonio Creek confluence would be *less than significant*. It should also be noted that the Arroyo de la Laguna watershed is the major contributor to sediment supply in Niles Canyon and lower Alameda Creek.

[Additional discussion on geomorphology in Alameda Creek downstream of the diversion dam was prepared in response to comments on the Draft PEIR. Please refer to Section 15.2, response to the letter from the Regional Water Quality Control Board, San Francisco Bay Region, (Vol. 7, Chapter 15).]

Impact 5.4.2-3: Effects on channel formation and sediment transport along San Antonio Creek downstream of San Antonio Reservoir.

Current spills from San Antonio Reservoir are minimal and would continue to be minimal. Therefore, impacts on fluvial geomorphologic characteristics would be *less than significant*, and no mitigation measures would be required.

5.4.3 Surface Water Quality

The following setting section describes surface water quality in streams and reservoirs in the Alameda Creek watershed that could be affected by the WSIP. The impact section (Section 5.4.3.2) provides a description of the changes in water quality in streams and reservoirs that would result from WSIP-induced changes in stream flow and reservoir water levels.

5.4.3.1 Setting

Calaveras Reservoir

Calaveras Reservoir collects and stores water from the local watershed; this water is subsequently treated at the Sunol Valley WTP and distributed for municipal use. Reservoir inflow is dominated by winter rainfall events. Because the reservoir stores local runoff only, water quality is fairly consistent. However, the reservoir stratifies during the warm months, which leads to changes in water quality depending on the time of year and depth within the reservoir. When the reservoir stratifies during the late summer and fall, the bottom, lower layer (the "hypolimnion") is aerated to increase oxygen levels, thereby reducing the concentrations of dissolved iron, manganese, and hydrogen sulfide in the raw water (Weiss Associates, 2003).

Calaveras Reservoir exhibits characteristics typical of "mesotrophic"[1] waters, which include the following:

- Moderate nutrient levels and microbiological activity
- Oxygen concentrations that may vary considerably
- Variable light penetration
- Shallow to deep lake with sloping sides
- Potentially fertile soils, heavily vegetated and/or disturbed watershed (SFPUC, 2002)

The biggest water quality concerns in the reservoir are turbidity and algae control. Algal blooms can result in consumer complaints regarding odor and taste and can also limit production at the Sunol Valley WTP due to increases in filter head loss. Several algal blooms have caused the reservoir to be temporarily removed from production, and an algae bloom in October 2003 was treated with copper sulfate. The reservoir is sampled every two weeks for basic water quality parameters; algal growth is usually indicated by increasing surface dissolved oxygen (DO) levels and a rise in pH, with June and October generally being the months of greatest concern. Problems with algal growth often resolve themselves as zooplankton feed on the algae; however, zooplankton may not be completely effective in controlling blue-green algae (SFPUC, 2002). The growth of blue green algae is occasionally managed with low doses of copper sulfate, which is the only herbicide used in the reservoir. Treatment with copper sulfate can reduce DO levels associated with the decay of dead algae (SFPUC, 2002).

Reservoir water temperature is considered a key water quality parameter with respect to aquatic life. Calaveras Reservoir water temperatures are typically isothermal[2] during December through

1 The ratio of watershed to surface area is 60:1, which places the lake in the "potentially mesotrophic" group.

February, which indicates complete mixing of the reservoir. From March through November, the reservoir typically stratifies, with the most intense period between June and October; during this time, the thermocline[3] is 20 to 40 feet below the water surface, with water temperatures reaching 24 to 26 degrees Celsius (°C) in the upper level of the water (the "epilimnion"), and 10 to 14 °C in the hypolimnion (Weiss Associates, 2003).[4]

Figure 5.4.3-1 presents water temperature profiles for Calaveras Reservoir during 1998. These data were collected before the DSOD limited the operational capacity of the reservoir due to seismic concerns, and thus represent a "full" reservoir.

Figure 5.4.3-1
Temperature Profiles for Calaveras Reservoir, 1998

Water quality conditions in the reservoir are shown in **Table 5.4.3-1**. When Calaveras Reservoir is isothermal, DO concentrations are near saturation; however, when the reservoir stratifies, DO concentrations in the hypolimnion historically dropped to less than 1 mg/L while remaining near saturation in the epilimnion. The values for pH ranged from 6.6 to 8.3, and turbidity remained below 5 nephelometric turbidity units (NTU) throughout most of the year. The SFPUC commissioned a feasibility study to select a technology for effectively maintaining the DO concentration within the hypolimnion at levels protective of water quality (DO > 2 mg/L) and fish habitat (DO > 5 mg/L) (Merritt-Smith Consultants, 2003). The technology selected was an "unconfined small bubble soaker hose diffuser" consisting of approximately 1,000 feet of diffuser operated from a liquid oxygen supply based on the lake shoreline. The oxygen is distributed along the full length of the line deep within the reservoir during operation, thus spreading the oxygen

2 Refers to constant temperature in the water column; this conditions is present when the reservoir is not stratified, typically during the winter months.
3 The boundary between the warmer surface waters and cooler waters below.
4 To convert Fahrenheit to Celsius (Centigrade), subtract 32 and divide by 1.8. To convert Celsius (Centigrade) to Fahrenheit, multiply by 1.8 and add 32.

TABLE 5.4.3-1
SUMMARY OF WATER QUALITY IN CALAVERAS RESERVOIR

Parameter	Value	Status
Nitrate – winter average (mg/L)	0.13	Mesotrophic[c] to Eutrophic[d]
Orthophosphate – winter average (mg/L)	0.018	Mesotrophic
Total Phosphorus – winter average (mg/L)	0.06	Mesotrophic to Eutrophic
Secchi Depth[a] – growth season average (feet)	22.2	
Secchi Depth – growth season minimum (feet)	13.0	Mesotrophic
Chlorophyll *a* – annual average (µg/L)	4	Eutrophic
Chlorophyll *a* – annual peak (µg/L)	18	Eutrophic
Anoxia[b] presence	None	Eutrophic
Anoxia duration (days)	0	Mesotrophic to Eutrophic
Anoxic extent (acre-feet)	0	Eutrophic

µg/L = micrograms per liter; mg/L = milligrams per liter

a Secchi depth is a parameter used to determine the clarity of surface waters. High secchi depth readings indicate clearer water that allows sunlight to penetrate deeper.
b Anoxia generally refers to low-oxygen conditions in the hypolimnion.
c A body of water that has a moderate amount of dissolved nutrients.
d A body of water that is rich in dissolved nutrients (as phosphates) that stimulate the growth of aquatic plant life, resulting in the depletion of dissolved oxygen.

over a large area to achieve high oxygen transfer efficiencies and reduce oxygen expenditures. The oxygenation system has been implemented in Calaveras Reservoir and maintains DO values in the hypolimnion at between 2 and 5 mg/L (Merritt-Smith Consultants, 2003).

Calaveras Reservoir under low storage conditions remains sufficiently deep (approximately 80 to 90 feet) to experience persistent seasonal thermal stratification. The reservoir becomes strongly stratified by late June and generally develops a thermocline at approximately 30 feet of depth, with the hypolimnion occupying the bottom 40 or so feet of the reservoir profile. The historical depth to the thermocline was similar, but the reservoir maintained a notably deeper hypolimnion.

San Antonio Reservoir
