Traffic and Circulation

As recognized by the Department in the WSIP DEIR, the Bay Division Pipeline Reliability Upgrade Project is located in an urbanized area making the "open-cut trench" method of construction likely to result in significant impacts on traffic operations.[1] The WSIP DEIR traffic analysis appropriately considers the impact to regional transportation. Equally significant, however, are the localized traffic and circulation issues. At Menlo Business Park, Project construction activities may disrupt or block access to driveways and streets, and access to buildings. MBP is concerned about the Project-impacts on Menlo Business Park facilities and operations, and on the operations of MBP tenants. Many MBP tenants have regular shipments of equipment, supplies, hazardous materials and products from their buildings and require continuous access to their properties. MBP is also concerned that the construction activities could interfere with the ability of emergency response providers (e.g., police, fire and ambulance) to access the MBP facilities. As noted above, some MBP tenants use or handle hazardous materials in their operations and it is important that emergency response providers are able to access each of the buildings in the event of fire or other emergency. Finally, MBP is concerned about potential safety hazards if employees or customers need to walk through a construction work area or from remote off-site parking areas. 04

WSIP DEIR Mitigation Measure 4.8-1a states that SFPUC construction contractors will prepare a traffic control plan to "minimize traffic and on-street parking impacts on any streets affected by construction of the proposed program."[2] Measure 4.8-1a goes on to state that elements of this plan *could* include using steel trench plates to maintain access to driveways and private roads.[3] While MBP supports the development of traffic control plans to reduce potential Project impacts, it is unable to assess the effectiveness of the mitigation measure without more specific discussion of the particular plan elements and/or without appropriate performance standards. We ask that the Draft EIR for the Bay Division Pipeline Reliability Upgrade Project include traffic analyses and mitigation to assure continuous access to 05

private properties when construction crews are not actively constructing the underground pipeline.[4] We understand that this level of analysis may be more appropriately addressed in the project-level EIR and we want to ensure that this analysis will in fact take place. 05 cont.

Parking

In addition to restricting ingress and egress to Menlo Business Park, the Project activities may affect tenant access to parking at Menlo Business Park. Multiple MBP tenants currently utilize parking facilities located in the CCSF easement area. Excavating this area is likely to reduce temporarily the number of parking spots at Menlo Business Park, and cause MBP tenants and patrons to park in adjacent or nearby parking facilities (if available) or on surrounding streets. The Project activities may also disrupt customer patronage to tenant businesses and could present a safety hazard to pedestrians. The parking analysis in the WSIP DEIR focuses primarily on the impacts to public parking on city streets and does not address impaired parking on-site, and the direct and indirect impacts of the on-site parking dislocation. 06

It is not clear from the Project NOP if this impact will be addressed in the Project DEIR. Because parking lots could be effectively blocked during construction and portions may be temporarily unusable, the Project DEIR should assess these impacts and include mitigation, including coordination with MBP and individual business owners. Through such advance planning and related construction scheduling, it may be possible to reduce or avoid many potential adverse impacts. For example, it may be possible to develop and implement shared-parking arrangements among the impacted businesses or to otherwise make arrangements for alternative parking within a reasonable safe walking distance, or to coordinate the construction schedule so as to prevent disrupting the businesses operations. 07

Property Condition

The WSIP DEIR also does not specifically address the logistics of post-construction restoration work. The SFPUC Standard Construction Measures specifies that "upon project completion, the construction contractor will return the SFPUC project site to its general condition before construction, including re-grading of the site and re-vegetation of disturbed areas." [5] The timeline on this site restoration work is unclear. It is our hope that the trench will be backfilled and graded so that it can be re-paved and back in use by the tenants as soon as possible. 08

[4] Similar language was included in the EIR prepared by the California Public Utilities Commission for Pacific Gas & Electric Company's Jefferson-Martin Transmission Project: "At all times shall provide the ability to quickly lay a temporary steel plate trench bridge upon requires to ensure driveway access to business and residences and shall provide continuous access to properties when not actively construction the underground cable alignment. If trench stability could be compromised by this, the construction contractor may defer a request for access to the soonest possible time until the stability of the trench has been assured, provided 48 hrs of notice given to property owner." (PG&E Jefferson-Martin 230 kV Transmission Project Final EIR, Mitigation Measure L-7a (p. D.2-35)).

Re: Draft Program Environmental Impact Report, WSIP

Dear Mr. Malzer,

I am the chairman of the Steelhead Committee of the Northern California/Nevada Council of the Federation of Fly Fishers (NCCFFF). The NCCFFF is dedicated to the sport of fly fishing and fish conservation. We have approximately 900 regular members with about 6,000 members in affiliated clubs. I request that you include my written comments for the record on behalf of the NCCFFF Steelhead Committee.

Tuolumne River Flows

At a time when salmonid populations in the lower Tuolumne River are at near all time lows because of reduced flows, the WSIP proposes to divert an additional 25 million gallons per day. This means 25 mgd not reaching Don Pedro Reservoir and 25 mgd not available for release to support the already stressed salmon and steelhead populations in the lower Tuolumne.

Fall run Chinook salmon were historically documented to annually exceed 72,000 spawning adults. The 2006 estimate for returning adult Chinook salmon was 625. In the last 50 years, numbers have fluctuated between 45,000 to fewer than 100 individuals, with a steady downward trend. Biologists from California Department of Fish and Game, National Marine Fisheries, and U.S. Fish and Wildlife agree that the numbers of returning adult salmon is strongly correlated to flow volumes in the Tuolumne below the La Grange Dam.

The relationship between flow and fish is clearly stated in a recent letter from Steven A. Edmondson of the National Marine Fisheries Service to the Federal Energy Regulatory Commission regarding the Don Pedro Dam on the Tuolumne River: 01

> *"To date, studies conducted in the Tuolumne River (and in other Central Valley rivers) indicate that as spring flow magnitude and duration increases, the following responses occur: 1) salmon smolt survival increases; 2) water temperature decreases; 3) predation of salmonids decreases; 4) entrainment of salmonids decreases; 5) disease prevalence in salmonids decreases; and 6) both juvenile and adult salmon abundance increases. In addition, emerging science indicates that winter flow magnitude and duration, in addition to spring flow magnitude and duration, is important in determining smolt abundance, which is the primary life history stage influencing adult salmon escapement."*

The Tuolumne River historically supported large runs of sea-run steelhead trout (*O. mykiss*), now listed as threatened under the Federal Endangered Species Act. Present sightings of adult steelhead in the Tuolumne are few and far between. As with the depleted salmon runs, the consensus among agency biologists is that the depressed numbers of steelhead are due to low flows, especially in the summer months. In fact, agency biologists have concluded that existing summer flow regimes in the lower Tuolomne are inadequate for a viable steelhead population.

The DPEIR lists the impact of reduced flows in the lower Tuolumne as *potentially significant*. It goes on to state that the impact may be reduced to *less-than-significant* if SFPUC can reach agreement with the Don Pedro irrigation districts. If agreement with the districts cannot be reached, the DPEIR calls for implementing a Fisheries Habitat Enhancement plan, which supposedly would reduce the negative impact to *less-than-significant* through habitat improvement. As a result of these assumptions, *Table 5.3.6-4 Summary Of Impacts* in the DPEIR includes: "*Impact 5.3.6-4: Effects on fishery resources along the Tuolumne River below La Grange Dam – PSM* [Potentially Significant impact, can be mitigated to less than significant]." 01 cont.

The DPEIR seriously errs in this *PSM* designation. Even if SFPUC can reach an agreement with the irrigation districts, there will still be reduced flows in the lower Tuolumne. The only difference being the deficits will be charged to the irrigation districts rather than SFPUC. As to Fisheries Habitat Enhancement plan, the consensus among agency biologists is that habitat improvement will not be effective without improved river flows.

Three criteria for determining what constitutes a *significant fisheries impact* are presented on page 5.3.6-24 in the DPEIR. Considering the overwhelming scientific evidence which demonstrates the detrimental effects of reduced flows on steelhead and salmon populations, the WSIP for the lower Tuolumne meets all three criteria and therefore should be designated as having a ***significant fisheries impact.*** The DPEIR should be changed to reflect this.

San Joaquin River and the Sacramento–San Joaquin Delta

Just as the WSIP would reduce flows in the Tuolumne River between La Grange Dam and its confluence with the San Joaquin River, it would do the same in the San Joaquin River from the confluence to the Delta. The same adverse impacts of low flow on salmonid populations apply here. The DPEIR again errs when it assigns a *LS* [Less than Significant impact, no mitigation required] designation for this reach of the San Joaquin River. Clearly, the reduced flows and concomitant increase in temperature will adversely affect the movement and survival of salmonid populations. 02

There is no doubt that the Sacramento/San Joaquin Delta ecosystem is on the brink of collapse, and scientists agree that increased diversions and increased exports of Delta water are the principal causes of this decline. Implementation of the WSIP would result in 25 mgd less water reaching the Delta. This is a negative impact not addressed in the DPEIR.

Alameda Creek

A number of fish passage barriers on Alameda Creek have prevented adult steelhead from returning to their spawning grounds in the Alameda Creek watershed. The lowest of these barriers (the BART Weir) effectively blocks passage to any suitable steelhead habitat. 03

It now appears that all of the fish passage barriers will be removed by 2010 and steelhead will again have access to the sea and their spawning habitat. The SFPUC, ACWD and ACFCD are to be commended for their efforts to remove these barriers and reestablish steelhead in the Alameda Creek watershed.

The augmented flow schedule below the confluence of Alameda and Calaveras Creeks (Table 5.4.1-9) should be modified to extend the 20 cfs flows through May 15. Such a change will ensure *O. mykiss* spawning and migration success during late spring. This schedule may be modified when the Fisheries Restoration Workgroup flow studies are completed and comprehensive flow strategy is worked out. 03 cont.

The SFPUC is to be commended for its plans to implement a minimum flow plan for Alameda Creek below the diversion dam. When completed, the plan should be made available for public comment.

In Summary

The WSIP calls for diverting an additional 25 mgd from the Tuolumne River to help meet projected increases in demand through 2030. There is no doubt that such diversions will severely impact the already stressed steelhead and salmon populations of the Tuolumne and San Joaquin Rivers. While SFPUC is obliged to provide a safe and reliable water supply to citizens of San Francisco, it can do so without harming Tuolumne steelhead and salmon.

The WSIP and DPEIR do not adequately address strategies and conservation measures that could replace the 25 mgd diversions from the Tuolumne River. Some strategies and conservation measures include: water options and price incentives for wholesale customers to reduce their demand; incentives to reduce outdoor water use; and more stringent conservation requirements for wholesale customers. 04

Thank you for consideration of these comments.

Sincerely,

Dougald Scott

October 1, 2007

Paul Maltzer
Environmental Review Officer, WSIP PEIR
1650 Mission St., Suite 400
San Francisco, CA 94103

Dear Mr. Maltzer,

I serve as President of the Pacific Institute, an independent research institute in Oakland, California. I am writing with selective comments on the San Francisco Public Utility Commission's Draft Program Environmental Impact Report (PEIR) for the Water System Improvement Program (WSIP). We appreciate your careful consideration of the PEIR.

12.4-53

The SFPUC undertook a WSIP to increase the reliability of the regional water system through improvements with respect to water quality and supply, seismic response, and water delivery. We commend the San Francisco Public Utility Commission (SFPUC) for its efforts to improve seismic and delivery reliability, particularly given the region's vulnerability to earthquakes and other natural hazards. However, we question the SFPUC's assertion that "Additional supplies are needed to satisfy current demand in drought years as well as to meet future demand." Our analysis suggests this fundamental assumption may be incorrect. 01

In August 2006, the Pacific Institute conducted an independent review of the SFPUC's demand projections for its wholesale and retail customers. Our report concluded that significant untapped potential exists for reducing water use while providing for population growth and economic development, and that the water planning documents and efforts in the region underestimate this potential. The potential for recycled water to offset potable supplies is also underestimated. More specifically, we found the following: 02

654 13th Street, Preservation Park, Oakland, California 94612, U.S.A.
510-251-1600 | fax: 510-251-2203 | email: staff@pacinst.org | www.pacinst.org

- Per-capita demand for the wholesale customers is projected to increase over current (2001) per-capita demand, despite numerous studies that show that substantial cost-effective reductions in per-capita demand are possible with available technologies and policies. 03
- The analysis of SFPUC retail and wholesale demand does not include price-driven efficiency improvements, despite an estimated quadrupling of the price of water from the SFPUC by 2015. 04
- Increases in residential demand are largely due to outdoor water use. For the wholesale and retail customers, per-capita outdoor use is projected to increase, indicating that the proposed conservation does not adequately address this use. 05
- The non-residential sector is responsible for over 80 percent of the projected 2030 demand increase. About 35 percent of that increase is due to outdoor use. 06
- Future demand for the wholesale customers is not adequately evaluated. The forecasting method has two important errors that can lead to potentially large inaccuracies when forecasting demand: it assumes that the current composition of commercial and industrial businesses within the non-residential sector will not change over time, and it ignores the variability in water use in both quantity and purpose among users in the non-residential sector. 07
- The wholesale demand study may overestimate future employment, thereby inflating 2030 non-residential demand. Recent data indicates that economic growth in the San Francisco Bay Area has been slower than expected, and consequently, the job outlook for the region has been adjusted downward. A slower economic growth rate reduces projected water demand for the non-residential sector and suggests that the demand forecast should be adjusted according to the most current information available. 08
- For the wholesale and retail customers combined, the conservation activities proposed in the PEIR reduces 2030 demand by only four percent. Recent water conservation assessments indicate that the conservation potential identified in this demand analysis is too low. For example, SFPUC wholesale customers often fail to implement well-understood efficiency improvements and thereby fail to achieve water-use reductions achieved by utilities elsewhere. 09

- The potential to expand recycling and reuse of water to meet future demand appears to have been significantly underestimated. These options would further reduce the need to identify new supply sources, such as additional withdrawals from the Tuolumne River. 10

We include a copy of this report for your review. Below we provide recommendations for both improving the modeling and assessment efforts and capturing additional conservation and efficiency savings. 11

Recommendations: Modeling and Assessment Efforts

1. Non-residential demand is an important driver for future demand increases, and as a result, an adequate assessment of future demand and conservation potential is critical. The SFPUC should re-evaluate non-residential demand projections for its wholesale customers using industry-specific economic growth projections, water use, and conservation potential. Initial efforts should be regional in scope or focus on those agencies with high non-residential water use. If the projections from the new analysis differ substantially from those of the Demand Side Management Least-Cost Planning Decision Support System model, detailed analyses should be conducted for each of the wholesale customers. 12

2. As the price of water increases, demand decreases, particularly for non-residential and outdoor uses. Because the SFPUC expects to quadruple the price of water by 2015, the effects of projected water price increases should be integrated into the demand projections. Failing to do so may result in an overestimate of future demand and revenue shortfalls. 13

3. Estimates of the maximum, cost-effective conservation potential should be determined for each measure, major end use, and district or wholesale/retail user. The definition of "cost-effective" must be broadened beyond the utility perspective and should include benefits to consumers and quantification of the value of maintaining ecosystem flows in the Tuolumne River. 14

4. Better data are needed on the type of non-residential account and the water use associated with that account. The SFPUC and its wholesale customers must also standardize reporting methods. A focus on outdoor water use is especially needed. 15

5. Modeling efforts should include multiple scenarios so as to determine a range of future demand. 16

6. A better assessment of the potential for using recycled water for different end uses is needed. 17

7. Future studies should include the impact of climate change on projected demand and supply. 18

Recommendations: Conservation Implementation

1. Each agency should assess what is driving demand growth and measures to reduce that demand. Agencies must take a more pro-active role in identifying ways to reduce demand growth, particularly in new developments. 19

2. The SFPUC and its wholesale customers should implement water and wastewater rate structures that encourage water conservation among their customers and fund conservation programs. 20

3. All agencies should sign the California Urban Water Conservation Council Memorandum of Understanding and work to meet all applicable Best Management Practices. 21

4. SFPUC and the Bay Area Water Supply and Conservation Agency (BAWSCA) should work together to establish more effective regional water conservation and recycling programs. 22

5. Institutional mechanisms should be developed to encourage wholesale customers to move more effectively toward efficiency improvements. This can include cross-agency information sharing, consistent conservation programs and targets, economic incentives for demand reductions, conservation pricing for wholesale customers, regular reassessment of program effectiveness and implementation, and improvements in conservation data collection and reporting. 23

6. Serious consideration should be given to capping purchases from the SFPUC at current levels. BAWSCA and the SFPUC should institute financial incentives to encourage conservation efforts and financial disincentives to discourage demand growth. For example, water marketing among the wholesale agencies would allow water saved through conservation efforts by one agency to be sold to another agency, thereby promoting economic efficiency. 24

Thank you again for the opportunity to comment on the Draft PEIR.

Sincerely,

Dr. Peter H. Gleick

About the Pacific Institute

Founded in 1987 and based in Oakland, California, the Pacific Institute for Studies in Development, Environment, and Security is an independent, nonprofit organization that provides research and policy analysis on issues at the intersection of sustainable development, environmental protection, and international security.

The Pacific Institute strives to improve policy through solid research and consistent dialogue with policymakers and action-oriented groups, both domestic and international. By bringing knowledge to power, we hope to protect our natural world, encourage sustainable development, and improve global security. This report comes out of the Institute's Water and Sustainability Program.

More information about the Institute, staff, directors, funders, and programs can be found at www.pacinst.org and www.worldwater.org.

Introduction

The Pacific Institute is one of the nation's leading centers for assessing water conservation and efficiency potential. In August 2006, the Tuolumne River Trust asked the Institute to review the San Francisco Public Utilities Commission (SFPUC) wholesale and retail customer water demand projections and the companion reports on water conservation and recycled water as part of an effort to understand the potential for 25
increasing the efficient use of water in the region.[1] This report provides that review and concludes that significant untapped potential exists for reducing water use while providing for population growth and economic development, and that the water planning documents and efforts in the region underestimate this potential.

The SFPUC, a department of the City and County of San Francisco, provides water, wastewater, and power services to residents of San Francisco County (referred to as the **retail customers**). SFPUC also delivers water to 28 wholesale water agencies located on the San Francisco Peninsula and along the southern East Bay (referred to as the **wholesale customers**). In late 2004, the SFPUC formally initiated a Water System Improvement Program (WSIP) to "increase the reliability of the system with respect to water quality, seismic response, water delivery, and water supply to meet water delivery needs in the service area through the year 2030."[2] The objective of the water supply
component is to fully meet 2030 purchase requests during non-drought years and to 26
provide sufficient water such that water supply would be reduced by a maximum of 20 percent during any one year of a drought.

To determine 2030 purchase requests, the SFPUC commissioned a series of comprehensive assessments on the water demand, conservation potential, and recycled water potential of its retail and wholesale customers. Based on these studies, demand is projected to increase by 38 million gallons per day (mgd) for the wholesale customers and decline by about 5 mgd for the retail customers. To meet these additional demands,

[1] The Tuolumne River Trust is a non-profit organization dedicated to promoting the stewardship of the Tuolumne River and its tributaries to ensure a healthy watershed.
[2] SFPUC. 2005. Notice of preparation of an environmental impact report and notice of public scoping meetings. San Francisco, California.

purchases from the SFPUC system are projected to increase 35 mgd by 2030.[3] The SFPUC expects to satisfy this increased demand by relying upon a 25 mgd increase in diversions from the Tuolumne River plus an additional 10 mgd from conservation, water recycling, and groundwater supply programs within the SFPUC retail service area.

At the request of the San Francisco Board of Supervisors, the SFPUC examined the potential of a regional option that relies only on groundwater, recycled water, and regional conservation measures to offset the projected 35 mgd increase in system demand.[4] This study found that the "high range" yield from these projects is 28 mgd. Because the feasibility of many of these options is unknown, the study concludes that no such regional solution exists. 26 cont.

Our analysis, however, reveals that the wholesale and retail demand studies may significantly overestimate future regional demand for water and underestimate the potential for cost-effective demand management and recycled water and therefore are inadequate. More specifically, we found the following: 27

- Per-capita demand for the wholesale customers is projected to increase over current (2001) per-capita demand, despite numerous studies that show that substantial cost-effective reductions in per-capita demand are possible with available technologies and policies. 28
- The analysis of SFPUC retail and wholesale demand does not include price-driven efficiency improvements, despite an estimated quadrupling of the price of water from the SFPUC by 2015. 29
- Increases in residential demand are largely due to outdoor water use. For the wholesale and retail customers, per-capita outdoor use is projected to increase, indicating that the proposed conservation does not adequately address this use. 30

[3] SFPUC. 2005. Notice of preparation of an environmental impact report and notice of public scoping meetings. San Francisco, California.
[4] URS Corporation and San Francisco Public Utilities Commission. 2006. Investigation of Regional Water Supply Option No. 4. Technical Memorandum. Prepared for the San Francisco Public Utilities Commission.

- The non-residential sector is responsible for over 80 percent of the projected 2030 demand increase. About 35 percent of that increase is due to outdoor use. 31
- Future demand for the wholesale customers is not adequately evaluated. The forecasting method has two important errors that can lead to potentially large inaccuracies when forecasting demand: it assumes that the current composition of commercial and industrial businesses within the non-residential sector will not change over time, and it ignores the variability in water use in both quantity and purpose among users in the non-residential sector. 32
- The wholesale demand study may overestimate future employment, thereby inflating 2030 non-residential demand. Recent data indicates that economic recovery in the San Francisco Bay Area has been slower than expected, and consequently, the job outlook for the region has been adjusted downward. Slower economy reduces projected water demand for the non-residential sector and suggests that the demand forecast should be adjusted according to the most current information available. 33
- For the wholesale and retail customers combined, the proposed conservation reduces 2030 demand by only four percent. Recent water conservation assessments indicate that the conservation potential identified in the demand analysis is low. For example, SFPUC wholesale customers often fail to implement well-understood efficiency improvements and thereby fail to meet water-use reductions achieved by utilities elsewhere. 34
- The potential to expand recycling and reuse of water to meet future demand appears to have been significantly underestimated. These options would further reduce the need to identify new supply sources, such as additional withdrawals from the Tuolumne River. 35

Based on these findings, we conclude that the demand and conservation studies are inadequate and fail to realize efficiency levels achieved elsewhere. While no analysis is perfect, these flawed studies inform purchase estimates that, in turn, form the basis of future long-term water contracts. It is critical that water demand forecasts are based on good data and appropriate assumptions, and that water contracts are written in such a way as to encourage conservation and efficiency improvements. We close our analysis with a 36 series of recommendations that will improve the modeling and assessment efforts as well as encourage the implementation of cost-effective conservation measures. 36 cont.

Regional Water Agencies

37 The San Francisco Public Utilities Commission (SFPUC), a department of the City and County of San Francisco, provides water, wastewater, and power services to residents of San Francisco County. In addition, SFPUC provides water to 28 wholesale customers located on the San Francisco peninsula and along the southern East Bay through contractual agreements. A few retail customers are also located in isolated communities in Tuolumne County. Twenty-six of the customers are public (cities and water districts) and two are private utilities (Stanford and California Water Service Co.). In total, SFPUC provides water services to 2.4 million people in San Francisco, San Mateo, Santa Clara, Alameda, and Tuolumne Counties.[5] About 32 percent of the water from the SFPUC system is delivered to retail customers within San Francisco, and the remaining 68 percent goes to wholesale customers and large retail customers outside of San Francisco.[6,7]

38 The Bay Area Water Supply and Conservation Agency (BAWSCA) was created in 2003 to represent the interests of the 28 cities and water agencies that purchase water from the SFPUC. BAWSCA has the authority to coordinate water conservation, supply, and recycling activities; acquire water and make it available on a wholesale basis; finance projects, including regional water system improvements; and build facilities jointly with other public agencies. Thus far, BAWSCA and the SFPUC have coordinated only one project, a pre-rinse spray valve program, but are exploring additional opportunities. Regional partnerships will likely lead to greater cost-effectiveness for some conservation programs.

---

[5] Approximately 1.6 million people are outside the City and County of San Francisco.
[6] The large retail customers include the San Francisco County Jail, San Francisco International Airport, and Lawrence Livermore National Laboratory.
[7] URS Corporation. 2004. SFPUC Wholesale Customer Water Demand Projections: Technical Report. Prepared for the San Francisco Public Utilities Commission. Pg 1-2.

Water Resources

39 SFPUC retail and wholesale customers depend upon a variety of water sources to meet their needs, including local surface and groundwater; imported water from the SFPUC and the State (via the State Water Project); and recycled water. In FY 2001-2002, water from the SFPUC supplied 70 percent of the wholesale and retail customers needs. This average, however, hides substantial variation among customers. The City of Hayward, for example, received 100 percent of its supply from the SFPUC, whereas the City of Santa Clara received only 16 percent of its supply from the SFPUC.[8]

Current Conservation Programs and Policies

40 The SFPUC and wholesale agencies participate in a range of ongoing conservation programs, most of which are based on the California Urban Water Conservation Council (CUWCC) Memorandum of Understanding Regarding Urban Water Conservation in California (MOU). The MOU is a voluntary agreement in which participants implement a set of Best Management Practices (BMPs) with specified implementation schedules and coverage requirements. The SFPUC and 13 of the 28 wholesale customers are signatories of the MOU.[9]

41 Table 1 shows the BMPs implemented by the SFPUC wholesale customers. Those BMPs that target commercial, industrial, and institutional uses, BMPs 5 and 9, show the lowest levels of participation. Metering (BMP 4), residential clothes washer rebates (BMP 6), school education (BMP 8), and conservation pricing (BMP 11) show the highest level of participation. 42 Although agencies may be implementing a BMP, they may not meet the full coverage requirements of that BMP and thus may not be in compliance with the MOU. 43 Additionally, the CUWCC BMPs are the minimum level of conservation that agencies should be implementing and do not, by themselves, indicate that an agency has made a strong commitment to conservation. The BMPs have not been substantially

---

[8] URS Corporation. 2004. SFPUC Wholesale Customer Water Demand Projections: Technical Report. Prepared for the San Francisco Public Utilities Commission. Pg. 1-3.
[9] An additional four wholesale customers are located within the Santa Clara Valley Water District, which is a signatory to the MOU, and participate in the District's conservation programs

updated in many years, and they do not include all cost-effective water efficiency options. 43 cont.

BAWSCA and the Santa Clara Valley Water District, which also supplies water to eight SFPUC wholesale customers, are MOU signatories as well and thus implement the CUWCC BMPs among their members. BAWSCA, in particular, implements conservation programs that supplement those programs offered by its member agencies. Table 2 shows the conservation programs offered by BAWSCA, the number of agencies that participate in these programs, and the total amount spent in FY 2005-06. In FY 2005-06, 16 member agencies participated in at least one of BAWSCA's five conservation programs.[10] Nearly 80 percent of the money was spent on washing machine rebates. Although the other programs have been shown to be cost-effective, participation is low. In FY 2006-2007, BAWSCA intends to add two new programs: a cooling tower retrofit program and high-efficiency toilet replacement program. 44

The SFPUC implements conservation programs among its retail customers and participates in a number of regional programs. As shown in Table 1, the SFPUC implements all of the BMPs. The SFPUC also coordinates with BAWSCA on implementing a pre-rinse spray valve program and participates in a regional washer rebate program. 45

Conservation pricing has been shown to be an effective means of reducing water waste and is included in the CUWCC BMPs (BMP 11). The CUWCC recognizes increasing block rates and uniform volumetric rates as conservation rate structures. By this definition, all of the wholesale customers employ some form of conservation pricing: 17 of the 27 wholesale agencies institute increasing block water rates, by which the unit cost of water increases as the volume consumed increases, and the remaining 10 wholesale agencies use uniform volumetric water rates, by which the *unit cost* of water is independent of the volume consumed. [11,12] Among its wholesale customers, SFPUC charges a uniform volumetric water rate. The SFPUC implements increasing block water rates for all of its retail customers except governmental/institutional and irrigation uses, which have uniform volumetric rates.[13] The SFPUC has also instituted increasing block rates for wastewater for its residential customers, but uniform volumetric wastewater rates for all other customers. 46

Historically, the price of water has been low, failing to cover the cost of providing water services. These low costs provide a disincentive to water conservation and perpetuate wasteful water use. Increasingly, agencies have realized the importance of appropriate 47

[11] Report says 27 agencies because information is not provided on Stanford.
[12] BAWSCA. 2006. Bay Area Water Supply and Conservation Agency Annual Survey: FY 2004-05. San Mateo, California.
[13] Prior to June 2006, Proposition H prohibited the SFPUC from increasing or restructuring its water rates.

pricing policies. Although uniform rates are considered a form of conservation pricing, increasing block rates are among the most effective ways to encourage water conservation. A recent study on water-rate structures in the southwest United States found that per-capita water use is typically lower in cities with dramatically increasing block rates.[14] Aside from encouraging water-use efficiency, increasing block rates provide a number of other benefits, such as providing water at a lower cost for basic needs and stabilizing revenue for the utility.[15] Other pricing mechanisms, such as seasonal rates or priority pricing, can also effectively reduce water waste. The SFPUC and its wholesale customers should evaluate and implement water and wastewater rate structures that encourage water conservation among all of their customers. 47 cont.

Water Conservation Projections

The SFPUC commissioned two separate modeling studies on future water demand for its retail and wholesale customers. For the wholesale customers, future water demand with passive (i.e., plumbing codes alone) and active conservation programs was evaluated using the Demand Side Management Least-Cost Planning Decision Support System (DSS) model.[16,17] To forecast 2030 water demand with plumbing codes alone, the DSS model relies on demographic and employment projections, combined with the effects of natural fixture replacement due to the implementation of plumbing codes. 48

To forecast demand with additional conservation measures for each wholesale customer, an initial set of 75 conservation measures was screened by a committee comprised of personnel from the wholesale customers based on qualitative criteria: technology/market maturity, service area match, customer acceptance/equity, and if better measures are available. The 31 measures that passed the initial screening process were combined to 49

[14] Western Resource Advocates. 2003. Smart Water: A Comparative Study of Urban Water Use Efficiency Across the Southwest. Boulder, Colorado.
[15] Western Resource Advocates. 2006. Water Rate Structures in New Mexico: How New Mexico Cities Compare Using This Important Water Use Efficiency Tool. Boulder, Colorado.
[16] Here, I refer to the natural replacements of fixtures due to plumbing codes as "passive" conservation measures, i.e., these savings occur without any effort on the part of the water utility. Conservation measures that would require additional effort are referred to as "active" programs.
[17] Maddaus, W., Maddaus, M. 2004. Evaluating Water Conservation Cost-Effectiveness with an End Use Model, Proceedings Water Sources 2004, American Water Works Association.

49 cont. avoid duplication and take advantage of economies of scale, a process that resulted in 22 new measures. Ten additional Best Management Practices (BMPs) were added to produce a final set of 32 conservation measures. The DSS model then individually evaluated these 32 measures for each wholesale customer using a cost-benefit analysis from the utility perspective.[18] Conservation measures were combined to form three programs (A, B, and C) with increasing levels of water savings. Each program as a whole was then evaluated with the DSS model to avoid the duplication of costs and benefits. It is important to note that programs differ among wholesale customers. For example, Program A for the Alameda County Water District consists of different conservation measures than Program A for the City of Menlo Park.

50 Demand projections for the SFPUC retail customers were analyzed separately and with a different model (the Hannaford model) from that of the wholesale customers. Like the DSS model, the Hannaford model established 2030 baseline conditions that accounted for demographic and employment projections and implementation of the plumbing codes. An initial set of 48 conservation measures were then evaluated according to the costs and benefits of each measure from the "utility" perspective. A customer-utility benefit-cost ratio was also calculated. The initial 48 measures were reduced to 38 measures, which were then put into three packages (Packages A, B, and C). These three packages "represent a range of conservation potential that is considered cost-effective and achievable for long-range planning purposes."[19] Although the basic structure of the models was similar, treatment of non-residential demand varied significantly; this is discussed in greater detail later in the report (see page 31-38).

51 The conservation programs that the SFPUC retail and wholesale customers selected demonstrate a significant difference in their commitment to conservation in terms of the number of conservation measures implemented. For each wholesale customer, Program B, which contained fewer than 10 measures on average, was selected as the recommended program. The total 2030 waters savings for all 27 wholesale customers

[18] While the community perspective was included in the analysis, this perspective was not used to calculate the cost-efficiency of each measure or program.
[19] Hannaford, M.A. 2004. City and County of San Francisco Retail Water Demands and Conservation Potential. Prepared for the San Francisco Public Utilities Commission.

51 cont. was 14.5 mgd. Each wholesale customer was then allowed to pick which measures it deemed feasible, yielding an adjusted Program B with a 2030 total water savings of 13.4 mgd, or four percent less than projected 2030 demand with plumbing codes alone.[20] By contrast, Package C was selected as the recommended program for the SFPUC retail customers. Package C, which the SFPUC believes represents its full conservation potential, consists of 38 measures with an estimated 2030 water savings of 4.5 mgd, or five percent less than projected 2030 demand with plumbing codes alone. Throughout this report, the water use reductions from Program B and Package C for the wholesale and retail customers, respectively, are referred to as the "proposed conservation."

52 A cost-benefit analysis can be conducted from a number of perspectives, which determines the costs and benefits included in the analysis. Both the DSS and Hannaford models assess the economics of the conservation measures and programs from the "utility" perspective. Although community costs and benefits are discussed secondarily, they are not used to evaluate the measures. The utility perspective is based on costs and benefits to the water utility; whereas the community perspective is based on costs and benefits to the water utility *and* customer and can include energy savings, as well as savings from reduced landscape chemical and fertilizer application, less landscape maintenance, and reduced detergent application for dishwashers and washing machines.[21]

53 The utility perspective is much narrower than either the customer or community perspectives and misses important water-use efficiency cost savings that make many water-efficiency measures substantially cost-effective. The classic example is the high-efficiency clothes washer, which may not save sufficient water at present to cover their higher initial capital costs (although this is increasingly less true, as their costs come down). Water utilities therefore often view them as inappropriate for water conservation programs. Yet they have substantial energy savings as well, which makes them tremendously cost-effective to the consumer. Environmental benefits from greater instream flow are also likely, although these benefits are difficult to quantify and are rarely included in any economic analyses. When they are included, they typically have

[20] The wholesale customers, however, are not required to implement these measures; rather, they agreed to reduce their water use by the 13 mgd that the adjusted Program B indicates is possible.

12.4-63

the effect of making efficiency and conservation estimates even more economically attractive. 53 cont.

Analysis and Review of Water Demand

Total Water Demand

Figure 1 shows historic water demand and projected demand to 2030 for the SFPUC retail and wholesale customers. Two estimates for 2030 demand are shown: demand with implementation of plumbing codes alone and with implementation of plumbing codes plus the proposed conservation. The plumbing codes apply to toilets, urinals, showerheads, and faucets. Clothes washers are also included after 2007. 54

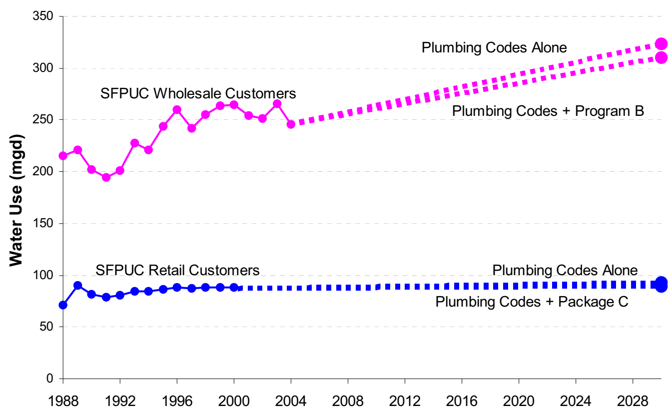

Figure 1: Historic (Solid Line) and Projected (Dotted Line) Demand for the SFPUC Wholesale and Retail Customers.

Figure 1 highlights dissimilar water use trends for the retail and wholesale customers. Water demand for the retail customers has remained relatively constant since 1988. In the future, conservation and efficiency improvements are sufficient to temper water-use increases due to population and economic growth. For the wholesale customers, however, water demand has increased over time. While demand has been fairly stable since 1996, population and economic growth are projected to increase water demand significantly 54 cont.

over the next 25 years. Note that water demand increases for the wholesale customers have not been linear, reflecting a range of sometimes conflicting factors that affect water use. A short, drought-induced reduction in water use in the late 1980s and early 1990s, for example, was followed by a rapid increase in water use. 54 cont.

Table 3 shows current (2001 for the wholesale customers and 2000 for the retail customers) and projected demand for the wholesale and retail customers. Wholesale demand is projected to increase over time due to a projected 19 percent and 31 percent increase in population and employment, respectively. With plumbing codes alone, wholesale demand is expected to reach 323.7 mgd in 2030, or 19 percent above 2001 levels. The proposed conservation moderates this growth slightly, reducing 2030 demand to 310.2 mgd, or four percent less than demand with plumbing codes alone.

For the retail customers, conservation is sufficient to temper water-use increases due to population and economic growth. Retail demand declines slightly (0.2 mgd) between 2000 and 2030 with implementation of plumbing codes alone despite a 12 percent and 25 percent increase in population and employment, respectively. Conservation measures, contained within Package C, reduce 2030 demand by an additional 4.5 mgd, or five percent below levels with plumbing codes alone. In total, water demand is projected to decline by 4.7 mgd between 2000 and 2030. 55

Overall demand (both retail and wholesale customers) is projected to increase by 51.2 mgd, or 14 percent, between 2001 and 2030 with implementation of the plumbing codes alone. Additional conservation helps mitigate this increase. With the proposed conservation, system demand is projected to increase by 33.3 mgd, or 9 percent, to 399.1 mgd in 2030.

Table 3 highlights substantial variation in water demand changes among wholesale and retail customers. Demand is projected to increase for most customers, although demand for seven of the 28 wholesale customers will remain constant or even decline. Demand increases for four of the customers (Alameda County Water District, Hayward, Milpitas, and Santa Clara) account for nearly 80 percent of the total demand increase (Table 3). 56

12.4-64

These four agencies, however, accounted for only 30 percent of 2001 total water demand, and thus are responsible for a disproportionate amount of 2030 demand growth. 56 cont.

Table 3. Current and projected (2030) water demand (mgd) with implementation of plumbing codes alone and plumbing codes plus proposed conservation.

Customer	Current	2030 Plumbing Codes	2030 Plumbing Codes + Proposed Conservation	Demand Change with Proposed Conservation

SFPUC Retail	93.6	93.4	88.9	-4.70
Total SFPUC System	365.8	417.1	399.1	33.3

Note: "Current" refers to the years 2000 and 2001 for the retail and wholesale customers, respectively. The wholesale customers shown in bold are responsible for nearly 80 percent of the total demand increase. Demand change refers to the difference between current demand and 2030 demand with implementation of the plumbing codes plus the proposed conservation.

Gross Per-Capita Demand

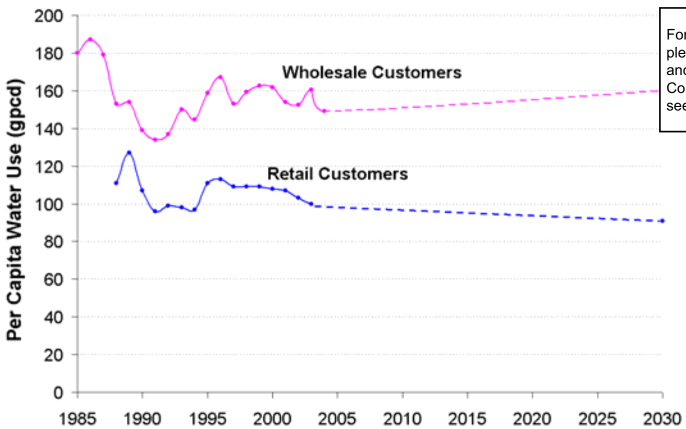
Per-capita demand patterns mimic water-use patterns but are more revealing. Figure 2 shows historic and projected gross per-capita demand for the wholesale and retail customers.[22] For the wholesale customers, per-capita demand reached a high of 187 gpcd in the mid-1980s but declined precipitously during the drought of the late 1980s and early 1990s. Like water demand, per-capita demand for the wholesale customers has been relatively constant since 1996. Projected 2030 per-capita demand increases slightly over 2005 levels but is similar to the per-capita estimates in previous years. 57

For retail customers, gross per-capita demand has declined over time. Per-capita reached a peak of 127 gpcd in 1989 but declined during the drought.[23] Since 1996, per-capita demand has declined steadily. By 2030, per-capita demand is projected to decline to 91 gpcd, nearly ½ of the per-capita demand of the wholesale customers. We note that simple comparisons of gross per-capita water demand between the wholesale and retail customers can be misleading because water use is affected by a variety of economic and demographic factors, such as housing type and density and the type of businesses present in a given region. Local climate conditions and water-use efficiency also affect demand. 58

While per-capita demand comparisons between the SFPUC retail and wholesale customers can be misleading, a comparison of the trends over time, however, is revealing. Since the drought of the late 1980's and early 1990's, per-capita water use has declined for the retail customers but remained constant for the wholesale customers. Thus suggests that water-use efficiency for the retail customers has improved but remains unchanged for the wholesale customers. Projections to 2030 indicate that these efficiency improvements are still not being implemented effectively for the wholesale customers despite the development of numerous technologies and policies to cost-effectively reduce water waste. For example, Seattle Public Utilities successfully reduced per-capita demand from 150 gpcd in 1985 to 105 gpcd in 2004 through higher water rates, plumbing codes, 59

[22] Gross per-capita demand includes UFW.
[23] Good data is not available for the years 1993 through 1995. Per-capita estimates during these years are likely higher than shown.

conservation, and improved system operation.[24] Likewise, East Bay Municipal Utility District reduced per-capita demand from 210 gpcd in 1970 to 155 gpcd in 2005 through a variety of conservation measures.[25] 59 cont.



For Comment 60, please see pp. 12.4-67 and 12.4-68, and for Comment 61, please see page 12.4-71

Figure 2: Historic (solid line) and Projected (dotted line) Gross Per-Capita Demand with Plumbing Codes Plus Proposed Conservation.

Analysis and Review of the Wholesale and Retail Customer Demand and Conservation Potential

This section reviews and analyzes the demand and conservation potential for the SFPUC wholesale and retail customers. Our analysis indicates that the proposed conservation programs fail to capture the substantial amount of water savings that are possible, particularly for outdoor and non-residential uses. Demand projections for the SFPUC 62

[24] Seattle Public Utilities. 2006. Demographics and Water Use Statistics. Seattle, Washington. http://www.seattle.gov/util/About_SPU/Water_System/History_&_Overview/DEMOGRAPHI_200312020908145.asp.
[25] East Bay Municipal Utility District. 2005. Water Conservation/Water Recycling Annual Report. Oakland, California. http://www.ebmud.com/about_ebmud/publications/annual_reports/2005_wc_rw_ar.pdf

retail and wholesale customers do not include price-driven efficiency improvements, despite an estimated quadrupling of the price of water purchased from the SFPUC by 2015. The conservation savings identified in the analysis are low, in comparison to savings achieved in recent water conservation assessments and in other water districts. For example, a recent Pacific Institute study concludes that existing, cost-effective technologies could reduce California's current (2000) urban demand by nearly 30 percent.[26] As a result, per-capita water use remains high, particularly for the wholesale customers.

Price-Driven Efficiency

Pricing is an important tool that allows water managers to reduce wasteful water use. The responsiveness of water demand to changes in water price is referred to as the price elasticity of water demand and is commonly expressed as a positive or negative decimal. If the price doubles and water use drops by 20 percent, for example, the price elasticity of water is -0.20. The price-elasticity can vary by region, water use (indoor vs. outdoor), customer type, etc. 62 cont.

A recent survey of price-elasticity factors by the Pacific Institute found that typical California price-elasticities of demand are around -0.20 for single-family homes, -0.10 for multi-family homes, and -0.25 for the non-residential sector.[27,28] Given that the SFPUC projects that price will quadruple over a 12-year period, from $383 per acre-foot ($1,177 per million gallons) in 2003 to $1,603 per acre-foot ($4,919 per million gallons) in 2015, price will likely be an important driver of conservation in the coming years.[29,30] Neither the SFPUC retail nor wholesale demand analyses, however, consider price-driven efficiency, citing concerns about double-counting conservation savings. While this concern is valid, the projected conservation is so low that double counting is also likely

[26] Gleick, P.H., D. Haasz, C. Henges-Jeck, V. Srinivasan, G. Wolff, K. Cushing, and A. Mann. 2003. Waste Not, Want Not: The Potential for Urban Water Conservation in California." Pacific Institute for Studies in Development, Environment, and Security. Oakland, California.
[27] A price-elasticity of -0.2 means that if price increases by 100 percent, demand would decline by 20 percent.
[28] Gleick, P.H., H. Cooley, and D. Groves. 2005. California Water 2030: An Efficient Future. Pacific Institute for Studies in Development, Environment, and Security. Oakland, California.
[29] Ellen Levin. 2006. Personal Communication. September 22, 2006.
[30] Dollar amounts are in real dollars.

low. A better mechanism is needed to incorporate the effects of price in future demand projections.

Failing to account for price-driven efficiency can create revenue shortfalls. As the price of water goes up, discretionary water use will decline, thereby reducing revenues. Rates 62 cont.
must be designed to account for this effect. As noted in a report to the Washington Legislature, "The key to ensuring adequate revenues is anticipation of the potential for a reduction in sales and design of rates based on reduced sales, rather than existing sales."[31] Overestimating demand can also result in the construction of unnecessary or over-sized facility, further exacerbating revenue concerns.

Demand Change by Sector

Figures 3 and 4 show changes in wholesale and retail customer demand between 2000/2001 and 2030 by sector with implementation of the plumbing codes plus the proposed conservation. For the wholesale customers, the total demand increase is 38.0
mgd between 2000 and 2030. The non-residential sector accounts for about two-thirds of 63
that increase, or 24.1 mgd. Over 40 percent of the increase in non-residential demand is due to outdoor use. Residential demand growth, largely due to increases in outdoor water use, accounts for the remaining one-third of total demand growth.

For the retail customers, conservation and efficiency are projected to reduce total demand. With the proposed conservation, 2030 demand for the non-residential sector is 3.1 mgd greater than 2000 demand. All of the projected increase in non-residential
demand is due to indoor use. Residential demand and unaccounted-for-water (UFW) 64
decline by 6.5 mgd and 1 mgd, respectively. Thus reductions in residential water demand and UFW are sufficient to offset increases in non-residential demand, and total demand declines by 4.7 mgd.

[31] Washington Water Utilities Council, Washington State Department of Health, and Economic and Engineering Services, Inc. 1995. Conservation-Oriented Rates for Public Water Systems in Washington. Report to the Legislature. http://www.mrsc.org/Subjects/Environment/water/doh331-113.pdf

12.4-66

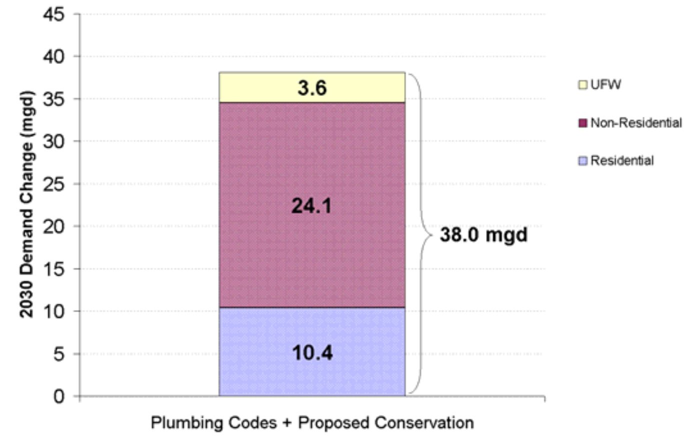


Figure 3: Demand Change between 2001 and 2030 for the wholesale customers by sector.

Figure 4. Demand Change between 2000 and 2030 for the retail customers by sector.

Residential Water Use Projections

Historic Per-Capita Water Demand

Total residential per-capita water use has been relatively constant since the mid- to late-1980s for both the retail and wholesale customers (Figure 5). Short-term, annual variations are likely a result of climatic variation.[32] Because detailed historic per-capita water-use estimates were not available for the wholesale and retail customers, we are 65
unable to perform a comprehensive analysis of per-capita water use trends over time. For example, we are unable to distinguish single-family from multi-family use. Likewise, we are unable to separate indoor and outdoor use. Despite these limitations, we can draw some general conclusions about residential water use trends over time.

As shown in Figure 5, total residential per-capita water use has been constant. Since the 1980's, however, indoor per-capita water use has likely declined due to the implementation of plumbing codes and other conservation programs, such as the BMPs. While indoor efficiency improvements could be countered by an increase in the fraction of single-family units, which tend to have higher water-use rates than multi-family units, 66
housing data indicates that the fraction of single-family units was fairly constant between 1990 and 2005 for both the wholesale and retail customers (Table 4). The relative constancy of total residential per-capita water use and fraction of single-family residences suggests that water-use reductions from indoor efficiency improvements were countered by increases in outdoor water use.

[32] Note that water-use trends for the retail customers are similar but less variable than those of the wholesale customers. Because outdoor water use is a minor component of retail demand, per-capita water 60
use is less sensitive to annual climate variations.

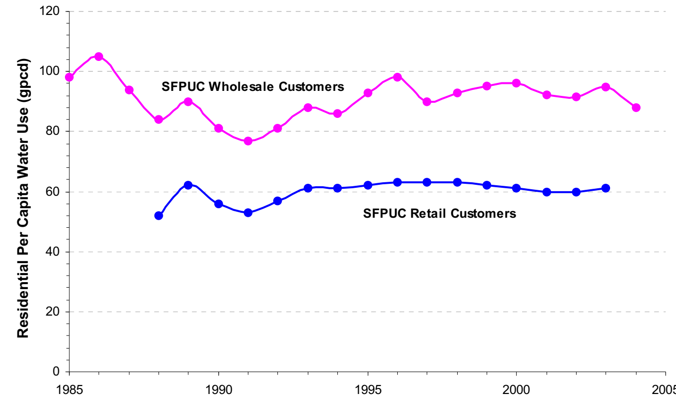

Figure 5. Historic Residential Per-Capita Water Demand for the SFPUC Wholesale and Retail Customers.

Figure 5 also shows that per-capita water demand for the wholesale customers is about 50 percent higher than that of the retail customers, in part due to demographic and climatic differences between the regions. The City and County of San Francisco have a larger fraction of multi-family units, whose residents have fewer fixtures and appliances and as a result, tend to use significantly less water than those living in single-family units (Table 67
4). Additionally, outdoor water use in the City and County of San Francisco is low due to cool summer temperatures and dense housing with few yards. Both of these factors tend to lower average residential per-capita water use. Differences in water-use efficiency, however, cannot be determined from the historic data but are discussed below.

Table 4. Percent single-family housing units for the wholesale and retail customers.

	1990	1995	2000	2005
Wholesale Customers	63%	63%	63%	62%
Retail Customers	32%	32%	33%	31%

Note:
The wholesale customer estimate is based on city-wide data for those cities served by the wholesale customers. The estimate for the retail customers is based on data for the City and County of San Francisco.

Projected Per-Capita Water Demand

Tables 5 and 6 show current and projected per-capita water demand estimates for single-family and multi-family customers, respectively.[33] In 2001, single-family water demand averaged 108 gpcd for the wholesale customers. Note the tremendous variation among wholesale customers; in some areas, per-capita water demand was 300 gpcd due, in large part, to high outdoor water use. The proposed conservation reduces average single-family total water demand by 10 gpcd to 98 gpcd, or by only 9 percent. These savings are from reductions in indoor water use. For most wholesale customers, improvements in outdoor water use are small, and in some areas, outdoor water use is projected to increase. In Hayward, for example, single-family outdoor water use is expected to nearly double, from 22 gpcd in 2001 to 43 gpcd in 2030. Likewise, single-family outdoor water use for the Purissima Hills Water District is projected to increase from 226 gpcd in 2001 to a staggering 332 gpcd in 2030. 68

For the wholesale customers, water demand reductions are larger for multi-family customers than for single-family customers (Table 6). Nearly all wholesale customers project a reduction in water demand, from an average of 75 gpcd in 2001 to 64 gpcd in 2030, a savings of nearly 15 percent. These savings are due to efficiency improvements 69

[33] Current is defined as 2001 for the wholesale customers and 2005 for the retail customers.

60 cont.

in indoor water use, as average outdoor water use is projected to remain constant at 14 gpcd. 69 cont.

Projected single-family and multi-family demand reductions for the retail customers are more substantial than those for the wholesale customers. By 2030, projected single-family water demand is 51 gpcd, a 10 gpcd or 16 percent reduction over 2005 per-capita demand. Demand reductions for the multi-family customers are even greater. Projected multi-family demand is 47 gpcd, an 11 gpcd or 19 percent reduction over 2005 per-capita demand. While projected savings by single-family and multi-family residential retail users results from reductions in indoor water use, outdoor water use remains only a minor component of total use. 70

Comparison with Other Conservation Studies

Recent conservation assessments indicate that there are a substantial number of cost-effective technologies that can drastically reduce residential water demand – both indoor and outdoor – to levels far below those projected for the wholesale and retail customers. For example, a 1997 study by the American Water Works Association (AWWA) found that conservation could reduce indoor water use from 65 gpcd to 45 gpcd for single-family homes, a savings of over 30 percent.[34] The largest reductions were realized by replacing inefficient toilets and clothes washers with more efficient models. 71

Similarly, a Seattle study found that conservation and efficiency could substantially reduce indoor water use. Installing new, water-efficient fixtures and appliances reduced single-family indoor water use from 64 gpcd to 40 gpcd, a savings of nearly 40 percent, and far below the 2030 levels projected in the SFPUC studies. The largest reductions were achieved by installing efficient toilets and clothes washers. Further, homeowners rated the performance, maintenance, and appearance of the efficient appliances higher than the older appliances.[35]

The savings achieved in the AWWA and Seattle studies are supported by a recent Pacific Institute study, which quantified the potential for water conservation and efficiency improvements in California's urban water use. The study concludes that existing, cost-effective technologies could reduce California's current (2000) residential indoor use by 39 percent. Outdoor water-use savings, estimated at 33 percent, are equally impressive and "result from improved management practices, better application of available technology, and changes in landscape design away from water-intensive plants." [36] Reductions in outdoor water use have the added benefit of improving water-system reliability by reducing both average and peak water demand. 71 cont.

The modest improvements in outdoor water-use efficiency projected for the wholesale customers indicate that additional attention and effort must be focused on reducing outdoor water use. Studies have shown that a number of outdoor conservation measures are cost-effective and yield substantial water savings, but these measures are rarely well integrated into demand forecasts or actual conservation programs and they appear to be absent here as well. The cities of Austin, Texas and Las Vegas, Nevada offer rebates or direct payments for removing water-intensive grasses and maintaining water use below budgets established by the city.[37] A study conducted by the Irvine Ranch Water District in California, for example, showed that evapotranspiration controllers reduced outdoor water use for large residential users by 24 percent,[38] and the District has run outdoor conservation efficiency programs for many years. The City of Santa Monica offers funding for new or remodeled innovative garden designs that include one or more of the following: native plants, water-efficient plants, water-efficient irrigation systems, stormwater catchment systems, graywater systems, and/or other innovative water-saving features. They note that "Research shows that converting turf and other water-thirsty plants, and traditional, high-volume spray sprinkler irrigation systems to California 72

friendly plants and water-efficient irrigation systems, can save up to 80% of water and 60% of maintenance costs."[39]

In addition, training programs for landscape professionals and application of efficiency technologies have also been shown to provide significant water savings. The Municipal Water District of Orange County initiated a Landscape Performance Certification Program targeting large landscape customers with dedicated irrigation meters in Orange County, California. The program provides technical training sessions to landscape contractors and property managers (includes homeowner associations) and prepares water budgets for all sites owned or managed by the company. Sites are then assessed for compliance with the water budget, and property managers or landscape contractors are awarded a bronze, silver, or gold certification award based on the level of compliance. Companies that achieve certification are promoted with the intention of increasing market opportunities. It is estimated that each customer saves approximately 765 gallons per day on average, a 20 percent reduction of their outdoor water use, at a cost of $165 per acre-foot – well below the current cost of water and far below the cost of new supply.[40] Educating landscape professionals about native and low-water-use plants and rebates available may also help increase participation in outdoor conservation programs. While results will vary regionally for all outdoor water-efficiency measures, the significant water use in landscaping and the large potential for savings suggest that more aggressive outdoor conservation programs are warranted. 72 cont.

Recent California legislation may also encourage additional indoor and outdoor water-use efficiency improvements. A bill signed in 2004, AB 2717, directed the CUWCC to convene a task force (the Landscape Task Force) to examine ways to improve the efficiency of new and existing irrigated urban landscapes. The Landscape Task Force compiled a comprehensive list of 43 recommendations that would save an estimated 600,000 to 1,000,000 acre-feet per year at an average cost of $250 to $500 per acre- 73

Prepared for the Municipal Water District of Orange County, the Metropolitan Water District of Southern California, and the U.S. Bureau of Reclamation, Southern California Area Office. http://www.mwdoc.com/documents/LPC-Evaluation_000.pdf

foot.[41] A subsequent bill, AB 1881, implements a number of these recommendations, including requiring local agencies to adopt a model ordinance that is at least as effective at conserving water as the updated state model ordinance. The bill also requires the California Energy Commission to adopt performance standards and labeling requirements for landscape irrigation equipment. AB 1881, authored by Assemblyman John Laird and approved by Governor Schwarzenegger in September 2006, will contribute to even greater outdoor efficiency improvements. 73 cont.

Plumbing code standards have been shown to be extremely effective in reducing demand, and a second bill, vetoed by Governor Schwarzenegger, AB 2496, would have updated the 1991 plumbing code standards for toilets and urinals. AB 2496 called for new plumbing standards to reduce the toilet flush volume from 1.6 gallons per flush (gpf) to 1.3 gpf and the urinal flush volume from 1.0 gpf to no more than 0.5 gpf. These new standards would have reduced 2030 residential and non-residential indoor water use by about 5 percent.[42] In his veto message, the Governor indicated that it was not yet clear that the technology was ready for widespread use. These toilets are already standard in Australia, Japan, and other countries, and it is only a matter of time before these standards are adopted in California. 74

Non-Residential Water Use Projections

For the wholesale and retail customers combined, increases in non-residential water use account for over 80 percent of the total 2030 demand increase. About 35 percent of the projected increase in non-residential demand is due to outdoor use. Because the wholesale customers account for 90 percent of the projected growth in non-residential demand, the following analysis and discussion will focus on those customers. 75

Our analysis indicates that the employment assumptions are significantly higher than are likely to materialize and that this assumption alone leads to an overestimate of future

[41] Landscape Task Force citation. 2005. Water Smart Landscapes for California: AB 2717 Landscape Task Force Findings, Recommendations, & Actions.

[42] Here we assume that all residential and non-residential toilets in the SFPUC service area are 1.6 gpf in 2030, and all urinals are 1.0 gpf (a highly conservative estimate). Replacing these toilets and urinals would reduce 2030 residential and non-residential indoor water use by about five percent. 61

water demand. Additionally, the forecasting method is inadequate, failing to recognize differences in water use among customers in the non-residential sector and potential changes in the composition of the non-residential sector over time. The forecasting method for the retail customers provides a better model and should be applied to the wholesale customers. In addition, a substantial fraction of the demand growth is due to outdoor use 75 cont.

Employment Projections

Increases in non-residential demand among the wholesale customers are largely driven by large projected increases in employment. In the DSS model, employment is projected to increase by over 31 percent between 2001 and 2030, rising from 1.13 million in 2001 to 1.49 million in 2030. These projections were based on the Association of Bay Area Governments' (ABAG) employment projections, released in 2002.[43] In 2005, however, ABAG revised the employment projections for the 9-county San Francisco Bay Area: "PROJECTIONS 2005 forecasts over 46,000 fewer jobs than Projections 2002. This is a result of the slow pace of job growth in the Bay Area during the early part of the forecast. The pace has been so slow that it has caused ABAG to reduce the long-term job outlook somewhat."[44] For the 9-county area, 46,000 fewer jobs represent only a one or two percent decline; because there is likely substantial regional variation, however, the effect on the wholesale customers is not immediately clear. Nevertheless, this downward revision reduces the projected growth in water demand for the non-residential sector and suggests that the demand forecast should be adjusted according to the most current information available. 76

Historical employment data provides further evidence that the employment projections used in the DSS study are extremely high and unlikely to materialize. Figure 6 shows the total number of commercial and industrial accounts for the wholesale customers between 1998 and 2005 and projections to 2030. Like the DSS model, we assume that the average number of users per account is constant, i.e., the number of employees per non-residential 77

[43] ABAG produces biennial population and employment projections for the 9-county San Francisco Bay Area. These 9 counties include Alameda, Contra Costa, Marin, Napa, San Francisco, San Mateo, Santa Clara, Solano, and Sonoma Counties.

[44] ABAG. 2005. ABAG Projections 2005: Summary of Findings. http://planning.abag.ca.gov/currentfcst/summary1.html

account does not change between 1998 and 2030. During the late 1990's, California's economy was strong, in part due to growth in the Internet sector and related fields; by 1999, the statewide unemployment rate was a low 4.9 percent, the lowest rate in 30 years.[45] Unemployment rates were likely even lower among the SFPUC wholesale customers, many of whom are dependant on computer-related industries. As the dot-com bubble burst in late 2000 through 2001, the region's economy experienced a mild economic downturn, as indicated by a slight dip in Figure 6. Jobs throughout the region recovered more slowly than expected and have been fairly stable since 1998. Because of the slow growth in recent years, the 2030 employment projections assumed in the DSS model are unlikely and should be adjusted. Furthermore, the projected employment growth is substantially greater than the 19 percent projected population growth. While employment growth can exceed population growth, such a large discrepancy is highly unusual given the low unemployment rate in the region. This suggests the need for a re-evaluation with another, more realistic employment projection. 77 cont.

Non-Residential Forecasting Method

As described previously, the DSS model relies on employment projections, combined with the implementation of plumbing codes and the proposed conservation measures to forecast future demand. This process as applied to the non-residential sector is described in greater detail below:

1. Base-year (2001) conditions are established
   - **Water Use by Account**: For each wholesale customer, base-year (2001) water use for the commercial and industrial sectors is divided by the number of commercial and industrial accounts, respectively. This yields an estimate of water use per account for the commercial and industrial sectors. If insufficient data is available, the commercial and industrial sectors are combined and one water-use number is calculated.
   - **Users Per Account**: The number of users per account are developed by dividing the base-year (2001) employment figure in each wholesale customer service area by the number of accounts billed in that year (2001). 78
   - **Fixture models**: Fixture models establish base-year fixture conditions (number of high-volume and low-volume fixtures) according to water usage data and additional water-use and fixture replacement studies. These models integrate plumbing codes over time to establish future fixture conditions.
2. Forecasting future (2030) demand
   - **Employment Growth**: The number of users per account is held constant, allowing projected employment growth to be translated into account growth.
   - **Demand Projections**: The model then forecasts future water use for each wholesale customer based on the account water use (adjusted to reflect plumbing code implementation) and growth in the number of accounts.
   - **Additional Conservation**: Conservation measures were applied by specifying the target user group and end use (e.g., irrigation), market penetration, measure water savings, and measure life.

This forecasting method is inadequate. It has two important errors which can lead to potentially large inaccuracies when forecasting demand: it assumes that the current composition of commercial and industrial businesses within the non-residential sector will not change over time, and it ignores the variability in water use in both quantity and purpose among users in the non-residential sector. These inadequacies are discussed in greater detail below.

The DSS model applies the economic growth rate to all non-residential accounts equally, thereby assuming that all subsectors grow at the same rate. This is highly unlikely. Table 7 shows the current (2000) and projected employment by subsector for the 9-county San Francisco Bay Area. The sector growth rates vary tremendously. For example, employment in the health and educational services and information subsectors [traditionally lower water-using sectors] is projected to increase by nearly 50 percent. Employment in the agriculture and natural resources and manufacturing and wholesale subsectors [traditionally higher water-using sectors], however, is projected to grow by a more modest four percent and 17 percent, respectively. Because of the differences in the employee growth rate across the region, the composition of the non-residential sector will likely change considerably over time. 79

Table 7: Current (2000) and Projected Regional Employment by Economic Subsector.

Sector	2000	2030	Change
Ag and Natural Resources	24,470	25,470	4.1%
Construction	231,380	339,350	46.7%
Manufacturing and Wholesale	685,480	798,630	16.5%
Retail	402,670	531,270	31.9%

Health and Educ. Services	623,590	941,730	51.0%
Arts, Rec., and Other Services	432,440	625,750	44.7%
Government	146,440	187,500	28.0%
Total Jobs	3,753,460	5,120,600	36.4%

Note: Regional projections for Alameda, Contra Costa, Marin, Napa, San Francisco, San Mateo, Santa Clara, Solano, and Sonoma Counties.
Source: Association for Bay Area Governments. 2005. ABAG Projections 2005: Current Forecast. http://planning.abag.ca.gov/currentfcst/regional.html

The DSS model also ignores differences in water use among users in the non-residential sector. Water is used in various quantities and for a variety of purposes among customers within the non-residential sector. Table 8 shows water-use coefficients in gallons per employee per day (gped) for various establishments in the non-residential sector. Note the tremendous range in water use. For example, water use in hospitals is about 124 gped whereas water use in hotels is nearly twice that amount. For golf courses, water use is estimated at 7,718 gped. Thus the industries present in a given area strongly influence the water use of the non-residential sector, a finding that is not reflected in the DSS model. 79 cont.

In combination, these omissions can lead to potentially large inaccuracies. Water-use variability among subsectors combined with uncertain changes in the composition of the non-residential sector lead to inaccurate estimates of water use in the non-residential sector. Because total demand growth is driven largely by changes in the non-residential sector, a more accurate, comprehensive analysis based on industry-specific growth and water-use rates should be employed. Such an analysis was performed for the SFPUC retail customers and should be applied to the wholesale customers.

The proposed conservation reduces 2030 non-residential demand by a mere four percent. While a quantitative assessment of the conservation potential in the non-residential sector is beyond the scope of this report, the conservation potential identified for the SFPUC wholesale and retail customers is weak and misses important efficiency opportunities. Although few of the conservation savings are a result of efforts to reduce non-residential demand, other conservation assessments have concluded that the actual conservation potential of the non-residential sector is substantially higher. A recent report by the Pacific Institute finds that existing, cost-effective technologies could reduce California's current (2000) water use for the non-residential sector by 26 percent.[46] Savings vary by industry, but are largest for schools, office buildings, golf courses, retail stores, and restaurants. Recirculating cooling towers, x-ray water recycling units, and restaurant pre- 80

rinse spray valves are among a few of the most promising technologies.[47] Similarly, the Santa Clara Valley Water District commissioned a survey of 26 commercial, industrial, 80 cont.
and institutional facilities and found that water conservation measures could reduce water use by 38 percent.[48] These studies suggest that additional emphasis should be placed on reducing non-residential water use.

Recycling and Reuse

Water reclamation, or recycling, refers to the process of treating wastewater to make it suitable for reuse. Reclamation can augment water supplies, as well as provide a means to treat wastewater and reduce environmental discharge. From a technical standpoint, wastewater can be treated to drinking water standards. Public perception, however, constrains potable reuse of recycled water, and it is typically reserved for irrigation, commercial and industrial purposes, toilets, and other non-potable uses. These uses, however, can be significant, and substantial fractions of some demands are likely to be met in the future with recycled water. The current and potential use of recycled water for the SFPUC retail and wholesale customers were evaluated separately and are discussed in greater detail below.

The *Wholesale Customer Recycled Water Potential Technical Memorandum* evaluates 81
the current and potential use of recycled water for the SFPUC wholesale customers.[49] According to this study, nine recycled water projects currently (2004) produce 12.6 mgd of water in the wholesale customer service area.[50] This water is used for a number of purposes, including irrigation and commercial end uses and wetland restoration. By 2020, recycled water projects for which wholesale agencies have completed planning studies, secured funding, and have begun or will start construction will provide an additional 6.3 to 7.8 mgd of water. The total recycled water potential for 2020 for SFPUC wholesale customers is estimated to range from 39.6 to 46.0 mgd, of which 8.9 mgd would be used for environmental restoration and the remaining 30.7 to 37.1 mgd would offset potable water use.[51]

The *Recycled Water Master Plan Update* evaluates the current and potential use of 82
recycled water for the SFPUC retail customers.[52] The SFPUC's current use of recycled

[49] Raines, Melton & Carella, Inc. (RMC). 2004. Wholesale Customer Recycled Water Potential Technical Memorandum. Prepared for the San Francisco Public Utilities Commission.
[50] Yield does not include recycled water use within wastewater treatment plants.
[51] The total recycled water project potential was based on summing the yields from the current (2004) projects, the "planned and being implemented" projects, and the "under study or previously studied" projects.
[52] RMC Water and Environment. 2006. City and County of San Francisco Recycled Water Master Plan Update. Prepared for the San Francisco Public Utilities Commission.

water is limited to two golf courses in San Francisco. The report concludes that feasible recycling projects can provide an estimated 11.8 mgd of non-potable water by 2030. The recycled water would be used primarily for irrigation, but also for commercial and industrial uses. Additional opportunities exist, such as using recycled water for residential irrigation or street cleaning/sweeping, but the uses are considered “less feasible” at this time and were not well quantified.

Despite the promising potential of recycled water identified within the SFPUC service area, recycling and reuse will provide only 13 mgd in 2030, or 3 percent of the retail and wholesale customers 2030 water demand (Figure 7). Of this total, the wholesale customers would produce 9 mgd, and the SFPUC would produce 4 mgd. This is only a fraction of the identified potential and is low in comparison to what has been achieved elsewhere (see below). Further, the outdoor and non-residential sectors are driving future demand growth. Recycled water can effectively offset increased freshwater demands for these sectors, highlighting the value of maximizing use of this resource. 82 cont.

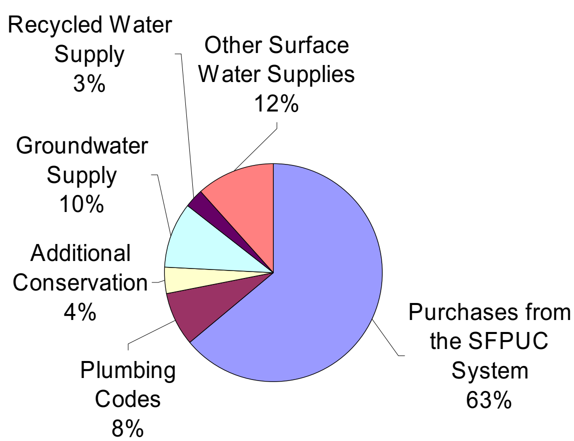

Figure 7: SFPUC Retail and Wholesale Customer 2030 Water Demand and Supply Estimates.

Implementing recycled water projects is not without challenges, and these challenges must be overcome to realize the full potential of recycled water. Challenges are associated with “securing outside funding necessary to make the project cost-effective, gaining public support, establishing new partnerships, and managing recycled water quality/salinity.”[53] Recycled water, however, has become an increasingly important component of the water-supply portfolios for water districts throughout the United States, suggesting that these challenges can and have been overcome. For example, the Irvine Ranch Water District, in Southern California, currently meets nearly 20 percent of its total demand with recycled water.[54] In 2004, the South Florida Water Management District reused over 25 percent of the total wastewater treated.[55] And more recently, a new residential community in Ventura County, California has decided to use recycled water for all of its landscaping needs at an estimated cost of $200 per acre-foot.[56] This suggests that significant opportunities exist to increase recycling and reuse throughout the region, effectively lessening the need to identify and develop new water supplies. 83

Conclusions

The SFPUC wholesale and retail demand studies project substantial increases in 2030 water demand, largely from the region’s wholesale customers. To meet these additional demands, purchases from the SFPUC are projected to increase by 35 mgd. The SFPUC relies upon a 25 mgd increase in diversions from the Tuolumne River plus an additional 10 mgd from conservation, water recycling, and groundwater supply programs within the SFPUC retail service area to meet future purchase requests from its retail and wholesale customers. 84

Our analysis, however, reveals that current studies may significantly overestimate future regional demand for water and underestimate the potential for cost-effective demand

management. A straightforward re-examination of conservation scenarios, using more plausible employment projections, more accurate non-residential water use estimates, and a price-driven conservation component would likely produce a more realistic 2030 demand forecast and identify priority policies for cost-effective efficiency improvements, recycling, and reuse. 84 cont.

Pacific Institute Recommendations

Modeling and Assessment Efforts

1. Non-residential demand is an important driver for future demand increases, and as a result, an adequate assessment of future demand and conservation potential is critical. The SFPUC should re-evaluate non-residential demand projections for its wholesale customers using industry-specific economic growth projections, water use, and conservation potential. Initial efforts should be regional in scope or focus on those agencies with high non-residential water use. If the projections from the new analysis differ substantially from those of the DSS model, detailed analyses should be conducted for each of the wholesale customers. 85

2. As the price of water increases, demand decreases, particularly for non-residential and outdoor uses. Because the SFPUC expects to quadruple the price of water by 2015, the effects of projected water price increases should be integrated into the demand projections. Failing to do so may result in an overestimate of future demand and revenue shortfalls. 86

3. Estimates of the maximum, cost-effective conservation potential should be determined for each measure, major end use, and district or wholesale/retail user. The definition of "cost-effective" must be broadened beyond the utility perspective and should include the value of ecosystem flows. 87

4. Better data are needed on the type of non-residential account and the water use associated with that account. The SFPUC and its wholesale customers must also standardize reporting methods. A focus on outdoor water use is especially needed. 88

5. Modeling efforts should include multiple scenarios so as to determine a range of future demand. 89

6. A better assessment of the potential for using recycled water for different end uses is needed. 90

7. Future studies should include the impact of climate change on projected demand and supply. 91

Conservation Implementation

1. Each agency should assess what is driving demand growth and measures to reduce that demand. Agencies must take a more pro-active role in identifying ways to reduce demand growth, particularly in new developments. 92

2. The SFPUC and its wholesale customers should implement water and wastewater rate structures that encourage water conservation among their customers and fund conservation programs. 93

3. All agencies should sign the CUWCC MOU and work to meet all applicable Best Management Practices. 94

4. SFPUC and BAWSCA should work together to establish more effective regional water conservation and recycling programs. 95

5. Institutional mechanisms should be developed to encourage wholesale customers to move more aggressively toward efficiency improvements. This can include cross-agency information sharing, consistent conservation programs and targets, economic incentives for demand reductions, conservation pricing for wholesale customers, regular reassessment of program effectiveness and implementation, and improvements in conservation data collection and reporting. 96

6. Serious consideration should be given to capping purchases from the SFPUC at current levels. BAWSCA and the SFPUC should institute financial incentives to encourage conservation efforts and financial disincentives to discourage demand growth. For example, water marketing among the wholesale agencies would allow 97

water saved through conservation efforts by one agency to be sold to another agency, thereby promoting economic efficiency. 97 cont.

Atten; Paul Maltzer,

Mr. Maltzer,

The Pilarcitos Creek Advisory Committee (Committee) is a watershed stakeholder organization made up of various interest groups in Half Moon Bay. The Committee has representatives from the environmental, agricultural, commercial fisheries and restoration communities. Our mission is to restore habitat conditions within the watershed for the native plant and animal communities and the public benefit of enhanced water quality. The Committee was initially established by the Dept of Fish and Game and the Regional Water Quality Control Board (Region 2) in 1993.

SFPUC has been an important stakeholder in our coastal watershed for over 100 years and has been a participant at our Committee meetings.

The initial phase of the Committee's work was to provide local oversight in the development of an initial "Restoration Plan" for the watershed (finalized in 1996). Subsequent to the development of the Plan, our Committee then advocated for projects which were identified in the Plan. Many of those projects have now been completed.

More recently, the SFPUC has been an active partner in a new initiative, an Integrated Watershed Planning Project for the Pilarcitos. This plan, funded by the State of California, is underway with strong support from the SFPUC staff, thru contribution of staff effort and dollar expenditure.

In each step of this decade long progression of steps (which has included agency driven watershed plans, public outreach and formal forums and now a State funded IWMP) there has been a recognition that only by thoughtful management and use of the waters developed within the Pilarcitos basin would we be able to restore and enhance aquatic habitats and "balance" the beneficial uses of the waters of Pilarcitos Creek (which includes domestic, agriculture, cold water fisheries and recreation).

It has been the position of the PCAC that the current system of upper watershed impoundments owned and operated by the SFPUC have reduced opportunities to 01

SI_PilarCrk

PILARCITOS CREEK ADVISORY COMMITTEE

accomplish the goals of "restoration and balance" supported by our Committee and the community at large. 01 cont.

With that background, the PCAC would like to make the following comments on the PEIR;

1. The PCAC appreciates the clear narrative explanation of the cross basin transfer of Pilarcitos Creek water, through the Coastal Mountains (through tunnels) over into the San Mateo Creek vicinity watersheds (impounded in Crystal Springs Res and others) as written in Vol. 1 Pg 157. The result of this transfer leads to the dewatering of the Pilarcitos Creek below the SFPUC operated Stone Dam during summer months, and the alteration of a winter storm hydrograph in Pilarcitos in the winter. **The PCAC would suggest that the significance of impacts of this cross basin transfer should be more closely analyzed and commented on in the PEIR with regards to the alteration of both winter and summer hydrographs, especially as they relate to the habitat of threatened and endangered species found I the riparian corridor during low summer and fall flows.** 02
2. A combination of statements in the PEIR (for example Vol 3 Pgs 393.394) explain that no intentional releases are made below Stone Dam and the "flow in the creek immediately below the dam consisted only of leakage through the spillway boards and seepage through the dam". Further, the PEIR states that no releases are required to maintain minimum stream flows in Pilarcitos Creek. The PCAC believes these statements conflict with "minimum bypass" requirements of both CDFG and NOAA Fisheries, mandated for the protection of sensitive aquatic species. **The PCAC requests that significant impacts which result from the lack of bypass flows should be analyzed in the PEIR. We believe that the historical failure to maintain minimum flows in no way limits SFPUC's obligation to heed state and federal laws.** 03
3. The Flows in Pilarcitos Creek are further discussed in Vol. 3 pages 403,404. In those paragraphs are described the winter "spills" which occur over Stone Dam into Pilarcitos in the wet months of wet years. This discussion reminds the PCAC of the physical conditions and age of both Pilarcitos Lake and Stone Dam. Each of the structures are over 100 years old. **The PCAC would suggest that the PEIR should look at the significance of impacts if these structures were they to fail (in terms of habitat, property and potential human loss in case of breach).** This issue was brought to our attention in a recent San Mateo County Grand Jury report. 04
4. **The PCAC has significant issue with the "Impact Conclusions" noted in the PEIR** which state,

   > "The WSIP would not alter the character of Pilarcitos Creek immediately below Stone Dam. Flow in the creek immediately below the dam is intermittent under the existing condition and would continue to be intermittent with the WSIP, so no adverse hydrologic effects would occur. With the WSIP, total spills to the creek immediately below Stone Dam would be reduced, but the magnitude of the flows in the lower reaches of the creek would be similar to those under existing conditions. Therefore, adverse impacts on water levels in Pilarcitos Reservoir and 05

Advocating for a Balance Approach to Restoration Since 1993

PILARCITOS CREEK ADVISORY COMMITTEE

on flow along Pilarcitos Creek below Stone Dam would be *less than significant*, and no mitigation measures would be required."

The PEIR is suggesting that the "baseline conditions" for Pilarcitos Creek below Stone Dam are established by the SFPUC's policy of "no discharge". That policy has led to the dewatering of Pilarcitos Creek, the blockage of migration for the native steelhead population and has had further negative impacts due to the reduction of available beneficial habitat to sensitive aquatic species such as the Red Legged Frog. The statement also ignores the substantial "leakage" discharge of recent years. **We feel that this acceptance of an artificial and manipulated "baseline condition" is not an appropriate condition from which to assess impacts**. We believe that the continuation of the current policy of "no discharge" will simply allow the existing significant impacts to this watershed to continue. 05 cont.

We suggest that a more appropriate "base line condition" should be considered. That condition would be one of a controlled spill or release out of Stone Dam, which more closely mimicked the natural flows above the SFPUC impoundments. This "baseline condition" existed this year due to "experimental releases" from Stone Dam by SFPUC, with clear increases in flows demonstrated at the Highway 1 USGS gauge approximately 10 river miles downstream. 06

Over $1,000,000 in public dollars and many thousands of dollars and hours of Landowner efforts have gone into restoring and enhancing in stream habitat conditions in the Pilarcitos watershed. SFPUC's management of Stone and Pilarcitos dams, consistent with protection of in stream conditions, is critical to the success of recovery of Steelhead populations and other aquatic species and is critical also for our joint Integrated Watershed Management Planning efforts. 07

Thank you very much for the opportunity to comment.

Sincerely,

The Pilarcitos Creek Advisory Committee

Ladies/Gentlemen:

Introduction. These are my comments on the Draft Program Environmental Impact Report ("PEIR") for the San Francisco Public Utilities Commission's ("SFPUC") Water System Improvement Program ("WSIP").

To put in the correct context the comments below it is instructive to begin with a succinct statement, taken directly from court decisions, of the applicable standards in determining the legal sufficiency of an Environmental Impact Report under CEQA. The following explanation is found in Association of Irritated Residents vs. County of Madera, 107 Call. App. 4th 1383, 133 Cal. Rptr. 2d 718 (2003):

> "When assessing the legal sufficiency of an EIR, the reviewing court focuses on adequacy, completeness and a good faith effort at full disclosure. (*County of Amador v. El Dorado County Water Agency* (1999) 76 Cal.App.4th 931, 954, 91 Cal.Rptr.2d 66 (*Amador*).) "The EIR must contain facts and analysis, not just the bare conclusions of the agency." (*Santiago Water Dist. v. County of Orange* (1981) 118 Cal.App.3d 818, 831, 173 Cal.Rptr. 602.) "An EIR must include detail sufficient to enable those who did not participate in its preparation to understand and to consider meaningfully the issues raised by the proposed project." (*Laurel Heights Improvement Assn. v. Regents of University of California* (1988) 47 Cal.3d 376, 405, 253 Cal.Rptr. 426, 764 P.2d 278 (*Laurel Heights*).)" 01

Keeping in mind the foregoing common sense set of standards for assessing the adequacy and sufficiency of an EIR, the following specific comments are offered, while noting that the below comments do not cover all respects in which the PEIR appears to be inadequate and legally insufficient. Time only allowed coverage of certain issues that might not be covered by other commentators. 02

1. The very heart of the environmental issues raised by the WSIP and the PEIR is the preference of SFPUC to meet the alleged increased 35 million gallons a day ("MGD") demand by extracting 25 MGD additional from the Tuolumne River while generating 10 MGD through some combination of conservation, water recycling, and groundwater supply programs. PEIR Section 3.6.1 states that about 4 MGD of the 10 MGD will come from recycled water projects.

SFPUC's Recycled Water Master Plan - March 2006 ("RWMP") can be found at ---
http://sfwater.org/detail.cfm/MC_ID/13/MSC_ID/165/MTO_ID/290/C_ID/2920)

At page ES-7 of the RWMP it says that in San Francisco alone there is the real potential for feasible water recycling to the tune of 11.8 MGD – that's almost 2 MGD more than the EIR says SFPUC plans to develop from the combined resources of conservation, recycling and groundwater throughout the service area.

Then at page ES-10 the RWMP says so-called Phase I of recycled water projects would target only 4.5 MGD of the 11.8 MGD of existing demand. The RWMP continues at page ES-10 simply saying, "The remaining potential demand represents future for expansion of the recycled water system to additional customers that are not planned to be served at this time."

a. Stated bluntly, the RWMP is simply uninformative as to why additional demand is not intended to be served in Phase 1 and when in the future that demand for recycled water will be met. It may be acceptable to some for the RWMP to be so deficient; it is not acceptable for the PEIR to not address those fundamental questions. Recall one of the principles stated above: "An EIR must include detail sufficient to enable those who did not participate in its preparation to understand and to consider meaningfully the issues raised by the proposed project." San Francisco's expressed intent to extract 25 MGD from the Tuolumne River is the single largest issue raised by the proposed project. In order for those "who did not participate" in the PEIR's preparation to meaningfully be able to evaluate the consequences of San Francisco's plans for greater extractions from the Tuolumne they must have much more information regarding the alternatives, including the admitted potential for much greater recycling in San Francisco. Only then can the readers of the PEIR determine whether it is reasonable that SF wants to take from the Tuolumne two and one-half times as much water as it and its customers are prepared to generate through conservation, recycling and groundwater resources.

The need for a much more thorough analysis in the PEIR of the potential for water recycling in San Francisco alone is accentuated by San Francisco's astoundingly poor record of water recycling. In connection with a draft of the Recycled Water Master Plan, this commentator submitted a six page comment letter to the SFPUC in November 2005. Below is a paragraph from that letter putting into context San Francisco's water recycling record.

02 cont.

SI_RHH1

"p. 22 – Footnote "a." to Table 2-1 references the May 2000 State Water Resources Control Board ("SWRCB") Survey of municipal recycling facilities. It is inexcusable for the draft RWMP to use that reference when it is common knowledge that an updated Survey was released in 2002, and updated in 2003. The draft RWMP "References" (p. 137) acknowledges this fact. It is inexplicable how the preparers of Table 2-1 cite the older Survey. Nonetheless, both Surveys are evidence of the accuracy of the Committee's prior statements that SFPUC exaggerates its commitment to water recycling and is, in fact, light years behind the rest of the state. First, compare the two Surveys. The 2000 Survey shows 234 recycled water facilities with an aggregate capacity of 401,910 acre feet per year ("AFY"). The 2002 Survey shows 278 plants with a capacity of 544,979 AFY; about a 35% increase in capacity over a two to three year period. Second, look at the list of facilities in the 2002 Survey and break it down by County. There are only 7 out of California's 58 counties not represented. San Francisco shows up with one facility – the Southeast plant with an alleged design flow of 85 MGD and an annual capacity of 6066 AFY. The reality is that a few trucks are washed each year at the Southeast plant. Thus, the fact is that there are eight counties in California doing no meaningful water recycling --- Alpine (population-1,210), Modoc (population-9,350), Trinity (population-13,100), Colusa (population-19,450), Glenn (population-26,800), San Benito (population-55,900), Sutter (population-81,900) and San Francisco (population-793,000)."

02 cont.

b. The PEIR needs to better address the question of future water recycling efforts by SFPUC's wholesale customers. PEIR Section 9.2.4 states that future water demand numbers of those customers takes into account their future recycling plans. Much more detail than is found in Table 9-11 needs to be provided so that the decision makers and interested parties can determine whether the wholesale customers, like San Francisco, are only willing to meet a fraction of feasible recycled water demand with actual projects. Only then can the readers of the PEIR determine whether it is reasonable that San Francisco wants to take from the Tuolumne two and one-half times as much water as it and its customers are prepared to generate through conservation, recycling and groundwater resources.

03

c. Subparagraphs a. and b. above address the need for the PEIR to more adequately and completely analyze water recycling alternatives, so that decision makers and interested parties can meaningfully consider the issues raises by SFPUC's preferred alternative of extracting 25 MGD from the Tuolumne, while only generating 10 MGD through conservation, recycling and groundwater. There is another aspect of the untapped potential for recycling in San Francisco and the service area that ought to be addressed in the PEIR. Section 9(h)of the Raker Act provides that San Francisco may not export from beyond the San Joaquin Valley any more water of the Tuolumne watershed "than, together with the water which it now has or may hereafter acquire, shall be necessary for its beneficial use for domestic and other municipal purposes." One acknowledged water law scholar has suggested that this provision may require San Francisco to develop available local resources, such as recycling and desalination, before looking to the Tuolumne River for additional water. (See Appendix C to Environmental Defense's Paradise Regained: Solutions for Restoring Yosemite's Hetch Hetchy Valley, 2004.) This commentator has not looked for legal authority on the question of whether an environmental impact report need discuss legal obstacles to the completion of a proposed project. However, common sense says that if there are significant

04

potential legal obstacles, they ought to be mentioned if there is to be an adequate, complete and good faith effort at full disclosure. 04 cont.

2. Chapter 10 of the PEIR lists 20 significant adverse environmental impacts resulting from the project that the PEIR concedes probably can't be eliminated, or reduced to a less-than significant level by other mitigation measures. 20 adverse environmental impacts that can't be fixed is a lot. Why not think bold and add one over-reaching mitigation measure to help soften the blow of the 20 individual problems that can't be fixed? There is case authority under CEQA that says that a governmental entity can satisfy the mitigation requirement by simply making a commitment to study an issue (Sacramento Old City Assn. v. City Council (1991) 229 Cal. App. 3d 1011, 280 Cal. Rptr. 478). That case involved the expansion of the city's convention center and construction of an office building. The EIR discussed several potential measures to mitigate the impacts on traffic and parking. The city did not adopt specific mitigation measures but committed to study the problem and prepare a transportation management plan. The court concluded that the city had "committed itself to mitigating the impacts" and stated that the EIR's consideration, discussion, and analysis of the mitigation measures supported the city's finding that the mitigation measures were "required in, or incorporated into" the project, under section 21081 of CEQA. 05

San Francisco could make a similar commitment to cooperate in the removal of O'Shaughnessey Dam and the restoration of the valley so long as certain conditions were met. A statement of commitment from the SFPUC or San Francisco's Board of Supervisors might read as follows:

"It is the policy of the City and County of San Francisco that Yosemite National Park's Hetch Hetchy Valley should be restored, and the reservoir covering the Valley should be removed. Reservoir removal should occur after the water and power currently supplied by the reservoir are fully replaced. Water and Power replacement must take place without any increase in water or power rates or property tax rates for San Francisco residents and businesses; and without any increase in the cost of government to the City of San Francisco. San Francisco elected officials and city employees shall support restoration of Hetch Hetchy Valley, and shall do their best to gain the replacement water and power supplies." 06

Note that the statement makes it abundantly clear that San Francisco would only support removal of O'Shaughnessy Reservoir if the lost power and water were fully replaced and if there was no additional cost to San Francisco residents and businesses. Stated more bluntly, a "no cost" mitigation option available to San Francisco would be a simple statement of policy that it will not continue to obstinately oppose valley restoration or even study of valley restoration, so long as those efforts result in no harm to San Francisco.

3. On page S-8 and elsewhere in the PEIR it is stated without qualification that SFPUC proposes to secure a water transfer with Turlock and/or Modesto Irrigation Districts to provide supplemental dry-year water from The Tuolumne 07

River. Remembering that an essential element of an EIR is "a good faith effort at full disclosure", the PEIR should go further. Have the irrigation districts agreed to such a water transfer? Have they even been asked? Is it not true that representatives of the districts have publicly stated that they don't intend to be involved in such transfers? Again, here as elsewhere, the PEIR must include sufficient detail for the reader to consider meaningfully the issues raised by the project. 07 cont.

Respectfully Submitted,

Jerry Cadagan

SI_RHH2

SF Planning Dept WSIP PEIR initial response at Sept 5, 2007 meeting at Sonora Opera Hall

I am Bob Hackamack, Tech/Engin Chair of Restore HH, home address P O Box 1886, Twain Harte.

It is apparent that the SF Planning Dept and its consultant have put forth significant effort in preparing the PEIR. I complement you. There are minor errors which are understandable. I learned several things that I did not know about the regional system. These are good reference manuals.

I want to explain how the preferred alternate called WSIP is disconnected from reality, but that a combination with alternatives will be a workable and wise solution.

1. You correctly stated that John Freeman projected his 1912 plan would ultimately provide 400 mgd of supply from TR, but you failed to say that the SFPUC didn't build the system according to Freeman's plan. Rather, the system was built for maximum hydroelectric profit, which resulted in a drastic reduction of firm yield. (2-36 & 7) 01

With a simple calculation on your preferred alternative, I find firm yield of HH is 207 mgd, plus 13 mgd from local sources for a sum of 220 mgd during the design drought, with 17% of reduced supply coming from rationing of 45 mgd. This leaves HH Res empty at the end of the 8.5 year design drought. No prudent manager will use that plan, so expect no rationing the first year with 25% rationing thereafter, the same as in past droughts. (2-19, Figure 2.5)

I ask you, why would your BofS agree to a tripling of water rates to pay for this WSIP and now tolerate the PEIR telling the ratepayers they will get a system that plans for up to 25% rationing every 13 or 26 or 41 years? 02 Your rate payers deserve better service for what they are going to be paying. (2-19, Figure 2.5)

2. The solution is obvious: Cap diversion from the TR at say 207 mgd and get all total needs above 220 mgd from water efficiency which is a very economical source, plus recycled treated waste water for landscape, and industrial and commercial cooling, groundwater banking inside your service area and by groundwater exchange outside, plus purchase, plus desal of brackish water. 03 Do all those things together and drought rationing will be tiny.

In other words, get busy to cut back from the preset 230 plus mgd so you can reach a sustainable level. At a capped average diversion of 207 you will have lots of entitlement to put into groundwater banking as exchange storage for drought. (S-8, Figure S.4 and SFPUC data for WY 2006)

I favor the options dealing with Aggressive Conservation/Water Recycling and Local Groundwater, plus added 04 groundwater banking and conjunctive, purchase, desal, and lower TR diversion. (S-74 and Chapter 8 & 9)

3. To move forward smoothly on this project, you must cap your take from the TR because you are obviously building 46% of the length of the 4th barrel that virtually guarantees more river diversion, in 05 spite of SFPUC saying last year that it abandoned the 4th barrel because of the cost. (3-49)

4. Last, you did not respond adequately to the Raker Act provision I spoke about here in this hall in Oct '05 requiring you to develop all water supplies in your and the wholesale service areas before diverting from the TR, as stated in Sec 9 (h) of the Act. The best you say about developing supplies in your PEIR scoping is "improve use of new water sources". This is totally unacceptable as a goal. 06 The proper goal would be to build a sustainable water supply system for the 21st Century as your predecessors did for the 20th Century. (Appendix A page 10 Water Supply, fourth bullet)

San Francisco, CA 94103

Dear Mr. Maltzer:

Santa Clara County receives water from the San Francisco Public Utilities Commission's Hetch Hechy pipeline and the Tuolumne River providing relief and diversification of our local water 01 supplies but even so the Santa Clara County Creeks Coalition opposes any increase in diversions from this critically important river.

We also feel that the Draft Program Environmental Impact Report (PEIR) used flawed modeling 02 to determine the anticipated increase in water demand, thus inflating projected future needs. We also feel that it fails to adequately identify and address all of the environmental impacts to the River. 03 Additional studies must be undertaken before finalizing this document.

Water conservation and efficiency measures are the cheapest, easiest to implement, and least destructive ways to meet demand and extend water supply. When it comes to water conservation, the Bay Area lags far behind other metropolitan areas such as Seattle and Los Angeles that are reducing water consumption even in the face of growth.

04

We do support alternatives identified that protect the Tuolumne River from new diversions. Requiring more water conservation, efficiency, and recycling is the best way to lessen impacts on the Tuolumne River while promoting a sustainable water plan for the Bay Area.

Only by ensuring that healthy amounts of water continue to flow into the Tuolumne River can we protect this irreplaceable natural treasure.

Sincerely,

Mondy Lariz

San Francisco Public Utilities Commission

To Whom It May Concern:

The Use of Water from the Tuolumne River for Urban Use.:

The snow pack of the Sierras, much of it located in a Yosemite National Park, is a convenient source of clean water for natural systems, agriculture system and urban systems. Since these systems are interlock by the needs for water, any change in one effect the other. Thus any plan to change water allocations for any systems, requires thought, research and negations that address the overall success of all the systems. To study the environmental change over time, is fundamental to the policy making process. Therefore it is important that scientific baseline studies be started, continued and evaluated over time.

Populations of living things, in natural or urban setting, follow much the same direction toward unchecked growth that is infinite in scope. In nature, the process of natural selection will mold the population to the carrying capacity of the environment as each habitat has a finite capacity. In the urban areas, planning for finite population or usage of finite resources reduces the process of natural selection. Before looking to watershed for more water, it is important to the planning process to look for ways for the San Francisco Public Utilities Commission to find sustainable methods through conservation, the use of modern technology for water monitoring, reusing waste water and efficiency in water use at all levels. Since it is humans and their cultural items that use water, government planning needs to address the finite nature of water and plan construction around these limits. 01

Bill Wycko
Environmental Review Officer, WSIP PEIR
San Francisco Planning Department
1650 Mission St., Suite 400
San Francisco, CA 94103

Dear Mr. Wycko:

The SPUR Sustainable Development Committee appreciates the opportunity to provide comments on the draft Program Environmental Impact Review (PEIR) of the SFPUC's Water System Improvement Program (WSIP). This document has not been reviewed by the SPUR Board of Directors, and as such does not represent the official position of SPUR. It does represent an effort by the members of the SPUR Sustainable Development committee to provide constructive comment on that substantial document. Our comments are focused on three areas: 01

1. The purpose of the WSIP: seismic reliability
2. Conservation and efficiency modeling
3. Drought and climate change modeling and assumptions.

First, we reassert SPUR's support for the Tuolumne River and the Water System Improvement Program. In 2002, SPUR convened an independent expert "Blue Ribbon Committee" to review the SFPUC Program to Improve Reliability of the Water and Sewer Systems, which on May23, 2002 issued its final report expressing confidence in the work of R. W. Beck on the SFPUC's Capital Improvement Program. Thereafter, on October 1, 2002, SPUR expressed its strong support for Proposition A, the $ 1.6 billion Hetch Hetchy Water Bond, by vote of its Board of Directors. SPUR's long history of leadership and support for the Tuolumne River and Hetch Hetchy additionally includes the designation of the Tuolumne as a Wild and Scenic River.

SPUR believes that seismic and delivery reliability upgrades to our water system are a public investment priority. In the spirit of this support, we want the final PEIR to be as robust and compelling a document as possible, including recommendations to provide the most stable, reliable water supply to the Bay Area while minimizing significant negative environmental effects on the river and its ecosystems.

1. The purpose of the WSIP: seismic reliability 02

Recent state and local laws overwhelmingly support improving the reliability of the San Francisco regional water system, including 2002's AB 1823, Measure A, and Measure E.[1] These measures all found that disruptions to the regional water system could have

[1] *AB 1823 Assembly Bill Chaptered, Wholesale Regional Water System Security and Reliability Act,* (California State Assembly and Senate) 2002. Official California Legislative Information, www.leginfo.ca.gov

severe, disastrous impacts on public health and the Bay Area's economy. San Francisco voters authorized, and SPUR strongly supported, the largest bond in the city's history for the SFPUC to restore the system, and amended the city's charter to emphasize a high priority on protecting and repairing the system as quickly as possible. Many of the regional water system's facilities are old–some over 100 years–and were not constructed under modern seismic standards. The SFPUC considers several major facilities to be at high risk of failure from earthquake events on the Hayward, San Andreas, and Calaveras faults. 02 cont.

Our committee recommends the final PEIR strongly reiterate the primary purpose of the WSIP–to improve the reliability of the water system that serves 2.5 million people in the Bay Area. The urgency of these upgrades and the implementation of the capital program should not be minimized or delayed by any debate over growth and the Bay Area's projected needs in 2030. In this era of world-wide construction cost escalation, we are naturally concerned, as is the SFPUC and the other parties to the system, about cost overruns due to delays, and emphasize that existing public policy stresses quick, efficient seismic retrofitting and delivery reliability as the WSIP's most significant priorities.

2. Conservation and efficiency modeling

We recommend more robust implementation of conservation and efficiency measures by both San Francisco's retail customers and the SFPUC's wholesale customers. According to the draft PEIR, wholesale customers projected a 19% increase in population and a 30% increase in the number of jobs. Total water demand, including commercial and industrial uses and driven by increased employment, will only go up only 19% by 2030, reflecting increased water conservation and recycling. Total per capita water demand, including commercial and industrial use, will remain flat in spite of the increased number of jobs. Wholesale customers have committed to implementing a suite of proven water conservation measures in addition to demand reductions due to passive conservation achieved through plumbing codes. Wholesale purchase requests from the regional water system will also be reduced by an increase in water recyling and desalination. 03

San Francisco will also experience growth in population and employment, both which exert additional demands for water. However, San Francisco water demand is expected to decline as much as 11%, in spite of an expected 12% growth in population. This decrease in demand is due to a plan to begin water recycling and increase water conservation in the city.

The SFPUC's preferred alternative to the WSIP, as reviewed in the PEIR, recommends that water be diverted from the Tuolumne River in order to meet the remaining water needs of both retail and wholesale customers in 2030. The draft PEIR also presents an "Environmentally Superior Alternative" that requires water recycling to begin in San Francisco and more water conservation than the wholesale customers have currently committed to implement. SPUR believes this alternative represents a better approach.

We believe San Francisco's WSIP should exceed or meet the California Urban Water Conservation Council Best Management Practices for Water Conservation. We are encouraged that both San Francisco and the wholesale customers evaluated the cost effectiveness potential of water conservation measures beyond those currently listed as Best Management Practices. However, we believe all of the agencies should continuously be improving their water conservation practices.[2] We recommend the final PEIR more fully describe and evaluate the Environmentally Superior Alternative, including the ways this additional level of conservation might be attained. 03 cont.

3. Drought and climate change modeling and assumptions

The draft PEIR acknowledges that climate change and global warming are a fact. Drought cycles are also a reality in California. We are concerned about the effects of combined forces of drought and climate change on the Hetch Hetchy system. Potential impacts could vary from an unsustainable level of instream flow, to the inability to meet delivery needs. We recommend that the PEIR seriously consider the combined effects of drought and climate variability. Absent a serious evaluation, it cannot be said that global warming will not negatively affect the WSIP.

In the SFPUC design drought model of 8.5 years, approximately 6 years are drought, dry, below-normal or normal-restoring years. With 60% of its water diverted at present, the Tuolumne River is already affected by these types of conditions, and would be at greater risk during an extended drought cycle, which could occur unpredictably due to future climate change. However, the draft PEIR concludes that climate change will have a minimal effect on the river. It states that current models of California water systems do not reflect potential global warming conditions, and that the existing Hetch Hetchy Local Simulation Model, based on 84 years of hydrologic records, is a more accurate predictor of impacts that may occur in the future. The draft concludes that the effects of climate change and global warming will not be measurable until near mid-century, at which time adjustments can be made. Without analyzing the combined and cumulative effects of two potential hydrological scenarios in the future – drought and climate change – the PEIR's conclusion that global warming will not affect the WSIP is unsubstantiated. 04

In other California jurisdictions, conservation, flexible management plans and regional strategies have been identified as best management practices in drought and climate risk scenarios. For example, recognizing the challenges and uncertainties of climate change and global warming, the East Bay Municipal Utilities District (East Bay MUD) analyzed and quantified possible climate change and global warming impacts, and developed operation models that included flexible management plans, efficiency and conservation. East Bay MUD became the first water district to join the California Climate Action Registry. 05

Following the local leadership of East Bay MUD, we recommend that the PEIR further address the combined effects of climate change and drought cycles to ensure that the

[2] Water conservation is a proven, efficient, reliable approach that is compatible with and supportive of local needs, growth, and development. (Nelson, Barry, Schmitt, Monty, Cohen, Ronnie, Ketabi, Noushin, Wilkinson, Robert, 2007. *In Hot Water, Water Management Strategies to Weather the Effects of Global Warming,* Natural Resources Defense Council, New York, NY)

Tuolumne River and its interconnected ecosystems are not exposed to potential, irreversible harm and damage. This, in turn, would protect water delivery reliability, and the health, safety, environmental, and economic stability of the Bay Area.

We believe that climate change should be further examined, but not at the expense of delaying the urgently needed seismic improvements to the regional water system. The PEIR should require that as the WSIP projects move forward, the climate change issues will be rigorously addressed and not merely swept aside for future generations to resolve. 05 cont.

Conclusion: Sustainability and the draft PEIR

The San Francisco Bay Area has a worldwide reputation for its strong commitment to sustainability, ecosystem protection, and climate change action.

The final PEIR developed for San Francisco's Water System Improvement Program should reinforce what San Francisco has already accomplished. The Environmentally Superior Alternative relies on increased levels of water conservation and recycling that represents a cost-effective strategy for the WSIP to protect the environment and provide growth and development for customers' needs. 06

Because of the potential risk to the river and its interconnected rivers, streams, delta, and eco-systems, the final PEIR should carefully analyze the effect of additional water loss to the Tuolumne. The final PEIR should evaluate additional opportunities to mitigate or avoid decreased flows in the lower Tuolumne River. Finally, the Bay Area's growing awareness of climate change, and our vulnerability to water being in the wrong places at the wrong time, strongly highlight the need for our water system to be as robust as possible for any future climate scenario. 07

The SPUR Sustainable Development Committee believes that the SFPUC can and should be a model of water leadership in the 21st century, and hopes you will receive these comments in that light. SPUR stands ready to support the SFPUC in this endeavor.

Sincerely,

Laura Tam
Sustainable Development Policy Director

SEP 2 6 2007
CITY & COUNTY OF S.F.
PLANNING DEPARTMENT
M E A

September 25, 2007

Mr. Paul Maltzer
Environmental Review Officer
Water System Improvement Program DPEIR
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Dear Mr. Maltzer:

The State Water Contractors (SWC) submits these comments regarding the Draft Program Environmental Impact Report (DPEIR) for the San Francisco Public Utilities Commission's (SFPUC) Water System Improvement Program (WSIP). As described in the DPEIR, the SFPUC proposes through the WSIP to increase the reliability of the regional water system, which provides drinking water to the City of San Francisco and areas of San Mateo, Santa Clara, Alameda, and Tuolumne Counties. WSIP implementation would provide for additional water supply to serve customers through 2030 as well as construction repairs and improvements to many facilities within the existing SFPUC system.

The SWC is an organization representing 27 of the 29 public water entities[1] that hold contracts with the California Department of Water Resources (DWR) for the delivery of water from the State Water Project (SWP). Collectively, the members of the SWC provide all, or a part, of the water supply delivered to approximately 23 million Californians, roughly two-thirds of the State's population. The members of the SWC provide this water to retailers, who, in turn, serve it to consumers throughout the San Francisco Bay Area, the San Joaquin Valley, the Central Coast, and Southern California.

The SWP supply delivered through the Sacramento-San Joaquin Delta constitutes a significant portion of the supplies available to SWC members. As a result, the SWC is very interested in matters affecting the quantity and quality of water supplies in the Delta. As described in the DPEIR, implementation of the WSIP would reduce inflow to Don Pedro Reservoir, resulting in reduced reservoir storage. During hydrologically wet periods, more inflow would be required to refill the reservoir storage, resulting in reduced flow in Tuolumne River below La Grange Dam and, as a result, reduced inflow to the Delta from the San Joaquin River. Reduced inflow to the 01

Mr. Paul Maltzer
September 25, 2007
Page 2

Delta from the San Joaquin River can result in negative impacts to both Delta water quality and the SWP supply.

As shown in Table 5.3.4-4 of the DPEIR, reductions in Tuolumne River flow below La Grange Dam attributable to the WSIP would occur most frequently during the months of January through June in wet and above normal years. Although the flow reductions generally would be less than 200 cfs, there would be several years in which the flow reduction during a single month would exceed 1,000 cfs. A flow reduction of this scale would likely result in significant negative impacts to Delta water quality and/or SWP supply. 01 cont.

Alternatively, the DPEIR identifies the Modified WSIP Alternative as the environmentally superior alternative. The Modified WSIP Alternative would meet the WSIP's objectives while reducing key impacts associated with implementation of the WSIP. As stated on pages 9-78 and 9-79 of the DPEIR, under the Modified WSIP Alternative:

> *"...a transfer of conserved water would be acquired for use every year, not only as a dry-year supplement, and doing so would avoid the WSIP impacts on the lower Tuolumne River below La Grange that result from the SFPUC increasing its diversions from the Tuolumne River."* 02

Due to the likely significant negative impacts associated with implementation of the WSIP described above, the SWC recommends that the SFPUC either (1) adopt the Modified WSIP Alternative as the preferred alternative with appropriate supporting environmental analysis or (2) provide an analysis of WSIP implementation attempting to adjust the timing of Don Pedro Reservoir refill both to reduce the scale of monthly flow reductions in Tuolumne River below La Grange Dam and to coincide with periods of excess conditions in the Delta. 03

We appreciate your consideration of our comments. If you have any questions, please feel free to contact me at (916) 447-7357.

Sincerely,

Laura King Moon for

October 1, 2007

San Francisco Planning Department

Paul Maltzer, Environmental Review Officer

WSIP PEIR

1650 Mission Street, Suite 400

San Francisco, CA 94103

Dear Mr. Maltzer,

Thank you for the opportunity to comment on the Draft PEIR for San Francisco Public Utilities Commission's Water Service Improvement Plan.

These comments represent the views of the six commercial outfitters who are permitted to conduct whitewater rafting trips on the Tuolumne River between Holm Powerhouse and Don Pedro Reservoir. The viability of our businesses, the quality of our trips and the satisfaction of our guests are all dependent on reliable and adequate flows downstream of SFPUC facilities.

We are opposed to any changes to the system that would or could potentially degrade the quality of our trips. The withdrawal of additional water from the river as described in the WSIP could be detrimental to our businesses however these negative impacts can be mitigated by management and operational decisions 01
outside the WSIP.

For the past several years we have worked together with SFPUC staff to develop a mutual understanding of our respective needs and constraints. During this time, each party has been accommodating and has made adjustments to help the other; power generation has been scheduled to allow for early releases from Holm Powerhouse to facilitate rafting trips and rafting trips have been modified to fit the daily, weekly and seasonal schedules of Hetch Hetchy operations. Great progress has been made and the arrangement seems to be working well; we hope to see this relationship and cooperation continue.

The PEIR describes this relationship and situation accurately; however there are some technical points and specific figures regarding recreational flows that need official clarification. These comments will focus on Section 5.3.8 Recreational and Visual Resources and more specifically on the portions of that section that pertain to whitewater recreation flows.

02

One of the confusing and misleading premises behind the specific figures in the PEIR has to do with the context of the terms "minimum" and "adequate". The "minimums" we have expressed and that the PEIR cites are based on and influenced by our understanding of the Hetch Hetchy system and of the financial and water supply needs of San Francisco. In the same way that "*if SFPUC were to operate solely to meet its own municipal and retail demand for energy or to maximize revenue from power sales, it would generate hydropower during the midday period only*"; if we were to operate the system "*solely to meet our own recreational needs and to maximize the quality of our trips, we would generate hydropower to produce higher flows, earlier and longer release periods and longer seasons*."

Our "minimums" are based on system constraints, Hetch Hetchy operational goals and the SFPUC policy of "water-first"; they represent a "survival" scenario, not an "optimal" scenario. If a restaurant can ONLY obtain four-ounce chicken breasts and cabbage, it will say that four-ounce chicken breasts and cabbage are the minimum ingredients that it needs to provide a meal. But, if patrons prefer eight-ounce chicken breasts and coleslaw, (the "optimal" meal), the prudent restaurant will try to find and provide them. The restaurant may be able to survive on the minimums, but in order to prosper, the restaurant needs to meet the needs of its patrons by offering the optimal meal.

The "minimums" expressed in the PEIR are four-ounce chicken breasts and cabbage; the "optimals" are as follows: 02 cont.

Volume of water in the river: 1,500 to 2,000 cfs

Days per week of reliable flows: 7

Hours per day of reliable flows: 8 (peak flow at Meral's Pool by 7:00 am)

Weeks per season of reliable flows: 31 (March 15 – October 15)

In terms of the PEIR, the third paragraph on Page 5.3.8-10 should read:

> A ~~900 cfs~~ 1,100 cfs flow at Lumsden Campground is the minimum required for whitewater paddleboats and oar boats; a ~~600 cfs~~ 900-cfs flow is the minimum required for kayaks ~~and oar boats~~, and a ~~1200 cfs~~ 1,500 to 2,000-cfs flow is considered optimal. The commercial outfitters prefer ~~a six-hour~~ an eight-hour release, but a ~~three-hour~~ four-hour release allows them to launch one-, two-, or three-day trips. 03

Under current operating conditions and during the "core" part of our season (June through August) the "minimum" flows in the stretch of river on which we operate are delivered from the Cherry Lake/Holm Powerhouse side of the system. While changes to the Hetch Hetchy/Kirkwood Powerhouse side of the system could potentially impact us, these impacts, as described in the PEIR, can be mitigated through operational changes and concessions on the Cherry side.

It is our sincere hope and expectation that the current "minimum" flows and the potential for future "optimal" flows will not be jeopardized by the Water System Improvement Plan. 04

SI_TROA

Sincerely submitted on behalf of the six commercial outfitters on the Tuolumne River (ARTA River Trips, All-Outdoors, OARS, Whitewater Voyages, Sierra Mac and Zephyr Whitewater.

Water System Improvement Program PEIR

1 message

Amy Meyer <a7w2m@earthlink.net> **Fri, Sep 28, 2007 at 12:58 PM**
To: wsip.peir.comments@gmail.com

September 28, 2007

Paul Maltzer, Environmental Review Officer
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103 via e-mail

Dear Paul:

I was one of the founding members of the Tuolumne River Trust. I became involved in preserving the Tuolumne because of its incredible biological and recreational attributes. We helped designate 70 miles of the river as "Wild and Scenic" in 1984. I understand the need for rehabilitation of the Hetch Hetchy delivery system, but I do not want it to take place at the expense of the Tuolumne River.

01

The new threat to the Tuolumne is the prospective diversion of more water than it can give up without severely damaging the splendid diversity of its ecological communities—from the free-flowing headwaters in the mountains to its freshwater outflow into San Francisco Bay. More than 60% of the river is already diverted, and the proposed additional diversion would remove another 25,000,000 gallons per day. Considering the threat of global warming and a smaller snow melt than we have enjoyed in recent times, we ought to do everything we can to keep as much water as possible flowing in the river.

Other large cities have reduced water consumption. The service area of the Hetch Hetchy system has not utilized all possible methods of conservation and recycling. One conspicuous area ripe for improvement and much more widespread use is the development of "gray water" systems for irrigation.

02

Scott MacDonald, Assistant General Manager of the SFPUC, said in the September 24, 2007 SF Examiner, "Despite recent water rate increases, San Franciscans still pay lower water rates than most other Bay Area and California cities, including San Diego, Los Angeles, Oakland, Berkeley, Palo Alto and San Jose."

It seems to me that the SFPUC's pricing structure does not encourage enough conservation and recycling of water to meet increased water demand. That is where some of the investment in our water system needs to go, and that is what the SFPUC should be emphasizing in order to preserve the flow of the Tuolumne River.

Sincerely yours,
Amy Meyer

Re: Comments regarding the Draft Program Environmental Impact Report (DPEIR) for the San Francisco Public Utilities Commission's Water System Improvement Program (WSIP)

Dear Mr. Maltzer:

The Tuolumne River Trust, Clean Water Action and Sierra Club appreciate the opportunity to comment on the Draft Program Environmental Impact Report (DPEIR) for the San Francisco Public Utilities Commission's (SFPUC) Water System Improvement Program (WSIP). Our groups wholeheartedly support the timely completion of projects needed to repair aging and seismically-vulnerable infrastructure in order to protect the SFPUC's water supply system from earthquakes and other disasters.

The WSIP also includes a proposal to divert more water from the Tuolumne River to meet an anticipated increase in demand among the SFPUC's wholesale customers. Our review of the water supply aspects of the WSIP, and the DPEIR, uncovered several technical flaws and pitfalls. The attached comments provide greater detail on these shortcomings that we hope the San Francisco Planning Department will find useful in completing an adequate environmental review.

Creating a water plan for 2030 presents a unique opportunity for San Francisco, and the SFPUC's wholesale customers, to become a leader in water use efficiency, conservation and recycling. By pursuing a sustainable path, the Bay Area can increase water supply reliability and become a better steward of the Tuolumne and Bay Area Watersheds. As we work to pursue collaborative approaches through the planning and environmental review process, we welcome the opportunity to discuss our comments with you in greater detail.

Sincerely,

Peter Drekmeier
Tuolumne River Trust

Jennifer Clary
Clean Water Action

John Rizzo

SI_TRT-CWA-SierraC

Executive Summary

Comments on the WSIP DPEIR from Tuolumne River Trust,
Sierra Club and Clean Water Action
October 1, 2007

The Tuolumne River Trust, Sierra Club and Clean Water Action have reviewed the Draft Program Environmental Impact Report (DPEIR) for the proposed Water System Improvement Program (WSIP). Our combined comments focus on inadequacies in the DPEIR regarding the proposal to divert additional water from the Tuolumne River.

There are a number of areas in which the DPEIR fails to produce adequate baseline data, relies on flawed modeling, or reaches erroneous conclusions. It is difficult, if not impossible, to predict the impacts of diverting additional water from the Tuolumne River without adequate information, modeling and analysis.

The DPEIR attempts to assess the impacts to biological resources of WSIP-related flow changes with little or no reference to current biological conditions. This lack of information regarding current biological conditions creates two problems: (1) there is no biological baseline against which to compare conditions under the WSIP, and (2) there is no indication that current conditions are satisfactory with respect to a desired condition or legal requirements. As a result, there is no way to interpret the meaning of the DPEIR's claims that biological conditions under WSIP would be acceptable because WSIP would produce "small," "infrequent" or "rare" changes from current conditions. 01

Following is a summary of our primary concerns:

- Some studies referenced in the DPEIR were incomplete drafts. For example, a 1992 instream flow study conducted by the United States Department of Fish and Wildlife never moved beyond its draft stage, and the data is now 15 years old. The study concluded that minimum flow releases below O'Shaughnessy Dam needed to be increased; however, this recommendation was never adopted.
- The DPEIR lacks data on the health of Chinook salmon (a species of special concern) and steelhead trout (listed as "threatened"). The Chinook salmon population has declined from a high of approximately 130,000 in 1944 to just a few hundred individuals in recent years. The DPEIR presents no analysis of current population size for steelhead.
- Studies referred to in the DPEIR are old, outdated and may no longer be accurate. For example, there has not been a comprehensive study of the upper Tuolumne River in over fifteen years. Without information on baseline conditions, the DPEIR fails to assess the impacts of the proposed diversion in this part of the watershed.
- The DPEIR concludes, without any critical analysis, that hydrological and meteorological conditions in the next 82 years will be identical to those in the preceding 82 years. The analysis dismisses the potential impact of climate change on precipitation and river hydrology, and failed to identify or consider trends over the 82-year period.

- According to the DPEIR, per-capita demand for wholesale customers is projected to increase over current demand, despite numerous studies that show that substantial cost-effective reductions are possible using available technologies and policies. More specifically:
  - The analysis of future water demand does not include price-driven efficiency improvements, despite an estimated quadrupling of the price of water from the SFPUC by 2015.
  - Per-capita outdoor water use is projected to increase, indicating that the proposed conservation does not adequately address this issue.
  - The forecasting method for future water demand assumes that the current composition of commercial and industrial businesses will not change, and it ignores the variability in water use in the non-residential sector.
  - The wholesale demand study may overestimate future employment, thereby inflating 2030 non-residential demand.
  - The DPEIR did not adequately analyze the full potential for water conservation and recycling. It ignores a 2006 SFPUC study that identified measures that would reduce the need for more diversion by 74%.

- The DPEIR fails to define thresholds of significance in measurable, quantifiable terms. It consistently confuses the frequency of an event with the severity of its impact. A severe impact (*e.g.*, a seismic incident) could be significant even if it is unlikely to occur frequently. By the same token, a frequent impact (*e.g.*, a modest level of soil erosion each time it rains) could be cumulatively significant even if a single occurrence would have only a small impact.

- The DPEIR obscures analysis of potential impacts related to flow fluctuations by aggregating data into monthly averages. However, many biological, hydrological, and geomorphological processes respond to changes in flow on a daily or hourly basis. 01 cont.

- It is unclear whether the SFPUC has the right to divert more water from the Tuolumne. The SFPUC's pre-1914 appropriative right was for storage of water for hydroelectric power generation. Hydropower generation is considered a non-consumptive use right because the water is returned to the stream system.

- A proposal to enter into water transfer agreements with the Modesto and Turlock Irrigation Districts (MID/TID) is uncertain because the Districts have not expressed interest in the plan.

- Two proposed fishery habitat restoration projects are problematic because they mitigate for different problems than what would be created by reduced flows.

- In some cases, the SFPUC would rely on other agencies to meet flow objectives. However, the California Environmental Quality Act (CEQA) requires that mitigation measures "must be fully enforceable through permit conditions, agreements, or other legally binding instruments."

- The DPEIR fails to address the impact of recent Delta pump rulings on releases from Don Pedro Reservoir.

In conclusion, the Tuolumne River Trust, Sierra Club and Clean Water Action have identified numerous inadequacies in the WSIP DPEIR. Please see our complete comments for a thorough evaluation.

COMMENTS ON THE WSIP DPEIR

From the Tuolumne River Trust, Sierra Club and Clean Water Action

October 1, 2007

The Tuolumne River Trust, Sierra Club and Clean Water Action have reviewed the Draft Program Environmental Impact Report (DPEIR) for the proposed Water System Improvement Program (WSIP). Our combined comments focus on inadequacies in the DPEIR regarding the proposal to divert additional water from the Tuolumne River.

Our comments are organized under three main categories:

1. Inadequate Studies/Lack of Baseline Data
2. Flawed Modeling/Analysis
3. Faulty Assumptions

In addition to the various comments made in this letter, we offer a number of additional specific comments in Attachment A.

We also include the following Attachments:

Attachment A:	Matrix of additional comments.
Attachment B:	Tables 1 and VI from *Instream Flow Requirements for Rainbow and Brown Trout in the Tuolumne River Between O'Shaughnessy Dam and Early Intake*, Michael Aceituno for the U.S. Fish and Wildlife Service, 1992.
Attachment C:	Graph of decline of Chinook salmon.
Attachment D:	*Central Valley Steelhead*, Dennis R. McEwan, 2001.
Attachment E:	*In Hot Water: Water Management Strategies to Weather the Effects of Global Warming*, Natural Resources Defense Council, 2007.
Attachment F:	Reports on Climate Change and the Sierra Snowpack.
Attachment G:	*Leaders talk climate change at Hetch Hetchy*, Union Democrat, September 24, 2007.
Attachment H:	*A Review of the San Francisco Public Utilities Commission's Retail and Wholesale Customer Water Demand Projections*, Pacific Institute for Studies in Development, Environment and Security, 2007.
Attachment I:	Studies on Water Conservation.
Attachment J:	Selected presentations from "Sustainable Water Supply Briefing," September 28, 2006.

General: Water Enterprise Environmental Stewardship Policy

"It is the policy of the SFPUC to operate the SFPUC water system in a manner that protects and restores native fish and wildlife downstream of SFPUC dams and water diversions, within SFPUC reservoirs, and on SFPUC watershed lands." So states the SFPUC's Water Enterprise Environmental Stewardship Policy (WEESP) adopted in 2006. 02

The Policy establishes environmental stewardship as a fundamental component of the Water Enterprise mission, and was adopted with the explicit intent that implementation of the policy would occur through: "Integration of the policy into the Water System Improvement Program and individual infrastructure projects (i.e., repair and replacement programs)," and by ensuring "that the policy guides development of project descriptions, alternatives and mitigation for all SFPUC projects during the environmental review process under CEQA 02 cont.
and/or NEPA."

The WEESP is a foundational policy for the WSIP, but is missing from Table 2.3 (DPEIR, Vol. 1, p. 2-46). Because the proposed program would have significant impacts on downstream native fish and wildlife populations, the SFPUC has failed to "integrate" the Environmental Stewardship Policy into the WSIP.

I. INADEQUATE STUDIES / LACK OF BASELINE DATA

There are a number of areas in which the DPEIR fails to produce adequate 03
baseline data. It is difficult, if not impossible, to predict the impacts of diverting additional water from the Tuolumne River without adequate information.

The DPEIR attempts to assess the impacts to biological resources of WSIP-related flow changes with little or no reference to current biological conditions. This lack of knowledge regarding current biological conditions creates two problems: (1) there is no biological baseline against which to compare conditions under the WSIP, and (2) there is no indication that current conditions are satisfactory with 04
respect to a desired condition or legal requirements. As a result, there is no way to interpret the meaning of the DPEIR's claims that biological conditions under WSIP will be acceptable because WSIP will produce "small" or "infrequent" or "rare" changes from current conditions.

This section of our comments addresses the lack of baseline data in the following areas:

a) A 1992 Instream Flow Study Was Never Completed
b) Lack of Data on the Decline of Chinook Salmon
c) Lack of Data on Steelhead Trout 05
d) Lack of Baseline Data for the Upper Tuolumne
e) Lack of Data on Impacts to Streamside Meadows
f) Lack of Data on the Potential Impacts of Climate Change
g) Lack of Data on Groundwater Resources

a) <u>A 1992 Instream Flow Study Was Never Completed</u>

Pursuant to California State Fish and Game Code § 5937[1], the SFPUC is obligated 06
to maintain healthy populations of fish below its dams. Before assuming that

[1] Fish & Game C. § 5937 states, in pertinent part: "The owner of any **dam** shall allow sufficient water at all times to pass through a fishway, or in the absence of a fishway, allow sufficient water to pass over,

meeting minimum flow standards is adequate to maintain healthy fish and wildlife populations in the future, the SFPUC must show that its minimum flow standards are currently maintaining healthy fish and wildlife populations. The baseline documentation, particularly for the reach below O'Shaughnessy Dam, fails to demonstrate this due to the lack of recent studies.

The DPEIR references the rough draft of a report entitled "Instream Flow Requirements for Rainbow and Brown Trout in the Tuolumne River Between O'Shaughnessy Dam and Early Intake." This report was never completed, and 06 cont.
the draft is more than 15 years old, however, it states:

> "In 1988, the U.S. Fish and Wildlife Service's Instream Flow Incremental Methodology (IFIM) was applied to the Tuolumne River below Hetch Hetchy Reservoir…An annual fishery allocation of between 59,207 acre-feet and 75,363 acre-feet is recommended, based on the findings of the instream flow study."[2]

The study concluded that minimum flow releases below O'Shaughnessy needed to be increased (see "Attachment B"), however, this recommendation was never adopted.

In a letter submitted during the scoping phase for the DPEIR, the State Water Resources Control Board stated, "it appears that the DEIR should include sufficient information for the State Water Board to use the document for water right permitting purposes. However, the document still fails to evaluate the availability of unappropriated water after taking into consideration prior rights 07
and the water required to maintain public trust resources. Division staff recommends that any evaluation utilize a cumulative flow impairment methodology, such as the assessment method described in the *Guidelines for Maintaining Instream Flows to Protect Fisheries Resources Downstream of Water Diversions in Mid-California Coastal Streams (Draft)* prepared by NOAA Fisheries Service and the Department of Fish and Game and dated June 17, 2002."

The impact evaluation in the DPEIR does not employ a cumulative flow impairment methodology and falls short of answering the question of whether there is sufficient water available to maintain public trust resources.

08

If recent fish population surveys are lacking for the upper watershed, how was the SFPUC able to determine if public trust resources are being maintained currently, let alone with the WSIP?

around or through the **dam**, to keep in good condition any **fish** that may be planted or exist below the **dam**."

[2] Michael Aceituno for the U.S. Fish and Wildlife Service. 1992. "Instream Flow Requirements for Rainbow and Brown Trout in the Tuolumne River Between O'Shaughnessy Dam and Early Intake"

12.4-92

b) Lack of Data on the Decline of Chinook Salmon

Historically, the Tuolumne River supported at least two distinct runs of Chinook salmon – spring and fall, and populations in this river were believed to be "very large" (Yoshiyama et al. 2001).[3] By the early 1950s, the Tuolumne's spring-run Chinook were extirpated. The fall-run Chinook salmon population has declined from a high of approximately 130,000 in 1944 to just a few hundred individuals in recent years (see "Attachment C").

The 1996 Federal Energy Regulatory Commission (FERC) Order Amending the License for the New Don Pedro Project, which was based on the 1995 Settlement Agreement, to which the San Francisco Public Utilities Commission was a signatory, required a restoration program for Chinook salmon and 10-years of monitoring. Despite the implementation of four of the ten required restoration projects, the salmon population continues to decline. Additionally, monitoring has shown that flows do have a strong influence on the number of adult salmon that return to spawn. Additional withdrawals of water from the Tuolumne will only compound the problem and further harm a population of fish that is already on the verge of extirpation. The DPEIR must explain the reasons for the decline in Chinook salmon. 09

As best we can tell, TID and MID routinely divert less than the total amount of water guaranteed under their water rights. In approximately 72% of years TID/MID combined diversions are less than their water rights as reported in the DPEIR. Average diversions (861,451 afy) are approximately 44% of the computed maximum annual allotment (1,940,000 afy). Apparently, TID and MID do not routinely divert their total annual entitlement. This suggests that these two entities may have latitude to increase their usage if they feel the need to do so. As a result, the DPEIR's assumption that annual TID/MID diversions would remain constant at 867,000 afy seems unrealistic. An adequate analysis of the proposed SFPUC diversion must include an estimate of future water use by these agencies and an analysis of the cumulative impact of all future increases in diversions from the Tuolumne River. 10

c) Lack of Data on Steelhead Trout

Steelhead trout (*Oncorhynchus mykiss*) were listed as a "threatened" species under the federal Endangered Species Act in 1998, and retain that protected status today. Yet, the DPEIR presents no analysis of current population size for steelhead (or the alternate life-history form, commonly called "rainbow trout"). Instead, the DPEIR relies on a FERC report from 1995 that concludes that steelhead do not occur in the Tuolumne or occur there only rarely. In fact, more recent reports have concluded that steelhead spawning does occur on the 11

[3] R.M. Yoshiyama, E.R. Gerstung, F.W. Fisher, and P.B. Moyle. 2001. "Historical and Present Distribution of Chinook Salmon in the Central Valley Drainage of California" *in* "Contributions to the biology of Central Valley Salmonids," Volume 1, *ed.* Randall Brown. California Dept. of Fish and Game. Fish Bulletin 179.

Tuolumne River; for example, McEwan (2001)[4] (see "Attachment D") provides a detailed account of reports of this species on the Tuolumne in recent years. An adequate draft PEIR must include current information about steelhead presence and population. (*See* CEQA Guidelines § 15125(a))[5] 11 cont.

Because the DPEIR references no monitoring program that would accurately assess the status of *O. mykiss* in the Tuolumne River, there is no way to evaluate the numerical response of this species to proposed flow changes. Perhaps more importantly, because SFPUC and other users of the Tuolumne hydrosystem have not yet established a monitoring program for *O. mykiss*, there is no way to tell whether *current* operating practices for the Tuolumne River hydrosystem produce acceptable conditions for this or other important fish species. The DPEIR does mention that the SFPUC is about to implement a monitoring program, but results do not exist today. It is quite possible that current operations lead to unacceptable conditions for Central Valley steelhead and that these operations violate requirements of the Endangered Species Act and other laws and regulations, such as Fish and Game Code § 5937. 12

The fact that steelhead were historically abundant in the Tuolumne (Yoshiyama et al., 2001; Lindley et al., 2006[6]) and are "rare" today emphasizes the need to operate the Tuolumne hydrosystem in ways that encourage steelhead population growth.

An adequate review and mitigation proposal for impacts to anadromous species, including *O. mykiss*, requires that the SFPUC implement a comprehensive monitoring system on the Tuolumne River below La Grange Dam for several years. Results from this monitoring are needed before impacts can be adequately assessed or mitigated, and should be in hand before flow reductions on the Tuolumne are proposed and analyzed, let alone approved or implemented. *See Sundstrom v. County of Mendocino* (1988) 202 Cal. App. 3d 296, 306-08 (studies essential to adequate CEQA review must precede project approval). 13

d) Lack of Baseline Data for the Upper Tuolumne

There has not been a comprehensive study of the upper Tuolumne River in over fifteen years. Without information on baseline conditions, the DPEIR does not adequately assess the impacts of the proposed diversion in this part of the watershed. 14

In 2006, the SFPUC initiated the first comprehensive study of the upper Tuolumne River in over 15 years. Initial findings from the first year of study

[4] Dennis R. McEwan. 2001. "Central Valley Steelhead."

[5] (Draft EIR "must include a description of the physical environmental conditions in the vicinity of the project, as they exist at the time the notice of preparation is published....")

[6] Lindley, ST, RS Schick, A Agrawal, M Goslin, TE Pearson, E Mora, JJ Anderson, B May, S Greene, C Hanson, A Low, D McEwan, RB MacFarlane, C Swanson, and JG Williams. 2006. Historical population structure of Central Valley steelhead and its alteration by dams. San Francisco Estuary and Watershed Science 4(1) Art. 3.

show significant alteration of the natural hydrology, especially in dry years and "recovery" years following dry years, when the SFPUC restores reservoir levels.

The National Park Service initiated its "Tuolumne Wild and Scenic River Comprehensive Management Plan" in 2006. This plan will cover the 54 miles of designated Wild and Scenic River within Yosemite National Park, including the six-mile reach of the Tuolumne River, downstream of the Hetch Hetchy Reservoir, that passes through the Poopenaut Valley. The intended purpose of the plan is to establish the overall goals and vision for the river corridor. It will provide broad, conceptual-level management objectives that may amend the *General Management Plan for Yosemite National Park* (1980) for the river corridor. 14 cont. The draft environmental impact statement is scheduled for release in 2008, with the final report expected in 2009 (NPS, 2006b, 2007). (DPEIR Vol. 3, 5.2-16)

As with the DPEIR's failure to provide current information regarding the presence of steelhead, its lack of current baseline data regarding the upper Tuolumne River provides no rational basis for conclusions regarding the potential impacts of increased water diversions on the upper Tuolumne and associated resources. *See* CEQA Guidelines § 15125(a) (quoted above). With no immediate need for additional water supply or the proposed diversion, any proposal to divert additional water from the Tuolumne must be tabled until these two studies have been completed.

e) Lack of Data on Impacts to Streamside Meadows

The DPEIR acknowledges that it does not provide baseline data as to the "extent, species composition and condition of the existing meadow vegetation within the Poopenaut Valley." (p. 6-50.). It speculates that some (but not all) of this data may be available in the study mentioned above, but the DPEIR does not provide it. The DPEIR states in footnote 5 (page 6-50) that this ongoing study will 15 "examine sediment transport and deposition relationships with flow." It does not mention the collection of data regarding the extent of rare or endangered plant species or impacts to wildlife.

For these other impacts, the DPEIR states that baseline data collection surveys will be conducted in future years, with the implication that this would be well after the Final PEIR is approved. This is inadequate under CEQA. There are no assurances or approval stages to guarantee that this data collection will actually occur. CEQA requires the project agency preparing the DPEIR to provide the 16 data that describe the existing environmental setting. Without baseline data as to the current condition of the meadows and other features of the Poopenaut Valley, it is impossible to perform an adequate analysis of the impacts of the WSIP project on native meadow vegetation, the animals that depends on the vegetation, other natural resources, and access by recreational users.

Measure 5.3.7-2, "Controlled releases to recharge groundwater in streamside meadows and other alluvial deposits," requires the SFPUC to manage releases 17 from O'Shaughnessy Dam during the spring to recharge groundwater in the riverside meadows in the Poopenaut Valley. It does not specify the time or

SI_TRT-CWA-SierraC

magnitude of these releases. This measure appears to assume that flows would 17 not need to be increased, just released in a different manner. cont.

The DPEIR does not provide any supporting studies that detail how current SFPUC operations interact with the downstream meadows. In fact, the most recent ecological study of the Upper Tuolumne Watershed could only hypothesize about the relationship between flows and meadows in the riparian corridor and recommends future monitoring in order to understand this relationship. 18

Without completed studies that illuminate the meadow/groundwater dynamics, the SFPUC cannot know whether substantial flow increases will be necessary in order to protect the sensitive habitats and special-status species. Without the proper studies, it is speculative to assume that any flow release pattern adjustments will mitigate the impacts on these sensitive habitats.

There are no mitigations proposed or discussed for Recreational and Visual Resources for the Poopenaut Valley. This section simply states, "none required" without explanation. As a popular destination for recreational hikers within 19 Yosemite National Park, the DPEIR should identify possible impacts to access for recreational users due to changes in dam releases.

f) Lack of Data on the Potential Impacts of Climate Change

The longstanding consensus in the scientific community about the reality and potential large-scale impacts of global climate change has recently been accepted as a matter of public policy. Indeed, in Section 5.7.6, the DPEIR provides a sampling of recent studies and analyses that address this potential problem. Unfortunately, the DPEIR dismisses the potential impact of climate change on WSIP impacts. The report states, "There is no clear scientific consensus on exactly how global warming will quantitatively affect California water supplies…" (DPEIR Vol. 3, 5.7.-92). But exact quantification of the effects of climate change is not a prerequisite to having to examine these effects in an environmental analysis. *See, e.g., NRDC v. Kempthorne* (U.S. Dist. Court, E.D. Cal., 5/30/07) 2007 WL 1577896 at *38 - *41 (despite uncertainties, impacts of 20 climate change must be analyzed in evaluating impacts of water project operations on protected fish species).

Each of the general trends listed in this section, for which the DPEIR recognizes a scientific consensus, indicate that the SFPUC's reliance on the 82-year hydrological record for this system will overestimate water availability and underestimate water demands. In other words, an analysis built solely around the historic hydrological patterns in the Tuolumne basin underestimates the potential impacts of removing more water from the Tuolumne system. The DPEIR's "thumbnail" analysis of a 1.5°C increase in temperature between 2000 and 2025 is weak. It minimally addresses only one of the likely patterns resulting from global climate change identified in the DPEIR itself:

> "Reduction in the average annual snowpack due to a rise in the snowline and a shallower snowpack in the low- and medium-elevation zones such as in the Tuolumne River basin, and a shift in snowmelt runoff to earlier in the year" (DPEIR Vol. 3, 5.7.-92)

This "back of the envelope" analysis concludes that, because the shift in seasonal snowpack and snowmelt over the next 20 some odd years will be "within the current range of interannual variation in runoff…" there will be no significant impact of global warming. This conclusion ignores the fact that, during the last several decades, changes in hydrological conditions have been the primary culprit in declines of one species in the Tuolumne (steelhead) and several species in the larger Sacramento-San Joaquin system (Chinook salmon, Delta smelt, green sturgeon) that necessitated protection under the Endangered Species Act. The report should not equate "change within the historical range" with "no impact."

Other changes resulting from existing climatological trends that will persist over the next 20 years (such as decreased vegetative growth, decreasing water quality in the Delta, increased need for irrigation water, etc.) are not analyzed at all in the DPEIR. Even a simple translation of air temperature changes into water temperature changes in stretches of the Tuolumne and San Joaquin Rivers where fish species may be impacted was not attempted. 20 cont.

The DPEIR must do a much more complete analysis of global climate change impacts. Modeling an increase in temperature should encompass the following parameters:

- Increase in evaporation and transpiration from all system reservoirs.
- Increase in in-stream water temperature.
- Potential water quality impacts from increase in algae formation and other organic matter due to increased runoff and higher temperatures.
- Increase in water demand for agriculture.
- Impacts to riparian resources.
- Impacts of dwindling snowpack:
    - Smaller snowpack due to later onset of winter snow season.
    - Earlier snowmelt and peak runoff.
    - Reduction in water content of snow.
    - Increase in precipitation falling as rain rather than snow will change the operation of reservoirs, particularly Eleanor and Cherry, whose watersheds lie at lower elevations than Hetch Hetchy. This will require a change in reservoir operation which, when combined with the change in reservoir operations based on 300mgd demand, will result in a greater cumulative impact than that studied in the DPEIR.
- Reduction in hydropower generation.

Further, the increase is water usage assumed in this program is in conflict with California statute (AB 32, 2006), which mandates a 25% decrease in greenhouse gas (GHG) emissions by 2020. This statute should be cited in Chapter 4.2 (Vol. 2) and the impacts analyzed. The projected increase in gross per capita water use 21

SI_TRT-CWA-SierraC

assumed in the 2030 demand figure will increase the per capita GHG emissions due to increases in energy used for water treatment, use and disposal. The impacts should be analyzed for each of the alternatives, and mitigation proposed to ensure that each is in compliance with state law. 21 cont.

The argument that "there is no consensus" regarding the magnitude of changes over the next 20+ years is specious – mathematical models are specifically designed to assess the impact of changed assumptions on system outcomes. The hydrological and temperature models utilized by the DPEIR can be run with a range of different inputs predicted by the variety of climate change studies cited in the DPEIR.

In July of 2007, the Natural Resources Defense Council published *In Hot Water: Water Management Strategies to Weather the Effects of Global Warming* (see Attachment E). This paper outlines specific measurable impacts that have been identified with temperature increase. For instance:

- Snow levels are predicted to rise 500 feet for every degree Celsius of temperature rise. (This differs from the results of the modeling included in the DPEIR.) 22
- The increase in evaporation and transpiration due to a 2 degree Celsius increase in temperature would reduce mean annual runoff by 4-12%. (This has not been included in the modeling in the DPEIR.)
- The risk of a 100-year flood event will grow larger in the 21st century, rising from a 1 percent chance in any given year to as high as a 6 percent chance. This means occasional extreme events will become much more common.

Numerous studies exist that explore how climate change might affect the Sierra snowpack (see Attachment F). At a meeting of water industry leaders in September 2007, SFPUC spokesman Tony Winnicker said, "Water utilities, in many ways, are the first responders to the effects and consequences of global climate change," (see Attachment G). His acknowledgement emphasizes the need to consider the impacts of climate change in the WSIP DPEIR.

g) <u>Lack of Data on Groundwater Resources</u>

The document contends that impacts limited to shallow groundwater aquifers would be less than significant, since municipal and irrigation wells typically access deep aquifers. However, domestic wells typically access shallow groundwater, and a significant number of Central Valley residents rely on domestic wells for their drinking water supply. The DPEIR must review information at the county level and estimate the number of domestic wells in the vicinity of the Tuolumne River in order to make a rational determination on the significance of the impact. Because these residents have fewer alternatives than municipal water users, the impact of a loss of supply would be greater for them. This is a potentially significant, although mitigable, impact. 23

While it is appropriate to use conservative values for water system planning and for CEQA analysis, the combination of a lack of historic data and the failure to consider the potential of using local stormwater supply to enhance natural 24 aquifer recharge has led to an underestimate of the yield of the Westside Groundwater Basin. This, in turn, increases the impact on the Tuolumne River, as shortfalls in local supply are expected to be met by increased withdrawals from the Tuolumne. 24 cont.

The DPEIR should confirm at the beginning of Section 5.6 that both local and regional groundwater projects are subject to project-level CEQA review. 25

Figures 5.6-3 and 5.6-4 give some idea of historic pumping levels from municipal users of the aquifer, but contain only one data point (from 1965) for total withdrawals. Figure 5.6-4 is particularly baffling, as it shows only municipal usage for the period since 2000, a period when the aquifer has been closely monitored. In order to better understand past and current usage (and thus future sustainable yield) of the aquifer, it would be helpful to have these figures reflect total pumping volumes. The narrative in this section is confusing as it contains many individual pieces of data that would be more easily understood if contained in a table. 26

The DPEIR states that the amount of groundwater used for irrigation of the Golden Gate National Cemetery in San Bruno is undetermined (page 5.6-8)? Why is this so? Is this an unmetered use, and if so, what is the plan to measure this use? 27

The conjunctive use program outlined in the WSIP for the South Westside Groundwater Basin (p. 5.6-25) relies on passive recharge of the groundwater supplies and withdrawals based upon historic pumping levels. However, the available capacity of this aquifer exceeds the capacity of Crystal Springs Reservoir. The DPEIR should evaluate the potential of a proactive recharge program that uses local stormwater (for example, the same stormwater that Daly City is planning to dispose of in the ocean as part of its Vista Grande project) as a resource to increase the yield of the aquifer, reduce flooding, and meet increasingly rigorous NPDES stormwater regulations. 28

Impact 5.6-5 addresses contamination of drinking water due to groundwater pumping in the Westside Groundwater Basin. According to the analysis, current wells in this basin already exceed the drinking water standard for nitrates, an acute contaminant. Furthermore, sites for production wells have been identified as part of the basin management plan, and groundwater testing at these locations has shown similar contamination. Given this fact, a Source Water Assessment should be part of the DPEIR, and potential actions to address the contamination identified. 29

II. FLAWED MODELING/ANALYSIS

There are a number of areas in which the DPEIR uses flawed modeling or improper analysis of data to achieve its conclusions. It is difficult, if not impossible, to predict the impacts of diverting additional water from the Tuolumne River without adequate modeling and analysis. 30

This section of our comments addresses problems with flawed modeling or improper analysis of data in the following areas:

a) The DPEIR Uses Inflated Water Demand Projections
b) Underestimated Potential for Conservation and Recycling
c) Impacts of Reduced Flows on Hydrology and Geomorphology
d) Failure to Define Thresholds of Significance 30 cont.
e) Aggregation of Data into Time-Steps that Lack Relevance to Biological, Hydrological, or Geomorphological Processes
f) Lack of Significance Criteria for Groundwater Impacts
g) HH/LSM Modeling Methodology
h) HH/LSM Modeling Conclusions
i) Tables Are Inconsistent with Narrative

a) <u>The DPEIR Uses Inflated Water Demand Projections</u>

In *A Review of the San Francisco Public Utilities Commission's Retail and Wholesale Customer Water Demand Projections* (Attachment H), the Pacific Institute states:

> "Our analysis, however, reveals that the wholesale and retail demand studies may significantly overestimate future regional demand for water and underestimate the potential for cost-effective demand management and recycled water and therefore are inadequate."

Specifically, the study found:

- Per-capita demand for wholesale customers is projected to increase over current (2001) per-capita demand, despite numerous studies that show that substantial cost-effective reductions in per-capita demand are possible with available technologies and policies.
- The analysis of SFPUC retail and wholesale demand does not include price-driven efficiency improvements, despite an estimated quadrupling of the price of water from the SFPUC by 2015. 31
- Increases in residential demand are largely due to outdoor water use. For the wholesale and retail customers, per-capita outdoor use is projected to increase, indicating that the proposed conservation does not adequately address this issue.
- Future demand for the wholesale customers is not adequately evaluated. The forecasting method is flawed in that it assumes that the current composition of commercial and industrial businesses within the non-residential sector will not change over time, and it ignores the variability in water use in both quantity and purpose among users in the non-residential sector.
- The wholesale demand study may overestimate future employment, thereby inflating 2030 non-residential demand. Recent data indicates that economic recovery in the San Francisco Bay Area has been slower than expected, and consequently, the job outlook for the region has been adjusted downward. A slower economy would reduce projected water

demand for the non-residential sector. The demand forecast should be adjusted according to the most current information available. 31 cont.

By inflating demand projections, the DPEIR attempts to justify increased water diversion from the Tuolumne River. However, the water supply may then induce growth beyond ABAG and General Plan projections. The DPEIR states, "*SFPUC Projections (Section 7.2)*. Accurate demand projections are important in ensuring that future water supplies will be adequate while not surpassing the needs of planned growth." (Vol. 4, 7-5). The DPEIR goes on to state, "In some jurisdictions (Foster City, Half Moon Bay, and Burlingame), the WSIP could support more population growth than is forecasted in adopted general plans. In other jurisdictions (East Palo Alto, Foster City, San Bruno, Fremont, Newark, and Union City), the WSIP could support more employment growth than is forecasted in the adopted general plans of the respective jurisdictions." (Vol. 1, p. S-62)

The expanded water supply would accommodate a 28.8% increase in employment and a 16.8% increase in population between 2005 and 2030 in its service area. This is about 5% more jobs and 5% less population than what the EIR estimates the general plans would allow. The DPEIR cites the environmental analysis done for the general plans in its service area. None of these plans has a time horizon that extends to 2030, so it is speculative to make conclusions about consistency. It is also speculative to assume that the local jurisdictions would plan for a continuing rate of growth beyond their horizon years, as assumed in the DPEIR. So it cannot be concluded that the EIRs done for the general plans adequately cover the growth allowed by the increased water supply. The DPEIR acknowledges this fact on p. 7-35 and p. 7-69. The DPEIR finds that the water supply growth is generally consistent with ABAG projections to the year 2025, but ABAG projections are not subject to environmental review. 32

Furthermore, the DPEIR looks at the indirect effects of the growth it would accommodate on air quality, traffic, and water quality, but not on the other factors mandated by CEQA: Land Use, Population and Housing; Noise, Biological Resources, Geology, Agriculture, Public Services, Cultural Resources, and Visual Resources. 33

The DPEIR acknowledges (p. 7-70) that the environmental analysis done for the general plans, on which it relies, did not address impacts on greenhouse gas emissions and global warming. This is an issue on which the Attorney General has sued San Bernardino County for inadequacies in its general plan EIR. The DPEIR fails to address this vital issue. 34

The project-level impacts on growth also depend on the mitigation measures identified in the general plan EIRs, as noted on page 7-71 and Appendix E, Section E.6. Thus, there is insufficient mitigation for the impacts for the projects up to the year 2030. 35

SI_TRT-CWA-SierraC

The DPEIR also must address how infrastructure redundancy measures, such as building a second New Irvington Tunnel, would increases system capacity and growth potential. 36

b) <u>Underestimated Potential for Conservation and Recycling</u>

The Master Water Sales Agreement requires that wholesale customers employ best efforts to use all sources of water owned or controlled by them, including groundwater (San Francisco Public Utilities Commission (SFPUC) and Bay Area Water Users Association (BAWUA), Water Supply Master Plan, April 2000).

The SFPUC's report entitled *Investigation of Regional Water Supply Option 4* (March 2006) identified numerous conservation, recycling, and groundwater possibilities available to the wholesale customers. However, the DPEIR did not adequately analyze this alternative – it just used some information from the report with no additional analysis. The report identifies existing conservation potential to eliminate the need for 74% of the proposed diversion.

Although industry trends show a decrease in gross per capita water demand, the wholesale agencies are predicting an *increase* in gross per capita water consumption. The DPEIR should investigate this discrepancy and determine whether the 2030 demand forecast accurately reflects industry trends. 37

According to the Pacific Institute the conservation measures included by the wholesale customers of the SFPUC have several critical flaws:

- The 4% average conservation savings identified by the wholesale agencies is a significant understatement of potential savings.
- Planned conservation efforts focus almost wholly on indoor water use, even though 60% of the planned increase in demand is projected to come from outdoor water use.
- The demand estimate fails to take into account foreseeable changes in conservation standards.

The same report finds shortfalls in the analysis of the recycled water potential for the wholesale agencies, which is projected at 3% of 2030 demand. This falls well short of the recycling goals for the state of California of 1.5 million acre feet per year by 2030, or those of local agencies – 6% of total demand for the East Bay Municipal Utility District and 10% for the Santa Clara Valley Water District. Again, this document should investigate this discrepancy and determine whether the 2030 demand forecast accurately reflects industry trends. 38

While the SFPUC and the BAWSCA agencies have committed to implementing additional conservation measures and recycled water and groundwater projects as part of WSIP, the SFPUC further studied the potential and identified additional conservation, recycling, and renewable groundwater projects that could yield 28.5 mgd. The SFPUC has proposed to pursue 10 mgd of that potential; however, the remaining 18.5 mgd is not currently being considered as part of the WSIP. 39

The wholesale conservation study also identified an additional 6 mgd of savings that could be achieved through cost-effective conservation programs. However, the wholesale customers did not factor those savings into their purchase request 39 cont.
to the SFPUC. As a result, the DPEIR is based on flawed demand and supply projections despite the availability of additional analyses.

The actual demand and supply projections, including the water conservation potential studies that were used in developing the demand projections evaluated in the WSIP, also were flawed. The SFPUC conducted studies to determine the water conservation potential for their retail and wholesale customers. The studies estimated how much water would be saved by 2030 through the natural replacement of fixtures due to implementation of the existing plumbing code, as well as through active conservation measures. For the study of conservation potential in the retail area of San Francisco, the SFPUC considered 48 different conservation measures and selected 38 for implementation as part of its plan. 40
The wholesale conservation study initially considered a set of 75 measures, but, on average, selected fewer than 10 to include in their conservation plan.

All of the conservation measures selected by the wholesale agencies were deemed cost-effective based on the estimated future cost of water at $1,100/acre-foot. The wholesale customer study identified an additional 6 mgd of *cost-effective* conservation savings that could be achieved by 2030; however, the wholesale customers have chosen not to pursue those savings without providing sufficient justification or explanation. The wholesale conservation study also failed to determine the *total cost-effective* conservation potential of the region.

12.4-97

(Please see and comment on Attachments I and J regarding the potential for water conservation and recycling..) 41

c) <u>Impacts of Reduced Flows on Hydrology and Geomorphology</u>

Changes in freshwater flow stored and released from behind dams on the Tuolumne will impact local hydrology, fish resources, and geomorphic characteristics of the Tuolumne; hydrological and biotic resources affected by the WSIP may extend downstream through the San Joaquin River and, potentially, into the Sacramento-San Joaquin Delta. Changing (and in most cases, reducing) freshwater releases in the Tuolumne system may affect changes in fish populations (including, in particular, federally protected steelhead (*O. mykiss*)) by altering the volume of available spawning, incubation, rearing, and emigration habitat and by altering water quality (e.g., temperature and chemical 42
concentrations), and geomorphological characteristics (e.g., the abundance and quality of spawning substrate or rearing habitat). The timing and magnitude of freshwater releases have an obvious impact in hydrological characteristics of the river, including water quality characteristics such as flow rate, temperature, and chemical concentrations. In addition, flow reductions (as proposed under the WSIP) may lead to changes in local and regional groundwater tables as recharge rates are altered and groundwater pumping rates increase (a potential outcome of the WSIP that receives little attention). Furthermore, changes in the magnitude and inter-annual distribution of peak flows in the Tuolumne (and

SI_TRT-CWA-SierraC

specifically, truncation of the high-magnitude end of the hydrograph) may impact geomorphic attributes of the river continuum (such as channel depth and breadth, bank and bed armoring, particle size distribution) which may, in turn, affect biological resources in the river. 42 cont.

The DPEIR incorrectly dismisses the potential for hydrological and geomorphological impacts by arguing that changes in flow will be "within the current range" of flow fluctuations. This casual dismissal does not suffice for analysis.

d) <u>Failure to Define Thresholds of Significance</u>

The DPEIR persistently fails to define significant impacts in measurable, quantifiable terms. Thus, it is not possible to evaluate when truly significant impacts will occur. Impact thresholds should be (a) quantifiable (b) measurable (c) defensible and (d) account for **both** the severity and frequency of an impact. 43
A severe impact (*e.g.*, a seismic risk connected to a project) could be significant even if it is unlikely to occur frequently. By the same token, a frequent impact (*e.g.*, a modest level of soil erosion each time it rains) could be cumulatively significant even if a single occurrence would have only a small impact.

The DPEIR consistently confuses the frequency of an event (also poorly defined in the report) with the severity of the impact. Thus, there is a proliferation of words like "occasional," "rare," "uncommon," and "sometimes" that are intended to alleviate concern that impacts will be significant. However, if an impact is severe, it really does not matter how frequent it is. Thus, when the 44
report concludes (on page 5.3.6-33) that the impact of flow reduction and temperature increases on emigrating salmonid juveniles is "infrequent" and thus, not significant, this assessment is incomplete because it does not incorporate the severity of the potential impact (nor does it define "infrequent").

Another indication of the poorly defined impact thresholds is that the DPEIR routinely assumes that changes that are not "substantially out of the range experienced under current conditions" are insignificant. Under this logic, if mean conditions (of temperature, or flow, or sediment transport) under the WSIP approximate the low (or high) range of current variation, there has not been an 45
impact of the WSIP. This kind of logic leads, step-by-step, to serious cumulative impacts. For example, if the WSIP is adopted, could a *subsequent* plan also claim "no significant impact" if the changes *it* produced still fit just inside the extreme end of the "range" produced by the WSIP?

e) <u>Aggregation of Data into Time-Steps that Lack Relevance to Biological, Hydrological, or Geomorphological Processes</u>

The DPEIR obscures analysis of potential impacts related to flow fluctuations on the Tuolumne River by aggregating data over coarse time-steps. For example, the hydrological modeling used throughout the report produces output on a 46
monthly time-step. This level of resolution may be valuable for water balance equations and estimates of "average" changes in monthly flow, but it does not

allow insight into variations that are the components of that "average" – the weekly, daily, and even hourly conditions that actually affect biological, hydrological, and geomorphological conditions on the Tuolumne River. So, for example, on page 5.3.6-31 the DPEIR states that, under some conditions, average monthly flows will be reduced by 25% (the conditions are documented elsewhere). This means that sometimes flow reductions will be greater than 25% 46 cont.
-- that is the nature of an average. Whereas the report "analyzes" the impact of a 25% habitat reduction, the reality is that about _ of the time under these conditions, habitat reductions will be worse than 25%. Even in months with these conditions when habitat is actually reduced exactly 25% on average, the flow reduction during any particular day or week can be greater than 25% (again, that is the nature of an average).

Similarly, in some places the DPEIR aggregates historic flow patterns across different "water-year types" (e.g. wet years, above normal years, etc.) and then analyzes changes anticipated under WSIP from these average, within "water-year type," conditions. As a result, the DPEIR tends to understate potential impacts to biological, hydrological, and geomorphological features of the Tuolumne River due to implementation of the WSIP. First, it should be noted that some of the average changes in flow are themselves potentially significant (see Tables 5.3.1-5 and 5.3.1-6, for examples). But, the report fails to note or 47
discuss that this kind of change is only the "average" change expected for a given month in this "water-year type" under the WSIP. Changes in any particular year (of a given water-year type) may be greater than or less than this average. Because the DPEIR **never** reports the variance or the range around the means it presents, the reader has no way of assessing what kind of faith to place in the averages.

The problem with the DPEIR's reliance on monthly (or even more coarse "Water-year-type") averages is that many biological, hydrological, and geomorphological processes respond to changes in flow at a much finer time step. Fish and other organisms experience actual habitat reductions, as these occur on an hourly, daily, or weekly basis, not the average monthly habitat reductions The DPEIR presents no assessment (even a very general assessment) regarding the appropriate hydrological time-step needed to analyze different impacts. For example, biological resources may respond to flow-related 48
temperature changes on the scale of one or a few days. On the other extreme, river geomorphology may not change at all as a result of reduced flows in one year; however, a persistent reduction in peak flows can cause significant changes in river geomorphology on broad spatial scales (e.g., channel downcutting and meander patterns), or on fine spatial scales (e.g., bank and bed armoring) that are biologically significant (*see* TNC 2006 for a review).

Another example of this tendency to underestimate impacts is provided on pages 5.3.4-6 of the report. The DPEIR concludes that most impacts to Tuolumne River flows below La Grange Dam will occur in relatively wet years. This is true; however, a review of table 5.3.4-4 indicates that flow reductions would have 49
occurred in 20% (5 of 25) of dry and below normal years and in more than 10% (16 of 125) of months between October and April during those years under WSIP.

SI_TRT-CWA-SierraC

The DPEIR tends to ignore flow impacts during years of "below normal" and lower runoff because it finds that such impacts will be "rare" or "infrequent". But given that biological resources may already be stressed during these periods, the failure to analyze flow reductions during these periods is unacceptable. 49 cont.
Again, we wish to emphasize that biological resources are not living in the "average" low flow condition, they are experiencing the conditions that actually occur for variable lengths of time; thus, the average "below normal" year condition is not a relevant metric for assessing impacts.

The meaning and proper application of averages should also be included in a discussion of model resolution, as the two are intrinsically linked. Monthly averages represent the peak of a normal distribution (and many hydrologic variables are not normally distributed) and do not incorporate information about the true distribution or its range (i.e., the tails of a distribution). As a result, 50
variability seen in daily and or weekly flows cannot be directly assessed using monthly averages. Therefore, any conclusion about the potential effects of the WSIP on daily and weekly flows is only an assumption based upon somewhat subjective measures.

f) Lack of Significance Criteria for Groundwater Impacts

The City and County of San Francisco has not formally adopted significance criteria for impacts related to groundwater, but generally considers that implementation of the WSIP would have a significant groundwater impact if it were to:

- Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of preexisting nearby wells would drop to a level that would 51
not support existing land uses or planned uses for which permits have been granted).
- Substantially impair a water body's ability to support beneficial uses designated by the State Water Resources Control Board or Regional Water Quality Control Board.
- Otherwise substantially degrade water quality.

This document should set measurable criteria for groundwater impacts. As written, this is a subjective rather than scientific assessment.

g) HH/LSM Modeling Methodology

The HH/LSM is, in essence, a reservoir and system routing model that uses an 82-year historical period of record for analysis of the effects of the WSIP. Several issues regarding model development and error estimation persist. Modeling scenarios developed with the HH/LSM consist of two types: a base-line scenario meant to simulate hydrologic conditions of the system over the period of record using 2005 (base-line year) conditions, and alternative scenarios including the WSIP scenario and Variants 1, 2, and 3. Results from both the base-line model

12.4-99

and each variant including the WSIP are then compared. Several issues about the modeling approach are apparent:

- *Modeling Error:* Models of any sort inherently contain error. The amount of model error depends on the accuracy of the data inputs, potential error in the underlying model calculations, and the factors that are incorporated or not incorporated into the model. Model error can potentially be significant. Most error is reduced through model calibration (comparing outputs with actual values and altering the model logic or assumptions until differences are minimized). Although this is standard practice, no mention of calibration and error reduction efforts and final error rates for the HH/LSM were discussed in the DPEIR. The accuracy of projections generated by the HH/LSM under the WSIP scenario is impossible to evaluate because there is no indication of how closely model projections reflect actual outcomes. Furthermore, because the base-line model contains inherent, unknown error and the scenarios contain inherent, unquantified error, any comparison of the scenarios with the baseline (or among scenarios) contains inherent, unquantified error. We found no discussion of analytical or model error in the DPEIR.

  Model error produces uncertainty around model outputs (estimates). For example, if model error is ±5% for a given output, then the model output (which represents the "mean expected" output given the inputs) is only accurate to within ±5%. For instance, during some extremely dry periods in some years, the HH/LSM model predicts that flows below 52
O'Shaughnessy Dam may be reduced up to 90% of average flow. However, if the error rate is 5%, then the model is really saying that average flows reductions expected in this area are between 85% and 95%.

  Another potential difficulty with conducting a comparative analysis between modeled scenarios is possible compounding of model error. For example, if both the base-line model and the Variant model (in this case the WSIP scenario) have an inherent error of 5% (for illustration purposes), then the potential error of any analytical comparison could be up to 10%.

  Model error (uncertainty regarding the mean estimate) increases as one uses inputs that are at the extremes of the range of data used to create relationships in the model. For analysis of the WSIP (and other variants), the HH/LSM model was applied to conditions that are towards the extremes of those that were used to construct the fundamental relations in the model. In other words, the mathematical relationships used to construct the model become more tenuous as the input conditions deviate further from the norm. Further complications with model errors arise when attempting to translate averaged monthly-modeled results to finer time scales, as these typically have a much greater variance.

  We could not find a discussion of model error rates anywhere in the DPEIR; certainly, they were not incorporated into the analysis conducted

SI_TRT-CWA-SierraC

in and conclusions reached by the report. This could have significant implications for possible impacts of the WSIP, yet these implications are not mentioned in the DPEIR. This is particularly important because some 52
conditions modeled under the WSIP scenario represent extremes that are cont.
not seen in current conditions and are thus not reflected in the 82-year record.

h) <u>HH/LSM Modeling Conclusions</u>

Conclusions presented in the DPEIR about the possible effects of WSIP implementation based upon the assumptions put forth in the HH/LSM and within the context of the report reflect monthly means; they are limited when evaluating effects at shorter time-scales and they do not incorporate deviations from mean projections (i.e. error). Potential effects resulting from changes in the 53
distribution of daily, weekly, and peak flows are given only minor consideration. Of these, peak flows are the most difficult to predict, and the analysis of WSIP impacts on the occurrence, magnitude, and duration of peak flows is simplistic. Since peak flows are critical for channel geomorphology and stream ecology, this is a significant issue. In short, because of the limitations of the HH/LSM model, the DPEIR does not fully describe the effect of WSIP implementation on peak, daily, or weekly flows; this limits the actual analytical usefulness of the HH/LSM outputs for analysis in the DPEIR.

i) <u>Tables Are Inconsistent with Narrative</u>

On numerous occasions, the tables presenting data are inconsistent with the narratives that refer to them. For instance, on page 9-88, Section 9.3.1, the Comparison of Alternatives (subsection Tuolumne River Watershed) says, "Table 9-7 summarizes the potentially significant impacts on the Tuolumne River...from 54
each of the alternatives." Then on page 89 the DPEIR states, "Four alternatives...would **avoid** this significant impact associated with the delay in spring releases." Yet, Table 9-7 does not agree with this narrative. It states that the alternatives will have "similar impact" to the proposed project, or the "same as proposed project."

III. FAULTY ASSUMPTIONS

There are a number of areas in which the DPEIR bases its conclusions on faulty assumptions. This section of our comments identifies erroneous conclusions in the following areas:

a) Questions about SFPUC Water Rights
b) MID/TID Transfer Agreements Are Not Certain 55
c) The 1997 FERC Settlement Agreement Will Affect Future Transfers
d) Effects on Flow along the San Joaquin River and the Sacramento-San Joaquin Delta
e) HH/LSM Primary Assumptions
f) The Historic Record of Calculated Runoff that Supplies the Hetch Hetchy System Does Not Accurately Reflect Future Conditions

g) Alternatives Analysis Improperly Quantifies the Demand, Yield and Drought Impact of All Alternatives 55 cont.

a) Questions about SFPUC Water Rights

The discussion of Tuolumne River water rights in the DPEIR fails to address the issues raised by the State Water Resources Control Board in its letter of October 3, 2005, which states:

> "For the City and County of San Francisco, the water rights were quantified in *Meridian Limited v. City and County of San Francisco et al.* It appears that the pre-1914 appropriative right was solely for storage of water. The project listed in the NOP is a direct diversion project. Any new diversions must be accomplished pursuant to an appropriative right obtained from the State Water Resources Control Board... In reviewing the Meridian case, Division staff notes that most of the water appropriated from the Tuolumne River for the Hetch Hetchy project was used for hydroelectric power generation. Hydropower generation is considered a non-consumptive use right because the water is returned to the stream system. In general, a non-consumptive water right cannot be used as the basis for new, consumptive uses of water." 56

The Raker Act clearly limits the amount of water that San Francisco can divert from the Tuolumne River. In addition to requiring San Francisco to release water to meet the senior water rights of Turlock Irrigation District and Modesto Irrigation District, the Act further limits Tuolumne diversions because San Francisco may not divert more water than is "necessary" from the Tuolumne.

Raker Act Section 9(h) provides:

> "That the said grantee shall not divert beyond the limits of the San Joaquin Valley any more of the waters from the Tuolumne watershed than, together with the waters which it now has or may hereafter acquire, shall be necessary for its beneficial use for domestic and other municipal purposes."

Since San Francisco must fulfill its "beneficial use" water needs with "waters which it now has or may hereafter acquire," Tuolumne River water must be a source of last resort for San Francisco. San Francisco has interpreted this section of the Raker Act as follows: "section 9(h) of the Raker Act requires San Francisco to make full use of its local sources of water."

The Notice of Preparation interpreted this requirement in the Raker Act in an overly narrow way:

> "under the WSIP, the regional water system would continue to comply with the conditions of all applicable institutional and planning requirements, including: . . . maximizing use of water from local watersheds." 57

The Raker Act does not define the "water which it now has" as "water from local watersheds." It is true that San Francisco "now has" water rights to water from Bay Area creeks including Alameda, Arroyo Hondo, Calaveras, San Antonio, San Mateo, Pilarcitos, and San Andreas. However, it also is true that San Francisco "now has" waters that it is discharging from waste water treatment plants that could be recycled, and waters recoverable through water use efficiency and water conservation measures. 57

The Raker Act requires San Francisco to use the "waters which it now has" (normally described by the SFPUC as its "local sources of water") to the full extent possible. Then, and only then, may San Francisco divert water from the Tuolumne River. "Local sources of water" should include local creeks, groundwater, conservation, recycling, and desalination. San Francisco must maximize water from these sources before it proposes to increase the amount of water it diverts from the Tuolumne River.

b) MID/TID Transfer Agreements Are Not Certain

As stated in the DPEIR, the proposed MID/TID water transfer "involves some uncertainty because its implementation depends on the SFPUC negotiating and reaching agreement with MID/TID and possible other water agencies." (p. 6-48) The measure would require that MID/TID conserve water or meet their needs with an alternative water source so that releases from Don Pedro Reservoir remain unchanged.

The DPEIR does not present any evidence that the Districts are interested in pursuing any such agreement with the SFPUC nor that the SFPUC and the Districts are even in discussions regarding such an arrangement. In fact, in scoping comments submitted to the Planning Department in October 2005, the Turlock Irrigation District indicated that the SFPUC has not approached the District regarding any water transfer arrangements. It stated: 58

> "As a long-time partner on the river with the City and County of San Francisco, the District is disappointed that CCSF staff did not discuss with the District the proposed water transfers from the District before the proposal was publicly announced...It is imperative that the WSIP define the characteristics of 'additional water supply via district transfers.' As the District has seen no official proposal and as such, has neither discussed nor accepted any terms for a transfer, the EIR must address this issue."

The DPEIR states that if the SFPUC is unable to secure a water transfer arrangement with MID and TID, then it will conduct one of two fishery habitat restoration projects (5.3.6-4b, Fishery Habitat Enhancement): spawning gravel enhancement or removal of a former gravel quarry pit from the river corridor. These proposed mitigation measures are problematic for several reasons.

First, the gravel augmentation project proposed in 5.3.6-4b would enhance the spawning phase of the salmon life-cycle, while changes in flow would primarily 59 harm out-migration and rearing of juveniles. In other words, the proposed mitigation measure is mitigating for a different problem that what is created by reduced flows. Although gravel augmentation is probably needed as a result of spawning gravel degradation due to dam operations, the impact and the mitigation are poorly matched in this case. 59 cont.

Secondly, the alternative mitigation proposed in 5.3.6-4b (removal of a former gravel quarry) is of dubious benefit. The Turlock Irrigation District, as part of its obligation under the 1996 FERC Order, has completed a pond removal project at the "SRP-9" site. The project was intended to reduce predator habitat, however, the results do not show any success in achieving this goal. In fact, the District's assessment was that the project "was not successful in reducing largemouth bass linear density during the low flow years that have occurred since project construction" and "the project appears to have increased smallmouth bass abundance at the site relative to pre-project conditions at other SRP sites" (2005 Summary Report, p 3-48). 60

Thirdly, these projects do not consider impacts specifically to steelhead trout. Steelhead have a different life cycle and different habitat requirements than Chinook salmon. Steelhead are listed as "Threatened" under the Endangered Species Act, and as such, it is illegal to harm these fish in anyway.

In the Tuolumne, steelhead typically up-migrate in the winter and spring and summer-over in the river. As such, these fish require cool waters, below 65^{0}F, preferably below 60^{0}F. Further withdrawals would only serve to exacerbate the high temperatures already experienced in the river, particularly in the summer when air temperatures along the river frequently climb above 100^{0}F. None of the projects proposed by the SFPUC would mitigate the impacts to steelhead. 61

There is no evidence that implementation of one of these fishery habitat enhancement projects would be an effective measure for mitigating the impacts of reducing flows in the Tuolumne River below La Grange Dam. 62

Finally, the DPEIR fails to identify the impacts on the Tuolumne River between the Hetch Hetchy Reservoir and the Don Pedro Reservoir if the MID/TID transfers were approved. 63

c) The 1996 FERC Settlement Agreement Will Affect Future Transfers

"TID and MID own and operate Don Pedro Reservoir (built under the New Don Pedro Project) and are solely responsible as project licensees for meeting the Federal Energy Regulatory Commission (FERC) requirements for fishery releases. Nevertheless, under the Fourth Agreement with TID and MID (see Chapter 2, Section 2.5.3), the SFPUC may be required to provide water for these FERC-imposed fishery releases from Don Pedro Reservoir if TID and MID demonstrate that their water entitlements are being adversely affected by providing the flows. 64

The SFPUC, TID, and MID entered into two funding agreements to implement

12.4-101

the FERC Settlement Agreement; the SFPUC now pays TID and MID to provide all of the additional water required under the 1996 FERC order amending the requirements for fishery releases from Don Pedro Reservoir. The current FERC license expires in 2016, at which time TID and MID will be required to apply for a new license for hydroelectric operations on Don Pedro Reservoir. As part of the license renewal, FERC may modify the fishery release requirements. Although the fishery release requirements that FERC may impose in 2016 cannot be anticipated at this time, the SFPUC assumes, for purposes of the WSIP, that it will be able to continue its current agreement with TID and MID to pay them to provide all of the additional water, if any, required for the fishery releases." (Vol. 1, 3-43) 64 cont.

The SFPUC cannot assume future FERC flows will stay constant. In fact, they are likely to increase due to dwindling salmon numbers and the listing of steelhead. As noted, the SFPUC/CCSF may be responsible for increasing fishery releases as part of re-licensing in 2016. However, the CCSF also make the false assumption that the funding agreement with MID and TID will continue. The funding agreements between MID, TID and the CCSF do not guarantee that MID and TID will cover all fishery releases under the FERC Settlement of 1995.

d) Effects on Flow along the San Joaquin River and the Sacramento-San Joaquin Delta

Under Impact 5.3.1-5, the DPEIR acknowledges that "following protracted droughts, reductions in San Joaquin River flow attributable to the WSIP would be sufficient to cause flow in the river at Vernalis to fall below the objective. Under these circumstances the USBR would be expected to increase releases from New Melones on the Stanislaus River to meet the flow objectives at Vernalis."

It goes on to read, "following protracted droughts, reductions in Delta inflow attributable to the WSIP would be sufficient to cause Delta outflow to fall below the objective. Under these circumstances the USBR and DWR (operators of CVP and SWP) would be expected to decrease diversions from the Delta so that Delta outflow objectives are met." 65

The conclusion of a less than significant impact is based on San Joaquin and Delta flow objectives being met by other agencies, which is outside of the control of the SFPUC. Under CEQA, any mitigation measures relied upon to reduce otherwise significant impacts to a level of insignificance "must be fully enforceable through permit conditions, agreements, or other legally binding instruments." (CEQA Guidelines § 15126.4(a)(2)). The DPEIR's assumption that USBR and DWR will make up for flows lost to increased Tuolumne River diversions is not a mitigation measure enforceable at all by SFPUC, let alone "fully enforceable." Moreover, in light of the frequent failure of USBR and DWR to provide sufficient flows for fish and water quality protection in the Delta in the past, this assumption is not well-founded.

In 1958 the CCSF applied to the Department of Interior for a change of location for their aqueduct right-of-way as provided under Section 2 of the Raker Act. In approving the change, DOI also required a revised schedule and study for minimum water releases from O'Shaughnessy Dam. In March 1987 the CCSF and DOI signed an agreement stating that the CCSF would fund **four-year** fish and habitat studies that would determine if flows in the upper Tuolumne should be increased. The CCSF further agreed to adjust minimum releases as set forth in said Agreement and a previous 1985 Flow Agreement. The CCSF contracted with the United States Fish and Wildlife Service (USFWS) to conduct the study. 66

On July 20, 1992 the USFWS completed a draft of this study and called for increased flows. However, a revised and increased flow schedule was never adopted or implemented by the SFPUC or the CCSF, and the USFWS study was never completed. Given these contractual agreements, the CCSF is legally obligated to complete the study and augment flows from O'Shaughnessy Dam. Complying with these agreements may be compatible with increasing diversions by 25 mgd at the same time. However, the DPEIR makes no effort to analyze the impact that these required flow increases would have on the CCSF's plan to increase diversions from the Tuolumne by 25 mgd, and seems to assume these agreements would have no impact.

Additionally, the recent ruling by Judge Wanger to protect the endangered Delta smelt will impact both inflows and pumping from the Delta. That means that loss of Tuolumne River inflows will have a significant impact, and that additional releases from south of the Delta storage in the Central Valley Project (CVP) and State Water Project (SWP) will be not be available for this purpose. The DPEIR must also address the impacts of the Delta pumps rulings on water releases from La Grange and New Melones Dams. 67

e) HH/LSM Primary Assumptions

The conclusions presented in the DPEIR regarding the potential impact of WSIP implementation on all components of the regional water supply system, especially the Tuolumne River, rely upon some of the assumptions maintained in the HH/LSM model and application of these assumptions to analysis of HH/LSM modeling results. Of the assumptions presented in the HH/LSM model, several are conditional and dependent upon the resolution of ongoing negotiations; other assumptions suppose unchanging conditions between 2005 base-line conditions and the target 2030 WSIP conditions. Among the questionable assumptions are: 68

- *The SFPUC will execute a water transfer agreement with both TID and MID that makes available to the SFPUC an additional 23 million gallons/day from Hetch Hetchy Reservoir (5.1-5, 5.3.6-33, Appendix H1-5).* This condition is contingent upon an agreement with TID and MID to allow the SFPUC to withdraw more water from its water bank account in Don Pedro Reservoir than is currently being withdrawn. The specifics of how the SFPUC proposes to repay this water to TID and MID have not been discussed, most likely because negotiations are ongoing and an

SI_TRT-CWA-SierraC

agreement has not been reached. However, since inflow into Don Pedro Reservoir will be reduced during most years, as determined by the HH/LSM and reported in the DPEIR, TID and MID will be required to capture more inflow in order to make up for this deficit. 68 cont.

- *TID and MID diversions from La Grange will be the same as those that were diverted during the base year (2005) (Appendix H2-1 Page 5).* The basis for this assumption is not discussed in the DPEIR. It is highly unlikely that TID and MID water requirements in the 2030 target year will be the same as they are now. The DPEIR assumes that current TID/MID combined diversions are ~ 867,000 acre-feet/year (App H, Tables on pages 48 and 49). However, in Vol. 1 section 2.3 (p. 37), the DPEIR implies that TID/MID's total water rights exceed 1.9 million acre-feet (when natural river flows at La Grange can support that volume of diversion). Thus, based on information in the DPEIR, it appears that TID/MID sometime divert less than their water right would allow. The assumption that they will not increase water diversions over the project period is questionable at best. MID's 2005 Urban Water Management Plan estimates an increase in demand of 70% by the year 2030. Additionally, the DPEIR's section on global climate change (Vol. 3, 5.7.6) acknowledges that with regional increases in temperature, agricultural water needs are anticipated to increase as well. 69

f) The Historic Record of Calculated Runoff that Supplies the Hetch Hetchy System Does Not Accurately Reflect Future Conditions

The DPEIR assumes, without any critical analysis, that hydrological and meteorological conditions in the next 82 years will be identical to those in the preceding 82 years. The DPEIR includes no analysis of the probability or return period of meteorological events. The only discussion of the probability of an event is that a 30% chance exists that the region will experience a drought greater than or equal to the 1987 – 1993 drought within the next 82 years (Appendix H, section 1.3.1, p. 13). This statement refers to studies that are not cited. Although this assessment may reflect the historic record, trends in hydrological and meteorological conditions that are already being observed (*see above* "Inadequacy or Lack of Monitoring Baseline") are not accounted for in the hydrological analysis, despite the fact that the DPEIR acknowledges the scientific consensus that global climate change has already occurred and will continue to impact this region in the immediate future. 70

The blind reliance on the 82-year hydrological record is a serious flaw in the DPEIR as global climate change can affect nearly every input into and assumption of the HH/LSM model and, thus, the outputs that define the impacts of the WSIP scenario (and other alternatives). An increase in the frequency of droughts of any magnitude has the potential to significantly impact system operation. If the return period for such conditions decreases (i.e., droughts occur with greater frequency), then several droughts may be experienced sequentially. According to the HH/LSM analysis, the hydrosystem is most vulnerable during less-than-normal and dry years (during extremely dry years alternate sources and rationing are maximized) and wet years following a drought period. This will increase the magnitude and duration of stress on the entire system. For further discussion, see the section on climate change and global warming above. 70 cont.

The failure to incorporate observed or predicted meteorological trends into the hydrological projections is particularly significant because error estimates (model error) are already missing from the results presented in the DPEIR and the report does not indicate that the models were run under alternative input assumptions that would reflect potential variability in environmental conditions.

g) <u>Alternatives Analysis Improperly Quantifies the Demand, Yield and Drought Impact of All Alternatives</u>

Table 9-4 offers a description of the CEQA alternatives. Although each alternative includes a different estimate for conservation and recycling, the same 300 mgd figure for 2030 system demand is used in all except the "No Increased Purchase Request" alternative. Since water conservation and recycling *reduce* that demand figure, it should be changed to reflect the revised demand for each of the alternatives. For example, the no supplemental water alternative identifies 29 mgd in conservation/recycling/groundwater. The yield of the conservation and recycling projects should be subtracted from the 300 mgd 2030 demand figure to determine the actual demand under that scenario. 71

While it is appropriate to maintain a number that reflects conserved water in the service area, including that number in the calculation of actual water use improperly inflates customer demand and skews modeling of drought year shortages. Similarly, it is unclear how the drought model is changed to reflect the varying supply alternatives. The "Level of Service" discussion in Chapter 8 for the program variants provides an analysis of the impact of a change in demand on the design drought.

The discussion of "demand hardening" on page 9-54 is vague and unquantified, and is not accompanied by a discussion of the reduced number of dry years due to the reduction in demand, or by a discussion of the modeling results. The fact that 60% of the increased 2030 water demand is for outdoor use would seem to "soften" the drought shortage figure, as outdoor conservation is the most easily enforced and has fewer economic impacts. 72

The no additional diversions alternative assumes that there will be no conjunctive use program for the Westside Basin aquifer. While the scope of the program may be reduced due to limitations on Tuolumne River withdrawal, aquifer replenishment will still occur due to replacement of groundwater with reclaimed water for irrigation, potential for stormwater recharge, and reduced pumping due to conservation. 73

IV. ADDITIONAL COMMENTS

a) <u>Does the WSIP Comply with NEPA?</u>

Chapter 5 of the DPEIR acknowledges that changes in the water releases from the Hetch Hetchy reservoir due to the WSIP will impact the Poopenaut Valley, a popular hiking destination and fragile wetlands ecosystem inside of Yosemite National Park. The DPEIR acknowledges impacts to the physical landscape of the Valley, including streamside alluvial deposits and meadow resources. Given that the WSIP will have an impact on a national park, is any federal approval necessary, and if so, what NEPA compliance is the relevant agency undertaking? 74

b) <u>Inadequate Public Noticing of the San Francisco Hearing</u>

The public was not adequately notified of the DPEIR hearing held on September 20, 2007 in front of the San Francisco Planning Commission, which is the body tasked with determining the adequacy of the document. We believe at least one additional hearing before the San Francisco Planning Commission must be held before the DPEIR is approved.

The meeting was noticed in the San Francisco Examiner on September 10, only 10 days before the hearing. Given the size of the DPEIR (more than 3,000-pages), this was not a reasonable amount of time to expect the general public to review the document and prepare informed comments.

Public notice was not given as to the time of the meeting until September 17, just three days before the meeting. The start time was not published in a newspaper, and the WSIP DPEIR item was not taken up until more than five hours after the meeting began.

The meeting began at 1:30 pm. The starting time for the WSIP item was identified as 5 pm, again, only three days before the hearing. The actual time the item was taken up was 7pm. Several dozen members of the public arrived at the hearing at 1:30 pm. It is not reasonable to expect the public to wait for five hours to testify. 75

At the hearing, the San Francisco Planning Commission was not given a presentation or briefing on the WSIP, and several Commissioners complained about the lack of information.

Planning Commissioner Christina Olague chided the SFPUC, saying it was "irresponsible" for the commission to not have been given a presentation on the project. The Commissioner requested that one or two additional public hearings be held for the WSIP DPEIR.

The result was that members of the public were giving comments to the DPEIR decision-making body without the benefit of having the governing body being properly prepared, thus giving comments in a vacuum.

3	5.1.4	12	Table 5.1-1 Modeling Assumptions Used In The CEQA Analysis Displays a list of modeling assumptions made in the development of the HH/LSM model run for the CEQA analysis.	This table includes some of the primary assumptions used in the CEQA analysis. Not included in this list are the assumption that TID/MID diversions and entitlements will remain static (as indicated in Appendix H), and that the SFPUC will be able to negotiate an agreement with TID and MID for the transfer of 27,000 acre-feet per year. These are rather large assumptions and must be identified as the entire analysis rests on their validity.	76
3	5.1.4	12	Table 5.1-1 Modeling Assumptions Used In The CEQA Analysis Displays a list of modeling assumptions made in the development of the HH/LSM model run for the CEQA analysis.	An even larger assumption, that the entire hydrological modelling process relies on, is that means, variances, and patterns in the 82-year hydrological record for this system (a) were constant (i.e. temporal trends were not directional) and (b) will be representative of the project period (2007-2030). Neither of these assumptions is accurate as patterns in regional climate (e.g. temperatures, drought frequency, etc.) appear to have been directional through the 82-year hydrological record and that directional change is predicted to continue through the project period (*see, for example, DPEIR Sect 5.7.6 "Climate change and gobal warming")*. As a result, the 82-year hydrological record, upon which these analyses are based, may offer only a weak approximation of conditions anticipated through the project period. Specifically, the hydrological record of the past 82 years is likely to overestimate the supply of water and underestimate the demand for that water (particularly by agricultural users under business-as-usual assumptions).	77
			Table 5.1-1 Modeling Assumptions Used In The CEQA Analysis Displays a list of modeling assumptions made in the development of the HH/LSM model run for the CEQA analysis.	The temporal availability of that water is likely to change. As a result, analyses of the WSIP based on this record are likely to underestimate the potential hydrological impacts of the program and the biotic and geomorphological impacts that are related to hydrological conditions.	78

Prepared by the Tuolumne River Trust
October 1, 2007

[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	
3	5.1.4	14	Paragraph two under the heading Model Limitations describes model limitations as they apply to the Pilarcitos Reservoir	What are the specific limitations/deficiencies in the HH/LSM model that preclude its application to the Pilarcitos watershed? How do these model limitations impact analyses of other hydrosystem components and/or the hydrosystem overall? Again, very little metadata regarding the accuracy and limitations of the HH/LSM models is provided in the text. As a result, it is impossible for the reader to evaluate whether the model is being applied appropriately or whether model outputs are being interpreted with enough caution.	79
3	5.1.4	15	Table 5.1-2 describes model features and their respective outflow parameters.	Model outputs are reported in acre-feet while corresponding charts shown in previous chapters and sections report these values in either elevation or cubic-feet per second. Units of measure should be consistent throughout the report to improve readability and ease of analysis.	80
3	5.1.4	15	Table 5.1-2 describes model features and their respective outflow parameters.	Some system outputs are presented in "acre-feet" whereas others are presented in "million gallons". This makes analysis and comparisons difficult. Units of measure should be consistent throughout the report to improve readability and ease of analysis.	81
3	5.1.4	17	Paragraphs one and two describe the possible implications of the monthly time interval used in the DPEIR analysis. "...in some cases, the modeling limitation of only providing information at a monthly time interval required additional considerations ... when simulating intermittent phenomena such as infrequent spills or releases from reservoirs that may last only a few days"	We agree that the modelling river flows at a monthly time-step is a "limitation" of the WSIP analyses because it does not account for "short-term variations" in flow volume or quality below dams in this hydrosystem. As noted above, the impact of these "short-term variations" (i.e. those on a daily or weekly time scale) may be significant and are worthy of consideration and documentation. Unfortunately, although this passage indicates that "operator knowledge" was used to "refine" analysis of the WSIP, these "refinements" are not available to the reader and thus the true impact of the WSIP on hydrological, biological, and geomorphological features cannot be determined.	82
3	5.1.4	17	Paragraph four describes the possible implications of the monthly time interval used in the PEIR analysis. "HH/LSM results were refined or teired to provide additional insight into the effects of the WSIP on stream flow for time periods of less than a month"	How were monthly results for Hetch-Hetchy releases "refined or tiered to provide additional insight into the effects of WSIP on stream flow for time periods of less than a month" ? As noted elsewhere, the inability of model results produced at a monthly time-step to capture the ecological, hydrological, and geomorphological implications of WSIP is a major concern. Thus, methods used to produce this finer grained resolution of WSIP impacts, and insights gained from it, are of great interest. Without documentation of the methods used to produce, and the insights gained from, this "refinement", the reader cannot evaluate the true impacts of the flow changes produced by the WSIP.	83
3	5.2	3	Table 5.2-1 Applicable federal, state, and local statutes and agreements	There is no mention of California State Fish and Game Code § 5937 that requires: "The owner of any dam shall allow sufficient water at all times to pass through a fishway, or in the absence of a fishway, allow sufficient water to pass over, around or through the dam, to keep in good condition any fish that may be planted or exist below the dam."	84

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

Volume	Section	Page Number	What the DPEIR says ("" indicate direct quote, otherwise paraphrase)	Our Comment	
3	5.3.1	12	Paragraph 2 refers to an agreement between USDOI and SFPUC requiring minimum stream flow from Hetch Hetchy reservoir. "...the agreement provides for an additional supplemental release, depending on hydrologic year type, subject to the completion of a fish habitat study and the determination of appropriate timing for the release..."	The Hetch Hetchy Fishery Investigation was initiated but never completed or adopted by the SFPUC. To our knowledge the several studies required under this agreement were never completed or adopted by the SFPUC. The failure of SFPUC to have completed and adopted the studies it agreed to indicates that the PUC does not know the condition of fish populations below O'Shaugnessy Dam or the impacts that its hydrosystem operation has had on fish populations or habitat resources. As a result, statements made about the current condition of fish populations in this stretch of river and the impacts of WSIP on fish resources in this stretch of river are highly speculative. Also, this failure to document fish populations and habitat conditions below O'Shaugnessy Dam calls in to question whether the PUC can claim to be in adherence with California Fish and Game Code § 5937 that requires maintenance of healthy fish populations below dams.	85
3	5.3.1	13	Table 5.3.1-2 "Schedule of Daily Minimum Required Releases to Support Fisheries Below O'Shaughnessy Dam"	A 1992 draft of the USFWS report "*Instream flow requirements for rainbow trout in the Tuolumne River between O'Shaugnessy Dam and Early Intake*" documented a "detailed instream flow analysis using the Service's ... IFIM" technique. This was the first of four studies agreed to by the SFPUC to document and mitigate the impacts of new facilities on and diversions from the Tuolumne, although, to our knowledge, this study has never been finalized or adopted by the PUC. Table VI on page 26 of that draft document (attached) called for substantial impacts in releases from O'Shaughnessy for the protection of fish populations over what is reported in Table 5.3.1-2 of the DPEIR. Specifically, flows during Year Type C (dry years) were 43-100% higher in the USFWS draft report than those reported under the DPEIR.	86
3	5.3.1	13	Table 5.3.1-2 "Schedule of Daily Minimum Required Releases to Support Fisheries Below O'Shaughnessy Dam"	Throughout this DPEIR, the SFPUC maintains that maintenance of mandatory minimum flows are sufficient to maintain fish populations below dams in the Tuolumne hydrosystem. No evidence is presented to support that assertion. The PUC could have monitored fish populations and fish habitat availability in the Tuolumne to assess whether hydrosystem operations impact fish populations. Indeed, one might argue that they are required to do so under State Fish and Game Code § 5937 and under agreements with USFWS and non-profit organizations such as the Tuolumne RIver Trust. Yet, there is no indication that the trout populations or important habitat variables (spawning and rearing habitat availability) have been measured in this reach since the draft USFWS report was completed in 1992. As a result, there is no way to determine the impact on fish populations of actual flows in this reach of the Tuolumne.	87

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

Volume	Section	Page Number	What the DPEIR says ("" indicate direct quote, otherwise paraphrase)	Our Comment	
3	5.3.1	22	Figure 5.3.1-8 presents the modelled average changes in reservoir releases from Hetch Hetchy with corresponding changes in the range of potential storage at Hetch Hetchy.	This figure compares monthly average ranges of storage, not the actual statistical range. As a result, this presentation could lead the reader to conclude that reservoir storage will not be significantly impacted in any month of any years; indeed, the DPEIR makes this claim on page 24 of this section. However, actual changes in the range of storage at Hetch Hetchy are, in some months, far greater than the **average** changes depicted here. Analysis of the data used to create this Figure (HH/LSM Result Viewer v. 1.0) indicate that, in some months, the range of resevoir storage under WSIP may change as much as 69%.	88
3	5.3.1	24	Sentence 6 of paragraph two states: "The WSIP would not alter water levels in Hetch Hetchy Reservoir such that they would substantially be outside the range experienced under the existing condition."	What constitutes being "outside of the existing range" is not explicitly defined. Figure 5.3.1-8 shows the **range** in modelled average reservoir storage increases approximately 25% to 30% (all of this additional **range** translates into potential **reductions** in actual reservoir storage) over the current condition during June, with an increased range (**potential reduction in storage**) of approximately 10% to 20% persisting through October. These potential changes in reservoir storage, at least during peak demand, seem to constitute a significant deviation from current conditions.	89

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

[illegible]	[illegible]	[illegible]	What the DPEIR says [illegible]	Our Comment	
			Sentence 6 of paragraph two states: "The WSIP would not alter water levels in Hetch Hetchy Reservoir such that they would substantially be outside the range experienced under the existing condition."	Our analysis of the percent difference between the modeled storage for Hetch Hetchy compared with that during the period of record reveals that, in some instances, the range in reservoir storage changed up to 69% (this analysis was conducted using data from the HH/LSM Result Viewer Version 1.0). Although the frequencies of these effects are limited over the entire extent of the period of record, this difference shows that the range in modeled reservoir values could increase well beyond what is implied (i.e., significant change).	90
3	5.3.1	18	Discussing water quality objectives for the Sacramento-San Joaquin Delta. "These objectives have been the subject of much controversy and have frequently been revised. Some issues remain unresolved, including the degree to which parties that divert water upstream of the Delta are responsible for meeting Delta objectives."	This passage and the discussion that precedes it indicate three things: 1) Flow objectives for the Delta (and lower San Joaquin) are changing and increasing over time 2) SFPUC diversions affect San Joaquin flow in the Delta, and 3) The SFPUC's responsibility for maintaining San Joaquin flow and water quality standards are unresolved. Nowhere else in this DPEIR does the SFPUC address these facts and uncertainties or the question that stems from them: How will the WSIP affect the SFPUC's ability to respond to future demands for increased flows downstream to protect water quality? Given the tremendous uncertainties surrounding the future water needs in the Delta and the SFPUC's legal responsibilities to maintain that water quality, how can the SFPUC consider additional constraints on their ability to provide water by allocating it to customers outside of San Francisco?	91

SI_TRT-CWA-SierraC

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

[illegible]	[illegible]	[illegible]	What the DPEIR says [illegible]	Our Comment	
3	5.3.1	19	Paragraphs covering the "Vernalis Adaptive Management Program"	Here again, the DPEIR makes clear that downstream requirements for Tuolumne River water may increase in the future, in this case, to protect fishery resources as agreed to under the "San Joaquin River Agreement". It's very name implies that the VAMP may determine that additional flows are needed to protect fish in the lower San Joaquin River and/or Delta (that is the meaning of "adaptive management"). Yet, the WSIP would appear to foreclose opportunitied for increasing flows downstream (and it may jeopardie the ability to provide for existing flow requirements). The DPEIR fails to adequately address the impacts (legal, political, or biological) or foreclosing options related to increasing flows in the San Joaquin as necessary to protect fish populations.	92
3	5.3.1	20	Section titled "Significance Criteria" "The proposed program would have a significant impact if it were to: Substantially alter stream flows such that they were outside of the range of pre-project conditions and result in adverse hydrological effects."	What does "pre-project" mean in this context? If it means pre-Tuolumne River hydrosystem (prior to construction of La Grange, Don Pedro, or O'Shaughnessy Dams), then it is hard to believe that the WSIP would not lead to conditions that violate this significance criteria. If it means pre-WSIP conditions, then the impact threshold implicitly assumes that "adverse" hydrological impacts cannot occur unless flows are "outside of the **range" experienced under current conditions. Given the deterioration of conditions on the Tuolumne and San Joaquin River during the past several decades (e.g. the listing of steelhead as federally "threatened")**, it is not clear that current operations are an acceptable baseline for comparison. Continued deviations (e.g. WSIP) from an impacted state (current conditions) may lead to cumulative impacts. The report fails to consider whether flows may need to be *increased* on the Tuolumne to restore fish populations, water quality, and geomorphic processes.	93

SI_TRT-CWA-SierraC

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

Volume	Section	Page Number	What the DPEIR says ("" indicates direct quote, otherwise paraphrase)	Our Comment	
3	5.3.1	23	Figure 5.3.1-9 Presents modelling of Hetch Hetchy storage and releases to the Tuolumne River under historical conditions.	There are too many panels to this figure and too much information in each one to present them all on one page. As a result of packing each of these panels into such a small space, their ability to convey information is lost. For example, real changes in storage and flow are obscured because the range on the y-axis is so large and the space allocated to the image is so small. For example, whereas most changes in storage and flow "look" very small because of the format of these graphs, that obscures significant changes in the percentage of water released from Hetch Hetchey that occur in 2001 and 2002. Also the change in storage expected to occur under WSIP in the winter 1987, 1988, and 1989 looks minor but actually amounts to reductions between 10-25% of what they were without WSIP.	94
3	5.3.1	25	Impacts of flow along the Tuolumne River below O'Shaughnessy Dam. Fourth full paragraph states "... the greatest reduction in stream flow would occur in normal, below normal, and dry years ..."	Basically, this statement says that flow will be affected in most years; which contradicts an earlier statement that flows will not be affected or affected minimally in most years.	95
3	5.3.1	25	Impacts of flow along the Tuolumne River below O'Shaughnessy Dam. Paragraph three discusses the possible changes to release schedules to the Tuolumne with implementation of the WSIP.	What would happen to the stated pattern if inflows were consistently reduced during a dry period? Would flow releases to the Tuolumne be delayed indefinitely until the reservoir is filled to capacity? There is no discussion of alternate release schedules or operational practices and their affect on the Tuolumne if the reservoir does not fill to capacity.	96
3	5.3.1	25	Impacts of flow along the Tuolumne River below O'Shaughnessy Dam. Paragraph three discusses the possible changes to release schedules to the Tuolumne with implementation of the WSIP.	Flows may follow the same pattern in normal and above normal years, but presumably, the magnitude of releases will be less even though the pattern of releases will be the same. This in turn translates to a reduction in peak and sustained flows in this reach as a result of the WSIP during dry periods.	97
3	5.3.1	26	Table 5.3.1-5 Estimated Average Monthly Flows For The Tuolumne River Below O'Shaugnessy Dam Under Various Conditions Provides a column by-column comparison between flows in the Tuolumne during all water year types for both the modeled current condition and conditions under WSIP.	The table illustrates the differences between the averaged indexed (over the period of record) Tuolumne flows below Hetch Hetchy and modeled flows under WSIP conditions. The "Difference and Percent Change" panel of this table shows only an **average** of all modelled percent differences in flows expected to result from the WSIP. This incorrectly suggests that the maximum percent decrease that can be expected under WSIP for all hydrologic year types is 30%. As stated in the DPEIR, Tuolumne flows below O'Shaugnessy Dam (reflective of releases from Hetch Hecthy) will be reduced up to to 90% in certain years.	98
			Table 5.3.1-5 Estimated Average Monthly Flows For The Tuolumne River Below O'Shaugnessy Dam Under Various Conditions Provides a column by-column comparison between flows in the Tuolumne during all water year types for both the modeled current condition and conditions under WSIP.	Biotic and geomorphological resources will not experience the average flow reduction; they will experience the actual flow reduction in a given month, which, in some cases, may be up to 90%. Thus, this table limits the reader's ability to assess the true potential impacts of WSIP implementation on stream flows in the Tuolumne below O'Shaugnessy Dam. These impacts are likely to be far greater than implied by the average impacts presented in the table.	99

7

SI_TRT-CWA-SierraC

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

Volume	Section	Page Number	What the DPEIR says ("" indicates direct quote, otherwise paraphrase)	Our Comment	
3	5.3.1	26	Table 5.3.1-6 Estimated Average Monthly Flows For The Tuolumne River Below La Grange Dam Under Various Conditions Presents deviations under WSIP from the average of monthly average flows under various "water-year types".	How were the "existing condition" and "Future with WSIP" values calculated? Presumably the former were based on the hydrologic record and the latter estimate is based on model runs which use the historical data as input? How many model runs were conducted? What is the variance in these estimates (i.e., how much estimation "error" exists)? A formal analysis of environmental variability and model error is required here (and throughout the hydrological sections of this report) in order to understand the level of certainty that we have regarding estimates of mean conditions). As presented, there is no way to evaluate the potential accuracy of modelling projections in the DPEIR because the reader does not know whether projections are accurate to within ±1%, ±10%, or ±100%.	100
3	5.3.1	26	Table 5.3.1-6 Estimated Average Monthly Flows For The Tuolumne River Below La Grange Dam Under Various Conditions Presents deviations under WSIP from the average of monthly average flows under various "water-year types".	Regardless of the exact method of calculation, aggregating (averaging) by month across many years (within the different water-year type categories) obscures the potential impact of changes under WSIP. There will be variance from the mean in these estimated changes in stream flow under WSIP because there is variance in flows under existing conditions and there is error (variance) in the model used to estimate flows under WSIP conditions. Impacts are caused by **extremes** in flow (high or low) more than by estimates of **average** flow. Since variances are not presented (*see above*) we cannot know the true extremes of flow to which the Tuolumne will be subjected. As a result, these **average** estimates are meaningless for purposes of understanding risks to biological, hydrological, and geomorphic features of the Tuolumne.	101

8

SI_TRT-CWA-SierraC

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

[illegible]	[illegible]	[illegible]	What the DPEIR says ("" indicates direct quote, otherwise paraphrase)	Our Comment	
			Table 5.3.1-6 Estimated Average Monthly Flows For The Tuolumne River Below La Grange Dam Under Various Conditions Presents deviations under WSIP from the average of monthly average flows under various "water-year types".	As mentioned elsewhere in these comments, hydrologic flow regimes often have response periods (usually weekly and daily) that are shorter than the monthly scale at which the DPEIR presents results. Thus, on a daily or weekly basis, actual flows will be lower than those indicated in this table approximately 50% of the time (that is the nature of an average). Therefore, where flow declines are anticipated under the WSIP, the true impact of those decreases in flow are underestimated by the averages presented in these tables. Rather than presenting simple "average" estimated deviations from "average" flow conditions that existed in previous years, the DPEIR should include some estimate of maximum daily (or at least weekly) deviations from current conditions.	102
3	5.3.1	28	The first sentence under the heading "Impact Conclusions" states: "The WSIP would not alter flow in the Tuolumne River below O'Shaughnessy Dam such that it would be outside the range experienced under the existing condition, nor would the flow alterations result in adverse hydrologic effects or be sufficient to change the character of the river."	The statement does not summarize the preceeding discussion of the effects of WSIP implementation on flows at smaller time-steps. That discussion indicates that the HH/LSM model cannot assess the effect of WSIP on flows with time steps of less than one month. Because the potential effects of the WSIP on these types of flows cannot be determined or modeled, the claim regarding the impact of the WSIP on Tuolumne flows below O'Shaughnessy Dam is incomplete. The claim that flows will not be outside of the range experienced under the current condition is also misleading. Table 5.3.1-5 shows a percent difference of average monthly flows up to 30% during dry years, with a potential percent difference of up to 90% in some months of some years during extremely dry years.	103
			The first sentence under the heading "Impact Conclusions" states: "The WSIP would not alter flow in the Tuolumne River below O'Shaughnessy Dam such that it would be outside the range experienced under the existing condition, nor would the flow alterations result in adverse hydrologic effects or be sufficient to change the character of the river."	The data presented here clearly show the potential for a significant deviation from the modeled range under normal conditions, and as such, the referenced statement is not supported. The DPEIR minimizes the possible impacts of the WSIP on Tuolumne flows, and limits the reader's ability to assess this claim. Furthermore, the fact that what constitutes a significant deviation from normal is not quantified (or clarified) elsewhere in the PEIR makes assessing changes in stream flow between modeled scenarios difficult.	104

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

[illegible]	[illegible]	[illegible]	What the DPEIR says ("" indicates direct quote, otherwise paraphrase)	Our Comment	
3	5.3.1	28	Impacts Conclusions re: Flow along the Tuolumne River below O'Shaughnessy Dam First full paragraph states: "The WSIP will not alter stream flow in the Tuolumne River below O'Shaughnessy Dam such that it would be substantially outside the range experienced under existing conditions, nor would the flow alterations result in adverse hydrological effects or be sufficient to change the character of the river."	This statement is based on many incompletely stated assumptions; it is little more than an assertion. The report acknowledges that daily and weekly sustained and peak flows could very well be affected by a delay in releases and a reduction in the volume of releases. Such volume reductions are anticipated in about 20 years (during the spring) in the 82 year simulation. The DPEIR admits that analysis of the effect of the WSIP on peak flows cannot be conducted because the model uses a monthly time-step, and peak flows usually last only a few hours or days. Yet, it is these peak flows that will determine "the character" of the River below O'Shaugnessy Dam.	105
3	5.3.1	28	Impacts of Flow along the Tuolumne River below O'Shaughnessy Dam First (partial paragraph) states: "Peak flows in years when runoff is less (dry years) might be reduced by the WSIP, depending on decisions made by reservoir operators."	This statement is vague. When Hetch Hetchy does not fill to capacity (as has occurred almost 25% of the time over the period of record), what exactly will happen to the magnitude, frequency, and duration of peak flows in this reach? The answer to this question can have broad implications for fish and wildlife habitat and changes in geomorphology.	106
3	5.3.1	28	Impacts of Flow along the Tuolumne River below O'Shaughnessy Dam First full paragraph states: "...the effects of the WSIP on flow along the Tuolumne River below O'Shaughnessy Dam would be less than significant..."	This claim should be amended to state that monthly affects *may be* less than significant and that daily and weekly affects cannot be assessed. Mitigation measures may be required if changes in daily and weekly flow regimes affect habitat and adversely affect stream morphology.	107
3	5.3.1	29	Section: Impact 5.3.1-2 Effects on Flow along Cherry Creek below Cherry Dam	A comparable graphical summary as the one provided for Hetch Hetchy Reservoir Volumes (Figure 5.3.1-8) is not provided. This creates the impression that such data are not available (which, most likely, is not the case). A similar chart should be included to supplement the discussion of reservoir storage under the heading Water Storage and Water Levels in Lake Loyd, and so that changes in the range in storage between the current condition and conditions under WSIP can be evaluated. This is especially important since these changes are not summarized elsewhere, and that, as stated, operation of Lake Loyd may change after periods of drought to satisfy TID and MID flow requirements and compensate for reductions in Don Perdro Reservoir storage due to reductions in Hetch Hetchy releases. Because Lake Loyd will most likely experience a change in water elevation, the actual magnitude and frequency of such changes should be analyzed and documented.	108

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

[illegible]	[illegible]	[illegible]	What the DPEIR says ("" indicate direct quote, otherwise paraphrase)	Our Comment	
3	5.3.1	35	Table 5.3.1-6 Estimated Average Monthly Flows for the Tuolumne River Below La Grange Dam Under Various Conditions Presents deviations under WSIP from the average of monthly average flows under various "water-year types."	The table illustrates the differences between the averaged indexed (over the period of record) modeled Tuolumne flows below La Grange Dam and modeled flows under WSIP conditions. The Difference and Percent Change section of the table shows only an **average** of the range of possible percent differences in flows anticipated under the WSIP. This presentation incorrectly suggests that the maximum percent decrease that can be expected under WSIP for all hydrologic year types is 25%. Yet, as stated in the DPEIR, Tuolumne flows at La Grange Dam will be reduced up to 92% during some months in some years.	109
			Table 5.3.1-6 Estimated Average Monthly Flows for the Tuolumne River Below La Grange Dam Under Various Conditions Presents deviations under WSIP from the average of monthly average flows under various "water-year types."	Biotic and geomorphological resources will not experience the average flow reduction; they will experience the actual flow reduction in a given month, which, in some cases, may be up to 92% Thus, as presented, this table impedes assessment of the true potential impacts of WSIP implementation on stream flows in the Tuolumne below La Grange Dam. These impacts are likely to be far greater than implied by the (already substantial) average impacts presented in the table.	110
3	5.3.1	35	Table 5.3.1-6 Estimated Average Monthly Flows for the Tuolumne River Below La Grange Dam Under Various Conditions	Even as presented, this table indicates that there will be substantial reductions of flow in the Tuolumne River under most conditions. Of the 60 Month-by-"year type" combinations presented, more than 1/3 are expected to show average flow reductions of greater than 5%. This reduction in flow can have serious impacts on hydrological, biological, and geomorphological features of the Tuolumne River that are not analyzed by the DPEIR.	111

11

SI_TRT-CWA-SierraC

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

[illegible]	[illegible]	[illegible]	What the DPEIR says ("" indicate direct quote, otherwise paraphrase)	Our Comment	
3	5.3.1	37	Paragraph two continues a discussion of the WSIP on the operation of Don Pedro Reservoir and Tuolumne releases below La Grange: "Although the WSIP would commonly reduce winter and spring flow in the river below La Grange Dam, it would not affect very infrequent large peak flows produced primarily by rainstorms."	The model used for this analysis is based on a monthly time-step while peak flow usually occurs over a much shorter period. Thus, this statement cannot be derived from model output (as output is in a monthly time-step) and must rely on some undocumented source of information. It is not clear whether release operations change as a result of these infrequent storm events or whether this refers only to flows that enter the River below La Grange dam. This should be clarified. In either case, the hydrological model cannot inform us about the impact of weekly and daily peak flows, even though these are probably important in determining impacts to aquatic habitat and river geomorphology.	112
3	5.3.1	38	The first sentence under the heading "Impact Conclusions" states: "The WSIP would not alter flow in the Tuolumne River below La Grange Dam such that it would be substantially outside the range experienced under the existing condition, nor would flow alterations result in adverse hydrologic effects or be sufficient to change the character of the river."	The statement does not summarize the preceeding discussion of the effects of WSIP implementation on flows at smaller time-steps. This discussion indicates that the HH/LSM model cannot assess the effect of WSIP on flows with time steps of less than one month. For example, in a month with **average** flows that are 25% below current conditions (such as June of "Above Normal" years), flows on any given day, or during any given week may be above or below the 25% average reduction. Flow reductions in excess of the average should occur about half the time, but the extent, duration, and frequency of these reductions in daily or weekly flow are unknown because the model does not produce output on that fine a scale. Because the potential effects of the WSIP on these types of flows cannot be determined or modeled, the claim regarding the impact of the WSIP on Tuolumne flows below La Grange Dam is unsupported.	113
3	5.3.1	38	The first sentence under the heading "Impact Conclusions" states: "The WSIP would not alter flow in the Tuolumne River below La Grange Dam such that it would be substantially outside the range experienced under the existing condition, nor would flow alterations result in adverse hydrologic effects or be sufficient to change the character of the river."	Once again, the significance threshhold for significant impacts is not adequate to protect biological populations, hydrological characteristics, and geomorphological processes of the Tuolumne River. Under the DPEIR's formulation, flows that do not lie **substantially outside the range experienced under existing conditions** do not consititute a significant impact. From this perspective, even if the WSIP consistently reduced average monthly flows to the low end of their current "range", there would be no impact. There is simply no analysis in the DPEIR (or anywhere else) that would support such a finding. Similarly, there is no analysis that demonstrates that *current* operating practices and diversion schedules adequately protect aquatic resources in th Tuolumne River.	114
3	5.3.1	38	The first sentence under the heading "Impact Conclusions" states: "The WSIP would not alter flow in the Tuolumne River below La Grange Dam such that it would be substantially outside the range experienced under the existing condition, nor would flow alterations result in adverse hydrologic effects or be sufficient to change the character of the river."	The data presented here clearly show the potential for a significant deviation from the modelled range under normal conditions; so, the referenced statement is not supported. This presentation minimizes the apparent impact of the WSIP on Tuolumne flows, and limits the reader's ability to assess this claim. Furthermore, because there is no quantification or definition of a ""substantial" deviation from the range experienced under existing conditions, assessing the significance of changes in stream flow between modeled scenarios is difficult. Similarly, it is difficult to determine what kind of changes would affect the "character of the river" because no measures or definition of that character are provided nor are thresholds proposed that would indicate when a "substantial" change in river character has occurred.	115

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

Volume	Section	Page #	What the DPEIR says ("" indicates direct quote, otherwise paraphrased)	Our Comment	
3	5.3.1	38	The last sentence of the first paragraph under the heading Impact 5.3.1-5 "Effects on Flow Along the San Joaquin River and the Sacramento-San Joaquin Delta" states: "Flow reductions of these magnitudes would be rare events ocurring four or five times in the 82-year period of hydrologic record."	"Rare" is a subjective term. There is no *apriori* definition of what "rare" means or whether "rare" events are those whose imapcts can be ignored. This substitution of frequency with severity of impact recurs throughout the document. It is unjustified and cannot subsitute for specific definitions of changes in frequency (rare, occassional, infrequent) or actual analyses of the severity of impact.	116
3	5.3.1	38	The last sentence of the first paragraph under the heading Impact 5.3.1-5 Effects on flow along the San Joaquin River and the Sacramento-San Joaquin Delta states: "Flow reductions of these magnitudes would be rare events ocurring four or five times in the 82-year period of hydrologic record."	Although the frequency of these events is <10% in the period of record, no information is provided about the distribution of these events. If they occur in sequential years or sequential months, such a prolonged reduction in flows could have deleterious effects on fisheries and ecosystems downstream. Even if they do not occur sequentially, such major changes in flow would likely have an impact on salinity intrusion and water quality (e.g., dissolved oxygen) in Sacramento-San Joaquin Delta.	117
3	5.3.1	38	The paragraph under the heading "Impact Conclusions" summarizes impacts to the Tuolumne below Don Pedro after implementation of the WSIP "Overall, the effects of the WSIP on flow along the Tuolumne River below La Grange Dam would be *less than significant,* and no mitigation measures would be required ."	This conclusion is based on a finding that monthly average flows under WSIP will not exceed current flows and that mimimum flows are governed by an agreement that will be maintained. However, this ignores the fact that the distribution of river flows (within those extremes) may change dramatically. The change in distribution of flow rates (principally, a truncation of the upper part of the hydrograph) could "be sufficient to change the character of the river". This statement refers to an analysis of monthly flows (the time-step at which the model was run), but not weekly and daily flows. In fact, as stated in the DPEIR, some releases could be delayed by several days or up to a week under some hydrologic conditions. Therefore, the monthly resolution of analysis obscures the potential impact of WSIP implementation on daily and weekly flows.	118
3	5.3.2	5	Geomorphological impacts -- approach to analysis "No modeling or field measurements have been performed to estimate program-generated changes in sediment transport in the Tuolumne River"	The analysis of sediment transport and gravel bed conditions in the Tuolumne is purely qualitative and largely speculative. Because there are no studies of baseline (historic) or current substrate conditions for much of the Tuolumne, it is impossible to know (a) how substrate conditions have changed over time, (b) the response of substrate to operational changes in the Tuolumne, or (c) the current state of Tuolumne River substrate.	119
3	5.3.2	5	Geomorphological impacts -- approach to analysis. "No modeling or field measurements have been performed to estimate program-generated changes in sediment transport in the Tuolumne River"	Steelhead, rainbow trout, and introduced trout species use gravel as a substrate for spawning and incubation. Steelhead juveniles also use pores in the streambed to hide (Williams 2006). The quality of this substrate (e.g. sediment size distribution) can have substantial impacts on a river's ability to support spawning salmonids (Kondolf 1997, 2000). Gravel degradation (bed armoring via slow sedimentation) is a major force driving the loss of salmonid spawning habitat in the Central Valley (Kondolf 1997, TNC 2006). The lack of information about current spawning gravel availability or how it is changing over time (and in response to hydrosystem operations, is a major flaw in this DPEIR. There is no way to evaluate the impact of WSIP to spawning habitat for salmonids without this information.	120

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

Volume	Section	Page #	What the DPEIR says ("" indicates direct quote, otherwise paraphrased)	Our Comment	
3	5.3.2	6	The first paragraph attempts to characterize the frequency of geomorphically significant peak flows in the Tuolumne River by comparing them to the periodicity seen in the Clavey River	It is not at all clear that the rate and frequency of geomorphic processes on the Clavey and Tuolumne River are comparable. Where is the evidence for this comparison?	121
3	5.3.2	7	The second sentence of the first (partial paragraph) under section 5.3.2.1 discusses the potential effect of WSIP implementation on sediment transport below O'Shaugnessy Dam, and states: "However, because the changes in peak flow would occur infrequently, they would not expect to result in a substantial change in erosion or siltation rates."	The duration and magnitude of peak flows will be uniformally reduced under WSIP between O'Shaugnessy Dam and Don Pedro Reservoir. Thus, a reduction in stream power available to move sediment must be expected. Simply stating that alterations to peak flows would be "infrequent" does not characterize the extent of the potential impact to geomorphic processes in the river. [This is another example of the DPEIR's practice of substituting frequency for magnitude of impact]. In some months, peak flows will be diminished in frequency, duration, and magnitude. These variables are the primary components in determining potential stream sediment transport. Thus, sediment movement will be undeniably altered, although the magnitude of the impact cannot be determined with the information provided here.	122
			The second sentence of the first (partial paragraph) under section 5.3.2.1 discusses the potential effect of WSIP implementation on sediment transport below O'Shaugnessy Dam, and states: "However, because the changes in peak flow would occur infrequently, they would not expect to result in a substantial change in erosion or siltation rates."	The reduction in Tuolumne sediment transport can be expected to increase armoring of gravel beds which would reduce available salmonid spawning habitat. Also, the persistent reduction in peak flows can be expected to gradually reduce the availability of interstitial spaces where juvenile rainbow trout overwinter.	123
3	5.3.2	7	The second sentence of the first (partial paragraph) under section 5.3.2.1 discusses the potential effect of WSIP implementation on sediment transport below O'Shaugnessy Dam, and states: "However, because the changes in peak flow would occur infrequently, they would not expect to result in a substantial change in erosion or siltation rates."	Curiously and unfortunately, the DPEIR makes no reference to the USFWS' draft IFIM report from 1992 wherein the Service assessed the abundance and distribution of available spawning and rearing habitat for native and introduced trout species in this stretch of river. Undoubtedly, this information is now out-of-date, however, it would serve as a basis for comparison if measures of gravel quality and abundance were made to day. That comparison would allow an assesmenet of how reservoir operations impact sediment transport in the Tuolumne between Hetch-Hetchy and Don Pedro dam.	124
3	5.3.2	7	The second to the last sentence of the final paragraph of section 5.3.2 discusses the potential effect of WSIP implementation on sediment transport below La Grange Dam, and states: "However, because WSIP-induced changes in peak flow would occur infrequently, they would not expect to result in a substantial change in erosion rates, siltation rates, or channel form."	Peak flows will be uniformally reduced under WSIP below La Grange Dam, as will the duration and magnitude of such events. Thus, a reduction in available stream power to move sediment is expected, whether this occurs on a regular basis or an irregular basis. Considering that the HH/LSM does not consider potential impacts on a daily or weekly scale, little can be said about the weekly and daily hydrology of this reach, other than that in some months over some years, peak flows will be diminished in frequency, duration, and magnitude, and as these variables are primary components in determining potential stream sediment transport, sediment movement will be undeniably altered, although the extent of alteration cannot be determined. Additionally, as previously mentioned in Section 5.3.1-4 page 37, implementation of the WSIP will likely reduce the magnitude and number of pulse flows from Don Pedro Reservoir in years where releases are above the minimum required. This will reduce the frequency and magnitude of sediment-moving flows.	125

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

[illegible]	[illegible]	[illegible]	What the DPEIR says ("" if direct quote, otherwise paraphrase)	Our Comment	
3	5.3.2	7	The second to the last sentence of the final paragraph of section 5.3.2 discusses the potential effect of WSIP implementation on sediment transport below La Grange Dam, and states: "However, because WSIP-induced changes in peak flow would occur infrequently, they would not expect to result in a substantial change in erosion rates, siltation rates, or channel form."	The use of the term "infrequently" is misleading because "infrequent" high flows perform the majority of the geomorphic work in streams like the Tuolumne. The DPEIR presents no information regarding the abundance and distribution of spawning gravel below La Grange Dam. This is a major data gap given that both fall-run Chinook salmon and the federally threatened Central Valley steelhead use this stretch of river for spawning. Both species depend on the presence of high quality spawning gravel for egg deposition and incubation. Gravel quality deteriorates inexorably below dams that severely regulate peak flows (e.g. Kondolf 1997). The persistent slow armoring of spawning gravels is believed to be a major cause of the decline in available spawning habitat below dams in the Central Valley (e.g., Lindley et al, 2006; TNC 2006, Williams 2006).	126
			The second to the last sentence of the final paragraph of section 5.3.2 discusses the potential effect of WSIP implementation on sediment transport below La Grange Dam, and states: "However, because WSIP-induced changes in peak flow would occur infrequently, they would not expect to result in a substantial change in erosion rates, siltation rates, or channel form."	Given that the abundance of both fall-run Chinook salmon and steelhead has declined severely on the Tuolumne (McEwan 2001; Lindley et al, 2006; Williams 2006), it is surprising that the DPEIR did not analyze spawning gravel conditions (and the effect of current and proposed water system operations on those conditions) more thoroughly.	127

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

[illegible]	[illegible]	[illegible]	What the DPEIR says ("" if direct quote, otherwise paraphrase)	Our Comment	
3	5.3.3	3	Table 5.3.3-2 "Maximum summer-fall water temperatures in the Tuolumne River from La Grange Dam to Modesto 1996-2004. This table provides information on maximum temperatures along the longitudinal profile of the Tuolumne River.	There is useful information in this table but it is far from comprehensive or well-explained. These are maximum river temperatures, but are they "instantaneous" maxima, maximum daily average, or was some other time scale employed? Organisms are capable of withstanding short term exposure to certain temperatures even if they cannot tolerate those temperatures for a full day or week. Therefore, the temporal scale of these data is a very important consideration. Temperatures are categorized as < or > 20 °C. There is no explanation of why this temperature cut-off was used. Nine years of data are presented but none of them reflect "critically dry" conditions, so the overall distribution of temperatures may by skewed towards lower water temperatures.	128
3	5.3.3	3	Table 5.3.3-2 "Maximum summer-fall water temperatures in the Tuolumne River from La Grange Dam to Modesto 1996-2004. This table provides information on maximum temperatures along the longitudinal profile of the Tuolumne River.	Temperatures presented are summer maxima. Maximum temperatures are useful for evaluating lethal effects to fish and other biota; however, other important temperature thresholds are not addressed by these data and are not reported or discussed elsewhere in the text. For example, metamorphosis of salmonid juveniles (smoltification) into seagoing fish may be impeded by high temperatures in the spring. Whereas reservoirs allow for release of artificially cold waters during the summer, the same thermal intertia can cause them to release artificially warm water during fall, winter, and spring when smoltification occurs. For steelhead, temperatures above 11-12°C inhibit smoltification whereas for fall-run Chinook, the temperature threshold may be closer to 17°C (Richter and Kolmes 2005). Artificially high winter and spring temperatures below dams (i.e. those that inhibit smoltification) may be an important force in the decline of Central Valley steelhead (McEwan 2001).	129
			Table 5.3.3-2 "Maximum summer-fall water temperatures in the Tuolumne River from La Grange Dam to Modesto 1996-2004. This table provides information on maximum temperatures along the longitudinal profile of the Tuolumne River.	The DPEIR should present information regarding current spring and winter temperature impacts resulting from hydrosystem operations and those anticipated under the WSIP and global warming scenarios and relate these to potential impacts on fish populations in the Tuolumne and San Joaquin Rivers.	130
3	5.3.3	16	Last paragraph, last sentence states: "...the impact of the WSIP on water quality in Hetch Hetchey Reservoir in the Tuolumne River would be less than significant..." And 5.3.6 page 3 second (full) paragraph states: "Water temperatures within [this same stretch of river] have been observed to exceed the maximum daily temperatures of 21°C."	These statmentes are internally inconsistent. **Any** increase in the frequency, duration, and magnitude of water temperatures in this stretch above 21 degrees C may constitute a significant impact to resident rainbow trout in this stretch of river.	131

16

SI_TRT-CWA-SierraC

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

[illegible]	[illegible]	[illegible]	What the DPEIR says ("" indicate direct quote, otherwise paraphrased)	Our Comment	
3	5.3.3	16	Last paragraph, last sentence states: "...the impact of the WSIP on water quality in Hetch Hetchy Reservoir in the Tuolumne River would be less than significant..." And earlier: "On very rare occassions under existing conditions … the water quality objective that limits increases in water temperature to 5 degrees Fahrenheit to protect coldwater fish would likely be exceeded. ... In the future, with the WSIP, very infrequent exceedences of the water quality standard would continue to occur, but could last longer by several days or weeks than under the existing conditions."	These statements are internally inconsistent and generally not well supported. Because no quantifiable, measureable significance thresholds were employed for evaluating this impact, its "significance" is difficult to determine. Once again, the DPEIR confounds frequency with severity of impact. The water quality objective mentioned is in place because exceeding it is expected to cause significant impacts to coldwater fish populations (e.g., salmon and trout). The fact that such exceedences have occurred in the past does not justify their occurence under the WSIP and certainly does not allow for increasing the duration of the violation. The DPEIR does not present any analysis of the **severity** of this impact to coldwater fish resources. If the impact is severe, then its frequency is not very relevant. Indeed, the fact that violations occur currently suggests that current operations are inadequate to protect the Tuolumne's coldwater fish resources.	132
			Last paragraph, last sentence states: "...the impact of the WSIP on water quality in Hetch Hetchy Reservoir in the Tuolumne River would be less than significant..." And earlier: "On very rare occassions under existing conditions … the water quality objective that limits increases in water temperature to 5 degrees Fahrenheit to protect coldwater fish would likely be exceeded. ... In the future, with the WSIP, very infrequent exceedences of the water quality standard would continue to occur, but could last longer by several days or weeks than under the existing conditions."	This impact is of particular concern if water temperatures and water demands increase, as is expected under global climate change. Under global climate change scenarios, the frequency, duration, and magnitude of such violations of water quality objectives may all increase., The DPEIR's reliance on the 82-year hydrological record prevents any analysis of this possibility.	133

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

[illegible]	[illegible]	[illegible]	What the DPEIR says ("" indicate direct quote, otherwise paraphrased)	Our Comment	
3	5.3.3	18 & 1[illegible]	Figures 5.3.3-3 and 5.3.3-4 depict modeled temperature changes along the longitudinal profile of the river under two different reference environmental scenarios under current operating practices and under WSIP.	No indication of optimal or threshold temperatures is provided, so, for illustration purposes, we will use 20oC as a threshold temperature for impacts; steelhead experience sublethal negative consequences of elevated temperatures above this threshold (Reese and Harvey 2002, Richter and Komes 2005). Under existing operational rules and June 1993 environmental conditions, temperatures in the Tuolumne (as depicted in the DPEIR) do not exceed 20oC but they would exceed the threshold after ~25mi under WSIP operations. Under current operating conditions and June 1999 environmental conditions, steelhead may have experienced negative impacts more than 37mi downstream of La Grange dam, but under WSIP they would be expected to experience unsuitable temperatures beyond ~22miles below La Grange. Thus WSIP is expected to increase temperatures above a critical biological repsonse threshold over a large and measureable stretch of the Tuolumne River. The impacts of such changes in temperature under WSIP should be fully evaluated. Other biologically meaningful thresholds should be evaluated as well.	134
			Figures 5.3.3-3 and 5.3.3-4 depict modeled temperature changes along the longitudinal profile of the river under two different reference environmental scenarios under current operating practices and under WSIP.	Again, the potential impact of global warming has not been evaluated. Simply adding a given annual temperature increase to river temperatures is simplistic, but would give some sense of the potential loss of salmonid rearing habitat in the Tuolumne.	135

SI_TRT-CWA-SierraC

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

3	5.3.3	19	Second full paragraph states: "...[temperature increases below La Grange dam] would be less than significant..." And "Water quality objectives for the Tuolumne require that water temperatures not be increased by more than 5oF. The WSIP would comply with this objective almost all the time. On rare occassions ... there would be exceedences of the objective, but these rare exceedence would not impair the river's ability to support ... designated beneficial uses ... including coldwater fisheries."	These statements are internally inconsistent and generally not well supported. Because no quantifiable, measureable significance thresholds were employed for evaluating this impact, its "significance" is difficult to determine. However, the water quality objective mentioned was instituted to protect resources dependent on cold water. The DPEIR's insistence that violations would be "rare" is subjective and not relevant. The **severity** of the impact is not evaluated at all. The basis for the DPEIR's claim that temperature impacts would not impair benificial uses is not provided.	136
3	5.3.3	20	First (partial) paragraph states: "....most of the reductions in flow would occur from February through June in wet or above -normal years when flow in the San Joaquin River is at its seasonal maximum. As a consequence, most of the time, WSIP induced changes in flow would have little effect on water quality in the San Joaquin River." Second paragraph states: "Almost all of the time, reductions in San Joaquin RIver flow attributable to the WSIP would not be sufficient to cause salinity ... at Vernalis to rise above the objective." This paragraph then expresses that water quality problems in the lower San Joaquin River are the responsiblity of the USBR and that that agency would take corrective actions..	Another way of saying this is: The WSIP ***will*** cause water quality violations in the lower San Joaquin River and Delta occassionally and the USBR will have to mitigate that impact. Again the DPEIR confounds frequency with severity of impact. The terms used to describe frequency of impacts are vague and subjective. The **severity** of the impact is not evaluated; however, the DPEIR plans actions that anticipate violations of environmental regulations that would appear to be significant. Also, the DPEIR's assumption that the USBR will have to mitigate any water quality impacts caused by implementation of the WSIP is not supported.	137
3	5.3.3	10 & 1	Table 5.3.3-6 identifies water quality objectives in the project area. Dissolved oxygen objectives are identified for the San Joaquin River, Tuolumne River, and other Delta waters. The lower San Joaquin River DO threshold is identified as 6.0 mg/L between September 1 and November 30.	The table does not display the 5.0mg/L standard that exists between December 1 and August 31. More importantly, the subsequent analysis of water quality impacts does not address impacts to dissolved oxygen in the lower San Joaquin River (specifically the Stockton Deepwater Ship Channel - SDWSC) that may result from WSIP operations. Part of the reason for frequent water quality violations in the SDWSC are low flow rates in the Lower SJR (Physcial Process Model; http://www.sjrdotmdl.org/concept_model/about.htm).	138
			Table 5.3.3-6 identifies water quality objectives in the project area. Dissolved oxygen objectives are identified for the San Joaquin River, Tuolumne River, and other Delta waters. The lower San Joaquin River DO threshold is identified as 6.0 mg/L between September 1 and November 30.	These low flows may be exacerbated and prolonged due to flow reductions from the Tuolumne under WSIP. The impact of flow rate reductions on DO concentrations in the lower SJR must be evaluated. This analysis should account for the fact that violations of the DO standard in the SDWSC are already frequent (Stevens et al. 2006); thus, it could be argued that status quo releases from the Tuolumne hydrosystem are lower than those required to maintain water quality standards. Any increase in the frequency, duration and magnitude of low DO events in the lower SJR or Delta may represent a significant impact of the WSIP.	139

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

3	5.3.4	5	Paragraph 3 provides a summary discussion of the potential impacts on winter and spring Tuolumne River flows below La Grange Dam during dry years. "The WSIP would have no effect on flow in the Tuolumne River below La Grange Dam or the San Joaquin River under [below normal and drier years]"	In general, the analysis of flow during drier years is not given much attention. This may occur because the report erroneously concludes that flow changes will not occur during drier years. As stated multiple times through the DPEIR, drought year conditions have the potential to adversely affect river flows due to reductions in reservoir volume and increased municipal demand. Changes in irrigation demands are likely to be correlated (negatively) with the availability of freshwater (i.e., water year type) but these are not discussed. It is true that, under "critical year" types, the report indicates no change from current conditions as a result of the WSIP (*See table 5.3.4-4)*. However, under "Below Normal" conditions, flows are reduced under the WSIP in several months of 3 of the 12 years (25%) considered in the record. Similarly, flow reductions occur in 2 of 13 (15%) of "Dry" years in the record. Thus, it is an overstatement to say the WSIP would have "no effect" on Tuolumne River flows below La Grange Dam.	140
3	5.3.4	6	Paragraph 2 provides a summary discussion of the changes in modeled releases from La Grange Dam. "Occassionally, changes are in the range of 1,000 cfs to a little over 3,000 cfs."	The use of the word "occassionally" is misleading. This is another example of the DPEIR's persistent substitution of frequency for severity of impact. This statement of potential flow reductions is not meaningful out of context. A meaningful context is provided by Table 5.3.1-1 on p. 5.3.1-12. This table shows mean monthly flows below La Grange Dam from 1974-2004 do not exceed 1,884 cfs (mean flow during February). Reducing flows 1,000 to 3,000 cfs represents a major reduction in flow when compared to average monthly flows of 1,884 cfs.	141
			Paragraph 2 provides a summary discussion of the changes in modeled releases from La Grange Dam. "Occassionally, changes are in the range of 1,000 cfs to a little over 3,000 cfs."	Another specific example of the potential flow reductions is in Table 5.3.4-4 which reveals that flows during a water year like 1964 would be reduced in several months. During Novembers of years like 1964 (a "Dry year"), flows would be reduced by 832 cfs. Table 5.3.1-1 reveals that average flows (i.e. higher than those expected in "dry" years) below La Grange Dam for November are 368 cfs. This reveals that reductions in flow under WSIP are as much as 225% of the average flow. That is a rather large impact.	142
3	5.3.4	7	Table 5.3.4-4 Average Monthly Changes In Tuolumne River Flow Below La Grange Dam Attributable To the WSIP Provides a summary of average monthly changes in river flow below La Grange Dam.	The table provided is virtually unreadable, and does not lend itself to an analysis of changes in flows beneath La Grange Dam attributable to the WSIP.	143

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

Volume	Section	Page Number	What the DPEIR says ("" indicate direct quote, otherwise paraphrase)	Our Comment	
3	5.3.4	10	Paragraph 2 provides a summary discussion of the potential impacts on Tuolumne River flows below La Grange Dam and the San Joaquin River during dry years . "Occassionally, changes [in river flow] are in the range of 1,000 cfs to a little over 3,000 cfs."	This statement of potential flow reductions is not meaningful out of context. A meaningful context is provided by Table 5.3.1-1 on p. 5.3.1-12 as it shows that mean monthly flows below La Grange Dam from 1974-2004 do not exceed 1,884 cfs (mean flow during February). This average includes all years and, clearly, flows may be higher in wet years; but the fact remains that reducing flows 1,000 to 3,000 cfs represents a major reduction in flow.	144
			Paragraph 2 provides a summary discussion of the potential impacts on Tuolumne River flows below La Grange Dam and the San Joaquin River during dry years . "Occassionally, changes [in river flow] are in the range of 1,000 cfs to a little over 3,000 cfs."	Additional context for this flow reduction can be found in Table 5.3.4-1 on page 5.3.4-3) which provides flow and water quality objectives for the SJR at Vernalis. The Tuolumne provides a significant fraction of these flows (see DPEIR, p. 5.3.1-16). The table reveals that, during wet and above normal years (the years when we might expect Don Pedro refilling to occur following a prolonged drought), minimum required flows at Vernalis are between 5,730 and 8,620 cfs. Reduction in Tuolumne flow of between 1,000 and 3,000 cfs represent a significant impediment to maintaining flow and water quality objectives in the SJR and downstream in the Delta (part of the rationale for these flows is maintenance of salinity standards in the Delta).	145
3	5.3.6	2	First (partial) paragraph states: "the SFPUC has initated a fishery monitoring program within the river to assess potential effects of project operations on habitat quality and availability for resident trout and other fish species that over time will provide additional site-specific information on the effects of seasonal and interannual variation in stream flows on fishery populations..."	Details of this monitoring program are unavailable. It is not clear that the monitoring program has begun. **Results** from this kind of monitoring program are required to determine the potential impacts of WSIP operations. Without this monitoring, there is no baseline with which to compare impacts to fisheries that result from WSIP. A monitoring program that begins after the adoption of the WSIP cannot be used to evaluate the potential impacts of the WSIP.	146

SI_TRT-CWA-SierraC

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

Volume	Section	Page Number	What the DPEIR says ("" indicate direct quote, otherwise paraphrase)	Our Comment	
4	5.3.7	2	Second (full) paragraph lists two studies of fish populations in the Tuolumne below Hetch Hetchy and an unspecified number of observations of rainbow and brown trout spawning in this reach.	All of these observations and studies are over 15 years old (the most recent is from 1992). The estimate of 7,000 total adult rainbow trout and brown trout in the stretch below O'Shawughnessy Damand Early Intake is outdated.	147
4	5.3.7	2 & 3	Third (full) paragraph refers to a USFWS 1992 study of available habitat in the Tuolumne River below O'Shaughnessy Dam. And On page 5.3.6-3, (first partial paragraph) "the stream flow study did not identify physical habitat as a major limiting factor, although seasonal water temperatures were identified as a factor affecting both brown and rainbow trout within the river."	The reference to this study is curious given that the study is a "rough draft" and has never been adopted by the SFPUC, despite the fact that it is 15 years old. This study called for substantially higher minimum flows in this stretch of the Tuolumne than the minimum flows identified by the DPEIR (see Table VI of USFWS 1992). If the SFPUC accepts the validity of this study (as implied by its citation here), then why has it not cited this study's recommendations regarding minimum instream flows in this stretch of the Tuolumne? The study is now over 15 years old; thus, the fact that physical habitat was not believed to be limiting at the time the study was written, does not mean that it is not limiting today. Operation of dams tends to degrade downstream physical rearing habitat conditions inexorably and gradually (Williams 2006; TNC 2006).	148
3	5.3.6	15	Table 5.3.6.2 Tuolumne River Spawning Survey Summary	These results are in some cases different from those presented in AFRP data; the difference is inexplicable. We present our Figure 1 (from the AFRP website: http://www.delta.dfg.ca.gov/afrp/documents/Doubling_goal_graphs_032807.ppt#281,35,Slide 35) to review Chinook salmon populations on the Tuolumne. Clearly, populations since 2000 and from 1988 through 1999, were well below the AFRP recovery goal of 38,000 fall run Chinook salmon. Indeed, only 500 fish returned in each of the last two years of record (2005 and 2006). The 1992-2006 average (8,941 fall-run) is <50% of the 1967-1991 average which the AFRP uses as its "baseline condition". The DPEIR's tepid insinuation that Chinook salmon populations are in better condition than they were prior to the FERC settlement agreement (page 15) is not supported.	149

22

SI_TRT-CWA-SierraC

3	5.3.6	18	First paragraph states: "Water temperatures in the lower Tuolumne River are in the 25-30 °C range for an extended period of time during the summer in many locations... and are unsuitable for steelhead." And FERC concluded that no significant populations of steelhead/rainbow trout are present in the lowe Tuolumne system.	McEwan (2001) concludes that there is "substantial evidence" that a self-sustaining population of steelhead exists in the San Joaquin River. His report documents very large *O. mykiss* with all the morphological characteristics of anadromous steelhead as recently as January 2001. Certainly, steelhead populations were known to exist in the Tuolumne historically (McEwan 2001; Lindley et al. 2006). Thus, this paragraph serves as an indictment of the steelhead spawning and rearing conditions created by dams in the Tuolumne River. Maintenance of these "unsuitable" conditions (not to mention further degredation of conditions required by spawning steelehad) may constitute a violation of California Dept. of Fish and Game Code and/or the Federal Endangered Species Act. This is another example demonstrating that the baseline against which the WSIP is compared may itself represent unacceptable conditions.	150
			First paragraph states: "Water temperatures in the lower Tuolumne River are in the 25-30 oC range for an extended period of time during the summer in many locations... and are unsuitable for steelhead." And FERC concluded that no significant populations of steelhead/rainbow trout are present in the lowe Tuolumne system.	The 1996 FERC report that the DPEIR references is out-of-date and was conducted before the species was listed under the ESA. This may account for the lack of documented sightings of steelhead in the FERC report. As McEwan (2001:15) notes: "Until very recently, steelhead were considered by some to have been exterpated from the San Joaquin River system ..). However, this conclusion was based on little information and no field studies."	151
3	5.3.6	18	Second paragraph states: "...only 10 of the fish in this extended period of snorkel survey were in excess of 400 millimeters in length, suggesting that large anadromous steelhead probably occur in the system very infrequently"	The logical foundation for this statement is seriously flawed. *O. mykiss* come in two forms, resident (called "rainbow trout") and migratory (called "steelhead"). These two forms are indistinguishable until migration occurs. All *O. mykiss*, whether they become resident "rainbow trout" or anadromous "steelhead" pass through a stage where they are smaller than 400mm. Also, steelhead juveniles are expected to emigrate to marine waters (as "smolt") at lengths below ~200mm (CDFG 1996). Thus, any of the fish observed by the snorkel survey may have become anadromous steelhead.	152

SI_TRT-CWA-SierraC

3	5.3.6	18	Steelhead/Rainbow Trout -- in general	"Steelhead" and "rainbow trout" are two life history forms of the same species. Some populations of this species are "polymorphic," meaning that resident "rainbow trout" can produce anadromous "steelehad" offspring and vice-versa. The extent and distibution of "polymorphic" populations in the Central Valley is undocumented. The mere fact that *o. mykiss* are observed in the Tuolumne indicates a strong possibility that the stream produces "steelhead" during at least some years. These steelhead are legally protected under the ESA.	153
3	5.3.6	18	Largemouth and smallmouth bass. Section states: "Non-native largemouth and smallmouth bass have colonized the lower Tuolumne River, taking advantage of the low-velocity, and pond-like habitats of the river...below RM 25....Both the low flow and high water temperatures in this reach stress juvenile salmon and enhance predation by bass".	These statements are correct. They indicate (a) that curent conditions created in the River by hydrosystem operations support non-native species impacts on native species of concern (particularly fall-run Chinook salmon and threatened steelhead) and (b) that operations that further reduce flow and increase temperatures in the Tuolumne will increase the spatial extent and magnitude of impacts of these non-native species. Changes anticipated by the WSIP will increase temperatures and reduce flows in the lower Tuolumen and thus increase impacts to species-of-concern by non-native predators.	154
3	5.3.6	20	First full paragraph: "Bass density could thus be reduced by recontouring the channel to enhance riffle and run habitats, combined with manipulation of flow to increase velocities....[this] would be expected to benfit out-migrating juvenile salmon."	No reference to literature, studies, or magnitudes of change are provided to support or parameterize this statement. Also, the paragraph ignores a more obvious solution to invasive bass problems in the Tuolumne: increase flows and storage in the Tuolumne hydrosystem decrease temperatures and decrease suitable habitat for these bass species. Changes anticipated by the WSIP would have the opposite impact.	155
3	5.3.6	24	Significance criteria: "The CCSF has not formally adopted significance standards for impacts related to fisheries, but generally considers that implementation of the proposed program would have fisheries impact if it were to: Have substantial adverse effect ... on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG, NMFS, or USFWS....[or] Have the potential to degrade the quality of the environment, substantially reduce the habitat of a fish or wildlife species, cause a fish or wildlife population to drop below self-sustaining levels ... substantially reduce the number or restrict the range of an endangered, rare, or threatened species"	Failure to adopt a formal, quantifiable, measureable threshold for determining significant impacts is a persistent and major flaw of the DPEIR. Ther is no way to evaluate the magnitude of changes caused by the proposed plan because the significance thresholds lack a rigorous definition. For example "substantial" impacts are not defined. On the other hand, the Andromous Fish Restoration Program (AFRP) defines the goal of doubling anadromous fish populations above their baseline averages. Also, the Federal Endangered Species Act prohibits "Take" of endangered species; this is a much more rigorous, quantifiable, and measurable standard than "substantial reduction."	156
3	5.3.6	26	Effects on fishery resources along the Tuolumne River between Hetch Hetchy Reservoir and Don Pedro Reservoir. Indicates that minimum flow requirements below Hetch Hetchy (as described in Table 5.3.1-2) are met.	The USFWS draft instream flow report (1992) recommended that the minimum flows in the referenced table be revised upward substantially (see Table VI of the draft report). The failure of the SFPUC to adopt these recommendations may already have impacted fish populations in this area. The DPEIR's adherence to the older standards suggests that the WSIP will continue to impact rainbow trout populations. In general, because the SFPUC lacks a recent evaluation of rainbow trout populations in this area or habitat conditions in this area, it is hard to see how the imapcts of WSIP can be evaluated for this resource.	157

SI_TRT-CWA-SierraC

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

Volume	Section	Page Number	What the DPEIR says ("" indicate direct quote, otherwise paraphrased)	Our Comment	
3	5.3.6	26	Final paragraph states: "In spring months…operations under…WSIP would reduce average monthly flows between 4 and 30 percent…the greatest percentage reduction would occur in normal, below-normal, and dry years …[and] the modeling tool used for this analysis reports information in a monthly time step; it cannot provide weekly or daily information about flow releases...the flow reduction would not occur evenly over a month..."	The effect of presenting results in a monthly time-step is accurately portrayed here. If **monthly average** flows are reduced up to 30 percent, daily and weekly flows will sometime decrease **more than** 30% because the flow reduction will "not occur evenly over the month". Given their magnitude and timing (i.e., in drier years), these flow reductions may have serious impacts on rainbow trout populations in this reach.	158
3	5.3.6	27	Final two paragraphs discuss temperature impacts on rainbow trout populations in this reach. "This potential temeprature increase [under certain drought conditions water released from HH could be 10 to 12 °C warmer than under non-WSIP operations] would result in a less-than-significant impact on the fisheries in this reach [because] it would occur infrequently [and this temperature increase would not occur during the spawning period for rainbow trout."	First, the anticipated temperature increase violates the Central Valley RWQCB objective of limiting temperature changes in rivers to < 5°C (objective referenced on page 28 of this section); the frequency of this violation is not relevant -- it is still a violation that can be avoided by operating the hydrosystem correctly. A sudden 10-12oC temperature increase during the fall would likely have deleterious effects on trout as they prepare to overwinter. The DPEIR's dismissal of any impact is simply not supported by any literature reference. The temperature analysis does not account for the impact of regional climate change. Section 5.7.6 allows that there may be a 1.5 oC increase throughout the watershed over the project period. How would this direct temperature impact affect water temperatures and fish populations? Also, the increased temperatures, decreased water supplies, and increased demand for water created by regional climate change would all be expected to cause an increase in the frequency of conditions that produce the extreme temperature increases envisioned in this section of the DPEIR.	159
3	5.3.6	28	First full paragraph: "Potential impacts to resident fish population inhabiting the river are less than significant…"	Actual quantifiable analysis of this impact is not presented in the DPEIR, which simply dismisses the impact. A quantifiable impact assesment is made more difficult by the SFPUC's lack of a current baseline for this population or river conditions in this area. The draft studies from 1992 are too old and preliminary to provide a current baseline.	160

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

Volume	Section	Page Number	What the DPEIR says ("" indicate direct quote, otherwise paraphrased)	Our Comment	
3	5.3.6	28	Impact 5.3.6-4 states: "Changes in [hydrological conditions] have the potential to affect the quality and availability of habitat for resident and anadromous fish species. Chinook salmon is the species of most concern in this reach of the River. …Steelhead, which is a federally listed threatened species, may inhabit the river in low abundance."	We agree that hydrological changes anticipated under the WSIP are likely to impact Chinook salmon populations and steelhead populations on the Tuolumne below La Grange Dam. It is not clear why the DPEIR focusses on Chinook salmon, given that steelhead are an ESA listed species, their numbers are lower, and they are exposed to conditions on the Tuolumne year-round (because they rear in freshwater for two years before emigrating to the ocean). The fact that Steelhead may inhabit the River in "low numbers" cannot serve as a justification to ignore their requirements. Indeed, their lower numbers and more protected status indicate that *current* Tuolumne hydrosystem operations are inadequate to protect this species and that any additional impacts created by the WSIP are particularly significant.	161
			Impact 5.3.6-4 states: "Changes in [hydrological conditions] have the potential to affect the quality and availability of habitat for resident and anadromous fish species. Chinook salmon is the species of most concern in this reach of the River. …Steelhead, which is a federally listed threatened species, may inhabit the river in low abundance."	The extemely low populations of fall-run Chinook salmon observed in the Tuolumne in recent years (figure 1) also indicate that Tuolumne hydrosystem operations provide inadequate protection for this species-of-concern. Even slight, marginal habitat impairment caused by WSIP operations may be interpreted as significant impacts against this highly impacted baseline condition.	162

26

SI_TRT-CWA-SierraC

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

[illegible]	[illegible]	[illegible]	What the DPEIR says ("" indicates direct quote, otherwise paraphrase)	Our Comment	
3	5.3.6	29	Bulleted list at the top of the page presents potential mechanisms for adverse effects on fishery habitat.	An important impact mechanism missing from this list is: Reduction in salmonid spawning gravel quality and quantity as a result of reduced frequency, duration and magnitude of peak flows. Hydrosystem operations tend to impact salmonid spawning gravel inexorably over time. This occurs as a result of reduced spawning gravel recruitment (via erosion) and sedimentation and armoring of available spawning gravel (Kondolf 1997, TNC 2006, Williams 2006) This impact is believed to be a major cause of salmonid decline in the Central Valley of California (TNC 2006). Reductions in peak flow magnitude, duration, and frequency are a critical impact of the WSIP and the DPEIR has not analyzed the impacts of reduced sediment transport on spawning/rearing habitat availability.	163
3	5.3.6	29	Final paragraph discusses projected changes in flow over a variety of water year types and references Table 5.3.6-1.	See numerous earlier comments regarding the effect of aggregating flow reductions across water year types as in Table 5.3.6-1. Despite the DPEIR's efforts to characterize flow changes as "infrequent," the anticipated flow reductions in the Tuolumne River under WSIP will undoubtedly reduce sediment transport rates in the River. This reduction in sediment transport may translate into accelerated degradation of spawning substrate for salmonids and rearing habitat for numerous fish species. The fact that most of these reductions occur only during the highest flow periods actually *increases* the impact on sediment transport since most sediment transport occurs during high-flow events. As a result of the truncation of the upper end of the natural hydrograph, WSIP can be expected to reduce recruitment of spawning gravel to the river and increase gradual armoring of spawning substrate, making it unsuitable for salmonid spawning.	164
3	5.3.6	31	First (partial paragraph): "...in some years, when the flow reductions are more substantial, the WSIP changes would adversely affect juvenile fall-run Chinook salmon rearing habitat." And First (full) paragrap: "Based on the magnitude of the stream flow changes, it is not expected that flow reductions under the WSIP would result in significant adverse impacts on juvenile fall-run Chinook salmon migration."	The DPEIR correctly identifies that there will likely be impacts to fall-run Chinook salmon from implementation of the WSIP. Its assesment of which DPEIR flow reduction would cause an impact, the frequency of those events, and the life stages that would be impacted are unsupported -- they represent a guess. Actual impacts could be far more frequent and affect more parts of the life-cycle than the report admits. For example, the relationship between flow and juvenile outmigration success and rate are poorly understood (Williams 2006).	165
3	5.3.6	31	Second full paragraph states: "...Flow reductions in June would likely result in seasonally elevated water temperatures and a corresponding reduction in the linear extent of suitable habitat for steelhead/rainbow trout rearing..." And "Changes in flow in June of average wet years ... would have a minor effect on steelhead/rainbow trout...a reduction in average monthly flow in June of approximately 102 cfs would cause a moderate change in habitat conditions, potentially affecting oversummering steelhead/rainbow trout as well as reducing physical habitat within the river for other aquatic species."	We quantify the modeled linear reduction in habitat for two different June model scenarios (see comments re: Figures 5.3.3-3 and 5.3.3-4). The DPEIR could have done a similar (or more comprehensive) quantifiable analysis to back up this assertion. What is the defintion of a "minor" effect" How does it differ from a "moderate change in habitat conditions"? As stated elsewhere in these comments, the **average** monthly reduction of flows by 25% (under some conditions) means that sometimes flow reductions will be greater than 25%. Reducing habitat space by 1/4 for periods of a month or more would be expected to have a large impact on populations. The population discussed here is a federally-threatened population; the DPEIR acknowledges that steelhead are "rare" in this stretch of the river. Reducing their habitat by 25% or more from time to time seems inadvisable.	166

27

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

[illegible]	[illegible]	[illegible]	What the DPEIR says ("" indicates direct quote, otherwise paraphrase)	Our Comment	
3	5.3.6	31	Third full paragraph states: "Almost all the time, WSIP-induced flow reductions ...would have no effect on temperature [below La Grange Dam]." And "On very rare occassions, WSIP-induced flow reduction would cause mean daily temperature increases of 10oC downstream near the San Joaquin River..."	It is difficult to understand how the DPEIR calculated daily temperature increases when their hydrological model does not produce daily flow estimates. The volume of flow has a huge impact on the temperature gain of water as it flows through the Tuolumne. Without knowing the flow on a given day, calculation of temperatures for that flow are problematic. The DPEIR should provide a more detailed description of how it conducted that modelling. The DPEIR again confuses frequency with severity of impact. Without changing their meaning, these two sentences could be rewritten to say: Sometimes WSIP induced-flow reductions would impact temperatures in the river in ways that would have determinetal effects on rearing salmonids.	167
			Third full paragraph states: "Almost all the time, WSIP-induced flow reductions ...would have no effect on temperature [below La Grange Dam]." And "On very rare occassions, WSIP-induced flow reduction would cause mean daily temperature increases of 10oC downstream near the San Joaquin River..."	The severity and frequency of these temperature-related impacts would be expected to increase because of expected increases in regional temperature (see DPEIR Sect 5.7.6 "Climate change and gobal warming"). These temperature-related impacts must be reanalyzed to account for the effect of regional air temperatures and related impacts on flow volume and timing. Even seemingly small increases in temperature can have dramatic effects on salmonid survival and reproductive success (Richter and Kolmes 2005).	168

28

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

SI_TRT-CWA-SierraC

[illegible]	[illegible]	[illegible]	What the DPEIR says ("" indicate direct quote, otherwise paraphrase)	Our Comment	
3	5.3.6	32	First (partial) paragraph: The flow reduction would reduce available habitat in the entire reach of the river used by juvenile salmonids below La Grange Dam. The elevated temperatures, although infrequent, would truncate the length of the river reach suitable for juvenile salmonids. These adverse effects on flows and temperature in the river under the WSIP would not substantially alter or degrade fishery habitat or jeopardize the continuation of the fishery populations in the lower Tuolumne River in most years. And The WSIP's small but incremental contribution to adverse effects on the lower river would make planned restoration of habitat and fishery resources more difficult.	What does it mean that WSIP-induced flow alterations will only jeopardize the continued existence of fish populations *some of the time*? This is nonsensical. Again the frequency of the impact is not nearly as important as the severity of the impact when the severity is potentially catastrophic. We agree that the WSIP's significant contribution to adverse effects on the lower river would make planned restoration of fish species in this area more difficult.	169
3	5.3.6	32	First (partial) paragraph: Proposes implemetation of Measure 5.3.6-4a, "Avoidance of Flow Changes by reducing demand for Don Pedro Reservoir Water." And/or Proposed implemetation of Measure 5.3.6-4b "Fishery Habitat Enhancement," if 5.3.6-4a is not possible.	The ability to implement (mitigation) measure 5.3.6-4a is completely speculative as it involves procuring water from TID and MID. The prospects for this seem unlikely but, until an agreement is in place, it is doubtful that this proposal can serve as a mitigation measure because it is outside of the SFPUC's control. The alternative mitigation measure 5.3.6-4b does not respond to the anticipated impact. The impact is related to loss of habitat due to decreased flows and associated increased temperature. Physcial habitat restoration may be necessary in this area but it will not change the impact of substantial flow reductions and temperature increases.	170
3	5.3.6	32	Last paragraph (p32) states: "Increased water temperatures, particularly during the late spring juvenile salmonid migration period... would also be expected to adversely affect juvenile salmon survival."	Agreed	171

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

SI_TRT-CWA-SierraC

[illegible]	[illegible]	[illegible]	[illegible]	[illegible]	
3	5.3.6	33	Inflow to the lower San Joaquin River from the Tuolumne River would not be less than the minimum stream flow specified in the FERC license of the Don Pedro Project. As a result of this minimum flow requirement, the WSIP would not have a significant impact on flows...	Maintenance of minimum flows specifed by FERC does not equate to protection of the San Joaquin or Lower Tuolumne's fish resources. Indeed, that minimum requirement was established before steelhead were listed as threatened and before their presence was confirmed in the Tuolumne River. Quoting from Calfed (2000): *It is important to note that all of the agreed upon or proposed flows (AFRP, Tuolumne River Settlement Agreement, FERC, VAMP, Davis-Grunsky, and DFG recommended flows) in the Stanislaus, Tuolumne, and Merced Rivers were designed to facilitate Chinook salmon recovery, and little or no consideration was given to steelhead recovery in the design of these flow strategies. Flow and temperature requirements of steelhead will need to be evaluated and integrated into the proposed flow regimes.*	172
3	5.3.6	33	Last Paragraph states: "To the extent that infrequent reduction in flow and corresponding increases in water temperature occur during the spring... WSIP operations would contribute to adverse impacts on habitat conditions for downstream migrating Chinook salmon and steelhead. However, this potential impact would occur so infrequently that it does not represent a significant impact to fishery resources."	Once again, the significance threshhold for significant impacts is not adequately defined. If severe impacts occur only "infrequently" does that mean they are not significant? What is the threshold of severity frequency that defines a significant impact? These threshods must be laid out and justified in advance, otherwise the assesment of impacts amounts to no more than wishful thinking. Steelhead are listed as a threatened species. Fall-run Chinook salmon are a species of special concern. Numbers of both species are severely reduced on the Tuolumne from historic norms. As a result, any negative impact to these species that results from a discretionary action (like WSIP) must be regarded with extreme caution. Also, given the historic decline in these populations, it is highly likely that current operations of the Tuolumne hydrosystem provide inadequate protection for these species -- thus, marginal decreases in habitat quality from this already highly impacted state cannot be regarded as insignificant.	173
	H1.3.1	13	Paragraph 4 provides a description of drought planning inputs to the HH/LSM model and states: "Studies suggest that there is a 30 percent chance that the SFPUC system will experience a drought in the next 75 years equal to or more severe than the 1987-1992 drought."	No citation of these "studies" is provided.	174

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

[illegible]	[illegible]	[illegible]	[illegible]	Our Comment	
Appendix H	H1.3.1	15	Paragraph three describes the possible implications of the monthly time interval used in the DPEIR analysis, and states: "In additional instances such as the analyses of flow effects below Hetch Hetchy Reservoir and Alameda Creek Diversion Dam, HH/LSM results have been refined or tiered to provide additional insight to the effects of the WSIP upon stream flow for periods less than a month."	What methods were used to "tier" monthly results to analyze effects of the WSIP on stream flows below Hetch Hetchy Reservoir and Alameda Creek Diversion Dam for periods less than a month? Using a monthly interval for analysis limits the feasibility of conducting analyses of the effects of the WSIP on daily and weekly flow regimes. Considering that the monthly time-step constitutes a serious limitation for analysis of the proposed changes to daily and weekly hydrologic flow regimes, data resulting from the "tiering" process, analysis of these data, and the methods used to produce that data and analysis should be provided.	175
Appendix H	H1.3.1	16	Table 5.1-2 describes model features and their respective outflow parameters.	Only accumulated precipitation is presented as a model input for Hetch Hetchy Reservoir. Why were Lakes Eleanor and Lloyd excluded as inputs?	176
Appendix H	H2-1	49	Table 1-2 Summary of Modeling Results (Part 1/2) Provides a summary list of setting characteristics and modeling assumptions for the HH/LSM model.	Under the item Study Average Production & Disposition (1921-02) and the sub-items TID Diversion and MID Diversion assumes that both TID and MID diversions will remain static. What is the basis for this assumption? On page 5.7-92 of Volume 3, the DPEIR identified that the studies of global climate change summaried in Table 5.7-21, indicate that "changes in urban and agricultural water demand" and increases in evaporation and concomitant increased irrigation need" are likely outcomes of climate changes in the Central Valley and southern Sierra Nevada. Thus, the assumption that TID and MID agricultural water demands in 2030 will remain the same is unsupported.	177
Appendix H	H2-1	49	Table 1-2 Summary of Modeling Results (Part 1/2) Provides a summary list of setting characteristics and modeling assumptions for the HH/LSM model.	Under the item Study Average Production & Disposition (1921-02) and the sub-item Water Bank Account water transfers from TID and MID supplies are presumed to be 27,000 acre-feet. Has the SFPUC reached an agreement with TID and MID on this proposed transfer? If so, where is the documentation of that agreement? If not, because this assumption has a high degree of uncertainty, modelling results based on this assumption also have a high degree of uncertainty.	178
Appendix H	H2-1	55	Table 2.1-1 Provides a list of differences in total modeled system-wide delivery with implementation of WSIP	The data contained is difficult to review in this format. These types of data should be displayed as a single hydrograph or a set of hydrographs. Presenting extensive datasets as long table without corresponding graphs makes it very difficult to compare between the two scenarios. Without entering the data into a statistical or graphical software package, the reader cannot accomplish the required comparisons.	179
Appendix H	H2-1	61	Table 2.3-3 provides a list of differences in total modeled system-wide delivery with implementation of WSIP.	The data contained is difficult to review in this format. These types of data should be displayed as a single hydrograph or a set of hydrographs. Presenting extensive datasets as long tables without corresponding graphs makes it very difficult to compare between the two scenarios. Without entering the data into a statistical or graphical software package, the reader cannot accomplish the required comparisons.	180

These types of data should be displayed as a single hydrograph or a set of hydrographs. Presenting extensive datasets as long tables without corresponding graphs makes it very difficult to compare between the two scenarios. Without entering the data into a statistical or graphical software package, the reader cannot accomplish the required comparisons.	187

SI_TRT-CWA-SierraC

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

[illegible]	[illegible]	[illegible]	What the DPEIR says ("" indicate direct quote, otherwise paraphrased)	Our Comment	
4	6.4.2	48	Measure 5.3.6-4a states: "The SFPUC will pursue a water transfer arrangment with MID/TID and/or other water agencies such that the water acquired is developed through actions that result in reduction of demand on Don Pedro Reservoir as a result of conservation, improved delivery efficiency, inter-agency water transfer or use of an alternative supply such as groundwater....The counsequent increase in water storage in Don Pedro Reservoir would offset the reduction in inflow ... attributable to WSIP [and thus] the release pattern from La Grange Dam would be the same or similar to the existing condition ..."	None of these potential sources of "new" water for Don Pedro Reservoir are confirmed. SFPUC cannot guarantee that these new water sources will become available or that their size or the timing of their availability will be sufficient to completely mitigate impacts 5.3.6-4 and 5.3.7-6. Given that (a) MID and TID currently divert less than their water right allows and there is every reason to believe that their needs for water will increase (especially given the trends expected to continue from global warming); reaching an agreement in which TID/MID divert less water than under current conditions seems hopelessly optimistic.	188
4	6.4.2	48	Measure 5.3.6-4b states: "If Measure 5.3.6-4a is not implemented, then the SFPUC will mitigate potential fishery effects on the lower Tuolumne River by implementing one of the following two habitat enhancement actions....gravel augmentation or isolating or filling a captured former gravel quarry pit along the river."	The first alternative (gravel augmentation) has nothing to do with the impact identified. Impacts 5.3.6-4 and 5.3.7-6 have to do with reductions in juvenile salmonid rearing and migration habitat. Gravel augmentation will increase spawning habitat for these species. Spawning habitat may indeed be limiting to these species; however, because the SFPUC has not monitored spawning habitat availability or use in this stretch of the river, we cannot assess the effect of current hydrosystem operations on spawning habitat availability. Restoring spawning gravel will not mitigate for impacts to the later life stage; indeed it may exacerbate that impact by increasing densities of juveniles competing for limited rearing habitat.	189

Review of the Draft Program Environmental Impact Report (DPEIR) for the Water System Improvement Program (WSIP)
Specific comments on the hydrologic, geomorphic, and fishery impacts of the WSIP
Prepared by the Tuolumne River Trust
October 1, 2007

[illegible]	[illegible]	[illegible]	What the DPEIR says ("" indicate direct quote, otherwise paraphrased)	Our Comment	
			Measure 5.3.6-4b states: "If Measure 5.3.6-4a is not implemented, then the SFPUC will mitigate potential fishery effects on the lower Tuolumne River by implementing one of the following two habitat enhancement actions....gravel augmentation or isolating or filling a captured former gravel quarry pit along the river."	The second alternative (isolating a former quarry) would be expected to benefit rearing salmonids because it would reduce habitat for their predators. There is no analysis of the current impact of predators in this quarry on Chinook salmon or steelehad (the magnitude of these impacts are bound to be somewhat different); therefore the mitigative effect of isolating this captured quarry cannot be evaluated. Impact 5.3.7-6 deals with likely impacts to terrestrial species that rely on riparian habitat; neither of the proposed alternatives under Measure 5.3.6-4b would have any beneficial effect on these species/habitats.	190
			Measure 5.3.6-4b states: "If Measure 5.3.6-4a is not implemented, then the SFPUC will mitigate potential fishery effects on the lower Tuolumne River by implementing one of the following two habitat enhancement actions....gravel augmentation or isolating or filling a captured former gravel quarry pit along the river."	By suggesting the need to restore spawning gravel in the Tuolumne River, the SFPUC indicates that it believes spawning gravel quality and/or availability are insufficient in this area. Because current hydrosystem operations in this area are almost certain to have had some impact on spawning substrate quantity and quality in this area, the SFPUC should be required to monitor both salmonid spawning habitat and salmonid rearing habitat to determine which of these habitat types is limiting in this stretch of river.	191

Volume	Section	Page number	What the DPEIR says ("" indicate direct quote, otherwise paraphrase)	Our Comment
4	6.4.2	48	Measure 5.3.6-4b states: "If Measure 5.3.6-4a is not implemented, then the SFPUC will mitigate potential fishery effects on the lower Tuolumne River by implementing one of the following two habitat enhancement actions….gravel augmentation or isolating or filling a captured former gravel quarry pit along the river."	In 1992, the USFWS conducted an evaluation of salmonid spawning habitat upstream of Don Pedro Dam; it is not clear why the SFPUC has not conducted a similar (or more comprehensive) analysis of spawning and rearing habitat availability under different flow regimes in the lower Tuolumne. Given that Tuolumne hydrosystem operations impact spawning and rearing conditions for native salmonids in the lowerTuolumne, it seems that the SFPUC should be required to conduct such monitoring to ensure that its operations do not impact the threatened Central Valley steelhead population or the ESA-candidate fall-run Chinook salmon population. 192

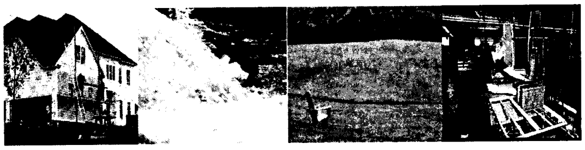
A Review of the SFPUC Retail and Wholesale Customer Demand Projections



Sustainable Water Supply Briefing
September 28, 2006

Heather Cooley
Peter Gleick
Pacific Institute, Oakland, CA

PACIFIC INSTITUTE

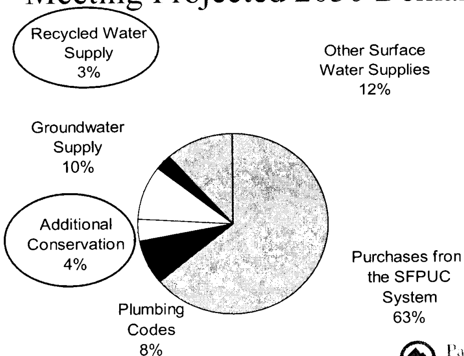
Summary

- We reviewed current and projected water demand and conservation programs for SFPUC wholesale and retail customers.
- Demand increases are projected to vary dramatically from user to user.
- Demand increases are driven by non-residential and outdoor uses.
- Projected conservation programs inadequately address projected demand.
- Better efficiency studies are needed.

197

Pacific Institute

Meeting Projected 2030 Demand



Pacific Institute

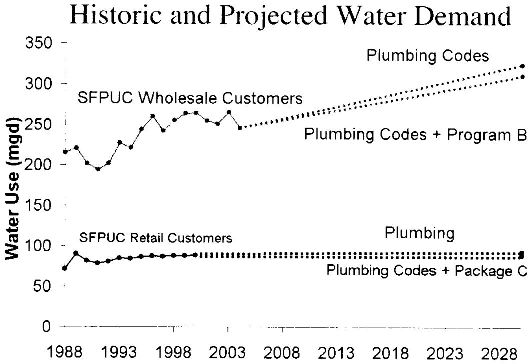
SFPUC Assumed Conservation Programs

- Wholesale Customers (Program B)
  - Fewer than 10 measures
  - Estimated savings: 13.4 mgd
- Retail Customers (Package C)
  - 38 measures
  - Estimated savings: 4.5 mgd

Pacific Institute

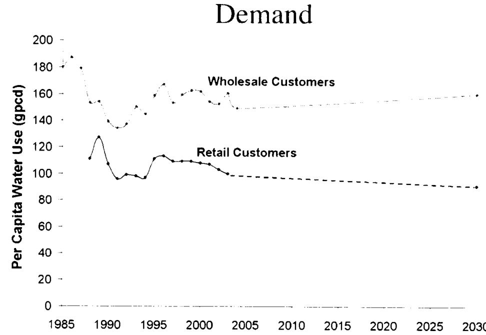
SI_TRT-CWA-SierraC

Historic and Projected Water Demand



Pacific Institute

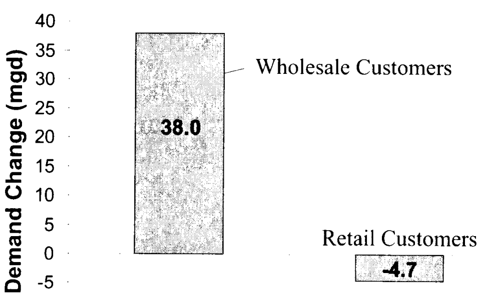
Historic and Projected Gross Per-Capita Demand



197 cont.

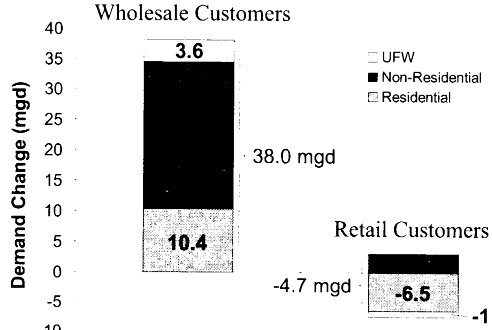
Pacific Institute

Demand Change (Current - 2030)



Pacific Institute

Demand Change (Current - 2030)



Pacific Institute

SI_TRT-CWA-SierraC

Residential Per-Capita Demand (gpcd)

		Current		2030	
Customer	Sector	Indoor	Outdoor	Indoor	Outdoor
Wholesale	Single-family	69	**39**	58	**40**
Retail	Single-family	56	4	47	5

Efficient Indoor Water Use

AWWA: 45 gpcd

Seattle Study: 40 gpcd

Pacific Institute

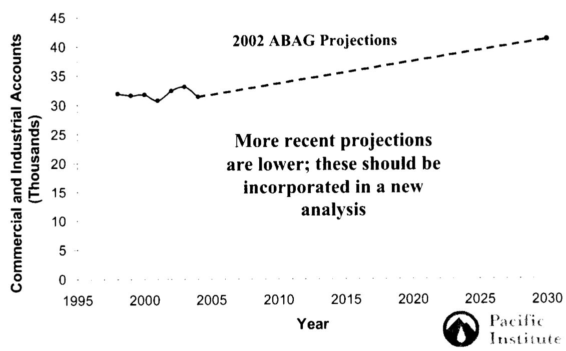
Non-Residential Demand

- Accounts for over **80%** of demand increase
- Employment projections too high
- Forecast method for wholesale customers is inadequate.
- Conservation measures fail to reduce demand to levels achieved elsewhere.

Pacific Institute

197 cont.

Employment Projections



Pacific Institute

Forecast Method (Wholesale, Non-Residential Customers)

- Assumes that all non-residential users grow at the same rate (31.3% in accounts by 2030)
- Assumes water use among these non-residential users is the same
- This approach appears to overestimate 2030 demand.

Pacific Institute

SI_TRT-CWA-SierraC

Non-Residential Conservation

- Proposed conservation reduces non-residential demand by 4%.
- Santa Clara Valley Water District study: 38%
- Pacific Institute study: 39% (minimum cost-effective savings of 26%)

Price-Driven Efficiency

- Price-driven efficiency improvements are **not** considered separately.
- But we know that water demand **IS** elastic.
- Water prices projected to quadruple by 2015 (in real dollars).

197 cont.

Pacific Institute

Conclusions

- Demand increases are driven by non-residential and outdoor uses.
- Proposed conservation programs do not address these projected demands.
- Non-residential demand and conservation potential are inadequately evaluated.
- Price-driven conservation is not included.
- Projected recycled water use is small.

Recommendations

- More emphasis needs to be placed on reducing outdoor water use.
- Non-residential demand and conservation potential must be reassessed using industry-specific data on economic growth, water use, and conservation potential.
- Price-driven conservation must be included.
- Recycled water use must be expanded.

SI_TRT-CWA-SierraC

Review of SFPUC Wholesale Demand Projections for 2030

Edward R. Osann
Potomac Resources, Inc.
September 28, 2006

Documents Reviewed

- Sustainable Water Supply Briefing Background Information Package 2006
- Wholesale Customer Demand Projections Technical Report (URS 2004)
- 2030 Purchase Estimates Technical Memorandum (URS 2004)
- Settlement Agreement and Master Water Sales Contract 1984

198

Key findings of the SFPUC Analysis

- Increased demand for water
  - +52 mgd suburban (+19%)
  - SF retail decrease
- Anticipated increases in SFPUC purchases
  - +35 mgd suburban (+19%)
  - SFPUC retail decrease
- 2030 Purchases *above* Supply Assurance
  - +24 mgd (+13%)
- Increased diversions from Tuolumne & Delta
  - ???

Has the Case Been Made for Increasing the Assured Supply?

- Are there shortcomings in the regional demand forecast?
- How sensitive is the projected demand to unmodeled factors, new technologies?
- Are there shortcomings in the conservation practices of individual wholesale customers?
- Are the demand increases contained in the forecast truly compelling?

SI_TRT-CWA-SierraC

Are there shortcomings in the regional demand forecast?

- Pricing and elasticity
  - Missing analysis of the effects of rising costs for water and wastewater service on future demand;
  - Lack of consideration of pricing as a conservation strategy.
- 'Unaccounted for' water (e.g., leaks, unauthorized uses)
  - Crude projection of increased losses in lockstep with increased demand;
  - Lack of consideration of loss reduction as a conservation measure.

How sensitive is projected demand to new developments?

- New plumbing standards now on the Governor's desk (AB 2496)
  - Effective 2011, all new toilets must be 1.3 gpf, approx. 18 % more efficient
- New clothes washer standards pending before the Secretary of Energy
  - Effective 2010, all new washers in CA must have max WF of 6.0, approx. 30% more efficient
- 'Smart' Irrigation controllers -- weather based, moisture sensing
  - Performance still being verified, but 10% improvement should be obtainable

198 cont.

Are there gaps in the conservation practices of individual wholesale customers?

Considerations --

- Efficiency comes in small increments, no one 'silver bullet'
- Demand management is not static, but a continuous process of seeking out cost-effective opportunities to save water
- Areas of highest demand growth may present best opportunities for leadership and new savings

Where is the Growth in Demand?

6 Systems Comprise 70% of Demand Growth

Hayward	9.4 mgd	+49%
Alameda County	8.2 mgd	+16%
Santa Clara	8.1 mgd	+31%
Milpitas	5.7 mgd	+48%
Stanford	2.9 mgd	+76%
East Palo Alto	2.3 mgd	+92%
total	36.6 mgd	+32%

SI_TRT-CWA-SierraC

Weak Price Signals for Water

	rate type	relative to average of all BAWSCA agencies ($2.55/ccf)
Hayward	3-tier	below av
Alameda County	uniform	below av
Santa Clara	uniform	below av
Milpitas	2-tier*	above av
Stanford	NA	
East Palo Alto	uniform	below av

*second tier starts 50% above average use

No Price Signal for Wastewater

BMP 11 calls for all signatories that provide both water and sewer service to employ volumetric rates for both.

	rate type	type of service
Hayward	flat	collection & treatment
Alameda County	NA	
Santa Clara	flat	collection
Milpitas	flat	collection
Stanford	NA	
East Palo Alto	flat	collection

198 cont.

Are the demand increases contained in the forecast truly compelling?

Hayward	*existing* SFR outdoor use projected to nearly double; 'nicer' landscaping
Alameda Cty	residential growth is all outdoors
Santa Clara	2/3 of projected increase in SFPUC purchase is growth on UAF (leaks/unauthorized uses)
Milpitas	new SFR and commercial use is over 50% outdoor use
Stanford	lake system use is nearly doubled
East Palo Alto	60% of new demand is new commercial development

Not 'bad' uses, but all present opportunities for intervention

Are the demand increases contained in the forecast uncontrollable?

Overall wholesale demand growth in outdoor use (20 mgd) and leaks and unauthorized uses (3.5 mgd) is comparable to the inferred increase in the Assured Supply (24 mgd)

Targeted strategies will dampen these demands:

- Outdoor: A combination of pricing strategies, site plan review, and technology deployment (incentives, requirements)
- Water losses: reject basing 'sufficiency' on fixed percentages; water accounting as per new AWWA M-36 manual, component analysis to determine cost-effective interventions

SI_TRT-CWA-SierraC

Review of the Role of Price in SFPUC Water Demand Forecasts

Thomas W. Chesnutt, Ph.D.
tom@antechserv.com
A & N Technical Services, Inc.
http://www.antechserv.com
September 28, 2006

Outline

- Summary
- Construct Validity—Which Water Demand?
- Questions—How was Price Handled?
- Some Answers—what could water price be integrated into water demand?

199

Overall Assessment of Water Demand Forecasts

- A consistent application of a consistent model
- A transparent modeling effort
- A monumental amount of work
- A programmatic focus on conservation programs
- A great improvement over that which preceded

Opportunities for Improvement

- Determinants of Demand—
  - better explanation of demand drivers improve long run prediction: human choice is involved
- Seasonality—Not all gallons are created equal
- More measurement, fewer assumptions
- Focus on customer demand
  - willingness to pay for safe reliable water service
- Need for the Utility to use WUE to
  - Communicate the value of water service

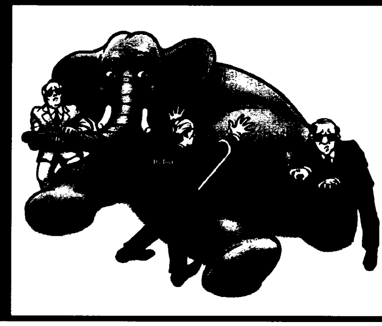
SI_TRT-CWA-SierraC

What is Water Demand?

If we are going to forecast it,
We should know what it is.

See Merritt, 2004,

Different notions of water demand



Different notions of water demand

Engineer – may view demand in terms of "demand load" – a production requirement, need

Water Planner – water demand as supply provided, use

Wastewater Planner – concerned with water use not consumed, but disposed

Financial Planner -- demand as revenue-producing consumption;

Economist – demand as a choice-based relationship between quantity and price, sometimes conditional on quality and reliability

Three Types of "Demand" Models

Water Requirements Model
Water Use Model
Water Demand Model

Flow of Water – Environmental View

Water Uses

Environmental
- forest/brush-land (ET)
- fishery flows
- stream morphology
- aquatic habitat (E&T)
- riparian habitat (ET)
- terrestrial habitat (ET)
- ecosystem restoration

Urban
- private sanitation
- public sanitation
- private landscape (ET)
- public landscape (ET)
- industrial cooling (E)
- industrial processing
- leakage and spillage

Agricultural
- range (ET)
- crop (ET)
- system (E&T)
- leaching
- seepage and spillage
- cultural

Recreational
- water sports
- game habitat (E&T)
- fishing habitat

Water Flowpaths

Sub-Basin Inflows
A. precipitation, all areas
B. surface inflows
C. subsurface inflows
D. imported water
E. desalinization

Sub-Basin Outflows
A. crop ET
B. landscape ET
C. natural vegetation ET
D. riparian habitat ET
E. aquatic habitat E&T
F. direct evaporation E
G. surface
H. subsurface

Internal Flows
A. reservoir releases
B. river & stream
C. river diversion
D. canal & pipeline
E. deliveries to users
F. seepage
G. deep percolation
H. GW extractions
I. surface runoff or spill
J. surface return
K. subsurface return
L. flows to salt sinks
M. recycling

Source Jack Keller

Questions Posed to Me

1. Was the future price of water appropriately considered when developing the 2030 water demand projections and conservation potential projections?
2. How could pricing issues have been more appropriately considered in these projections?
3. What are the risks of not appropriately considering the impact of water pricing?
4. What mechanisms (i.e. rate structures, stewardship fees) could the SFPUC and/or BAWSCA employ in order to finance regional conservation programs?
5. Given that the SFPUC and their wholesale customers will sign a new water sales agreement in 2009, are there any contractual elements you would recommend they consider that would enhance regional water conservation efforts?

199 cont.

Questions and Answers

Q1. Was the future price of water appropriately considered when developing the 2030 water demand projections and conservation potential projections?

A1. Price does not directly affect water demand forecasts. This is a shortcoming.

Why worry about Price?

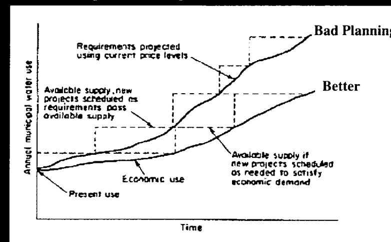

FIGURE 12-10 Projection of municipal water use.

SI_TRT-CWA-SierraC

Understanding Water Demand

Lesson 1: **Price influences demand.**

Lesson 2: **"Price elasticity" is the percentage change in demand induced by a one percent change in price, all other factors being constant.**

Lesson 3: **Demand can be thought of as the sum of demands for different end uses of water.**

Lesson 4: **Demand for outdoor uses are more price-elastic than demand for indoor uses.**

A summary from Phase I report of the CUWCC Urban Retail Water Rates Project:
October 1994.

Understanding Water Demand, cont.

Lesson 5: **Demand for water during peak (summer) periods is greater than demand during off-peak (winter) periods.**

Lesson 6: **Residential water demand is inelastic--The response of residential demand to rate changes, though not zero, is small.**

Lesson 7: **Demand is more elastic in the long run than in the short run.**

Lesson 8: **Demand is influenced by forces other than price—including population growth, the economic cycle, weather, and income growth.**

Lesson 9: **The response of demand is more difficult to predict for large changes in price.**

199 cont.

Demand Analysis

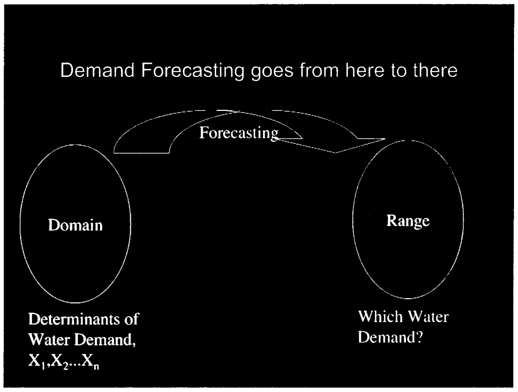
Ingredients needed for planning
- **a forecast of the** **of future water demand**
- **a forecast of the** **of future water demand**
- **quantification of the** **surrounding future water demand**
- **quantification of the** **of water demand to changes in rates**
- **an accounting of the** **achieved by demand-side management**
- **an estimate of the potential** **achievable through demand-side management**

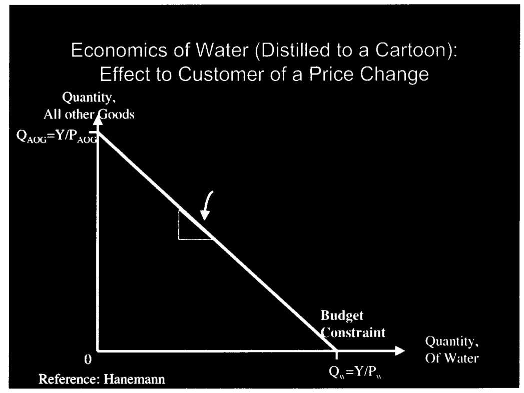
Questions and Answers

Q2. How could pricing issues have been more appropriately considered in these projections?

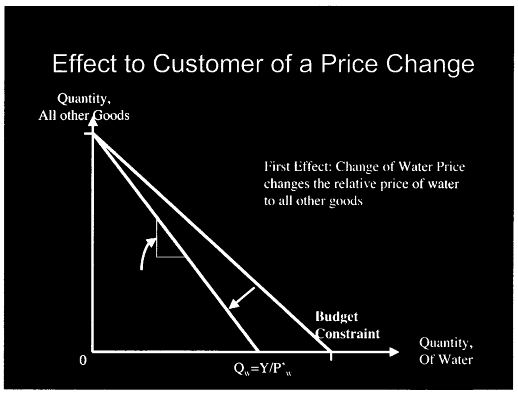
A2. The logical next steps for water demand forecasting include developing a better depiction of the long-run determinants of water demand.

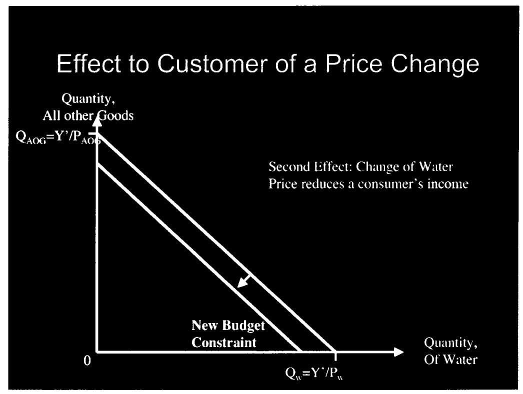
SI_TRT-CWA-SierraC





199 cont.





SI_TRT-CWA-SierraC

Questions and Answers

Q3. What are the risks of not appropriately considering the impact of water pricing?

A3. Short term sales forecasts will be off. Potential for revenue shortfalls.
Unexpected net revenue shortfall can affect other utility plans (recycled water, water use efficiency, etc.)

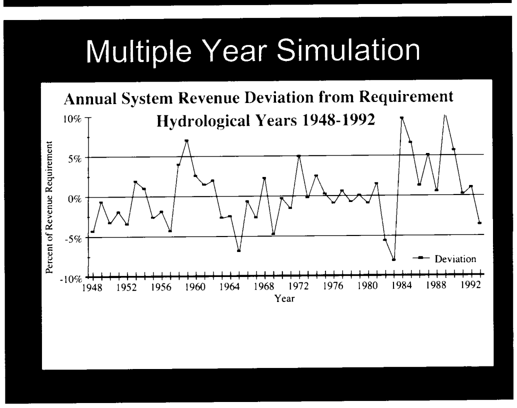
Why worry about Pricing and Planning?

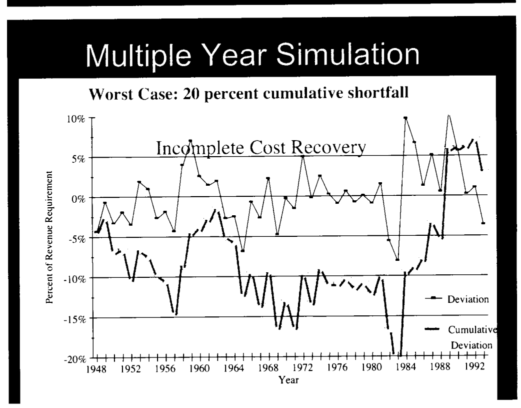
Besides Demand Response on long range planning

Short run financial effects—water utilities without sustainable financing cannot aggressively consider improvements in service provided

Sticky rate adjustments = chronic under recovery

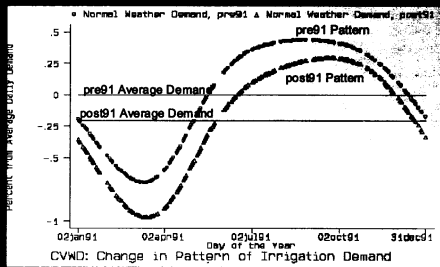
199 cont.





SI_TRT-CWA-SierraC

One response to price— 23 Percent Demand Reduction



Example of an aggressive tiered rate tied to account level water budget **with** customer outreach—Capistrano Valley WD.

Questions and Answers

Q4. What mechanisms could the SFPUC and/or BAWSCA employ in order to finance regional conservation programs?

A4. Alternatives include:

- Volumetric charge for regional conservation funding
- Regional WUE implementation (one stop shopping)
- Dedicated funding from tiered pricing

199 cont.

In a Situation of Resource Scarcity…

Water Use Efficiency (WUE) programs can provide customers with the information needed to balance new costs with their benefits.

There are economies of scale in the provision of information on WUE measures.

Questions and Answers

Q5. Given that the SFPUC and their wholesale customers will sign a new water sales agreement in 2009, are there any contractual elements you would recommend they consider that would enhance regional water conservation efforts?

A5. Regional Implementation of Conservation

- Sustainable Financing for Conservation
- Water Rate Reform—get your signals straight
- Research and Measurement of Demand

Dear Commissioners,

I am writing today because I am very concerned with the possibility of taking more water out of Tuolumne River. The environmental impacts that would occur as a result of the extra water being diverted, far out weigh the need for more lawns and suburban sprawl across East Bay, which is where 60% of water would be sent, as I understand. I think its a huge mistake, ~~and~~ you should focus your ~~efforts~~ on increasing water conservation and recycling programs. 01

I truly hope that you take these public comments into serious consideration before you make a horrible decision ~~that~~ that would affect all walks of life for generations to come.

Thank you.

[illegible]llo,

Thank you for your time. I am writing today to prevent more water from being taken out of the Tuolumne River. This Moter is before the Planning Commission today 9/20/07 Special Meeting item #21. I am unable to attend later today so here are my thoughts. 01

One of the many problems is the negative affects on wildlife. This will 02
cause Bio-diversity loss, and is bad for business in that area. 03

Please look at alternatives like other cities. We should be leaders in protecting the environment.

RE: Tuolumne River

Rita Allison <rallison48@sbcglobal.net> **Tue, Aug 28, 2007 at 11:28 AM**
To: wsip.peir.comments@gmail.com

I would urge you to reconsider diverting 25 million gallons from the Tuolumne. We need to protect the river and instead educate the public about native and drought-tolerant landscaping...homes can be attractively landscaped without acres of water-thirsty lawns. With conservation and sustainable landscaping we can protect the river. 01

More water should not be taken out of the Tuolumne River - I understand about 60% is taken out now — that's enough. Other options: recycling, more conservation & whatever "great" minds should be able to come up with 01

COMMENT CARD

San Francisco Planning Department
Draft Program Environmental Impact Report on the
SFPUC's Proposed Water System Improvement Program
Fremont, CA. September 18, 2007

Thank you for participating in tonight's public hearing on the Draft Program Environmental Impact Report (PEIR) for the San Francisco Public Utilities Commission's proposed Water System Improvement Program (WSIP). This is also an opportunity for you to submit written comments on the Draft PEIR for the proposed WSIP.

Written comments will be accepted through close of business on Monday, October 1, 2007. Written comments may be submitted in one of three ways:

1. Leave your written comments in the designated "Comment Box" tonight. These cards are provided for your convenience.

WRITTEN COMMENTS Write clearly and continue on back. Use multiple sheets if needed.

I urge you to cancel plans to divert any more water from the Tuolumne River.
If you consider the value of the river, it is easy to see the destructive effects that further diversion would have. The river is at the heart of a wonderfully diverse ecosystem that would be threatened by the loss of the water. The river also supports recreational activity. 01

12.5-4

C_Bail

WRITTEN COMMENTS (Continued)

The fact is that 60% of the river's water is already diverted for rural and urban uses. Also, the total volume of river water that the Tuolumne has is threatened by global warming. The SFPUC's growth only model predicts increased demand without considering the important steps that can be taken toward mitigating the increased demand. These are increased conservation efforts, improved efficiency in the uses of water, and recycling. If cities in Southern California are able to mitigate their demand for water significantly using these three factors, the SF Bay Area should, as an environmentally minded community, be able to champion similar effort. 02

Faced with the reduction in river volume due to global warming, the SFPUC should decide not to divert even more water than the 60% that is already diverted. As less destructive alternatives are available, one could even consider that it may be possible to lessen the diversion, not just blindly taking water from an already sensitive situation. 03

Thank you for your consideration.
Sincerely,
[signature]

Re: San Francisco Public Utilities Commission – Draft PEIR for SFPUC Water System Improvement Program

Honorable Commissioners :

Thanks to minimal notification to the public in San Francisco (ie Sept. 10th **print** ad in the S.F. Examiner), I had not even heard of this critical Draft PEIR for the SFPUC Water System Improvement Program until the evening of September 18th 2007 by word of mouth.

SFPUC was kind enough to give me a print copy of this immense 5 volume document late Tuesday afternoon, and I have been struggling through the 4000 + pages for much of the last 5 days between personal obligations on a very busy weekend.

As you have read and perused this vast report, I hope that you have borne solemnly in mind your primary responsibility to safeguard San Francisco's share of this water supply, and in fact to augment our city's share in light of the large upward boom in residential & commercial construction which I expect and hope may continue for some years. The burgeoning vertical expansions South of Market are actually a very sensible and well-construed way of expanding the residential and commercial capacity of San Francisco with as little impact to the rest of our built city as possible. The extra surge of prosperity that will ensue will allow this City to finance essential 21st Century improvements like high-speed "bullet train" interstate rail connections, and to upgrade our aging municipal infrastructure – one of the most basic elements of which is the water supply.

Hasn't the supply capacity of our huge Hetch Hetchy Water System for ourselves & our 27 large suburban customers in the Peninsula & 'Silicon Valley' almost been reached ? The April 2007 'Los Altos Hills General Plan' (one of our suburban customers) states frankly (on page 9., 01

subsection 321.) "Capacity limitations in the Hetch Hetchy system may be reached in 6 to 8 years, or sooner in times of drought." And in light of the constant escalation of urban development in our area, should we not be pursuing every means possible to **increase** our water supply capacity ?? The existing water system was not even intended to suffice **forever** !! 01 cont.

In light of the above, I was shocked to see that additional seismically-safe dams & water impoundments to augment this water storage for San Francisco to thus supply & promote additional population growth in this City, or provide alternate supply in the event of Climate (global warming) or Seismic Disaster, had long been rejected in this Water System Improvement Program (WSIP). There even seems to be some doubt about whether to design and construct a large Desalination Plant (Volume 5, page 186, Appendix H2-5). In San Francisco, we have been gambling for many decades that there may not be a repeat of the full seismic event that the City experienced in 1906, now added to this are the lively new concerns that there are in fact serious changes to Global Climate (re 'An Inconvenient Truth,' 'Not A Drop to Drink,' 'When the Rivers Run Dry,' etc.), which could result in serious drought years for Northern California and our San Francisco Bay Area in particular. Could SFPUC at least approve the Desalination Plant so that we have some minimal **drought-proof** water supply for San Francisco, so that we have a fighting chance to survive such disaster ? Remember that **alternative supply** could also be needed in the event of **terrorist** attack. Could 'Home Security' Funds not help with this last necessary precaution ? 02

As we are NOT one of the most impacted areas of the United States for water supplies (consider the foreboding plight of Las Vegas, San Diego, and the rest of the Southwest for example), and are also one of the most affluent areas of the United States, national sympathy for our water problems even if there **is** major political change soon, may be rather limited. So, we must be very wary of our geographic & demographic challenges in the near future, and take the first steps to avoid catastrophe as soon as possible.

I was also dismayed to see a rather cavalier assumption that San Francisco customers will continue to conserve water at the present extraordinary low rates of consumption, since we have human (huge population approaching 800,000, which may exceed this) and landscaping needs that will only INCREASE if there is serious drought, or fire disaster (our city is closely built, mainly with wood). I cannot imagine that all the water-saving diligence that my fellow citizens have undertaken here in San Francisco was done with the idea that our 03

C_Barbe1

suburban customers should then freely squander all that we have saved. Any favoritism exposes us to grave danger, and unfair suffering. 03 cont.

This Draft WSIP also makes rather confident predictions about exactly how much population growth, consumption, etc will occur in our area. How on earth do they arrive at these putative figures and how reliable are they ?! 04

Lastly, even though we are obligated to consider the rich natural environment that our Hetch Hetchy system has interfered with by the Raker Act, I certainly hope that the vast human populations of our region willing to live in some of the heaviest densities known in the United States are also considered an intrinsic part of this environment. The meticulous attention given to the problems of sport fishermen, and a not overly threatened species of trout, at the expense of the sole water supply of millions of people, seems excessive. Sorry if this sounds "anthropocentric," but Marine Biology is very advanced now in the 21st Century, and there are other methods of preserving this sturdy trout species while this vast water supply system is upgraded, retrofitted, and repaired.

Very Sincerely,

John Barbey

Because the Tuolumne River was designated a Wild and Scenic River in 1984, certain concessions allowing for recreational opportunities are mandated. It is currently difficult, in many years to get adequate flows for an adequate number of hours per day, for optimum white water boating on the Tuolumne River from Meral's Pool to Wards Ferry Bridge. It is anticipated that with increased water demand by SFPUC, the lack of adequate river flows for an adequate number of hours per day would become even more the norm rather than the exception. If this becomes the case, the tenets of the Wild and Scenic Rivers Act would be violated to a further extent than they are currently. SFPUC would be risking lawsuits on behalf of recreational users which might further delay any planned capital improvements. 01

Regarding water conservation and water recycling, the city and county of San Francisco is far below the standard for other large cities both in the state of California and throughout the west in general. How can San Francisco justify taking water from an out of county source, particularly from Tuolumne County which recycles a considerable amount of its water and which is currently on water rationing due to drought conditions. San Francisco should pursue a more aggressive water conservation and water recycling program before even considering taking more water from the Tuolumne River for water sales and power generation. 02

Dear Mr. Maltzer,

The Tuolumne River is in danger.

I am relying on you, Mr. Maltzer, to urge the city of San Francisco to reasses its water-demand projections and plans; to protect the Tuolumne River. Water conservation and recycling must be required rather than water diversion. 01

Thankyou!

Tuolumne diversion

Allan Berkowitz <ecorabbi@earthlink.net> **Fri, Sep 7, 2007 at 2:38 PM**
To: wsip.peir.comments@gmail.com

I strongly oppose the proposal to divert 25 million gallons/day of the Tuolumne River. It is simply unconscionable to place the river in jeopardy. 01

I register my opinion for the following steps to be taken at this time:

- The SFPUC should re-evaluate its projections for future water demand and conservation potential in light of flaws and inaccuracies in their studies. 02
- The SFPUC should conduct a study to determine the maximum technical potential for conservation and efficiency savings within the SFPUC service territory.
- Any additional demand should be met through increased investment in conservation, efficiency, and recycling.
- The SFPUC should adopt a policy of reducing diversions from the Tuolumne River over time. 03
- A comprehensive watershed study should be completed to adequately assess the environmental impacts of the WSIP. 04

Thank you

Members of the PUC

I am writing to urge you not to approve taking more water from the Tuolumne River. To do so would be an irreversable tragedy. We are in a time when it is urgent to protect our environment, not strip our natural resources from the face of the earth. To reduce the flow of the Tuolumne would end its wild + scenic status + undoubtedly effect much of our wildlife that depends on it. I rafted that river + hate to think future generations of nature-loving folks would be deprived of that experience 01

Thank you.

C_Bevia

Dear Mr. Maltzer:

We cannot and should not divert another 25 million gallons of water daily from the Tuolumne river, especially now that the fall Chinook salmon runs are in extreme jeopardy and that the the Tuolumne is an important spawning river. We must begin to look elsewhere for our water needs, principely towards conseravation and recycling of existing water supplies, rather than further depleting a healthy river system. Thank you. 01

Dear Mr. Maltzer:

As a resident of San Francisco and an avid hiker in the Sierras I am opposed to withdrawing any more water to support sprawl development in the Bay Area. 01

I support the alternatives to diversion that protect the Tuolumne. More water conservation, efficiency, and recycling are the best ways to both protect the River, and provide permanently sustainable water for the San Francisco Bay Area. 02

I was in attendance at the “Public Hearing on the San Francisco Public Utilities Commission proposed Water System Improvement Program (WSIP)” on September 05, 2007 in Sonora California. I understand that this was an “Environmental Impact Meeting”. I agree with most of the environmental concerns that was presented at that meeting.

What I have failed to understand is the logic that the San Francisco Public Utilities Commission is using to support this proposed Water System Improvement Program. I do not understand how the key elements of this program can be achieved with out additional major environmental impacts on the Tuolumne River area. 01

I have also failed to understand why the San Francisco Public Utilities Commission has not considered using new technology to achieve all of the key elements.

Please see attached file.

Subject: **San Francisco Public Utilities Commission's (SFPUC) Water System Improvement Program**

What I have failed to understand is the logic that the San Francisco Public Utilities Commission is using to support this proposed Water System Improvement Program. I do not understand how the key elements of this program can be achieved with out additional major environmental impacts on the Tuolumne River area.

I have also failed to understand why the San Francisco Public Utilities Commission has not considered using new technology to achieve all of the key elements.

One said technology would be desalinization. Desalination is being used more and more around the world to provide people with needed freshwater. Most of the United States has, or can gain access to, ample supplies of fresh water for drinking purposes. But, fresh water can be in short supply in some parts of the country (and world). And, as the population continues to grow, shortages of fresh water will occur more often, if only in certain locations. In some areas, salt water (from the ocean, for instance) is being turned into freshwater for drinking.

A promising method to desalinate seawater is the "reverse osmosis" method. Right now, the high cost of desalinization has kept it from being used more often, as it can cost over $1,000 per acre-foot to desalinate seawater as compared to about $200 per acre-foot for water from normal supply sources. Desalinization technology is improving and costs are falling, though, and Tampa Bay, FL is currently desalinizing water at a cost of only $650 per acre foot. As both the demand for fresh water and technology increase, you can expect to see more desalinization occurring, especially in areas, such as California and the Middle East.

12.5-11

Another method is The Modular High-Temperature Gas-Cooled Reactor (MHTGR) this system can supply an adequate supply of fresh water and electric power which are the essential requirements for a high quality of life. In many regions of the U.S., an acute need for new sources of fresh water is emerging as a consequence of sustained drought conditions, high local population growth and deterioration of existing water supplies from contamination and overuse. Although desalinization has been a major water source for Middle East countries and island nations, it has not been a significant source of water in the U.S. However the need for both water and electric power is a significant problem in populous regions with high growth projections. The MHTGR is an energy source for both water and power production which has the potential to overcome barriers to using nuclear power as a prime energy source for producing fresh water. The plant is divided into three process areas: the Nuclear Island (NI), the energy conversion area (ECA), and the water production plant (WPP). High- pressure superheated steam from the NI is converted to electric power in the ECA. Reject heat from the ECA in the form of hot circulating water is supplied to the WPP as the energy source for desalinating seawater. About 20% of the seawater supplied to the WPP is converted to fresh water and the remainder is returned to the ocean as slightly concentrated brine. 02

Of the more than 7,500 desalination plants in operation worldwide, 60% are located in the Middle East. The world's largest plant in Saudi Arabia produces 128 MGD of desalted water. In contrast, 12% of the world's capacity is produced in the Americas, with most of the plants located in the Caribbean and Florida. To date, only a limited number of desalination plants have been built along the California coast, primarily because the cost of desalination is generally higher than the costs of other water supply alternatives available in California (e.g., water transfers and groundwater pumping). However, as drought conditions occur and concern over water availability increases, desalination projects are being proposed at numerous locations in the state Why not in San Francisco?

Environmental impacts not addressed in the Scoping Meeting on the San Francisco Public Utilities Commission proposed Water System Improvement Program:

1) The increased delivery demands on the **salt water encroachment**. (Several methods have been examined for the control of saltwater encroachment. These techniques have included reduction of groundwater withdrawals, repositioning of withdrawal locations, utilization of recharge basins or injection wells to artificially maintain freshwater pressure, interception of intruding saltwater through a line of pumping wells parallel to the coastline, and emplacement of a subsurface groundwater barrier between the coastline and pumping wells. Reduction of groundwater withdrawals and relocation of pumping wells are the techniques found to be most effective and economically feasible in the control of saltwater encroachment. Run-off water, river flow, to offset encroachment.) 03

2) The increased delivery demands on the Tuolumne River watershed. (With the majority of the San Francisco's Water System Improvement Program based on a Hydrologic Cycle the demands will never meet the supply.) 04

Diana Sokolove <wsip.peir.comments@gmail.com>

SFPUC hearings on the draft Program Environmental Impact Report

Bramlette@aol.com <Bramlette@aol.com> **Thu, Sep 27, 2007 at 5:02 PM**
To: peter@tuolumne.org
Cc: wsip.peir.comments@gmail.com, ron@hetchhetchy.org, cameronconsults@comcast.net

To: Peter Drekmeier
Bay Area Program Director
Tuolumne River Trust
Subject: : San Francisco Public Utilities Commission's (SFPUC) Water System Improvement Program (WSIP)

I am sadden that with all the efforts of those who spoke, only a small number addressed the problems. *"The vast majority of those who spoke – more than 90% – favored the $4.3 billion seismic upgrades to the Hetch Hetchy water system, but expressed serious concerns about the proposal to divert an additional 25 million gallons of water per day from the Tuolumne River."*

The number one problem: San Francisco needs more water!
The number two problem: the increasing diversion will do further harm to the Tuolumne River. 01

We all know that San Francisco will need more water in the future, we also know that we do not have any more water to "give" San Francisco from the Tuolumne River. So why did the vast majority favor "*the $4.3 billion seismic upgrades to the Hetch Hetchy water system, but expressed serious concerns about the proposal to divert an additional 25 million gallons of water per day from the Tuolumne River."* This does not solve any problems. Also this vast majority has not provided a plan to meet the future demands for water for San Francisco. Therefore: no solution for problem number one or two!

Now lets talk about requiring more water conservation, efficiency, and recycling. This is also not an answer to lessening impacts on the Tuolumne River while promoting a sustainable water plan for the Bay Area. The projected need for water in San Francisco bay area will be far more than they can get from Tuolumne River even with more water conservation, efficiency, and recycling. 02

If this goes the way San Francisco Public Utilities Commission wants it to go, they also will not have a solution for either problem. The Tuolumne River and it's environment can not give up more water.

In summery, the San Francisco Public Utilities Commission should start an environmental impact report on the development of alternative sources of Water. San Francisco could be a leader in the development of desalination for California and the rest of the nation. Also by introducing reduction of groundwater withdrawals, repositioning of withdrawal locations, utilization of recharge basins or injection wells to artificially maintain freshwater pressure San Francisco could set a standard for the rest of California and the nation. By doing the above, San Francisco and California could return to our children, grandchildren and all future generations "The Grand Canyon of the Tuolumne River". 03

This is a solution to both problems!

A win-win for all!

If this response has not been directed to the correct department, please forward it. If anyone has any questions or if I can be of any assistance please feel free to contact me.

Paul Maltzer, Environmental Review Officer
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Dear Mr. Maltzer:

I am displeased by the packaging of improvements to San Francisco Water Department aqueducts and the diversion of water from Sierra rivers.

Put on separate ballots, I think you'll find broad support for improving the system and hardly any for taking more water from already depleted rivers. The issues are not related in kind, one being a maintenance issue, the other, water policy. Historically water policy has been made to serve real estate interests that invite growth at the expense of current residents. 01

Please separate these issues lest it be seen as a deception.

Sincerely,

Jobst Brandt

October 11, 2007

Paul Maltzer, Environmental Review Officer
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Dear Mr. Maltzer:

As a kayaker of the Tuolumne River I am concerned about your environmental review of the San Francisco Public Utilities Commission's plan to take more water from the Tuolumne River as it fails to adequately identify and address all of the environmental impacts to the River. Only by ensuring that healthy amounts of water continue to flow into the Tuolumne River can we protect this irreplaceable natural treasure and ensure that future generations will be able to enjoy this amazing river canyon. I urge you to undertake additional studies before finalizing this document. 01

As other communities in California are pursuing conservation of water resources, the SFPUC's "preferred alternative" ignores conservation, efficiency, and recycling measures that their own studies found could eliminate the need to divert more water from the Tuolumne by at least 74%. When it comes to water conservation, the Bay Area lags far behind other metropolitan areas such as Seattle and Los Angeles that are reducing water consumption even in the face of growth. As a region known for a strong environmental ethic, the Bay Area should be a leader in water efficiency and conservation. 02

I support the alternatives identified in your draft document that protect the Tuolumne River from new diversions. Requiring more water conservation, efficiency, and recycling is the best way to lessen impacts on the Tuolumne River while promoting a sustainable water plan for the Bay Area.

Sincerely,

Mark W. Bresolin
8049 Tetotom Park Way
Antelope, CA 95843

Subject: Please Protect the Tuolumne River

Dear Mayor Newsom, Mr. Paul Maltzer and Commissioner Ryan L Brooks

We should employ a more conservative approach to our use of natural resources - and, it should be a priority to educate the public as to the value of conservation.

We continue to consume water and other resources beyond what is really needed and reasonable to coexist with nature.

-Why can't we pass laws to stop individuals and businesses from hosing down the sidewalks when a broom is usually sufficient. 01
-Let's recycle and reclaim more water.
-Shouldn't we be rationing water as a matter of course?

The Tuolumne is a beautiful place and home to many species. I urge you to meet our water needs and protect the Tuolumne River for future generations through conservation and recycling, rather than by withdrawing more water and depleting the river.

Thank you,

Liz Brooking

Paul Maltzer, Environmental Review Officer
Water System Improvement Program PEIR
San Francisco Planning Department

Dear Mr. Maltzer:

I urge you to do additional studies of the Tuolumne River before finishing your environmental review of the SFPUC's plan to take more water from it. 01

I believe that the Tuolumne should be protected from any new diversions.

Sincerely,

Louis Bryan

PLANNING DEPARTMENT
MEA

Dear Commissioners;

I am writing because of my concern for the SF Public Utilities Commission plan to withdraw more water from the Tuolumne River. It is my understanding that, while the PUC is trying to plan for growth and provide resources, the growth projections seem to be excessive. 01

Instead, it is my strong feeling that water conservation should be pursued more aggressively in the plan, with increasing pricing if necessary to reflect the true cost of providing water. It is my understanding that other large metropolitan areas, such as Seattle and Los Angeles, have succeeded in providing for growth while limiting water usage. In the Bay Area, with our history of innovation and environmentally sensitive population I hope that we may also be able to limit our water usage. 02

Yours sincerely
Keith Buckingham

Re: Please implement conservation, not Water System Improvement Program
September 19, 2007

Thank you for the opportunity to review the 5 volume proposed Water System Improvement Program. I appreciate your consideration of the following constructive criticisms:

1) The proposal documents a trend (from 1965 to now) of decreased water use per customer, yet your water demand projections conflict with historical data. My experience as a homeowner and water customer over more than 20 years is that residential and commercial customers are conserving water and can easily use 10% less water if "incentivized" to do so by increasingly tiered water rates. 01

2) The 82 year hydrologic record upon which the proposal is based tends to ignore earlier historical, geological and anthropologic evidence that pre-modern and modern societies thrived in your service area for hundreds of years with almost no water storage or distribution. 02

3) The "significant impacts" and "lesser impacts" identified for the Tuolumne, Alameda and Peninsula watersheds are all unacceptable since voluntary conservation of water is more economical and effective for both the consumer and the utility. I believe engineering best practices will allow seismic upgrade of the water distribution system without the above impacts because of the vastly redundant nature of the nine major reservoirs and multiple parallel pipelines that characterize this system. 03

4) Continuing overdraft of the Westside Groundwater Basin, lowering of Lake Merced's water level, and likely contamination of drinking water due to groundwater pumping are all unacceptable impacts given that voluntary conservation of water in SFPUC's service region would meet realistic water supply objectives. Depleting our local groundwater truly leaves us exposed to catastrophic risks, since this groundwater ought to be able to sustain life and important commerce regardless of deliveries from the Sierras. Why use up local groundwater now, when it should be a reserve? If SFPUC is truly concerned about providing adequate water quantity and quality, it would negotiate, legislate and litigate an end to salinization and selenium poisoning of nearby water sources by our "uphill" neighbors like customers in the Westlands Water District. 04

5) The WSIP proposal seems to be inappropriately aimed inflated growth inducement by stream diversion and groundwater overdraft. Rather than just acknowledging the substantial impacts (increased traffic, air pollution, water pollution, global warming and decreased quality of life) caused by WSIP, please implement a version of the modified WSIP with the least diversion from the Tuolumne River and the least environmental impact. The "no purchase request increase" alternative should be combined with the least environmentally impacting modified WSIP alternative. It is not right for SFPUC to encourage "Los Angeles-like" traffic jams and pollution by making more water available than the service area needs. 05

6) Several of your "least environmentally impacting" alternatives are seriously flawed by continuing groundwater overdraft. Please re-frame as many alternatives as possible to include aggressive conservation but exclude using groundwater at a level which draws it below maximum storage capacity. 06

7) The "year round desalinization" alternative should be recognized as a bad idea due to direct costs and indirect costs such as from the air pollution (global warming) and water pollution (salt concentrate pumping) which will result. 07

8) The "regional desalinization for drought" alternative deserves further study, but should be implemented cautiously so as not to harm users by global warming and increased growth. I envision plants which run as little as possible until mandatory conservation (rationing) has been tried for a year. 08

9) Please raise the rates for all water users in a tiered manner which is explicitly directed at getting everyone to conserve water. 09

10) Please continue to study the "remove O'Shaughnessy Dam" alternative, since you should be offsetting any loss of income (from hydropower sales) with increased water fees. O'Shaughnessy Dam impounds only a small part of the system's water. Hetch Hetchy Valley could be restored as a national treasure within a generation. A modern Congress could be convinced to reverse the process which allowed SF to flood Yosemite National Park, especially since SF does not have the influence that it had 100 years ago. 10

In closing, I respectfully remind SFPUC that more than a generation of Americans have been exposed to the exploitative history of bay area water development through authors including David Brower, Marc Reisner, Wallace Stegner, Donald Worster, William Kahrl, Robert Righter and Kevin Starr. Many of us now agree with the assessment of John Wesley Powell, a trained engineer and hydrologist, that we must live within the resources of our small regional watersheds. "Meeting water supply objectives" does not impress us, when the objectives are to increase water supply beyond sustainable levels at a cost that includes destroying the fishery industry, fouling our already marginal air quality, crowding our already over-crowded roadways and increasing global warming. Many now recognize that the natural environment SFPUC is responsible for stewarding has both a economic value and the (increasingly rare) aesthetic values described by John Muir. 11

Sincerely, Juan Byron

COMMENT CARD

San Francisco Planning Department
Draft Program Environmental Impact Report on the
SFPUC's Proposed Water System Improvement Program
Palo Alto, CA. September 19, 2007

Thank you for participating in tonight's public hearing on the Draft Program Environmental Impact Report (PEIR) for the San Francisco Public Utilities Commission's proposed Water System Improvement Program (WSIP). This is also an opportunity for you to submit written comments on the Draft PEIR for the proposed WSIP.

Written comments will be accepted through close of business on Monday, October 1, 2007. Written comments may be submitted in one of three ways:

1. Leave your written comments in the designated "Comment Box" tonight. These cards are provided for your convenience.
2. Mail your comments by October 1, 2007 to the San Francisco Planning Department, Attention: Paul Maltzer, Environmental Review Officer, WSIP PEIR, 1650 Mission Street, Suite 400, San Francisco, CA 94103
3. E-mail written comments to wsip.peir.comments@gmail.com

I am writing today to prevent more water ~~to~~ being taken from the Toulumne River. The watershed for the Toulumne River is a delicate landscape and it would be devastating to the environment to remove more water for the Toulumne River. We have all the water we need and water conservation should be encouraged instead of destroying one of the most beautiful area in the US. 01

Thank you

To Whom It May Concern:

I urge the SFPUC to support the NO SUPPLEMENTAL TUOLUMNE RIVER SUPPLY.

SFPUC already takes as much as 265 mgd or 60% of Tuolumne River supply. I could not find SFPUC's total water right, but I suspect in a severe drought situation it could be all of the flow.

SFPUC is in a position to create a "dry" river bed because of it's extreme water right and it's profit motive to sell the excess at very high rates to its users south of San Francisco. There appears to be limited conservation efforts since the average usage of users in some communities has increased over the last decade. 01

Water pricing encourages excessive usage and little conservation. San Francisco has established an excessively large amount of water for it's first tier or "lifeline" residential usage. Some Southern California water districts establish "lifeline" residential usage at 3 units per month, not 7 units as is common here in Northern California.

Furthermore the price for water units above 7 units does not increase no matter how many units a residence uses. No attempt has been made to price water in a way that encourages conservation, as was done during the severe drought years when 4-7 rate tiers were in effect in Palo Alto. Residential usage fell dramatically. 02

SFPUC is guilty of encouraging more water usage by it's pricing methodology. Palo Alto and other Hetch Hetchy users followed suit.

According to a recent water audit from Santa Clara County, water loving landscapes account for at least 60% of water usage in residential and many commercial campuses. Almost all of this water is of drinking water quality, rather than recycled treated water.

Conspicuous consumption is everywhere. Water runs down the gutters nightly because of poor irrigation systems. Grass and lush tropical gardens abound in this semi-arid Mediterranean climate. 03

I intend to contribute as much as I can to the inevitable law suit that will accompany any SFPUC recommendation to take another 25 mgd from the Tuolumne. Conservation, recycling, and reusing is the answer.

Sincerely,

Lynn Chiapella

Subject: Review and Comments on the Draft Program Environmental Impact Report (PEIR)
San Francisco Public Utilities Commission Water System Improvement Program (WSIP)

RECEIVED
SEP 20 2007
CITY & COUNTY OF S.F.
PLANNING DEPARTMENT
M E A

This review looks at possible impacts and significant environmental issues in four areas: (1) the Hetch Hetchy Water Delivery Infrastructure Costs and Finances, (2) Drought, Climate Change, and Global Warming, (3) Water Use and Demand for More Tuolumne River Water, and (4) Mitigation Alternatives. 01

We support the retrofitting and renovation of the Hetch Hetchy infrastructure and the water delivery system. We trust that the final PEIR includes recommendations that avoid or will mitigate significant negative environmental effects for Hetch Hetchy, the Tuolumne River and connected eco-systems and water ways.

(1) <u>Hetch Hetchy Water Delivery Infrastructure Costs and Finances</u>

The PEIR's $4.3 billion estimated Water System Improvement Program (WSIP) includes the Hetch Hetchy infrastructure and water delivery system to SFPUC's 28 wholesale customers (primarily Peninsula, East/South Bay municipal and private organizations) and San Francisco City and County retail customers.

According to the draft PEIR, SFPUC wholesale customers' water demand is approximately 67% of the system's water. San Francisco retail customers' water demand is 33%.

a) Significant Environmental Effect Issues

The $4.3 billion bond indebtedness—which can be reasonably expected to increase over the course of the project—is a major concern. 02

One of the major overall WSIP goals and objectives is to "ensure cost-effective use of funds." [1] The environmental mitigations are an integral legal part of the complete WSIP program and its funding. If mitigations

1. City and County of San Francisco Planning Department, 2007. *Draft Program Environmental Impact Report for the San Francisco Public Utilities Commission's Water System Improvement Program,* Vol. 4: Chapter 9, CEQA Alternatives, Table 9-1.

required as a part of the cumulative environmental impact of the entire program are not funded, legal problems may result.[2]

The draft PEIR appears to indicate that San Francisco retail customers will be largely responsible for bond costs, water conservation requirements, and high water rate increases. San Francisco voters have agreed already to carry the burden of a $1.6 billion bond. 02 cont.

Who will pay for the remaining $2.7 + billion? Unfortunately, information in the draft PEIR is insufficient to determine if there will be adequate resources for the completion of the mitigations required for the over-all system improvement program.

b) Specific Requests for Final PEIR Report Analysis and Data

To ensure adequate and sufficient financial resources to complete legally required program environmental impact mitigations, both a detailed program costs analysis and documentation of how an equitable, proportional distribution of program costs will be achieved must be included in the final PEIR. Costs for each of the wholesale and retail customers should be based on water use and mandated conservation goals.

Because the SFPUC 2009 contract will have a collective environmental impact on the water system improvement program, a detailed environmental analysis of the 2009 contract needs to be included in the final PEIR. Separating the environmental review of the program from that of the contract is an illegal partition that prevents adequate review. 03

Because the wholesalers are required by AB 1823 to reimburse SFPUC for the wholesalers' share of costs, the final PEIR needs to include specific 2009 contract conditions for equitable, proportionate rates and charges for water use, including wholesale and retail incentives for water conservation requirements.

(2) <u>Drought, Climate Change, and Global Warming</u>

Although the draft PEIR addresses drought cycles, climate change, and global warming, the draft PEIR does not sufficiently analyze the potentially disastrous, exponential harm to the Tuolumne River brought about by the coalescing of the cumulative effects of drought cycles, climate change, and global warming. 04

a) Significant Environmental Effect Issues

The draft PEIR is limited and narrow in its review of climate change and global warming. The lack of adequate, up-to-date research and analysis is highly environmentally significant for the WSIP and the draft PEIR.

2. September 11, 2007: San Francisco Public Utilities Commission Regular Meeting: Commissioners discussed a possible cost increase from $4.3 to $4.6/ $5 billion as well as possible cost-driven reductions. No decisions were reached.

12.5-19

i) A Drought-Cycle State and Water Resources

Despite pictures of sun bathers on beaches and postcards of surfers on ocean waves, California is a drought-cycle state.

The PEIR design draft model is in 8.5 year intervals. Although there are variances in this model, 6 years are drought, dry, below normal or restoring years. In restoring years, additional river water is needed to refill the depleted Hetch Hetchy reservoir and other resources. 04 cont.

Because of the rate of current water diversions (60%), the Tuolumne River is immediately affected by drought, dry, below normal and normal restoring years. Continually, the river is at risk.

To augment water from the Tuolumne during difficult dry periods, the draft PEIR recommends diverting an additional 23 mgd of Tuolumne water from yet-to-be negotiated agreements with Modesto and Turlock Irrigation Districts. But the Modesto and Turlock Districts are also caught in California's drought cycle. The additional 23 mgd of water would be an additional draw down of water from the Tuolumne. 05

Without considering changes due to climate change and global warming, the Tuolumne remains a river constantly at risk.

The draft PEIR concludes that climate change and global warming are insignificant and have minimal, if any, effect on the river. Moreover, the PEIR concludes that the effects of climate change and global warming will not be significantly understood until near mid-century, at which time adjustments can be made. 06

The draft PEIR endorses a "use now and worry later" policy. A no-action response policy is insufficient and inadequate. Such a policy places the Tuolumne and all its connected eco-systems and water ways at great risk.

b) Effective Environmental Practices

Instead of a "use now and worry later" policy, the East Bay Municipal Utilities District (East Bay MUD) examined possible climate change and global warming impacts. Planning and operation models were developed. As a result, East Bay MUD took pro-active steps to protect its water system. The plan includes water efficiencies, conservation, and flexible 07 management strategies. East Bay MUD is cited as the first water district to join the California Climate Action Registry.

Leadership and action plans have developed across the western states in California, Arizona, Oregon, and Montana. Conservation, flexible management strategies, and coordinated regional plans have been identified as best practices. There is no excuse for the SFPUC not to develop and carry out these best management practices. 07 cont.

We all understand the critical importance of emergency and earthquake plans and preparedness. In the 21st century, the same is true for climate change, global warming, and drought cycles. The final PEIR must include a pro-action plan, and not a "use now and worry later" policy.

c) Specific Requests for Final PEIR Report Analysis and Data

Additional PEIR research and analysis is needed to address the exponential effects of climate change, global warming, and drought cycles as well as to protect the Tuolumne and all its eco-systems from potentially serious, significant environmental impacts. Conservation requirements, water efficiencies, and mitigations must be developed and implemented.

San Francisco's proposed no-action policy is a red flag for environmental challenges and criticisms. No-action ignores the importance of on-going conservation activities and effective management plans to protect the river; guard the safety and reliability of the water delivery system; ensure economic growth and meet customer needs. 08

The final PEIR should focus on conservation, recycling, re-use, and delivery management efficiencies as water first priorities. These are proven, cost-effective strategies that protect the environment and support growth and development. There is no excuse for the SFPUC not to take action. Volume 3, Chapter 5, 5.7.6 needs to be revised with adequate mitigations developed and implemented.[3]

(3) <u>Water Use and Demand for More Tuolumne Water</u>

At this time, 60% of the Tuolumne River is diverted for water consumption. The draft PEIR recommends that additional water be diverted from the river in order to meet the needs of wholesaler customers. 09

a) Significant Environmental Effect Issues

In the draft PEIR, there are major discrepancies in the assumptions, research models, and recommendations applied to the wholesalers and

[3] City and County of San Francisco Planning Department, 2007. *Draft Program Environmental Impact Report for the San Francisco Public Utilities Commission's Water System Improvement Program,* Vol. 3: Chapter 5, 5.7.6.

12.5-20

retail customer. The discrepancies and assumptions result in diametrically opposed policies for water use and active conservation.

A double standard is established. For example, additional mandatory conservation will not be required for wholesalers, but will be required for retail customers.

i) Double Standard: Discrepancies and Assumptions

<u>Wholesale customers</u>. Based on the assumption of "more growth, more water", the draft PEIR recommends an <u>increase</u> in water diverted from the Tuolumne to meet the growth needs of wholesalers. Wholesale conservation goals are left to suggested methods and parameters in "respective urban water management plans".[4]

As a result, the wholesale model not only offers limited incentives for water conservation, but also does not penalize additional water usage. The wholesale model produces a significant negative environmental effect—extra demand on water and less demand for conservation. 09 cont.

<u>San Francisco retail customers</u>. The assumption is "more growth, less water" for San Francisco retail customers. This model predicts a <u>decrease</u> in San Francisco water and an increase in growth and development. The model follows the lead of proven conservation and growth policies.

Various PEIR estimates predict San Francisco's water will decline between 4% and 11%. The decline will occur at the same time San Francisco's population is expected to increase by 12% and San Francisco employment by 25%.

San Francisco's water use decline is factored on a PEIR required 10 mgd conservation goal which includes groundwater supplies, recycling, and reuse. The San Francisco model produces a water first conservation priority—a positive environmental effect.

b) A Water First Conservation Priority: Effective Environmental Practice

A major over-all goal and objective of WSIP is to "improve use of new water sources and drought management including use of groundwater, recycled water, conservation, and transfers". [5] 10

4. . City and County of San Francisco Planning Department, 2007. *Draft Program Environmental Impact Report for the San Francisco Public Utilities Commission's Water System Improvement Program,* Vol. 4: Chapter 9, pg.62
5. Ibid: Chapter 9, CEQA Alternatives: Table 9-1.

In the Metropolitan Water District of Southern California, water use decreased 16% in a thirteen year period (1990-2003). Population increased by 14%. The MWD includes Los Angeles. During a thirty-five year period, retrospective, longitudinal data indicate 2005 Los Angeles water use is close to the 1970 water use with increases in population during the thirty-five year growth period.

Other cities and water districts have reduced water use during times of growth and development. Denver, Boston, and Seattle combine conservation, recycling, reuse, and efficient water management as a means to support growth and development. These water methods are cost-effective and reliable. Moreover, they construct a systemic, long-term approach to sustainable water management and use. 10 cont.

There is no excuse for SFPUC not to adopt water conservation measures without delay.

c) Specific Requests for Final PEIR Report Analysis and Data

Additional research is needed for an in-depth analysis of districts and cities in California and the United States which have decreased water use and met growth needs. The analysis should look at how these areas (now and in the future) differ from the SFPUC area and how they are the same. The analysis should address how San Francisco can specifically use methods and procedures from these models to facilitate the development and implementation of water first conservation policies to meet current and anticipated growth. The analysis should also address methods and procedures that would not be effective for SFPUC, and why the methods would not be effective. 11

Based on CEQA requirements, additional research is needed to provide expanded regional analysis of specific wholesale project growth needs that have an impact on the San Francisco Bay Area region. Significant impacts include major residential developments, large businesses, shopping centers, commercial, hotel and motel expansions, government and educational growth, and industrial, manufacturing, and processing plants. Based on this research and analysis, the final PEIR needs to develop an environmental plan to incorporate program-based and project-specific wholesale plans and conservation methods into an integrated system of local and regional planning and environmental protection.

Expanded research is needed to analyze fully the twenty-one year plan to divert additional water from the Tuolumne. Year by year, the research must evaluate the aggregate and collateral effects of less and less river water each year on (1) the health and welfare of the river, (2) potentially endangered species and habitats, and (3) all the eco-systems, including the 12

delta, that receive water from the Tuolumne. Based on the expanded research, the analysis needs to determine which sustainable environmental alternatives and superior mitigation methods are required in WSIP and the 2009 contract to address long-term environmental protection for the Tuolumne and all its interconnected environments. Although research is presented in the draft PEIR, this research does not address fully the over-all effects of long-term river water diversions and the necessary 2009 contract requirements to ensure the future, on-going health and welfare of the river. 12 cont.

The mitigations in Volume 2, Chapter 4, Attachment 4-A: Mitigation Measures to Minimize Facilities Impacts; Volume 3, Chapter 5, Attachment 5-A: Mitigation Measures to Minimize Water Supply and System Operations Impacts,: Volume 4, Chapter 6, Summary of all Impacts and Mitigation Measures, Tables: 6.3 through 6.15, and Chapter 9, CEQA Alternatives will need to be revised when the additional research and analysis recommended in sections 2-c and 3-c of this response are completed.[6] 13

d) Equitable Conservation: Specific Request for PEIR Alternative Mitigations

To avoid the complications and challenges of disproportionate standards, inequitable costs, and questionable assumptions, the final PEIR must analyze and recommend standards in which equitable and proportionate conservation requirements are mandatory for all wholesale and retail customers.

An Example of Equitable Conservation

The draft PEIR states that SFPUC wholesale customers use approximately 67% of SFPUC water while San Francisco retail customers use 33%.

Although estimates may vary, by 2030 the wholesale customer use increases to 77%. San Francisco use declines to 23%, with 10 mgd required conservation. Equitable conservation can be factored by correlating water demand with conservation requirements (million gallons per day, mgd). 14

Example of Equitable Conservation Requirements to 2030

SFPUC	Water Demand	Conservation Requirement
San Francisco Retail	23%	10 mgd
Wholesale Providers	77%	34 mgd
Total	100%	44 mgd

[6] City and County of San Francisco Planning Department, 2007. *Draft Program Environmental Impact Report for the San Francisco Public Utilities Commission's Water System Improvement Program,* Volumes 2,3,4: Chapters 4,5,6, 9: Attachment 4-A, pp 4-10, Attachment 5-A: Tables 6.3-6.15, Table 9-3.

An extensive list of possible water conservation measures for SFPUC wholesalers is available from the SFPUC. [7]

Equitable and proportionate conservation and efficiencies are in line with SFPUC's current tiered water rates, charges, policies, and practices. 14 cont.

Using draft PEIR data, the present level of Tuolumne water use combined with equitable and proportionate efficiency requirements and conservation are sufficient to meet growth and development needs in 2030. We can conclude that wholesale growth and development are feasible, without diverting additional water from the Tuolumne.

(4) Mitigation Alternatives

The Aggressive Conservation/Water Recycling and Local Ground Water, No Supplemental Tuolumne River Supply alternative is the environmentally superior mitigation. The draft PEIR/WSIP preferred alternative is inadequate. [8] 15

The 21st Century and Water Challenges
San Francisco's Sustainable Environmental Responsibility

San Francisco is known for its leading edge in green projects, sustainable design, environmental protection, and global warming and climate change awareness. The final PEIR/WSIP has the responsibility to reflect San Francisco's environmental leadership, 16

It is important that the San Francisco PUC and the San Francisco Planning Department work closely with the San Francisco Department of Environment and the Mayor's Office of City Greening to develop the best possible SFPUC water system improvement program and 2009 water contract. Together, San Francisco and SFPUC can become the leading edge in water management, efficiencies, and conservation. There is no excuse for this not to happen.

18 September, 2007

Paul Maltzer, Environmental Review Officer
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Dear Mr. Maltzer,

Please do not take additional water from the Tuolumne River. Moderate conservation measures will allow the Bay Area to grow while using the same amount of Tuolumne water. 01

At my vacation home in Tuolumne County I watch the Tuolumne River rapids. There is no water to spare in the river.

Of course, in Palo Alto we drink Tuolumne water. I support the Hetch Hetchy system and its existing dam and diversions, however, we should take no more water from the river. Fortunately, we do not need to.

Sincerely,

Gray Clossman

Gray Clossman

12.5-24

C_Colem1

Dear Commissioner Ryan L. Brooks,

01 How can you possibly allow the environmental degradation that would come as a result of ~~your~~ pulling more water from the Tuolumne? As the Sierra snowpack shrinks, Sierra rivers, like the Tuolumne, will become an increasingly unreliable source of water. Pulling more water from this river, for lawn watering is just ludicrous. Why give lawns clean pure drinking water when we already have water shortages across California? We can recycle water, from our showers & sinks and use that water for our lawns. There are so many possibilities for conservation that will sustain our cities growing water needs. San Francisco is supposed to be an environmentally friendly city. ~~[illegible]~~ Other cities like L.A. and Seattle have met their growing water needs through conservation. Can we do the same? Please?

Caroline Coleman
~~[illegible]~~ 308 Anza St.
San Francisco, CA
94118

C_Colem2

Dear Paul ~~[illegible]~~ Maltzer,

01 Please do not authorize the enormous water grab that will threaten so much fish & plant wildlife ~~of~~ the Tuolumne River. The effects are tremendous & I urge you to undertake additional studies or not go through w/ the project at all. There are so many alternatives that will help SF meet its growing water needs through conservation. Other cities like L.A. & Boston have had similar programs for a long time & they have proved successful. We can do it too. Please don't allow the draining of the Tuolumne

Re: Tuolumne River Water Theft

I speak as a native Californian who has rafted and backpacked in that most beautiful of God's creations, the Sierra, and I speak in opposition to the SF Public Utilities Commission plan to increase the already glutinous amount of river water they are currently removing from this pristine waterway.

This river is not a Utility that falls into Ronald Reagan's view of one of our natural resources---"If you've seen one redwood tree, you've seen them all". 01

Desk-bound bureaucrats who dwell in the forest of numbers, never having engaged in the spiritual communion of the wilderness, do not have the right to rape our environment using false statistics which are based upon predictions of unknown origin to suit their stilted justification.

They have not addressed, with any vision, the ramifications of global warming, which has already motivated the State of California to predict that the Sierra snowpack will be increasingly reduced over the coming years----- 02 the winter of 2006 has recently borne this out.

About 60% of the Tuolumne is already being diverted. Any more diversion will seriously affect the fresh water supply into the SF Bay and surrounding wetlands, thereby threatening the entire Bay Area ecosystem.

Many other cities have already incorporated proven conservation and recycling measures that are saving water resources. For the City that was 03 once recognized as "The City That Knows How"---San Francisco is turning its back on leadership and innovation. Please rethink this dangerous plan of draining our rivers, and think conservation, recycling and efficiency.

Sincerely,
Robert Collin

RE: Tuolumne River water to San Francisco

Dear Mr Maizer,

This letter is to state our response to SFPUC/City & Co San Francisco's request to take more water from the Tuolumne River, Tuolumne County, CA.

Allowing any further water allotments on the Tuolumne River would be detrimental to Tuolumne County – Tuolumne County
01 needs the water! Please, do not allow any more gallons of water to go to the San Francisco area.

San Francisco & the area it serves, needs to conserve water as we do here in Tuolumne County – this can be done through education and mandates.

Sincerely,

Leland Dahlin *Shirley Dahlin*

San Francisco, CA 94103

Dear Paul Maltzer,

As a San Francisco Peninsula resident, I am greatly disturbed by the proposal of the San Francisco Public Utilities Commission to divert an additional 25 million gallons of water per day from the Tuolumne River. This designated Wild and Scenic River contributes much needed freshwater to the San Francisco Bay and is a valuable asset to our watershed and the Bay Area. 01

Please make sure that the San Francisco Public Utility Commission re-evaluates its proposal and puts its research into finding and encouraging alternative ways of conserving water. This precious river needs to remain as it is!

Respectfully,

Mary Davey, Director Ward 2
Midpeninsula Regional Open Space District.

To: wsip.peir.comments@gmail.com

Paul Maltzer and San Francisco Planning Department,
I am writing as a frequent visitor to Yosemite and user of the crystal, clear water of the Tuolumne river.
I have lived in Palo Alto for the last 37 years. I beg you and the San Francisco Planning Department to protect this pristine, natural treasure through strong conservation efforts and use of recycling water programs rather than increasing water diversion. I am a strong advocate and practicer of conservation in my own water use. I've recently had a personal water audit for my own home which I am happy to say was quite conservative use. I, also, as secretary of my homeowner's association condo complex had a water audit for our complex by the Santa Clara County Water District and we are now in the process of implementing the recommendations from their report. Our water savings and use should allow us significant savings in water and costs. I urge you with all my heart please develop a sustainable water plan and protect our precious water resources. 01
Thank you for your consideration to allow my grandchildren (4) to experience the wild beauty of the Tuolumne River.
Sincerely,
Joel Davidsdon

Commissioner Ryan Brooks, President
San Francisco Public Utilities Commission
C/O Sierra Club SF Bay Chapter
2530 San Pablo Avenue, Ste. I
Berkeley, CA 94702

Dear President Brooks,

With its headwaters in Yosemite National Park, the Tuolumne River is a national jewel that is home to an outstanding native trout fishery, bald eagles, black bears, and thrilling whitewater.

Unfortunately, instead of increasing water conservation and recycling efforts, the San Francisco PUC plans on meeting future water demand by taking more water out of the Tuolumne, a federally designated Wild and Scenic River.

I urge you to meet our water needs and protect the Tuolumne River for future generations through conservation and recycling rather than withdrawing more water and depleting the Tuolumne River. 01

The fate of the Tuolumne River rests in your hands.

Sincerely,

Paul Maltzer, Environmental Review Officer
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Dear Paul,

The Tuolumne River already supplies water for 2.4 million people in the Bay Area. This potential increase in water intake from the Tuolumne River threatens further damage to the riparian ecosystem that includes bald eagles, spotted owls, prairie hawk and wild trout. Previous increased withdrawals reduced the chinook salmon population to less than 100 fish. Populations have rebounded back to 18,000 after more water was released into the river. 01

Increased withdrawals from the Tuolumne River may also decrease the amount of freshwater that flows into the San Francisco Bay-Delta Estuary. I was just on the Delta, in the growing town of Pittsburg, and the water doesn't smell too great! Plus, the resulting change in water chemistry in the estuary may threaten the health of this ecosystem that supports 750 species, 18 of which are listed as threatened or endangered. 02

Solutions
Withdrawing more water from the Tuolumne River is not necessarily the only option we have to meet our water needs in the future. One way to add to our water supply is to reduce usage. Although we have already made tremendous progress in conserving water (total water use in the US is the same as it was in 1975), there is the potential for even greater water savings. A study conducted by the Pacific Institute shows that we can save 1/3 of current urban water usage with existing technologies. Simple household retrofits can save the average household 22,000 gallons of water a year. More aggressive conservation techniques can ensure that we have enough water for our ecosystem as well as the human population.

Recycled water is another option that could conserve even more water. By reusing treated wastewater for non-potable sources such as landscape irrigation, toilet flushing and other industrial uses, even less water would be required out of the Tuolumne River. Some golf courses, parks and schools have already started using recycled water for irrigation without any complaints of illness. This drought-proof resource, if expanded, could potentially provide a greater share of non-potable water uses and reduce the stress on our water system. 03

One intriguing new option is desalination of brackish water. Once considered cost-prohibitive, new technologies are making desalination more feasible. The Alameda County Water District recently brought a desalination plant in Newark, which receives slightly brackish water resulting from saltwater intrusion into groundwater thus decreasing the amount of salt that needed to be extracted. Feasibility studies have already been conducted and a proposed schedule has the project completed by December 2009. 04

C_Dulma

Utilizing aggressive water conservation techniques, using more recycled water and constructing desalination plants are all ways of attacking the water supply issue at both the demand and supply ends. These resources may even be more cost-effective in the long run as water saved is water earned. Perhaps, more importantly, these options can ensure a sufficient water supply for the present and future generations without endangering the health of the Tuolumne River and the San Francisco Bay Delta-Estuary ecosystems. 05

Best Regards,

Diane

COMMENT CARD

San Francisco Planning Department
Draft Program Environmental Impact Report on the
SFPUC's Proposed Water System Improvement Program
Palo Alto, CA. September 19, 2007

Thank you for participating in tonight's public hearing on the Draft Program Environmental Impact Report (PEIR) for the San Francisco Public Utilities Commission's proposed Water System Improvement Program (WSIP). This is also an opportunity for you to submit written comments on the Draft PEIR for the proposed WSIP.

Written comments will be accepted through close of business on Monday, October 1, 2007. Written comments may be submitted in one of three ways:

1. Leave your written comments in the designated "Comment Box" tonight. These cards are provided for your convenience.
2. Mail your comments by October 1, 2007 to the San Francisco Planning Department, Attention: Paul Maltzer, Environmental Review Officer, WSIP PEIR, 1650 Mission Street, Suite 400, San Francisco, CA 94103
3. E-mail written comments to wsip.peir.comments@gmail.com

CONTACT INFORMATION

Name: Fred Duperrault

Affiliation:

Address: 500 W. Middlefield Rd., #45

City, State, Zip: Mountain View, CA 94043

Phone or E-mail:

WRITTEN COMMENTS Write clearly and continue on back. Use multiple sheets if needed.

Dear Mister Maltzer:

It appears to me, after hearing the comments at the SFPUC hearing in Palo Alto, last week, that it would be wrong to divert an additional 5 million gallons of water from the Tuolumne River each day. Conservation and recycling seems to me to ~~be~~ be the most wiser option. 01

Sincerely, Fred Duperrault

Inadequate EIR re Tuolumne

Jeb Eddy <jeb@mac.com> **Sun, Sep 30, 2007 at 9:04 PM**
To: wsip.peir.comments@gmail.com
Cc: Peter Drekmeier <Peter@tuolumne.org>

Dear Mr. Maltzer,

I attended and spoke at the public meeting in Palo Alto a few days ago.

THE CASE FOR DRAWING SO MUCH ADDITIONAL WATER from the Tuolumne River IS NOT PROVEN by the simple, almost linear projections based on estimated population growth. 01

YES by all means make SEISMIC protections, as soon as possible. 02

BUT...

WE MUST and CAN and WILL CONSERVE declining water resources, at every point, from the mountains to our fields and taps. MARKETS with PRICES, along with ranges of use, different levels of risk, and other flexible analyses and response mechanisms instead of per capita estimates are essential as we enter times of the greatest challenges man has ever faced. 03

I urge you to greatly reduce the proposed draw-down from the Tuolumne until revised, better quality investigation is done. If and only if a solid case is made should this option be considered further.

Thank you.

Sincerely,

Jeb Eddy

September 24, 2007

Dear Mr. Maltzer,

While it is necessary to safeguard our assurance of continued healthy water supply to the community all possible effects must be weighed carefully.

The environmental review of the San Francisco Public Utilities Commission's plan to take more water from the Tuolumne River fails to adequately identify and address all of the environmental impacts to the River. I urge you to undertake additional studies before finalizing this document. 01 In contrast to other metropolitan areas that have managed to reduce water demand in the face of growth, the anticipated 14% increase in demand projected by the SFPUC is large and out of step for the Bay Area. 02

I support the alternatives identified in your draft document that protect the Tuolumne River from new diversions. Requiring more water conservation, efficiency, and recycling is the best way to lessen impacts on the Tuolumne River while promoting a sustainable water plan. 03 The PEIR fails to properly identify and address all of the impacts of taking more water from the Tuolumne River. This failure largely stems from the lack of an adequate baseline study of the Upper Tuolumne River – a comprehensive study has not been conducted in over 15 years. 04

Only by ensuring that healthy amounts of water continue to flow into the Tuolumne River can we protect this irreplaceable natural treasure.

With sincerest intentions,

Dear Mr. Maltzer,

I am very disturbed to hear that S.F. water plans involve taking more water from the Tuolumne River. Why not do what Los Angeles did when the courts told them they had to limit water withdrawal from the Mono Basin. See page 6 - Mono Lake Newsletter - Fall 07 - enclosed.

I have never heard or read of any water conservation in San Francisco. My county (Santa Clara) supplies free low flow shower heads + faucet aerators (see Sierra Club insert Vol 27 # 10 enclosed. It's just an example of what can be done. 01

If Los Angeles is using the same amount of water they used thirty years ago and they have 4 million people, I'd say that's pretty darn impressive! Why can't S.F. and other users of Hetch Hetchy water do the same (or better)?

Thank you for reading this note and for considering my suggestions.

Statewide water droplets

by Geoffrey McQuilkin

DWP's Nichols departs

In July, Los Angeles Department of Water & Power (DWP) Commissioner Mary Nichols was appointed by Governor Schwarzenegger to chair the California Air Resources Board. As a result she has resigned from the DWP Commission. Her leadership skills will be of great benefit in Sacramento, where her new duties include implementing California's landmark global warming legislation.

Nichols had been the Commission's point person on Eastern Sierra matters and the leader of conceptual discussions about how DWP land holdings in Mono County might receive a guarantee of remaining open space (see page 7 for more). Commission Chair David Nahai will now fill that role and continue these discussions, commenting: "We remain resolutely committed to the protection and preservation of DWP lands in Mono County, to the ongoing fulfillment of all environmental standards, and to the continuing improvement of our relationship with Mono County and its residents."

Recycled water legislation AB 1481 advances

Recycled water projects are critical tools for Los Angeles to control water use. Important legislation (AB 1481) authored by Assemblyman De La Torre would standardize permitting requirements for use of recycled water for landscape irrigation.

Committee Executive Director Geoff McQuilkin testified in support of this legislation earlier this year and the bill is currently in the final stages of development in the State Senate. DWP officials hope to quickly increase use of recycled water—thus offsetting use of fresh Sierra water—if the new procedures take effect.

Water Board sees recycled water as critical

The State Water Resources Control Board will be promoting use of recycled water through a new policy due out this fall. The draft policy explains why recycled water use is in the best interest of the state and how Regional Water Boards can write permits to encourage use of recycled water while assuring the public that human health and the environment will be protected. At its center, the policy proposes the development of groundwater basin management plans to determine how increasing salts from all waters, not just recycled water, will be monitored and treated.

State Water Board members Gary Wolff and Frances Spivy-Weber have taken the lead in developing this policy. Spivy-Weber notes that the policy is particularly important in light of recent dry conditions in the Sierra and the West, increasingly dire predictions of hydrologic uncertainty in the future due to climate change, and the rising cost of energy to deliver imported water to Southern California. Further details are available at *www.waterboards.ca.gov*.

Los Angeles tops four million

Los Angeles' population grew by more than 37,000 people last year, state demographers reported this past summer. That pushes the city population to just over four million people. Los Angeles is still the country's second-largest city (New York City is first).

How do all those Angelinos get their water? Mono Lake supporters well know that the Eastern Sierra provides a tremendous amount of water to the city of Los Angeles. But take heart: through cutting edge conservation and reclamation programs—many of them advocated and supported by the Mono Lake Committee—the city is using the same amount of water it did thirty years ago despite the population increase. ❖

Geoff McQuilkin is the Committee's Executive Director. He saw his youngest daughter Ellery off to her first day of preschool this fall.

Mono Lake parcel from page 3

owned by MMSA includes all property portions west of Highway 395, including the existing structures and virtually all of the proposed subdivision sites. Recognizing the critical importance of this property, MMSA paid a premium of a half million dollars—and spent untold hours in lengthy negotiations. The final sale price was $4 million; a recently updated appraisal valued the land at $3.5 million. All the development rights associated with the property have transferred to MMSA.

This is the second time MMSA has taken ownership of the property. However this time there are no options or buyback clauses that would allow the Cunninghams to regain ownership in the future.

Mono Lake supporters familiar with this issue will note that 10% of the property remains under the ownership of the Cunninghams. This sliver of land is located east of Highway 395, between the highway and the boundary of the Mono Lake Tufa State Reserve. The Cunninghams' goals for the land are unclear, but rumor has it that they may seek to pursue a shaky claim of ownership to State Reserve lands.

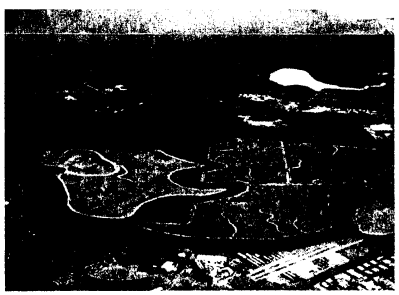
Monthly Meeting Information

When: THURSDAY Oct 11th 7:30pm
GRG General Meeting
Saratoga Library Community Room

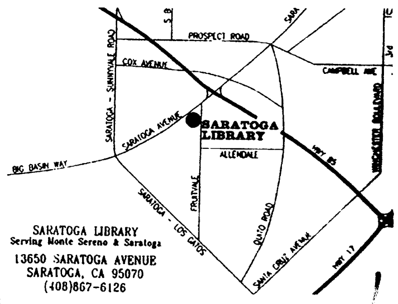
Salt Pond Restoration in San Francisco Bay
Clyde Morris, Refuge Manager,
Don Edwards San Francisco Bay NWR
U.S. Fish and Wildlife Service

Topic: The restoration of 15,000 acres of former Cargill commercial salt ponds for wildlife habitat

www.southbayrestoration.org
www.fws.gov/desfbay/AboutSF.htm



The Loma Prieta Chapter of the Sierra Club has been actively involved in the planning process for how the salt ponds will be restored. Of particular note is the possibility of increasing tidal marsh habitat for the endangered species: clapper rail and salt marsh harvest mouse.



Being Green – by Bob Groff

Water has been in the news again. Water rates are going up and the snow pack in the Sierra, where our water comes from, is going down. Using less water is becoming a must. There are some simple things you can do to save water. Putting in low-flow shower heads and faucet aerators will save water and you can get them free in Santa Clara County by calling the Water Conservation Hotline at (408) 265-2607, ext 2554. You can also schedule a free Water-Wise house call in Santa Clara County by calling 1-800-548-1882. In San Benito, call (831) 637-4378 for free showerheads, faucet aerators, and appointments. San Benito will even install the devices for you. There are also rebates for replacing your water thirsty lawn with drought tolerant plants and for upgrading specific items. Call the above numbers for more information. Give it a try. It is up to each one of us.

These steps could be taken by San Francisco.

Approve PEIR

FenwickJan@aol.com <FenwickJan@aol.com> **Sun, Sep 30, 2007 at 11:48 PM**
To: wsip.peir.comments@gmail.com

Paul Maltzer, Environmental Review Officer:

Being an "environmentalist" I am very concerned about our water future and misinformation that Peter Drekmeier and the Tuolumne RiverTrust are putting forth. I understand that the comment period for the PEIR closes at 5 pm on Monday.

Some points below refute what the TRT is saying:

For example, the voluntary 10% water conservation program in the SFPUC service area (including BAWSCA) has achieved a 13 % reduction in water demand in the last six months according to Susan Leal, and as reported at the BAWSCA meeting last Thursday night. Drekmeier was there. -- No mention of this in his Monday letter, because it doesn't suit his objective--- "an inconvenient truth". Also the River is not a 162 mile river that "Cascades", most of it meanders through the Central Valley, and only about 27 miles of it (in the Canyon) is designated "Wild and Scenic". Another point (not mentioned): the proposed SFPUC diversion from the Tuolumne is but 8/10 of one percent more of the average river flow." (SFPUC currently diverts about 12%. So they would be diverting about 12.8%). "Modesto and Turlock are the big water diverters, but TRT cannot get any traction with them and San Francisco is a much better target, and is in line with the legacy of John Muir. ... If we have a big recession, or if more conservation is achieved, the need may be even less. Meanwhile, if we have a big earthquake we could be out of water with catastrophic impact on a scale that matches or exceeds the Katrina impact on New Orleans. The legal challenges by NRDC and decision by Federal Judge Wanger regarding Delta pumping, places even more reliance on Hetch-Hetchy for an assured supply to the peninsula and East Bay. 01

Finally, he (Peter) states that the SFPUC's plan to increase diversions will delay the seismic improvements and result in cost overruns. What he does not say is that the TRT will sue San Francisco unless it drops the diversion plan. This threat was made in the BAWSCA meeting last Thursday. The effect of a lawsuit (standard environmental practice) is to delay the program, but the intervenors have no accountability or responsibility for adverse consequences."

Thus, my concern. It has taken the SFPUC YEARS to get to this point. We MUST move forward with the seismic upgrades. Thank you ! Jan Fenwick Past Board member of the Purissima Hills Water District.

Palo Alto, CA 94306

Paul Maltzer, Environmental Review Officer
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Dear Mr. Maltzer,

I do not support the current environmental review of the S.F. Public Utilities Commission's plan to divert more water from the Tuolumne River. This river is an asset to the state as it is, offering recreation opportunities to the citizens of California, 01
habitat to native species, and fresh water to our own Bay Delta system. Decreased snow pack from drought years is already affecting the flow of this river, we cannot afford further diversions.

However I was very pleased to see some of your alternative suggestions: requiring conservation efforts, increased efficiency and water recycling. The reality is that we will have to do these things anyway, as population grows. Let's get our water 02
consumptive culture thinking about conservation sooner rather than later. I would strongly support this kind of effort.

Enough is enough, it is time to prioritize the health of our Wild and Scenic rivers, and stop whittling away the water that flows through these watersheds. They are one of the legacies of this great state and should be treasured and protected.

Thank you for your attention to this letter.

Yours sincerely,

Diana Sokolove <wsip.peir.comments@gmail.com>

Personal Tuolumne perspective

Peter Fox <peter@peterfoxphotography.com> **Tue, Sep 25, 2007 at 1:17 PM**
To: wsip.peir.comments@gmail.com
Cc: Peter Drekmeier <pdrekmeier@earthlink.net>

Dear Mr Maltzer;

The day the Tuolumne was designated Wild and Scenic is very clear in my memory. I was guiding on the river that day. The crystal water and dramatic canyon seemed especially beautiful.

My perspective on the Tuolumne comes from two points of view. I am a Palo Alto home owner who enjoys the pristine water that comes out of my tap. I also have an intimate knowledge of the river, having guided it's white water for 27 years. It is hard to put the value of a wild river into hard facts and figures. There are few things that really change people in this world. I have seen hundreds of people changed by just a day or two on the Tuolumne. In an America more and more dominated by concrete shopping canters and corporate franchising, it is essential to
maintain the resources where nature can touch a person's life. There is very little that accomplishes this, like a white 01
water river; and there are very very few rivers that can be compared to the Tuolumne. The complexity of it's rapids, the isolation of the canyon, and the sheer beauty of the river itself make running it an experience that few forget.

Our Bay Area community, and our world need more resources like the Tuolumne river, where we experience something that make us all a little more humble and appreciative of the fragile natural world that is our home. One can lecture about global warming and the need to protect our environment. My experience, is that the Tuolumne river speaks for itself and for this world with an eloquence that is more persuasive than anything we can say.

Thank you,

Peter Fox

September 22, 2007

Mr. Paul Maltzer
Environmental Review Officer, WSIP PEIR
San Francisco Planning Department

Dear Mr. Maltzer,

Please act to protect the Tuolumne River for future generations by requiring water conservation, efficiency, and recycling, **instead of taking more water from this river.**
The SFPUC should re-evaluate its projections for future water demand and conservation potential for these reasons:

- The PEIR uses flawed modeling to determine the anticipated increase in water demand, thus inflating projected future needs. Other metropolitan areas (especially Seattle and Los Angeles) have managed to reduce water demand even in the face of growth. 01
- The PEIR fails to properly address all of the impacts of taking more water from the river because it lacks an adequate baseline study. A comprehensive study has not been done for 15 years, and a current study will not be completed in this review period. 02
- The PEIR does not take into consideration the impact of climate change on precipitation in the Tuolumne River watershed. 03

Decreasing reliance on the Tuolumne is critical not only for protecting the health of the River, but also for preparing for the future uncertainty of the Sierra snowpack due to global warming.

Water conservation and efficiency measures are the cheapest, easiest, and least destructive ways to meet demand and extend supply.

Respectfully, Caroline Garbarino, Technical Editor, Palo Alto, CA.

Dear Planning Commission,

Please make meetings available to people, by meeting after working hours.

I wanto to express my opinion about taking more water from the river. I want to express my total oposition to the PUC taking additional water from the tuolumne River.
no more water! 01

Tuolumne River

Marylyn Genovese <marylyn23@sbcglobal.net> **Sat, Sep 29, 2007 at 6:29 PM**
To: wsip.peir.comments@gmail.com

To: Paul Maltzer, Environmental Review Officer
San Francisco Planning Department

Your environmental review of the San Francisco Public Utilities Commission's plan to take more water from the Tuolumne River fails to adequately identify and address all of the environmental impacts to the River. I urge you to re-evaluate the projections for future water demand and conservation potential and to undertake additional studies before finalizing this document. 01

I believe that decreasing reliance on the Tuolumne is critical not only for protecting the health of the River, but also for preparing for the future uncertainty of the Sierra snowpack as a result of global warming. 02

I support the alternatives identified in your draft document that protect the Tuolumne River from new diversions. Requiring more water conservation, efficiency, and recycling is the best way to lessen impacts on the Tuolumne River while promoting a sustainable water plan for the Bay Area.

Sincerely,

Marylyn Genovese

Paul Maltzer, Environmental Review Officer
Water System Improvement Program PEIR
San Francisco Planning Department

Subject: Tuolumne River

Dear Mr. Maltzer:

Section 5.3 of the PEIR relates to the Tuolumne Watershed. The maps, tables and flow data are informative and are a great resource to get a better understanding of the complex hydrological and meteorological interactions and their effect on the biological resources in the watershed.

The additional water diversion from the Tuolumne River will have a significant effect, as is summarily acknowledged in the slide show presentation (#17, 21 & 22). 01
Since these effects are irreversible and, since there are other means of obtaining sustainable water supply for the SF Bay Area, further diversion from the Tuolumne River is not an acceptable solution.

I urge that other means be considered. For example, conservation; water recycling/gray water use; reduced water allocation to certain agricultural crops; price structures reflecting higher cost for excessive consumption; encouraging composting toilets where appropriate; changes in the Uniform Building Code to require separate plumbing for gray water; incentives for planting drought resistant gardens. I am sure there are many more creative ideas that should be considered. The natural resource of the Tuolumne must not be sacrificed or reduced in any way. The River is our heritage. 02

Cordially,

Ernest Goitein

Tuolumne River environmental review

Kass <vz22@yahoo.com> **Tue, Sep 25, 2007 at 11:19 AM**
To: wsip.peir.comments@gmail.com

(Date)

Paul Maltzer, Environmental Review Officer
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Dear Mr. Maltzer:

I support the alternatives identified in your draft document that protect the Tuolumne River from new diversions. Requiring more water conservation, efficiency, and recycling is the best way to lessen impacts on the Tuolumne River while promoting a sustainable water plan for the Bay Area.

Please note that I believe guidance for water conservation should be in terms of absolute use as well as percentages. Recent requests to reduce water usage by "20%' in the Bay Area does not adequately recognize those of us who have never stopped conservation of water since the last drought. My water usage today is almost alway less than the 100 gal per day (including sprinklers) recommended at the heighth of the last drought, due to xeriscaping and changing personal habits to permanently reduce water usage. It is half that in the winter. If everyone did the same, then there would be no need to take more water from the Tuolumne, even if population increased. 01

Please do a more thorough environmental review of the San Francisco Public Utilities Commission's plan to take more water from the Tuolumne River. The initial review fails to adequately identify and address all of the environmental impacts to the River, the Delta and the San Francisco Bay. I urge you to undertake additional studies before finalizing this document. 02

Only by ensuring that healthy amounts of water continue to flow into the Tuolumne River and the SF Bay can we protect this irreplaceable natural treasure.

Best wishes,

Kathleen M. Goldfein

Protecting the Tuolumne River

Rebecca <arrbecca@yahoo.com> **Wed, Sep 26, 2007 at 6:00 PM**
To: wsip.peir.comments@gmail.com

Dear Mr. Maltzer,

As an environmentally conscious San Francisco resident, I appreciate your recent review of the PUC's plan to withdraw more water from the Tuolumne River. However, I encourage you to delve further into the issues at hand before making any final decisions. 01

Before taking more water out of this valuable resource, it is essential to consider both the habitats and marine life of this river. Whereas there are alternatives to increased water extraction, such as water recycling and conservation, the Tuolumne animals and habitats have no choice but to be subject to our decisions. 02

Please consider the big picture and make the right decision. The Bay Area is lucky to be home to some important and wonderful resources. Let's keep it that way.

Sincerely,
Rebecca Goodman

SFPUC proposal to divert more water from Tuolumne River

David Greene <dg@bayarearesearch.org> **Tue, Sep 11, 2007 at 1:28 PM**
To: wsip.peir.comments@gmail.com

Dear Paul Maltzer,

A brief note in support of the environmentalists' campaign for SFPUC to re-evaluate its projections for future water demand and conservation, and to determine the potential for conservation and 01
efficiency savings. They should adopt a policy of REDUCING diversions 02
from the Tuolumne River over time, not increasing them. It's long overdue for our water management policies to take into account the impact of climate change on precipitation in the Tuolumne River 03
watershed. Conservation and efficiency should be our primary policy focus for a more sustainable water management future. 04

Best regards,

Tuolumne River under consideration for further diversion

Greene, Kat <Kat_Greene@intuit.com> **Fri, Sep 21, 2007 at 2:57 PM**
To: wsip.peir.comments@gmail.com

Mr. Malzer,

I learned that the river is being considered for further diversion for human water consumption. This deeply concerns me. Over half the water from this river is already diverted, having far-reaching consequences on the habitat it used to supply. I'd like to see reference to studies which show decreases in mammals, reptiles, and flora since the diversion began.

Please consider conservation and other methods of using what we have before taking more water away from the islands of wildlife we have left. Please revisit your study. I think there are important pieces missing. 01

I hope as a steward of public resources that you will represent my thoughts on this matter.

Thank you for your consideration,

Katherine Greene

San Francisco CC 94103
wsip.peir.comments@gmail.com

The Planning Department Draft PEIR for the SFPUC WSIP provided much information, but not enough on five questions:

I ask that the San Francisco Planning Department to expand the discussion in the PEIR for the impacts on San Francisco's numerous water rights on the Tuolumne River[1] of the SFPUC establishing a temporary or permanent policy for reduction in diversion from the Tuolumne River every year by using other measures[2] for reducing demand to the present average annual export[3] to reduce the hardship of rationing on their customers during drought[4]. 01

For the same question, discuss the impact of export reduction from the Tuolumne River on the operation under the Raker Act[5].

For the same question, discuss the impact of the Lower Tuolumne Diversion[6] on San Francisco's water rights. 02

For the same question, discuss the impact of the Lower Tuolumne Diversion[6] on the operation of the Raker Act[5].

For the same question, discuss the impact of the Lower Tuolumne Diversion[6] on the operation of the four agreements among SF, TID, and MID[7]. 03

Also, discuss the impact of lowered flow in the lower Tuolumne River on recreational activities of boating, duck hunting by boat, bass fishing by boat and from shore, and swimming and picnicking at the Stanislaus County parks and fishing accesses[8]. 04

Please note that the "improving and enlarging the Lower Cherry Aqueduct"[9] may not be provided for in Raker Act documents and a full EIR is requested. 05

Mr. Paul Maltzer, Environmental Review Officer, WSIP PEIR
San Francisco Planning Department
1650 Mission St, Suite 400
San Francisco CA 94103
wsip.peir.comments@gmail.com

Mr. Maltzer:

I appreciate the extra review time to make comments on the DPEIR for the WSIP. The Planning Department Draft provided much information, but not enough on the Raker Act compliance.

The Raker Act portions of the PEIR, Section 2.4.2 page 2-33 & 4, and Section 2.5.1 page 2-37, or elsewhere do not address the question I raised in the scoping meeting in October 2005 relating to the requirement that the City develop local supplies before diversion from the Tuolumne River as stated in Section 9(h) of the Act. Specifically, the WSIP is not developing the full amount of ground water, stressing water efficiency adequately and planning little recycling of waste water for cooling and landscape purposes as is required by the Act. Developing desal alone is not adequate compliance. Please discuss plans for compliance with this requirement in the City and in the service areas. 01

Tuolumne River Water Plan - comment

Diana Hall <dianahall39@yahoo.com> **Mon, Oct 15, 2007 at 8:55 AM**
To: wsip.peir.comments@gmail.com

Attn: Paul Maltzer

I urge you to support an environmentally sustainable plan for Tuolumne River usage that emphasizes conservation and recycling. Taking more water from the Tuolumne will be detrimental to wildlife and the natural environment as a whole. 01

More efficient water use and a more diverse mix of water supplies would also minimize the risks associated with a shrinking snowpack that is expected as a result of climate change. 02

Let's safeguard the Tuolumne River for future generations.

Diana Hall

812 Calderon Ave.

San Francisco Public Utilities Commission
+ San Francisco Planning

Sept. 20, 2007

I write the following as I was not able to return and speak before the board.

I can appreciate the San Francisco Public Utilities Commission's necessity to plan for future water needs. However, I do not agree with the proposal to divert an additional 25 million gallons a day from the Tuolumne River.

Since it appears that outdoor water use drives 60% of the anticipated increase in water demand, I urge water conservation as the top priority for meeting future water needs. Water conservation is cheap, relatively easy and much less destructive to the environment.

The Bay Area drastically lags behind other metropolitan areas when it comes to water conservation. I believe if a vast metropolis such as Los Angeles is able to implement conservation measures so that a precious body of water known as Mono Lake is allowed to recover from near extinction, then the Bay Area, a region known for strong environmental ethics, certainly has the capacity to be a leader in water efficiency and conservation in order to protect the health of the Tuolumne River. 01

Diversion of additional water from the Tuolumne River is destructive to the environment, wasteful and irresponsible. Again, let me stress, **conservation** is the key to he health of the Tuolumne River, and to the future water needs of the Bay Area,

Thank you,

Kimberly Hamilton-Lam

Sept. 25, 2007

Dear Mr. Maltzer,

I am strongly opposed to the plan for more water diversion from the already heavily impacted Tuolumne River. Approximately 60% is currently diverted for urban and rural use. Continuing to take more from the river seems to violate its 1984 designation as a Wild and Scenic River. 01

Bay Area residents need to become water conscious and realize the urgency to be much more efficient in outdoor water use. I understand that 60% of the new diversion is targeted for that purpose. We fall far behind other California metropolises in water conservation. 02

The Tuolumne River is the main tributary to the San Joaquin River flowing into the San Francisco Bay-Delta. The Delta is already under stress, and more diversion of fresh water could cause serious damage from the invasion of salt water, disrupting the estuarine ecosystem. 03

I support the alternatives proposed in your draft document that protect the river from new diversions. I urge you to protect the magnificent Tuolumne River. 04

Sincerely,

Carol Hankermeyer

8/15/07

Dear Commissioner Brooks,

With so many water conservation technology, with a water ~~[illegible]~~ crisis already at hand in California, why would you take water from the Tuolumne, especially to water lawns? Clean water used for watering lawns? Believing that we can ~~take~~ keep taking water from rivers such as the Tuolumne is insane. Rivers are not permanent sources of water, especially, as I said before, for watering lawns, which can easily be ~~[illegible]~~ watered with previously used water. On top of the sheer stupidity that the ~~sheer~~ thought of this ~~products~~ project emmits, it is also a waste of money. Money that could easily be used for more practical purposes such as the constantly growing homeless problem that areas such as San Francisco face. So, please rethink your views on this ~~subject~~ project and realize the idiocy of this water plan. 01

Sincerely
alex Helldorfer

Dear Commissioner Brooks.

Taking water that keeps our wildlife thriving is a preposterous idea. Taking water from the animals and plants that rely on this river as a source of life. The animals and plants along the beautiful banks of the Tuolumne River need the water more than people who need to water their lawns. The right choice would be to let the nature be. Make the right choice. 01

Dear Mr. Maltzer:

My name is Kristin and I am very concerned with the possibility of a taking more water out of the Tuolumne River. The environmental impacts that would occur as a result of the extra water being diverted, far out weight the need for more lawns and suburban sprawl across the East Bay, which is where 60% of the water would be sent to. I think that this is a huge mistake and a problem that has many other possible solutions. You should instead focus your efforts on increasing water conservation and recycling programs. This is a far better alternative for the river, the environment, the wildlife, our cities, and us. I truly hope that you take all of the public's comments into serious consideration before you make a horrible decision that would affect all walks of life for generations to come. 01

San Francisco Planning Department
Attention: Paul Maltzer, Environmental Review Officer
WSIP PEIR
1650 Mission Street, Suite 400
San Francisco, CA 94103

Dear Mr. Maltzer:

Here are my comments about the WSIP DPEIR
(San Francisco Planning Department File No. 2005.0159E,
State Clearinghouse No. 2005092026).

In general, the DPEIR is written to cover the possibilities that SFPUC's treated water could contain either chlorine or chloramine as the residual disinfectant; but occasionally it fails to mention both possibilities. Is it SFPUC's intent to have covered both possibilities consistently? 01

Does SFPUC believe that for the WSIP described in the DPEIR, there would be more environmental impact if chloramine were the residual disinfectant than if chlorine were the residual disinfectant? If not, why not? If so, would SFPUC be willing to switch from chloramine to chlorine, at least for the duration of the WSIP construction projects?

Thanks very much.

Jeff

Jeff Hoel
731 Colorado Avenue
Palo Alto, CA 94303

PS: Please see my more detailed comments and questions below. Thanks.

PPS: I became a member of Citizens Concerned About Chloramine (CCAC) on 9-26-07, and I have been attending their meetings for a while. I agree with their point of view that SFPUC shouldn't be using chloramine as a residual disinfectant until scientific human health studies can show it's safe. This message is from me personally, and does not necessarily represent the views of CCAC.

==

Detailed comments and questions:

6-29-07 (updated 7-6-07):
"Public Notice: Availability of Draft Program Environmental Impact Report"

<http://sfwater.org/detail.cfm/MC_ID/13/MSC_ID/167/C_ID/3512/ListID/6>

The above webpage says the DPEIR can be viewed online here:
<http://www.sfgov.org/site/planning_index.asp?id=37672>

The DPEIR mentions "chloramine" or "chloramines" or "chloramination" in these sub-documents:
(Google "site:www.sfgov.org/site/uploadedfiles/planning (chloramine OR chloramines OR chloramination)" 10 hits.)

Glossary:
<http://www.sfgov.org/site/uploadedfiles/planning/vol1_glossary_wsip-dpeir.pdf>

No comments or questions.

Chapter 2:
<http://www.sfgov.org/site/uploadedfiles/planning/vol1_ch2_wsip-dpeir.pdf>

No questions or comments.

Chapter 3:
<http://www.sfgov.org/site/uploadedfiles/planning/vol1_ch3_wsip-dpeir.pdf>

Table 3.12 mentions that project SF-2 has this operational change:

> Increased chlorination or chloramination supplies during drought years only, ... 02

Why? (If SFPUC is providing less water, as it does in a drought, why does it need more supplies?)

Chapter 4, Sections 4.1 to 4.5:
<http://www.sfgov.org/site/uploadedfiles/planning/vol2_sec4-1_to_4-5_wsip-dpeir.pdf>

Page 4.5-17:

> Discharge of Chlorinated Water
>
> Because chlorine is toxic to aquatic life in both freshwater and saltwater, the SWRCB considers that every discharger that uses chlorine has the potential to cause acute toxicity due to total residual chlorine (TRC) in freshwater and chlorine-produced oxidants in saltwater.

SWRCB thinks chloramine is even worse: 03
<http://www.swrcb.ca.gov/rwqcb2/Agenda/08-9-06/08-09-064eosr.doc>
"... chlorine toxicity to aquatic life persists longer in chloramine-treated water."

Page 4.5-21:

> In general, implementation of the WSIP projects would not have direct long-term effects on the hydrology or water quality of regional and local surface waters. However, short-term

construction impacts could result in erosion or sedimentation or discharge of construction-related pollutants to local water bodies, causing water quality effects.

Could short-term construction impacts also result in discharge of chlorinated or chloraminated water (which might not be classified as a construction-related "pollutant" per se)?

Operation of some projects could also result in the discharge of chlorinated or chloraminated water, treated stormwater, or recycled water to water bodies, causing potential water quality effects.

Why "potential"? *If* water is discharged, aren't the water quality effects actual?

I have the impression that chloraminated water would have a worse environmental impact than chlorinated water, because chlorine dissipates from water more readily than chloramine and because chloramine is typically used at a higher concentration than chlorine. Does SFPUC have that impression too? Is it relevant to the DPEIR? Did SFPUC consider the possibility of switching its residual disinfectant from chloramine to chlorine during construction (and/or subsequent operation!) to minimize environmental impact of discharges, both accidental and unavoidable?

Page 4.5-32:

... the following action pertaining to dechlorination of water prior to discharge would be implemented as part of the WSIP projects....

03 cont.

What does this mean if the residual disinfectant is chloramine?

Page 4.5-42:

While both chlorine and chloramine are effective disinfectants for potable water,

This dependent clause is misleading. Chlorine is orders of magnitude more effective than chloramine at killing E. coli and rotavirus. <www.who.int/water_sanitation_health/dwq/S04.pdf>

the discharge of chlorinated or chloraminated water into natural waters can be detrimental due to the toxicity of chlorine, ammonia, and chloramine to aquatic organisms. Chlorine residuals (both free and combined) are acutely toxic to aquatic organisms at low concentration and are persistent due to their stability.

Chloramine is much more "persistent" than chlorine.

What literature supports the view that chlorine, ammonia, and chloramine are toxic to aquatic organisms? Does the literature say specifically for each of these chemicals how toxic it is to which aquatic organisms?

Are humans considered to be aquatic organisms? If not, is the DPEIR nevertheless concerned about the toxicity of chlorine, ammonia, and chloramine to humans?

The San Francisco Bay Basin Plan standard for residual chlorine is 0.0 milligrams per liter

This document mentions four limits, all less than 0.02 mg/L but not zero: <www.tritac.org/documents/summaries/2006_05_Water_Issue_Summaries.pdf>

It is claimed that (the ionized form of) ammonia is not harmful, so that if only the chlorine portion of chloramine is removed, that's good enough. But is it really good enough? In Chapter 5, Section 5.5, it says that before chloraminated water is put into Crystal Springs Reservoir, the chlorine part is "completely" removed and "most" of the ammonia part is removed. I assume that is done because it is thought to be necessary.

03 cont.

Chapter 4, Section 4.6:
<http://www.sfgov.org/site/uploadedfiles/planning/vol2_sec4-6_wsip-dpeir.pdf>

No questions or comments.

Chapter 4, Sections 4.7 to 4.11:

No questions or comments.

Chapter 5, Section 5.5:
<http://www.sfgov.org/site/uploadedfiles/planning/vol3_sec5-5_wsip-dpeir.pdf>

Page 5.5.3-1:

In 2005,

On February 2, 2004....

the SFPUC changed the method it uses to disinfect water in order to comply with drinking water standards. Formerly, the SFPUC disinfected water with chlorine; now it uses chloramine, a chemical compound that contains both chlorine and ammonia. Ammonia is a form of nitrogen that rapidly decomposes in natural waters to another form of nitrogen called nitrate. Past studies have shown that the growth of algae in Crystal Springs Reservoir is limited by lack of nitrogen and phosphorous [sic], both of which are plant nutrients; therefore an increase in the concentration of either could increase the growth of algae. To avoid the discharge of nitrogen and the possible consequent increase in algae concentration in Crystal Springs Reservoir, the SFPUC constructed dechloramination facilities at the same time it constructed chloramination facilities. The dechloramination facilities completely remove the chlorine and remove most of the ammonia from water before it is discharged into Crystal Springs Reservoir. The use of chloramine as a disinfectant has resulted in a small increase in the concentration of nitrate in Crystal Springs Reservoir (SFPUC, 2006).

04

(I looked for the cited document online but didn't find it.)

Quantitatively, how much ammonia is removed -- and how much remains?

If the ammonia in chloramine is not completely removed when water enters Crystal Springs Reservoir, must it be removed later, before free chlorine primary disinfection can occur in the treatment plant(s) fed by Crystal Springs Reservoir? 04 cont.

(In this PDF file, phosphorus is misspelled as "phosphorous" 7 times.)

Appendix A:
<http://www.sfgov.org/site/uploadedfiles/planning/vol5_apdx-a_wsip-dpeir.pdf>

Section 6.2.1 (page 51) says that comments have been received about topics:

... including use of chloramines for disinfection and
effect of chloramines on pipe materials.

How can I view these comments?

What pipe materials will be used in the project described by the DPEIR? What documents the effect of chloramines on these materials? 05

PLANNING DEPARTMENT
MEA

Paul Maltzer, Environmental Review Officer
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Dear Mr. Maltzer:

I am strongly opposed to the San Francisco Public Utilities Commission's (SFPUC) proposal to divert an additional 25 million gallons of water per day from the Tuolumne River as part of its Water System Improvement Plan (WSIP). The SFPUC already diverts one third of the Tuolumne's water and 60% of the river's water is already diverted. Taking large amounts of water from a river is very harmful to the river, its surrounding ecosystems, and the plants and animals that depend on the river and the ecosystems. Too much water is already diverted from the Tuolumne River; the SFPUC should not exacerbate these harms by taking even more water. 01

The San Francisco ballot initiative that authorizes the WSIP was promoted as a badly need repair for San Francisco's water system. As the campaign coordinator for Sierra Club's "No on Prop A" campaign I was part of a coalition opposing that ballot initiative because of the environmental harm that would be caused by taking even more water from the Tuolumne, even though initiative proponents insisted that no additional water would be diverted. Unfortunately, our analysis of the initiative proved to be correct: the WSIP is as much about taking more water out of the Tuolumne in order to promote development of open space, which will cause further environmental harm, as it is about repairing our aging water system. I find the dishonest tactics of the proponents of this project to be rather egregious. 02

The large majority of us in San Francisco are strong proponents of protecting the environment. Unfortunately, the SFPUC promotes several projects outside of San Francisco, such as this one, that are very environmentally destructive. The actions of the SFPUC outside of San Francisco are in direct opposition to the will of the residents of our city. Please reconsider this ill advised plan to do further harm to the Tuolumne River, its ecosystems and wildlife by taking even more water from this river. The environment deserves better and the residents of San Francisco deserve actions from the SFPUC that are in harmony with our environmental concerns, not actions that are opposed to them. 03

Sincerely,

Jeff Hoffman

Comment on Draft Program Environmental Impact Report (PEIR)

Pei-Lin Hsiung <plhsiung@stanford.edu> **Fri, Oct 12, 2007 at 9:40 PM**
To: wsip.peir.comments@gmail.com
Cc: bill.young@sierraclub.org

Dear Mr. Maltzer:

Your environmental review of the San Francisco Public Utilities Commission's plan to take more water from the Tuolumne River fails to adequately identify and address all of the environmental impacts to the River. I urge the SFPUC to undertake additional studies to determine the maximum technical potential for conservation and efficiency savings before finalizing this document. 01

I strongly believe that requiring more water conservation, efficiency, and recycling is the best way to lessen impacts on the Tuolumne River. When it comes to water conservation, the Bay Area lags far behind other metropolitan areas such as Seattle and Los Angeles that are reducing water consumption even in the face of growth. 02

As a region known for a strong environmental ethic, the Bay Area should be a leader in water efficiency and conservation. The SFPUC should adopt a policy of reducing diversions from the Tuolumne River over time, with additional demand met through increased investment in conservation, efficiency, and recycling. Only by ensuring that healthy amounts of water continue to flow into the Tuolumne River can we protect this irreplaceable natural treasure.

Sincerely,

Pei-Lin Hsiung
397 College Ave. Apt. C

C_Ikemo

08-15-07

Dear Commissioner Brooks

How can you even think about taking water from the Tuolumne river and giving it to people so that they can water their lawns? 2.5 million gallons of water a day is alot of water. People can and should recycle their water if they are going to use it for landscaping. Please don't pull more water from the river, there are many more different things the city could do. 01

Kyle Ikemoto

Tuolumne River plan

Marian Isaac <MIsaac01@att.net> **Fri, Sep 28, 2007 at 2:25 PM**
To: wsip.peir.comments@gmail.com

Dear Mr. Maltzer,

I hope you will move San Francisco to developing water conservation, recycling and development of desalination to procure water for the Bay Area. 01

Taking more from the Tuolumne, which is already an overworked river, will be destructive to all of the wildlife, and the lands that live because of the river.

I was born and raised in San Francisco, and am very disappointed, actually stunned, that San Francisco would try for such an anti-environmental grab. Such an action is disgusting.

California is facing environmental disasters. Depleting one of the few remaining rivers is the wrong thing to do. The alternatives I mention above are the only reasonable and ethical courses to take.

Sincerely,

Marian Isaac

Re: WSIP PEIR

Dear Mr. Maltzer:

I have reviewed Section 5.5 in volume 3 of the referenced document, with regard to the impacts of the project on San Mateo Creek and Pilarcitos Creek, both in San Mateo County.

The document states that San Francisco PUC is not required to release water past its dams in these two important watersheds. The document does not explain why it believes it is exempt from Section 5937 of the State Fish and Game code, or why it believes that NOAA requirements and the Federal Endangered Species Act do not apply. 01

The document goes on to say that SFPUC does not release water into the stream beds downstream from the dams to maintain adequate streamflow for fish, and that it will not do so.

The PEIR then asserts that because the actions of the Water Department have made the creeks intermittent, this is the baseline condition for analyzing impacts. The baseline condition should be an approximation of the historic flow before dam construction.

This section of the PEIR should be re-written to recognize the SFPUC's responsibility to release adequate flows downstream of its dams, and fully describe the benefits of meeting those responsibilities. 02

Thank you for the opportunity to comment.

Promote water efficiency - don't take more water from the Tuolumne

Lindsay Joye <ljoye@pacbell.net> **Tue, Sep 11, 2007 at 7:32 PM**
Reply-To: ljoye@pacbell.net
To: wsip.peir.comments@gmail.com

Dear SFPUC,
Our family had the great pleasure of spending three days on the mighty "T" this summer and are dismayed to learn that the SFPUC is planning to take even more water from the Tuolumne.

Please look at other progressive water agencies to model their conservation programs before taking this step. Incentive programs coupled with new landscape standards can make a large impact on Bay Area water usage. A comprehensive watershed study should be completed to adequately assess the environmental impacts of this proposed Water System Improvement Program. 01

MEA

It is inexcusable to withdraw more water from our natural treasure, the Tuolumne River in Yosemite, when we have the means to meet our water needs already. Grey water systems, native plants, educational campaigns + incentives to encourage conservation, water-saving appliances, and many other options are currently available to provide enough water for the Bay Area's growing population. Our rivers are already in danger because of climate change. Think about the future of California. Golf courses are not the future. Protect the Tuolumne. 01

Thank you,

Gwynn Kaliher-MacKellen

COMMENT CARD

San Francisco Planning Department
Draft Program Environmental Impact Report on the
SFPUC's Proposed Water System Improvement Program
Palo Alto, CA. September 19, 2007

Thank you for participating in tonight's public hearing on the Draft Program Environmental Impact Report (PEIR) for the San Francisco Public Utilities Commission's proposed Water System Improvement Program (WSIP). This is also an opportunity for you to submit written comments on the Draft PEIR for the proposed WSIP.

Written comments will be accepted through close of business on Monday, October 1, 2007. Written comments may be submitted in one of three ways:

1. Leave your written comments in the designated "Comment Box" tonight. These cards are provided for your convenience.
2. Mail your comments by October 1, 2007 to the San Francisco Planning Department, Attention: Paul Maltzer, Environmental Review Officer, WSIP PEIR, 1650 Mission Street, Suite 400, San Francisco, CA 94103
3. E-mail written comments to wsip.peir.comments@gmail.com

To:

Paul Maltzer, Environmental Review Officer
Water System Improvement Program PEIR
San Francisco Planning Department

Dear Mr. Maltzer:

I write you in response to the approval for diverting additional water from the Tuolumne River for sale by the SFPUC. My background in ground and surface water hydrology, consumer finance, and raising children in San Francisco allows me to appreciate the complexities, economics, and long-term impacts of decisions such as this one. Further, I am an Eagle Scout, avid fly-fisher, and have been enjoying California (and drinking her waters) since 1976.

I imagine that, while you appreciate public concern and applaud the effort of people such as myself to voice them, your decisions are most heavily driven by your view of the economics of the situation with respect to the legislated environmental constraints such as EIR's. The time frame of such economic decisions is critically important. Money certainly has time-value, but our natural resources have an inverse value. To me it seems the longer we protect them, the better we understand them, and the more value we can derive from them in the future. Once gone, they are prohibitively expensive to recreate. 01

Margaret Thatcher said, "I never make a decision until I have to." As you have cleared the constraint of the commission, you are perhaps not obligated to divert or sell the waters. Please give careful consideration to the recommendations you get from all sides and make a decision that will benefit Californians in perpetuity.
In gratitude for you consideration of my voice,

--

Dear Council,

I am writing to you today to implore you to take another look at the planned redirection of 25 million gallons of water from the Tuolumne River to Bay area commercial interests. In the interest of California wildlife and conservancy, I truly believe this action is an outdated response to our water needs. We have seen water needs in other urban centers such as Los Angeles and Seattle met through water recycling and conservation. I believe that San Francisco and the Bay Area should be a leader in these issues and am dissappointed to learn of our government's current plans. We need a long term, sustainable solution to our growing water demands and the solution must be back by sound science, research and projections of our our water demand. Please reevaluate the environmental and economic consequences of your decision. Thank you for your time. 01

Draft PEIR: SF needs to conserve first!

ken king <exeditor2003@yahoo.com> **Mon, Oct 15, 2007 at 11:27 AM**
To: wsip.peir.comments@gmail.com
Cc: bill.young@sierraclub.org

Dear Paul Maltzer,

As a Californian born and raised here, I want to weigh in and say that conserving our natural resources, limited thought they might be, is vastly more important than engineering short term solutions that are costly and environmentally destructive. Therefore it is absolutely imperative that San Francisco pursue sustainable alternatives to diverting more water from the Tuolumne River. 01

I have read the draft and the arguments pro and con and know that you don't need to have them recited back, but I hope that you and your agency will go the extra distance to think creatively and economically, not to mention environmentally, in imagining the impact of your decison fifty and even one hundred years from now.

Thank you for your consideration of my comments,

Re: Comment period extended for DRAFT PEIR for SFPUC's Water System Improvement Program

John Howard Kramer <johnhkramer@gmail.com> **Thu, Oct 11, 2007 at 10:14 PM**
To: Diana Sokolove <wsip.peir.comments@gmail.com>

How convenient of you to provide this method of submitting a comment to the SFPUC. My comment is that this is a blatant water grab that has severe consequences for Tuolumne County, the rafting industry and ranchers. Have you adequately addressed and balanced the environmental impacts that will result from the economic stagnation brought about by this export of the water from the foothills? How can the fisheries survive? How can we continue to meet downstream commitments for healthy flows low in salt? The water you propose to take is put to maximum beneficial use now. 01

Why have you chosen a preferred alternative that is sure to encumber the project in legal wrangling, slowing the implementation of vitally needed seismic retrofits of the water delivery system? 02

COMMENT CARD

SFPUC's Environmental Impact Report of the proposed Water System Improvement Program

Written comments:

The focus of this report should be on seismic safety considerations. Seismic safety upgrades need to be undertaken ASAP. 01

* The evidence for taking an additional 25 million gallons of water per day is not warranted by the analysis presented. The current recommendations have many negative long-term environmental impacts. 02

Statistical time-series analyses used to forecast future needs can be simple or nuanced. The data analysis does not sufficiently take into consideration relatively recent developments in water conservation and recycling. 03 Also, the impact of global warming, which affects the annual snow pack which feeds our Sierra rivers and streams, is absent. 04

It appears that the equivalent of a butter knife, rather than a scalpel, has been used in the projections prepared. The planners should require more sophisticated data analyses, on which to base recommendations.

San Francisco Public Utilities
Commissioner Ryan L. Brooks

August 16, 2007

In 2002 I backpacked the Grand Canyon of the Tuolumne from White Wolf to Tuolumne Meadows. Three days and two nights. We did it too fast. I have not been back, but wish I would. That canyon --- !!!

Every year thousands go up there and have such a rich experience.

I have been to Kibbe Lake three times, and to Cherry Lake a few more than that. I may go this year to hike around Lake Eleanor.

I know you plan to divert below the dams,below Hetch Hetchy and Cherry Lake Reservoir. I think Cherry Lake area is dramatically underdeveloped! Sierra Club might not like to hear that, but it is greatly under-utilized for recreation. You might think of developing more of Cherry Lake, and drawing less water from it and the Tuolumne River.

Yosemite is marvelous, but it is too overused. Cherry could be a mecca of vacationers who want the boat, fish, hike, relax experience. It needs trails, and a lodge for visitors, and more camping areas north of the only camping area on the lake. One friend of mine took a kayak across the lake one year to camp with a group on the far shore and hike up the canyon.

I urge you to use conservation techniques for conserving water in the city of San Francisco. 01
Also, let me throw in a wild card, I urge you to vote for a tax on wealth in the U.S. A. This is the fairest, quickest method to establish aggregate demand (purchasing power) and keep our economy going. Fair distribution of wealth will do much to decrease the drain on our resources. Today, while riding my bike around Lake Chabot in San Leandro I thought of a plan for a general strike once a month, 12 times a year, with the purpose of studying our community. We would stop forging ahead in the wrong direction so quickly, develop informed democratic programs, distribute income and wealth more equitably, and have more inclination to travel to Hetch Hetchy and beyond. What wilderness will do for one's imagination. Send me a note, I'll send you an essay on A Wealth Tax to Eliminate Poverty. (See Milken Institute Review, 3rd Quarter, 2003, article by professor Edward Wolff, Where Has All the Money Gone?)

benleet@earthlink.net

Ben Leet

Sept. 20, 2007

To the S F Planning Commission:

I am writing to convey my concern with the idea of taking more water from the Tuolumne River. The environmental impacts that would occur as a result of extra water being diverted far outweigh the need for more lawns & suburban sprawl across the East Bay, the destination for 60% of the water. 01

I think this is a terrible mistake and a problem that can be solved in many other ways. You should instead focus your efforts on increasing water conservation and recycling programs. This is a far better alternative for the river, the environment, wildlife, our cities and us. 02

I truly hope that you take these public comments into serious consideration before you make the horrible decision that would affect all life in California for generations to come.

Sincerely,
Linda Lewin

I am very concerned with the proposed water grab from the Tuolumne River. The environmental impacts of this withdraw would far outweigh the "need" of sprawl across the East Bay for landscaping purposes.

Water conservation and recycling are much better options to help us meet increasing water demands. Even Los Angeles has managed to utilize these methods to keep their water demand flat in the face of growth. Let us continue to outshine smog and sprawl-ridden LA and pursue other alternatives to the water grab from the Tuolumne River.

Thank you very much for your time and consideration. 01

Tuolumne River

Bhushans@aol.com <Bhushans@aol.com> **Mon, Sep 24, 2007 at 1:20 PM**
To: wsip.peir.comments@gmail.com

Dear Mr. Maltzer, Protecting our rivers in California is a high priority. The Tuolumne River is threatened by the proposed increase in water diversion. The riparian habitat and pure water needed by wildlife and people can best be protected by increasing conservation efforts. There are many concerned environmentalists who want to work with you to find a win win solution to our shared concerns about water supply in this state. 01

One in particular, Peter Drekmeier, past founder of Bay Area Action (now Acterra) is one person who is thoughtful and willing to give you time, effort and assistance to bring about a conservation plan that will save the river, and bring ample water supply to our communities. I hope you will work cooperatively with Mr. Drekmeier and his associates to the benefit of the California riparian habitat, and cities and town that rely on an adequate water supply.

Thank you,

Judith LoVuolo-Bhushan

No Diversions From The Tuolumne! Conserve and recycle FIRST

1 message

Sf194122@aol.com <Sf194122@aol.com> **Mon, Oct 1, 2007 at 9:42 PM**
To: wsip.peir.comments@gmail.com

Mr. Maltzer:
I could not believe it when I heard about this wasteful plan being proposed by my own city, a city I moved to because I thought we were forward-thinking, environmentally conscious, and ethical.

I support alternatives that protect the Tuolumne from any new diversions. More water conservation, efficiency, and recycling are the intelligent and ethical ways to protect the Tuolumne and provide sustainable water for San Francisco and anyone to whom we sell water. Stop the sprawl, conserve, use intelligent means to retain local rainwater, and we and the East Bay would have enough water. 01

We can do much, much better than destroy the Tuolumne.

COMMENT CARD

San Francisco Planning Department
Draft Program Environmental Impact Report on the
SFPUC's Proposed Water System Improvement Program
Palo Alto, CA. September 19, 2007

Thank you for participating in tonight's public hearing on the Draft Program Environmental Impact Report (PEIR) for the San Francisco Public Utilities Commission's proposed Water System Improvement Program (WSIP). This is also an opportunity for you to submit written comments on the Draft PEIR for the proposed WSIP.

Written comments will be accepted through close of business on Monday, October 1, 2007. Written comments may be submitted in one of three ways:

1. Leave your written comments in the designated "Comment Box" tonight. These cards are provided for your convenience.
2. Mail your comments by October 1, 2007 to the San Francisco Planning Department, Attention: Paul Maltzer, Environmental Review Officer, WSIP PEIR, 1650 Mission Street, Suite 400, San Francisco, CA 94103
3. E-mail written comments to wsip.peir.comments@gmail.com

WRITTEN COMMENTS Write clearly and continue on back. Use multiple sheets if needed.

I am in full support of having an alternative plan of conservation and conservation outreach. We can save water by replacing lawns and sod growing operations with native plants that requiring significantly less water and no chemical fertilizers. Water recycling should 01

WRITTEN COMMENTS (Continued)

be mandatory for both residential, business and agricultural purposes. In this time of climate change we need sustainable plans for water usage - not dams. We should be offering rebates to people that replace their lawns with low or no water use landscapes. 01 cont.

To: wsip.peir.comments@gmail.com
Cc: bill.young@sierraclub.org

Dear Mr. Maltzer,

As you go through the process of evaluating changes to the water use plans please take serious our obligations to future generations. Please work to select a plan that is sustainable and far-sighted. The Tuolumne River and its watershed need to remain vibrant and flowing for future people to enjoy, not just for a few years more. We should require more conservation and better efficiency standards, recycling and other measures to reduce, or at least not increase, our take of this river system's gallons. 01

Sincerely,

James H. Marshall

Michael Martin, Ph.D.

September 26, 2007

Paul Maltzer, Environmental Review Officer
Water System Improvement Program PEIR
San Francisco Planning Department

Dear Mr. Maltzer:

I am a home owner in Tuolumne County, specifically in the Hetch Hetchy Subdivision, Block 5, Lot 2, Groveland. My home is on the Middle Fork of the Tuolumne River. I am a flyfisherman, as well as a professional fisheries biologist.

Your environmental review of the San Francisco Public Utilities Commission's plan to
consume (divert) more water from the Tuolumne River fails to adequately identify and
address all of the potential environmental impacts to the River, specifically how 14%
more diversions in the upper Tuolumne River basin with affect critical habitat in the
lower Tuolumne River, specifically spring-run Chinook salmon, fall-run Chinook
salmon, and Steelhead trout, along with potential impacts to the upper Tuolumne River 01
watershed. These federally recognized “threatened” or “species of concern” - designated
populations (ESU) will arguably require more water than less in future years. I urge you
to undertake additional studies of the lower Tuolumne River to provide protection and
enhancement of these depleted fisheries, before finalizing this document. There should
be no more diversions of the Tuolumne River at the expense of the San Joaquin River
Delta receiving water environment, period.

Your report shows that the majority of the potential future demand resides outside of San
Francisco. I recommend that you let those entities solve their water demand problems by
other means. Over ½ of the demand is outdoor water use and is a major cause for the
increased demand. Water conservation and efficiency measures, along with recycling, 02
should eliminate the need for additional future water supplies. There is uncertainty
regarding future increases in demand, as several demand factors in the analysis such as
projected growth, may have major challenges or be reduced because of economic
difficulties. As an owner in the upper river watershed, and I am concerned that increased 03
water diversions will reduce my property values, as well as my own, as well as tourists,
recreational opportunities. I am also concerned with the potential effects of atmospheric
shifts, such as global warming, and how that will affect (reduce) water supply. In
California, history has demonstrated how during critical water short years, full wet
weather deliveries continue for municipal and agricultural users, while natural resources 04
take the short end of the deal and brunt of the injuries and damages. Your feasibility
studies must include an analysis of the effects of drought and water shortage, and how

C_MartiM

San Francisco proposes substitute water demand (=supply) (i.e., reduced diversion from
the Tuolumne River) during those critical times. It is very clear that reduced water flows 04 cont.
in the San Joaquin River basin has resulted in seriously depressed recruitment of
anadromous Salmonid populations in the basin rivers.

I support all of the alternatives identified in your draft document that protects the
Tuolumne River from new diversions in future years. Requiring more water
conservation, efficiency, and recycling at the demand source is the best way to lessen
impacts to the Tuolumne River while promoting a sustainable water solution for the San
Francisco Bay Area. This will also afford more protection to the upper Tuolumne River 05
watershed fisheries and recreational usage. The San Francisco water scheme and power
generation operations have degraded the integrity of the downstream Tuolumne River
watershed. Further diversions will certainly maintain that degradation, and greatly limit
opportunities for restoration of those resources that depend upon the river. Your EIR
lacks sufficient description of the potential impacts upon the lower Tuolumne River,
especially with respect to anadromous fish populations, Chinook salmon and Steelhead
trout. It also fails to address consistency with on-going State and Federal resource 06
agency activities, studies, and actions that may be compromised by additional water
diversions in the upper Tuolumne River. I recommend that additional feasibility studies
and mitigation evaluation (and implementation where necessary) be included in your EIR
analyses, prior to adoption of the proposed water plan.

Only by reducing diversion and off-stream uses of water can we protect the anadromous fishes of the lower Tuolumne River and other San Joaquin River reaches, along with protecting the existing recreational fisheries of the upper Tuolumne River Watershed.

Sincerely,

Michael Martin, Ph.D.

PLANNING DEPARTMENT
M E A

Dear Sir,

I am writing to you about the upcoming review of the Hetch-Hetchy water system. Current operations are already a heavy burden on the Tuolumne River eco-system. It would be unconscionable to consider any further withdrawals from the river without first implementing all possible conservation measures which should include waterless urinals in all public buildings, a collection system for runoff falling on all impervious, man made surfaces, and a system that rewards residents and businesses for conserving more than the mean usage funded by charging those that use more than the mean. 01

Our rivers are treasures that are worth far more than their "usable" water. California's rivers are already heavily degraded by the projects of the 20th century. San Francisco has a reputation as one of the more environmentally conscious municipalities. It would be a shame to tarnish that by further degradation of the Tuolumne.

Please enter this letter into the offical comments.

Sincerely,
Jonathan McClelland

November 7, 2007

Paul Maltzer, Environmental Review Officer
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Dear Mr. Maltzer,

The environmental review performed by the San Francisco Public Utilities Commission to take more water from the Tuolumne River does not identify and address the environmental impacts of the river. There is a lack of information regarding the impacts of taking more water from the Tuolumne River. A lack of adequate baseline data of the Upper Tuolumne River does not provide an accurate picture of the outcomes of dewatering the Tuolumne. A new study was begun in 2006, however it was not completed in time to be part of the review process. Please take additional studies before finalizing this document. 01

Instead of taking water from the Tuolumne, I encourage you to take the alternatives in your draft document that protect the Tuolumne River from new diversions. These include more water conservation and water recycling. San Francisco is the leader in environmental action and your plan should parallel this trend. 60% of the Tuolumne River is already diverted for urban and rural uses and increasing diversion will do further harm to the river. Requiring more water conservation, efficiency, and recycling is the best way to lesson impacts on the Tuolumne River while promoting a sustainable water plan for the Bay Area. 02

Please protect this national treasure and make sure adequate water flow to the "T" keeps flowing.

Sincerely,

Karl McCollom

My husband and I have spent a great deal of time hiking, rafting and kayaking in and along the Tuolumne River (the "T"). We have introduced our children to this marvelous river – in the Yosemite back country, Tuolumne Meadows, and at sites well outside park boundries.

(over)

WRITTEN COMMENTS (Continued)

This river is vital to a healthy ecosystem in northern California.

The impact of diverting extra water from this river on the surrounding ecosystem far outweighs the ~~benefit~~ benefit that may be derived from the additional water to bay area residents. 01

The bay area water districts should be a model of conservation, grey water usage, and other recycling methods.

We have taught and will continue to teach our children how to reuse, recycle, and conserve. We want our utilities commissions to be equally dedicated to preserving and wisely using our natural resources.

Leave the river alone!! Any solution but river water. 01

C_Menuz

Sept 9, 2007

Dear Paul Maltzer

I am strongly opposed to taking more water from the Tuolumne River. Consumers will use all the water given to them, creating a never ending demand for more water. Instead, by limiting water consumers can be encouraged to conserve water & spur industry to develop water saving devices. 01

California's rivers need water to maintain natural environments. It is time to make a sustainable plan, instead of always trying to take more than we already have.

Sincerely,

Karen Menuz

C_Merlo

20 Sept 2007

I came to the planning commission meeting today to address the issue of taking even more water from the Tuolumne River. Since the item was moved on the agenda from 1:30 until 5:00, I am not able to stay.

Please consider this issue very carefully. 60% of the river's water is already being diverted. That leaves only 40% for what is refered to as "Mother Nature." There is an amazing wilderness between the Hetch Hetchy Dam and the San Joaquin River. You need to be at least as concerned about that wilderness as you are for future construction in the Bay Area. We as citizens can, and should, do more, ~~to~~ much more, to use that 60% of the river's water more efficiently. 01

Let the wilderness keep its 40%!

Paul Maltzer, Environmental Review Officer
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Dear Mr. Maltzer:

Your environmental review of the San Francisco Public Utilities Commission's plan to take more water from the Tuolumne River fails to adequately identify and address all of the environmental impacts to the River. I urge you to undertake additional studies before finalizing this document.

I believe we need to implement a mandatory landscaping policy that requires the installation of only native vegetation and drip irrigation technology to all new commercial projects going forward and provide tax-credits for existing commercial operations to change over to native vegetation. Google Inc. recently installed native plants in their corporate headquarters, so their project would provide a good case study for others to learn and model after.

Here are the benefits of Native Plants:

- Drought resistant
- Deer and bug resistant
- Disease resistant
- Requires less energy inputs
- Lower maintenance costs than traditional non-native landscaping 01

And here are some reasons why we cannot continue business as usual:

- Decreasing snow pack is predicted for the future due to global warming, which amounts to less water for drinking and irrigation for all Californians
- The state had its lowest water supplies this past year/winter
- The drought in Southern California will further exasperate the potential water crises by diverting more water from the Sierra's.

Some ideas to ponder….

When people deal with reality

- We have many options and choices to work with
- We have time to be proactive
- We can implement conservation and efficiency
- We have economic stability

When reality deals with people

- We have little or no options/choices
- *There will be* hard, difficult, sacrifices, shortages and severe economic consequences/hardships
- We have no time to be procative; we can only be reactive

C_Mijac

I support the alternatives identified in your draft document that protect the Tuolumne River from new diversions. Requiring more water conservation, efficiency, and recycling is the best way to lessen impacts on the Tuolumne River while promoting a sustainable water plan for the Bay Area. 01 cont.

Only by ensuring that healthy amounts of water continue to flow into the Tuolumne River can we protect this most irreplaceable natural treasure.

Sincerely,

Ivo Mijac

Tuolumne River

Bob Mindelzun <mindelzu@stanford.edu> **Sun, Sep 23, 2007 at 2:02 PM**
To: wsip.peir.comments@gmail.com

Paul Maltzer
Environmental Review Officer
San Francisco Planning Department

Dear Sir:

Like so many of my fellow citizens, I am extremely concerned about the SFPUC proposal to divert the 25 million gallons of water per day from the Tuolumne River.

Rather than diversion, this issue needs conservation and use of maximal efficiency for solution. 01

I urge you to support a reduced diversion from this Wild and Scenic River; a California Natural Treasure.

Thank you for your attention.

Professor Robert E. Mindelzun MD
Stanford University

Tuolumne River

Bob Mindelzun <mindelzu@stanford.edu> **Thu, Sep 20, 2007 at 6:11 PM**
To: wsip.peir.comments@gmail.com

from Naomi Mindelzun;
I am extremely concerned about the SFPUC proposal to divert the additional 25 million gallons of water per day from the Tuolumne River, and urge you to re-evaluate the SFPUC projections,and instead adopt a policy of reducing diversions from the river over time. 01
Please do not ignore conservation and efficiency measures in regard to this issue.
Thank you.

Comments on WSIP PEIR

Peter Neal <pneal1@mindspring.com> **Fri, Sep 21, 2007 at 1:20 PM**
Reply-To: pneal1@mindspring.com
To: wsip.peir.comments@gmail.com

Dear Mr. Paul Maltzer,

I wholeheartedly support the seismic upgrades and water system delivery improvements in the WSIP. These are necessary and urgent projects that need to be addressed without delay.

However, I am very opposed to the plan to divert more of the Toulumne River, and I do not believe the report adequately addresses the impact of this action. Nor have water conservation measures been properly evaluated and factored in to the plan to divert more Toulumne water. This beautiful wild river and its ecosystem should not be sacrificed to support water-hungry lawns, golf courses, and commercial landscaping. In fact, it seems incongruous and illogical to even include this recommendation in the WSIP. It is a conservation issue, not an infrastructure issue. 01

I strongly suggest that you decouple the Toulumne diversion plan from the rest of the WSIP. To include it is akin throwing out the baby with the bath water.

COMMENT CARD

San Francisco Planning Department
Draft Program Environmental Impact Report on the
SFPUC's Proposed Water System Improvement Program
Fremont, CA. September 18, 2007

Thank you for participating in tonight's public hearing on the Draft Program Environmental Impact Report (PEIR) for the San Francisco Public Utilities Commission's proposed Water System Improvement Program (WSIP). This is also an opportunity for you to submit written comments on the Draft PEIR for the proposed WSIP.

Written comments will be accepted through close of business on Monday, October 1, 2007. Written comments may be submitted in one of three ways:

1. Leave your written comments in the designated "Comment Box" tonight. These cards are provided for your convenience.
2. Mail your comments by October 1, 2007 to the San Francisco Planning Department, Attention: Paul Maltzer, Environmental Review Officer, WSIP PEIR, 1650 Mission Street, Suite 400, San Francisco, CA 94103
3. E-mail written comments to wsip.peir.comments@gmail.com

Phone or E-mail:

WRITTEN COMMENTS Write clearly and continue on back. Use multiple sheets if needed.

Thank you for providing this public hearing. As a Milpitas resident + consumer of Tuolumne River water I appreciate the need to update the system.

As a hiker in the Sierra I also appreciate wild + natural places. I hope the Tuolumne River will be kept in a healthy condition that will benefit fish, other wildlife + human recreation.

WRITTEN COMMENTS (Continued)

I try to conserve + recycle water as much as possible. I hope the SFPUC will pursue plans for conservation + recycling in order to prevent taking any more water from the Tuolumne River. I agree with the speakers at this meeting that our precious water should be used more wisely to prevent waste. 01

If we destroy our planet Earth we make it uninhabitable for human beings along with other life forms.

Sincerely,

Erna R. Nore

Tuolumne River water usage

1 message

Lola Noren <lnoren@sbcglobal.net> **Wed, Oct 10, 2007 at 12:21 PM**
To: wsip.peir.comments@gmail.com

Paul Maltzer, Environmental Review Officer
Water System Improvement Program PEIR
San Francisco Planning Department

Dear Mr. Maltzer:

Your environmental review of the San Francisco Public Utilities Commission's plan to take more water from the Tuolumne River does not adequately identify and address all of the environmental impacts to the River. I urge you to undertake additional studies of the Tuolumne River before finalizing this document. 01

I support the alternatives identified in your draft document that protect the Tuolumne River from new diversions. 02

Requiring more water conservation, efficiency, and recycling is the best way to lessen impacts to the Tuolumne River while promoting a sustainable water solution for the San Francisco Bay Area. 03

The public should have been steered down the conservation/sustainable use road long before this.

Personally, I think that agribusiness wastes a whole lot more water than the cities do; however, I think the usage by the city requires more energy resources to transport it to the tap, heat it for use, and then clean it before disposal. Therefore the issue must be addressed on two fronts, personal/company use and agribusiness uae. 04

In this day and age of technology, there are several major water savers that have not been implemented in society. Those along with cutting out the pork waste in agribusiness would go a long way towards easing up the burden on our limited water resources so that in the future, the only options left for water management are not negative ones 05

In the mean time, by ensuring that healthy amounts of water continue to flow into the Tuolumne River can we protect this irreplaceable natural wonder.

Please move water conservation to the top of the priority list where it should be!

Sincerely,

William W. Noren

WSIP PEIR comments

Margaret Okuzumi <okuzumi@silcon.com> **Fri, Oct 12, 2007 at 12:04 AM**
To: wsip.peir.comments@gmail.com

I am writing to provide comment on the WSIP PEIR. CEQA requires that the PEIR properly identifies and addresses the environmental impacts of the project. The PEIR must be amended to include information on baseline conditions of the Upper Tuolumne River. If a recent comprehensive study of baseline conditions is not available, then such a study must be conducted in order to provide per CEQA an accurate assessment of the environmental impacts of drawing an additional 25 million gallons a day from the Tuolumne River. 01

These impacts include impacts to fish populations such as Chinook salmon and steelhead; pollution in the San Francisco Bay Delta, and degradation in quality of recreational opportunities such as rafting. An alternative that includes of drawing an additional 25 million gallons/day from the Tuolumne cannot possibly be the environmentally preferable alternative when it supplies more water for growth than is planned for in local general plans. I am opposed to taking more water from the Tuolumne River. 02

Even given the flaws in the PEIR to date, it should be evident that the environmental superior alternative is one than requires water agencies to pursue additional water conservation and recycling instead of taking more water from this wild and scenic river. I have noticed a number of wasteful practices and waste of water in my local area such as companies that run sprinklers even when it's raining, and which have sprinklers that direct water onto the street or sidewalk instead of on to the landscaping. There is also much more that can be done to encourage consumers of all types to landscape so as to save water and virtually eliminate the need to irrigate, such as companies, individual homeowners, and homeowner's associations for condo and townhouse complexes where individuals may have more difficulty getting the association to implement water-wise gardening practices. Such an education program, such as the work that EBMUD has done, and other incentives to conserve and recycle, will ultimately prove more sustainable than relying on increasingly scarce water from the Sierras. 03

The PEIR must accurately identify impacts using realistic rather than inflated employment projections. The PEIR should identify as most environmentally preferable the alternative that emphasizes conservation and recycling over one that relies on consuming more of an ecologically precious resource, namely the water in a wild and scenic river.

Thank you for the opportunity to comment and your attention to these comments.

Sincerely,

Margaret Okuzumi

DO NOT TAKE PRECIOUS WATER FROM OUR RIVERS. THIS IS A SHORT SIGHTED SOLUTION TO A MUCH LARGER PROBLEM. AGRICULTURAL + INDUSTRIAL USE SHOULD BE REVIEWED, AND NOT SUBSIDIZED. LOOK AT THE MARKET, NOT JUST THE DEMAND. ENCOURAGE CONSERVATION & VALUE OUR WATER RESOURCES. 01

2530 San Pablo Avenue, Ste. I
Berkeley, CA 94702

Dear President Brooks,

With its headwaters in Yosemite National Park, the Tuolumne River is a national jewel that is home to an outstanding native trout fishery, bald eagles, black bears, and thrilling whitewater.

Unfortunately, instead of increasing water conservation and recycling efforts, the San Francisco PUC plans on meeting future water demand by taking more water out of the Tuolumne, a federally designated Wild and Scenic River. 01

I urge you to meet our water needs and protect the Tuolumne River for future generations through conservation and recycling rather than withdrawing more water and depleting the Tuolumne River.

The fate of the Tuolumne River rests in your hands.

Sincerely,

Anne Pagliarulo

Paul Maltzer, Environmental Review Officer
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Dear Mr. Maltzer:

I write as a concerned citizen as it relates to the Water Improvement Program (WIP) Program
Environmental Impact Report (PEIR). While the seismic upgrades are critical to maintaining the
water delivery infrastructure, I feel that the plan to divert additional water from the Tuolumne
River is premature. Given this clear distinction in the plan between the seismic upgrades and the 01
amount of water being distributed, it would be ideal to have the WIP split out in a way which
will provide an opportunity to approve each separately. This will allow for the seismic upgrades
to commence as soon as possible, while the environment impacts of additional diversions to meet
demand can be researched further.

Regarding the demand estimates and the plan to divert additional water from the Tuolumne, the
forecast seems to pay little attention to conservation measures as well as affects of price changes
on demand. It's surprising that only 4% of the demand is expected to be met with conversation
measures in light of the fact that an increase in per capital use is expected, with outdoor use 02
contributing 60% of the increase. This is counter to the trend in other metropolitan areas, as well
as the trend in the energy market to conserve. I encourage the SFPUC to challenge their
constituency to invest in conservation and recycling programs, similar to the drive in the energy
market. Why can't water supply and demand be managed in a similar way? Rebates, education 03
programs, scaled water rates that discourage waste, water credit trading, tax credits, recycling
programs etc., can all be effective tools to meet demand, and should be the focus of SFPUC
investment, not the diversion of more water from an already exploited resource. In addition to
unconvincing demand projections, there seems to be little known about the affects of additional 04
diversions on the Tuolumne River drainage ecosystem. A comprehensive study should be
required before additional diversions are approved.

I encourage the SFPUC to protect and restore our natural resources by exploring other options for meeting future water demand, rather then increasing diversions on the Tuolumne River.

Sincerely,

To whom it May Concern:

I am writing to take a stand against further environmental
impact, which would result from increasing the amount of
water taken from the wild and scenic Tuolumne River.
It is wrong-thinking to continue depleting our precious
and already strained natural resources, rather than to
enforce conservation, recycling and explore desalination 01
options. Not to mention educating people about the
grave danger to our planet from overpopulation.
Please save the Tuolumne River and the life
systems it supports!

Water Conservation and the Tuolumne River

jcpoulton@comcast.net <jcpoulton@comcast.net> **Wed, Sep 26, 2007 at 12:34 PM**
To: wsip.peir.comments@gmail.com

Paul Maltzer, Environmental Review Officer
San Francisco Planning Department
1650 Mission Street, Suite 400

Dear Mr Maltzer:

I believe that your environmental review of the San Francisco Public Utilities Commission's plan to take more water from the Tuolumne River is flawed. It appears that all you want is more water, not taking into question the impact on the river or the people that live on or near its banks. There appears to be no conservation in your plans. I urge you to take time for additional studies before implementing or finalizing this document. 01

I support the alternatives identified in your draft document that protect the Tuolumne River from future diversions. We need more consideration of ways to better and more efficiently use the water we have now.

Sincerely,

J. C. Poulton

Don't Let San Francisco Suck The Wild Tuolumne Dry!

Write a letter today to encourage the SFPUC to drop its proposal to divert more water from the Tuolumne and focus on water use efficiency and recycling to meet future water needs.

The San Francisco Public Utilities Commission (SFPUC) is pushing a "Water Improvement System Program" that proposes to divert an additional 25 million gallons of water daily from the Tuolumne Wild & Scenic River. San Francisco already diverts 60 percent of the river's water. The SFPUC "Improvement Program" could significantly reduce flows in the Tuolumne, which is one of the most popular whitewater and wild trout rivers in California. The SFPUC is using a flawed analysis that inflates future water needs, while underestimating how future needs could be met by increased water use efficiency and water recycling. 02

Please read the Key Points below, cut and past what you wish, add your own words, and send your letter to:
Paul Maltzer, Environmental Review Officer

Water System Improvement Program PEIR
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103
paul.maltzer@sfgov.org
Fax 558.6409

Key Points

Background

- From its headwaters in Yosemite National Park, the Tuolumne River cascades 162 miles before joining the San Joaquin River and flowing into the San Francisco Bay-Delta.
- The Tuolumne River supports a diverse biological community, including migratory waterfowl, raptors (including peregrine falcons and bald eagles), mule deer, black bears, foothill yellow-legged frogs, Sierra Nevada red fox, rainbow trout, steelhead and Chinook salmon.
- As the largest of three major tributaries to the San Joaquin River, the Tuolumne River contributes much-needed freshwater to the San Francisco Bay-Delta.
- The Tuolumne River offers unparalleled outdoor recreation opportunities, hosting thousands of hikers, whitewater boaters, anglers, and family campers each year.
- The Tuolumne was designated a Wild and Scenic River in 1984. 03

The Threat

- In total, about 60% of the Tuolumne River is already diverted for urban and rural uses, and increasing diversion will do further harm to the River.
- As part of its Water System Improvement Program (WSIP), the San Francisco Public Utilities Commission (SFPUC) has proposed diverting an additional 25 million gallons of water per day from the Tuolumne River.
- The SFPUC already diverts one-third of the Tuolumne River as it flows through Yosemite National Park.
- Outdoor water use alone is driving 60% of the anticipated increase in water demand.

Inadequate Studies/Flawed Analysis

- The Draft Program Environmental Impact Report (PEIR) used flawed modeling to determine the anticipated increase in water demand, thus inflating projected future needs.
- In contrast to other metropolitan areas that have managed to reduce water demand in the face of growth, the anticipated 14% increase in demand projected by the SFPUC is large and out of step for the Bay Area. 04
- The PEIR fails to properly identify and address all of the impacts of taking more water from the Tuolumne River. This failure largely stems from the lack of an adequate baseline study of the Upper Tuolumne River; a comprehensive study has not been conducted in over 15 years. A new study was initiated in 2006, but will not be completed in time to inform the environmental review process. 05
- The PEIR does not take into consideration the impact of climate change on precipitation in the Tuolumne River watershed. The State of California predicts that global warming could reduce the Sierra snowpack by 5% by 2030 and as much as 33% by 2060. 06

Conservation, Efficiency and Recycling

- Water conservation and efficiency measures are the cheapest, easiest, and least destructive ways to meet demand and extend supply.
- The SFPUC's "preferred alternative" ignores conservation, efficiency, and recycling measures that their own studies found could eliminate the need to divert more water from the Tuolumne by at least 74%. 07
- Per capita water use is projected to increase for wholesale customers, indicating they lack effective conservation programs.
- When it comes to water conservation, the Bay Area lags far behind other metropolitan areas such as Seattle and Los Angeles that are reducing water consumption even in the face of growth. As a

C_Raffa

region known for a strong environmental ethic, the Bay Area should be a leader in water efficiency and conservation. 07 cont.

Other Points

- Decreasing reliance on the Tuolumne is critical not only for protecting the health of the River, but also for preparing for the future uncertainty of the Sierra snowpack as a result of global warming. 08
- By pursuing a plan to divert additional water from the Tuolumne River, the SFPUC risks delaying their capital program, causing cost overruns and failing to increase the reliability of the water supply. 09

Recommendations

- The SFPUC should re-evaluate its projections for future water demand and conservation potential in light of flaws and inaccuracies in their studies. 10
- The SFPUC should conduct a study to determine the maximum technical potential for conservation and efficiency savings within the SFPUC service territory.
- Any additional demand should be met through increased investment in conservation, efficiency, and recycling. 11
- The SFPUC should adopt a policy of reducing diversions from the Tuolumne River over time. 12
- A comprehensive watershed study should be completed to adequately assess the environmental impacts of the WSIP. 13

Learn More

- Visit the Tuolumne River Trust website at http://www.tuolumne.org/
- The Draft EIR is available at www.sfgov.org/site/planning_index.asp?id=37672 (Scroll down to "Public Utility Commission (PUC) Projects: SF PUC Water System Improvement Program DPEIR.")

WRITTEN COMMENTS Write clearly and continue on back. Use multiple sheets if needed.

Without a doubt S.F. will need more water for a growing ~~area~~ population. However, there is a definite limit to how much can be drawn from the Tuolumne & still have a river. So make plans for more water conservation including desalinazion & reclaiming waste water which is much ~~to~~ less expensive. No more river water! 01

Environmental Review Officer, WSIP PEIR
San Francisco Planning Dept.

Dear Environmental Review Officer,

I would like to comment on the draft Program EIR for the SFPUC's $4.3 billion water system upgrade. The Program EIR indicates that additional diversions could result in damage to fisheries and sensitive riparian habitat, increased pollution problems in the S.F. Bay Delta and diminished recreational opportunities. I therefore urge that San Francisco protect the Tuolumne River for future generations by requiring water conservation, efficiency and recycling to the maximum extent possible to eliminate or greatly reduce the need for additional diversions from the river. Also, San Francisco should pursue a sustainable water plan that will fully protect the watersheds of the Bay Area and the Sierra Nevada. 01

Thank you.

WRITTEN COMMENTS Write clearly and continue on back. Use multiple sheets if needed.

I grew up in the Bay Area and moved to Tuolumne County 5 years ago. I have a deep pride in the progressive values of the Bay Area, and am shocked that cities like LA, Boston, and Seattle are besting SF in water conservation and reuse. I know the Bay Area can lead in this arena if the political will follows the heart values of the people who live there and develops the means to let them. thank you. 01

Richardson, Matt - SFMH <Matt.Richardson2@chw.edu> **Thu, Sep 6, 2007 at 12:28 PM**
To: "wsip.peir.comments@gmail.com" <wsip.peir.comments@gmail.com>
Cc: "matt_richardson@hotmail.com" <matt_richardson@hotmail.com>

Hello,
My comments are simple

1. no increase in water removal from the Tuolumne river. 01
2. increase marketing/public awareness programs to reduce/conserve water use (current programs are insufficient) 02
3. increase water recycling 03
4. NO new dams in California - old technology, and there isn't enough water in the rivers anyway 04
5. if you're wanting reliability - it's time for De-sal 05

Thank you,
Dr. Richardson

Subject SAVE THE TUOLUMNE RIVER

Dear Paul,

I sincerely appreciate you taking the time to understand the possibilities of enough water for everyone be they SF area customers and river users both human and fish. It is a disgrace that San Francisco has rested on it's laurels of Hetch Hetchy and the Tuolumne and now lags behind the nation in even minimal water conservation. More, more, more is not the answer...we are past that point of simplistic thought in environmental concerns. I urge you to Step Up to a new world of possibility and responsibility.

Background

- From its headwaters in Yosemite National Park, the Tuolumne River cascades 162 miles before joining the San Joaquin River and flowing into the San Francisco Bay-Delta.
- The Tuolumne River supports a diverse biological community, including migratory waterfowl, raptors (including peregrine falcons and bald eagles), mule deer, black bears, foothill yellow-legged frogs, Sierra Nevada red fox, rainbow trout, steelhead and Chinook salmon.
- As the largest of three major tributaries to the San Joaquin River, the Tuolumne River contributes much-needed freshwater to the San Francisco Bay-Delta.
- The Tuolumne River offers unparalleled outdoor recreation opportunities, hosting thousands of hikers, whitewater boaters, anglers, and family campers each year. 01
- The Tuolumne was designated a Wild and Scenic River in 1984.

The Threat

- In total, about 60% of the Tuolumne River is already diverted for urban and rural uses, and increasing diversion will do further harm to the River.
- As part of its Water System Improvement Program (WSIP), the San Francisco Public Utilities Commission (SFPUC) has proposed diverting an additional 25 million gallons of water per day from the Tuolumne River.
- The SFPUC already diverts one-third of the Tuolumne River as it flows through Yosemite National Park.
- Outdoor water use alone is driving 60% of the anticipated increase in water demand.

Inadequate Studies/Flawed Analysis

- The Draft Program Environmental Impact Report (PEIR) used flawed modeling to determine the anticipated increase in water demand, thus inflating projected future needs. 02
- In contrast to other metropolitan areas that have managed to reduce water demand in the face of growth, the anticipated 14% increase in demand projected by the SFPUC is large and out of step for the Bay Area.
- The PEIR fails to properly identify and address all of the impacts of taking more water from the Tuolumne River. This failure largely stems from the lack of an adequate baseline study of the Upper Tuolumne River; a comprehensive study has not been conducted in over 15 years. A new study was initiated in 2006, but will not be completed in time to inform the environmental review 03

process. 03 cont.

- The PEIR does not take into consideration the impact of climate change on precipitation in the Tuolumne River watershed. The State of California predicts that global warming could reduce the Sierra snowpack by 5% by 2030 and as much as 33% by 2060. 04

Conservation, Efficiency and Recycling

- Water conservation and efficiency measures are the cheapest, easiest, and least destructive ways to meet demand and extend supply.
- The SFPUC's "preferred alternative" ignores conservation, efficiency, and recycling measures that their own studies found could eliminate the need to divert more water from the Tuolumne by at least 74%. 05
- Per capita water use is projected to increase for wholesale customers, indicating they lack effective conservation programs.
- When it comes to water conservation, the Bay Area lags far behind other metropolitan areas such as Seattle and Los Angeles that are reducing water consumption even in the face of growth. As a region known for a strong environmental ethic, the Bay Area should be a leader in water efficiency and conservation.

Other Points

- Decreasing reliance on the Tuolumne is critical not only for protecting the health of the River, but also for preparing for the future uncertainty of the Sierra snowpack as a result of global warming. 06
- By pursuing a plan to divert additional water from the Tuolumne River, the SFPUC risks delaying their capital program, causing cost overruns and failing to increase the reliability of the water supply. 07

Recommendations

- The SFPUC should re-evaluate its projections for future water demand and conservation potential in light of flaws and inaccuracies in their studies. 08
- The SFPUC should conduct a study to determine the maximum technical potential for conservation and efficiency savings within the SFPUC service territory. 09
- Any additional demand should be met through increased investment in conservation, efficiency, and recycling.
- The SFPUC should adopt a policy of reducing diversions from the Tuolumne River over time. 10
- A comprehensive watershed study should be completed to adequately assess the environmental impacts of the WSIP. 11

Learn More

- Visit the Tuolumne River Trust website at http://www.tuolumne.org/
- The Draft EIR is available at www.sfgov.org/site/planning_index.asp?id=37672 (Scroll down to "Public Utility Commission (PUC) Projects: SF PUC Water System Improvement Program DPEIR.")

Dear SFPUC,

I was born in San Francisco, raised in San Carlos, educated at UC Davis, and I have worked and lived in Tuolumne County since 1976. I lobbied against the New Melones Dam Project not because I do not believe in hydropower, but for all of the ill-fated and unsubstantiated reasons attached to that project. Thousands of people in and around Tuolumne County ache from the loss of an incredible river flow, with accompanying educational, recreational and functional resources. I said then and I will say again, let us look at *how* we manage water -- usage and conservation, lifestyle, appropriate-for-the-environment/climate residential and commercial landscape, and local and statewide community policy addressing these vital- to-our-lives concerns. I wholeheartedly concur with the statement provided you by the California Department of Fish and Game: 01

"...it is irrefutable that the actions of the SFPUC on the Tuolumne River at Early Intake, Cherry Valley Dam, and Hetch Hetchy, and Lake Eleanor reservoirs influence the water releases from the New Don Pedro Dam. Increased diversion of waters from a river system which currently lacks sufficient flow to support sustainable anadromous fisheries (including Federally Threatened steelhead) should be considered a significant cumulative impact...In this context we believe the WSIP has the potential to cause anadramous fish populations to drop below self-sustaining levels and further reduce the number and restrict range Federal Threatened Central Valley steelhead – thereby requiring a finding of significant effect [CCR Title 14, section 15065 (a)(1)]. Given the dramatic decline in Tuolumne River salmon adult escapement between 2000 and 2006; we believe that if implemented as proposed, the WSIP would only exacerbate the current decline of anadromous fisheries in the Tuolumne River. Consequently, we respectfully request that the SFPUC use alternative water sources other than the Tuolumne river system or implement water conservation measures to meet drought year demands and 2030 purchase requests..." 02

Respectfully,

Trish Rowe

09/22/2007 12:45 PM	Subject	Tuolumne water diversion

Dear Mr. Maltzer:

It has come to my attention that the San Francisco Public Utilities Commission (SFPUC) is pushing a "Water Improvement System Program" that proposes to divert an additional 25 million gallons of water daily from the Tuolumne Wild & Scenic River. San Francisco already diverts 60 percent of the river's water. The SFPUC "Improvement Program" could significantly reduce flows in the Tuolumne, which is one of the most popular whitewater and wild trout rivers in California. The SFPUC is using a flawed analysis that inflates future water needs, while underestimating how future needs could be met by increased water use efficiency and water recycling. 01

The Tuolumne was designated a Wild and Scenic River in 1984. Surely this plan will severely impact it and the wildlife that depend upon it. The proposal seems more in keeping with the thinking of the 50's than current times, which look for recycling and water efficiency use to lessen the impact on our free ranging rivers. 02

I urge you to focus on these last means to provide water to your residents, rather than drawing off more water and threatening this magnificent river. Reclamation and reduced usage are what we are successfully using in our area to meet our water needs, as river flows are needed more and more to protect habitat and fish populations.

Sincerely,

Judy Schriebman

Dear Commissioner Brooks,

It is an enviromental absurdity to pull more water from the Tuolumne River. The enviromental effects would be devastating, and unneeded. The futility of this destruction is too much to bear for the concerned residents of San Francisco. As other cities such as Seattle and Los Angeles can learn to conserve so can we. I'll see you at the hearing. 01

Sincerely,
Kelly Shea

COMMENT CARD

San Francisco Planning Department
Draft Program Environmental Impact Report on the
SFPUC's Proposed Water System Improvement Program
Modesto, CA. September 6, 2007

Thank you for participating in tonight's public hearing on the Draft Program Environmental Impact Report (PEIR) for the San Francisco Public Utilities Commission's proposed Water System Improvement Program (WSIP). This is also an opportunity for you to submit written comments on the Draft PEIR for the proposed WSIP.

Written comments will be accepted through close of business on Monday, October 1, 2007. Written comments may be submitted in one of three ways:

1. Leave your written comments in the designated "Comment Box" tonight. These cards are provided for your convenience.
2. Mail your comments by October 1, 2007 to the San Francisco Planning Department, Attention: Paul Maltzer, Environmental Review Officer, WSIP PEIR, 1650 Mission Street, Suite 400, San Francisco, CA 94103
3. E-mail written comments to wsip.peir.comments@gmail.com

CONTACT INFORMATION

Name: Ann C. Sloan / Ron Sloan

Affiliation: resident of Tuolumne County

Address: 23949 Quaker Lane

MEA

September 26, 2007

Paul Maltzer, Environmental Review Officer
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Dear Mr. Maltzer,

I am writing to urge you to address the environmental impacts of diverting water from the Tuolumne River.

As a resident of the Bay Area for over 45 years, I grew up drinking Hetch Hetchy water and I understand both its quality and value. As a youth I saw the Tuolumne River firsthand, by raft and foot, and know it as a raw and wild scenic treasure that would likely suffer irreparable damage from additional water diversion. As a former park ranger in Yosemite National Park, I understand the need for a wise use policy that balances the needs of people and the requirements of healthy ecosystems.

I cannot, in good conscience, allow the Tuolumne River's natural wonders and resources to be lost due to lack of foresight, for my daughter and all generations to come. Enjoying natural places like the Tuolumne River are *what* we live for, using them wisely is *how* we protect them. Let's not waste its water on unsustainable and inappropriate uses.

While I support the need for seismic upgrade to Hetch Hetchy Dam, I implore you to further study the potential to the Tuolumne River and commit to water conservation, recycling, and efficient use as the best solution to creating a sustainable water plan for the SF Bay Area. 01

Sincerely,

Evan Winslow Smith

Tuolumne River Water Theft

Mjandpasmith@aol.com <Mjandpasmith@aol.com> **Sun, Sep 30, 2007 at 12:52 AM**
To: wsip.peir.comments@gmail.com, letters@mercurynews.com, grmjam@goldrush.com, mike.honda@mail.house.gov, senator@boxer.senate.gov, Feinsteinpress@
Cc: Mjandpasmith@aol.com

Cut the waste! Especially, cut the tremendous waste by agribiz that exceeds all other water wastage combined, even as they use a majority of California's water. Right now the plan is to give them the Tuolumne River, as we've done with other rivers in the past and more to come.

We don't have to shut down the truck farms or orchards. Just stop growing rice and cotton and alfalfa where it should not be grown. Do that by charging farm water rates that are closer to real costs, and not a huge subsidy carried on the backs of industry and California's householders. 01

Look, farmers are a tiny minority of Californians and get laughably minute productivity from water they use, compared to business, industrial, and residential users. Start weaning the handful of millionaire farmers from the taxpayers' teats. They could be encouraged to grow a different crop mix in a less wasteful way and still make their millions. But they won't do that if we just roll over and give them a bigger share of the water while they waste enough water to wash every CA car and driveway daily.

Please, don't just pee away the Tuolumne to further enrich the alfalfa barons.

Paul Smith, Los Gatos and Twain Harte

Dear Mr. Maltzer,

I am writing to comment on the Draft PEIR for the WSIP. I take no issue
with the analysis of the proposed seismic upgrades. But I see no need to bundle
into this upgrade program a proposal to increase diversions from the Hetch Hetchy 01
System. And in rushing to tack onto the retrofit an additional diversion, I believe
the Environmental Impact Report falls short of what is necessary. I believe the
report uses flawed modeling to inflate future water demands and understates the
efficacy of conservation. The PUC's own studies show that conservation 02
measures could easily eliminate three-quarters of the need for any increased
diversion. And I believe the discussion of potential impacts of global warming on
the Tuolumne's future flows is inadequate. The discussion defers global warming
impacts to a period beyond the purview of the project and shrugs off impacts as
being "within the same range that occurs under both the existing and proposed 03
operations and management of the system" – a range which includes of course
drought year levels which, spread out over years or decades by global warming,
would have devastating impact on fish and wildlife. More study of the upper
Tuolumne River is needed before effects can be adequately assessed. Climate
change could also cause increased diversions from the Tuolumne to have 04
significant impacts on the health of the Sacramento Delta and San Francisco Bay.

Sincerely,

Peter Steinhart

1650 Mission Street, Suite 400
San Francisco, CA 94103

September 26, 2007

Dear Mr. Maltzer:

I am writing you in regards to the environmental review of the San Francisco Public Utilities Commission's plan to take
more water from the Tuolumne River. I urge you to carry out additional studies before finalizing this report so that all 01
of the environmental impacts of this plan are taken into account.

Diverting additional water will have serious impacts on the ecology of the Tuolumne River watershed. More efforts
should be focused on exploring more sustainable alternatives mentioned in your report such as water conservation,
efficiency, and recycling. These methods have been shown to help reduce water demand in other metropolitan 02
areas. Not only will this help protect this valuable and awe-inspiring watershed but it will also help us decrease our
reliance on a water source that may not provide the amount of water it once did due to global warming.

Thank you for your time,

Marc Sugars

Tuolumne River

1 message

Karen Sundback <sundback@sbcglobal.net> **Mon, Oct 1, 2007 at 8:24 AM**
To: Paul Maltzer <wsip.peir.comments@gmail.com>

Mr. Maltzer,

The Tuolumne River Diversion Debate is a tough one. Presently this portion of Tuolumne River feeds the Delta. California voters rejected a peripheral canal around the Delta in 1982. Now that Governor Schwarzenegger is taking a different approach from his own blue ribbon water panel and is supporting the peripheral canal, who gets water rights to this portion of the Tuolumne River if the peripheral canal gets the okay? 01

Many of us would like to save the Tuolumne River. However, with the peripheral canal looming in the background, this becomes a more difficult issue.

Thank you for your consideration.

San Francisco, CA 94103

September 20, 2007

Paul Maltzer,

I do NOT want the SFPUC to accept the current Draft PEIR for SFPUC's Proposed Water System Improvement Program. I was at the Public Hearing on this issue in Palo Alto last night, September 19, 2007, and am strongly opposed to this Draft PEIR.

I demand the SFPUC separate two issues that are now combined in the current Draft PEIR. Separate:

1) Seismic Upgrades of the water delivery system, which is obviously needed, from

2) The plan to divert an additional 25 million gallons per day more of the Tuolumne River, which has NOT been accurately studied, planned, and addressed and is environmentally unsound.

The above are two separate environmental issues inappropriately joined into one single Draft Program Environmental Impact Report. 01

I demand that the SF Public Utilities Commision:

1) Reject the current Draft PEIR.

2) Separate these two SF water supply issues: Seismic Upgrades and Increased Tuolumne River Usage.

3) Create two new Draft PEIRs, one for each issue.

4) Have two NEW public hearings on each separate issue.

SFPUC, Reject this Draft PEIR!

Subject Tuolomne River "Improvement Program"

Dear Sir:

I am writing to urge the SFPUC to drop its proposal to divert more water from the Tuolumne River.

Decreasing reliance on the Tuolumne is critical not only for protecting the health of the river, but also for preparing for the future uncertainty of the Sierra snowpack as a result of global warming.
Instead of proposing more water withdrawals from the Tuolumne, The SFPUC should adopt a policy of reducing diversions from the Tuolumne River over time. 01
In adopting such a policy, the SFPUC should conduct a study to determine the maximum potential for conservation and efficiency savings within the SFPUC service territory. Any additional demand for water within its territory should be met through increased investment in conservation, efficiency, and recycling.
Thank you for working to protect the Tuolomne River by reducing water withdrawals over time. 02

PEIR comments - no more water from Tuolumne.

Tibor Toth <TToth@hilmarcheese.com> **Tue, Sep 4, 2007 at 4:12 PM**
To: wsip.peir.comments@gmail.com

I am writing to express my concern over taking more water from the Tuolumne river to pursue more water for the Bay Area.

While I understand the need to provide fresh water to a growing community, there is also the responsibility of the community to get the water with a minimal impact to the environment in a sustainable fashion. The bottom line is the Delta and River basin has long suffered from a lack of water which has resulted in high salt levels in the Valley. 01
The delicate balance in one of the world's most productive farming community is being hurt by the urban sprawl which has outgrown its natural resources.

A better and sustainable, although more expensive, solution is to use membrane technology to use sea water for fresh water. This technology has been well proven and is economically feasible with an increase in use tax for the people that need the water in the Bay Area. The energy to run the pumps can be utilized from wind and tide power that is also locally available and renewable. This forces the Bay Area communities to see where their water is growing instead of just relying on taking the snowfall in the Sierra's. And remember, if there's a drought in the Bay Area, there's the same drought in the Sierra's. Stealing from the Tuolumne River is not a solution, it's a bad environmental loan. 02

You can not continue to steal the water from the Delta so you don't have to pay as much money to fuel the Bay Area's growth. The Bay Area is a huge economic power - use that power to invest in their own water. Countries all over the world use thousands of membrane units to deliver clean water. There is no reason that the Bay Area shouldn't do the same.

Dear Paul / Environmental Review (SFPUC),

I'm a resident and homeowner in unincorporated Redwood City, and I'm writing to ask you to improve SFPUC's Water Supply Improvement Plan. Thanks for working on this, thinking ahead and preparing a draft Environmental Impact Report. However SFPUC's water plan is based on inflated projections, and does not do enough to protect the Tuolumne River and other watersheds. 01

Please make plans for more conservation and creative reuse of water, and rely less on drawing water from the Tuolumne River. As we can see this year already, the snow pack is likely to be more variable due to climate change and the ecosystems in the mountains and in the Bay ARea will be more stressed by climatic extremes. The fish and the plant life (which protect the watersheds and help filter rainwater) need the water more than we do. The correct response is more conservation and careful use of water, not higher use of river water. A more diverse mix of supplies will reduce risk for us and reduce stress on ecosystems . 02

I don't believe that the population will increase significantly in this area because the housing prices are too high, and salaries are not keeping up. I can only afford my house because we bought 10 years ago. Those who do move here are likely to be in more dense housing which won't need so much water for landscaping. 03

There is much that can be done by individuals, businesses and municipalities to conserve water. I'm happy that Redwood City has taken proactive steps such as offering low-water toilets free. I urge you to use your clout by insisting on aggressive water conservation measures and watershed protection, now - before climate change worsens the situation. THis will also save money for everyone. 04

Sincerely,

I am writing today in response to the proposal to take vast volumes of water from the ~~too Fo~~ Tuolumne River. The idea that we will dry up this wild and scenic river to feed east bay sprawl is appalling. The cities of the east bay can supply their water needs through conservation and improved engineering.

Other cities such as Seattle and Los Angeles have done this. They have achieved growth rates the east bay desires while keeping water usage flat. There is no reason that an area as innovative and rich as the bay area cannot do the same. We're every bit as smart, sensible, and resourceful as they are.

Instead we are proposing to draw down one of the very natural wonders that draws people to this area of the country. We are choosing to do so at a time when our snow pack is being depleted and flows will be declining. We can make a wiser choice. We can choose to ~~preserve~~ conserve and apply sound engineering to preserve the river for our own ~~F~~ old age, for our children's lives, and for future residents of this region. We are not consumers of today. We are ~~gu~~ guardians of tomorrow's Future

01

DEAR COMMISSIONER BROOKS

01 I WRITE THIS LETTER IN ORDER TO PLEASE ASK YOU TO NOT PULL OUT ANY MORE WATER FROM THE TUOLUMNE RIVER. THINK ABOUT YOUR FAMILY AND FRIENDS! WOULD YOU LIKE TO LIVE IN A CITY OR COUNTRY WHERE YOU HAD BARELY ANY WATER?? I DON'T THINK SO, SO THINK ABOUT IT AND DON'T DO IT.

SINCERELY,

[signature]

P.S... SEE YOU AT THE HEARING!!

Dear Commissioner Brooks,

01 The tremendous amount of water that is demanded by residents is ridiculous. The Tuolumne River is one of the most important water sources and trying to siphon more water out of it, especially for a reason such as watering plants and their lawns, is absolutely absurd. People who 'need' ~~water~~ perfectly good drinking water to water their lawns ~~are~~ obviously don't appreciate the people around us and our environment. ~~There are so many individuals out there~~ everything needs water to survive. What happens when we have a shortage in it? Please do NOT let water out of the Tuolumne River. ~~Are~~ Just think about it. Why give it to people who just need it to grow a single, dirty ~~flower piece of~~ patch of grass when you can use it the right way ~~&~~ use it when you really need it. Give it to those who really need it. Make the right decision.

Sincerely,

C_Unreadable4

August 15, 2007

To Commissioner Ryan L. Brooks, President of San Francisco Public Utilities Commission.

I recently was informed of the plan to take 25 million gallons of water out of the Tuolumne River. I feel this is such an opsered plan due to the fact that the water will not be used for drinking but to water lawns in four countres. There are so many other way we can water lawns such as using recycled water. With such a huge water crisis at hand in California I do not feel pulling out more water is the ausuer. I strongly opose this plan. 01

Paul Maltzer, Environmental Review Officer
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Dear Mr. Maltzer:

I am a whitewater rafter who travels to California every May and August to take advantage of the unequaled recreational opportunities of the Sierras, California's National Parks, and of course, Yosemite and the Tuolumne River. My love for the Tuolumne goes back over 30 years when my family took a vacation to Yosemite and we drove to Tuolumne Meadows. Even back in the summer of 1975 when I was only 10 years old, I was struck by the river's beauty in this beautiful meadow. One of my strongest memories of childhood family vacations is stepping into the gentle waters of the Tuolumne as it meandered across the highway while waiting for my father to secure backcountry hiking permits for us before our week long hike along its banks to its source.

I have returned often to that special place known as Tuolumne Meadows, and often I have repeated that backcountry hike. More recently, I have become a whitewater enthusiast. I have rafted the Tuolumne over a dozen times, including the Class V Cherry Creek Section. The Tuolumne River is a very special river to me, as it is to million of others who have visited it and to those countless millions who depend on it to provide them with drinking water. However, I don't believe the Tuolumne can support any more than it already does.
Your environmental review of the San Francisco Public Utilities Commission's plan to take more water from the Tuolumne River fails to adequately identify and address all of the environmental impacts to the River. I urge you to undertake additional studies before finalizing this document. 01

I support the alternatives identified in your draft document that protect the Tuolumne River from new diversions. Requiring more water conservation, efficiency, and recycling is the best way to lessen impacts on the Tuolumne River while promoting a sustainable water plan for the Bay Area. 02

Only by ensuring that healthy amounts of water continue to flow into the Tuolumne River can we protect this irreplaceable natural treasure.

Even though I currently live in North Carolina, I am a member of the Tuolumne River Trust Organization, and I hope you take my comments into consideration as seriously as those who live in San Francisco, the Bay Area, and the rest of California.
Sincerely,

Matthew S. Urdan

Comment on SFPUC's Proposal

Paul Vadopalas <paulvadopalas@california.com> **Mon, Oct 1, 2007 at 3:33 PM**
To: wsip.peir.comments@gmail.com

I attended Public Hearing on September 19, 2007 in Palo Alto at Avenidas.

My comments are:

Given the projected population growth, requirements for additional water will never cease . The availability of water is limited. We do not have the ability to create glaciers or snow-packs in the Sierras. We cannot damn more rivers, or pump more water from the existing water table without hurting or destroying our ecological system and economic base. The only way to produce drinkable water is by building desalination plants. This is the reality all public utilities in California will face.
Lets leave the few remaining untamed rivers alone, and apply technology to solve our projected water shortage problems. 01

Respectfully,

Paul Vadopalas
829 Northampton Dr.
Palo Alto, CA 94303

Tuolumne River water plan

Jim Vermeys <jimmypaul@jps.net> **Sun, Sep 30, 2007 at 11:01 AM**
To: wsip.peir.comments@gmail.com

Dear Mr. Maltzer:

I have been enjoying benefits of the Tuolumne River my entire life (46 years). I have fished, camped, rafted, watched my brother get married standing next to it, swam, hiked, lived and loved in, on and around that river. I urge you to take a better look at the environmental impact your plan would have on my favorite river. 01

Please consider better water conservation, efficiency and an improved recycling program rather than take water from the Tuolumne.

Thank you.

Jim Vermeys
Martinez, CA

Tuolumne River

Karen Vermeys <kvermeys@sbcglobal.net> **Mon, Sep 24, 2007 at 4:45 PM**
To: wsip.peir.comments@gmail.com

We are annual campers of Berkeley Tuolumne Camp, and in all the many, many years I've been a Tuolumne camper, I have never seen our river so low!

Therefore, I am very much against using water from the Tuolumne River. Please reconsider to ensure that the water level will go no lower than it is now (which actually would be dry!). 01

Thank you,

Karen Vermeys

C_Voyik

August 15, 2007

Dear Commissioner Brooks,

With all of the water problems and issues we are having in California, why would you let this plan pass? Just imagine: If you pass this plan, our clean drinking water will be used on something that would not be affected by recycled water. People need clean water, not plants. Do not get me wrong, plants need clean water to an extent, but not as bad as humans. Just think - you don't want to be worrying about your water! Think about it! If you extract more water from the Tuolumne, it will be left dry eventually. Don't do it! Be the bigger man! 01

Sincerely,
Ashleigh Voyikes.

To whom it may concern:

I am writing today to express my opposition to the Public Utilities Commission's plans to take more water out of the Tuolomne River. I feel these plans are not in our best interest for several reasons, but I wish only to express two of them in writing.

First, we are facing the very real possibility of a drought, and as such, we have ~~the~~ a responsibility to the future not to increase water consumption. We should instead focus more energy toward water conservation and water recycling. If Seattle & Los Angeles can meet their increased water demand without using more water, so should we here in the Bay Area. 01

Secondly, this river is beautiful, and home to diverse wildlife. We should not do anything to harm this area. 02

-over-

12.5-100

C_Vrana

I hope you will take the proper steps to make the Bay Area a leader in water conservation. 02 cont.

San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Draft PEIR – Hetch Hetchy Infrastructure Upgrade

Dear Mr. Maltzer:

The purpose of this letter is to comment on proposals to increase water supplies as part of the seismic upgrade to the Hetch Hetchy system.

I live in Menlo Park and am a user of Hetch Hetchy water. I also spend significant time walking and birdwatching around the San Francisco Bay and hiking and backpacking in California's mountains and wilderness areas.

12.5-101

I have been aware for a long time that the SFPUC is many years overdue in maintaining and upgrading the Hetch Hetchy delivery system infrastructure, and I applaud the PUC for embarking on the seismic upgrade so necessary to ensure a reliable water supply. However, I am concerned that the PUC is considering additional projects, i.e., stream diversion and increasing water supplies, as part of the seismic upgrade and maintenance project. Developing new sources of drinking water as part of this project is ill-advised. 01

The draft Program Environmental Impact Report (PEIR) is flawed in many respects, including:

- Additional water supplies are outside of the scope of the long overdue maintenance project. We the water customers do not want any further delays on the maintenance project. 01 cont.

- Water customers will be incurring significant increases in water bills for the purpose of securing and maintaining the present source of water. We do not want to pay for legal battles to be incurred because the PUC is adding an additional task of diverting more water from a wild and scenic river.

- It is no longer disputed that global climate change is occurring and that citizens and government agencies must take immediate action to adjust to that reality. It is not disputed that last winter's rains were below average. This reality requires SFPUC to undertake immediate conservation measures. 02

C_Walke

- Even without global warning and the current low rainfall concerns, California should have been implementing strong water conservation measures since the last drought. Significant areas of California have a desert climate, but Californians use water as it were an unlimited resource —lawns, tropical flower gardens, flood irrigation, large-scale commodity agriculture instead of food production. Californians have shown a lack of political will with regard to mandatory water conservation measures. The SFPUC must take the lead to reduce water demand within its service area. 02 cont.

- The PEIR fails to address the many environmental impacts of increased diversion of water from the Tuolumne River, including the impact on the watershed and the projected reduction of the volume of water in the Tuolumne due to reduced snowpack.

- Water conservation and efficiency measures are the cheapest, easiest, and least destructive ways to meet demand and extend supply. 03

- The PEIR does not address the potential increase of water supplies by water recycling. The State Water Resources Control Board and the Regional Water Resources Control Boards are currently considering water recycling programs and standards. The PEIR does not take these programs into account.

I urge the SFPUC to perform the seismic upgrades to the Hetch Hetchy infrastructure without diverting additional water from the Tuolumne River or any other watershed. Instead, the SFPUC should immediately undertake water conservation measures to reduce diversion from our stressed watersheds.

Thank you.

Very truly yours,

Patricia L. Walker

Comments on the PEIR for the WSIP.

Pete at Momentum Rafting <pete@momentumriverexpeditions.com> **Thu, Sep 27, 2007 at 10:49 AM**
To: wsip.peir.comments@gmail.com

Dear Mr. Maltzer:

As both a frequent visitor and huge fan of both the Tuolumne River and San Francisco I urge you to take another look at your environmental review of the San Francisco Public Utilities Commission's plan to take more water from the Tuolumne River before finalizing it. 01

The Tuolumne is an irreplaceable natural treasure, one of the most beautiful and unique rivers in the world. Alternatives requiring more water conservation, efficiency, and recycling are the best way to lessen impacts on the Tuolumne River, and reduce long-term infrastructure costs. Other cites have managed to grow while reducing water consumption. The Bay area is known for having a strong environmental ethic and I have no doubt that the area could easily become a leader in water conservation. 02

Around 60% of the water in the basin is already diverted. Good flows in the Tuolumne River are critical to protecting the river as one of our natural treasures and as a unique recreational playground.

Kind Regards,

Pete Wallstrom.

Paul Maltzer, Environmental Review Officer
San Francisco Planning Department
1650 Mission Street, Suite 400
San Francisco, CA 94103

Dear Mr. Maltzer:

I have hiked and rafted much of the Tuolumne river from Tuolumne Meadows to New Don Pedro Reservoir. Its beauty and environmental value are unmatched in Sierra, indeed, in California. I also work in San Francisco and appreciate the high quality of the water there.

Your environmental review of the San Francisco Public Utilities Commission's plan to take more water from the Tuolumne River fails to adequately identify and address all of the environmental impacts to the River. I urge you to undertake additional studies before finalizing this document. 01

I support the alternatives identified in your draft document that protect the Tuolumne River from new diversions. Requiring more water conservation, efficiency, and recycling is the best way to lessen impacts on the Tuolumne River while promoting a sustainable water plan for the Bay Area. Using pristine water from the Tuolumne to flush our toilets and water our lawns just doesn't make sense. 02

Only by ensuring that healthy amounts of water continue to flow into the Tuolumne River can we protect this irreplaceable natural treasure.

Sincerely,

Richard Weiss

Dear Mr. Walzer

Mr. Paul Maltzer
Environmental Review Officer, WSIP PEIR
San Francisco Planning Department

Dear Mr. Maltzer,

Please act to protect the Tuolumne River for future generations by requiring water conservation, efficiency, and recycling, instead of taking more water from this river. 01
The SFPUC should re-evaluate its projections for future water demand and conservation.

The PEIR uses flawed modeling to determine the anticipated increase in water demand, thus inflating projected future needs. Other metropolitan areas (especially Seattle and Los Angeles) have managed to reduce water demand even in the face of growth. 02
The PEIR fails to properly address all of the impacts of taking more water from the river because it lacks an adequate baseline study. A comprehensive study has not been done for 15 years, and a current study will not be completed in this review period. 03
The PEIR does not take into consideration the impact of climate change on precipitation in the Tuolumne River watershed.
Decreasing reliance on the Tuolumne is critical not only for protecting the health of the River, but also for preparing for the future uncertainty of the Sierra snowpack due to global warming. 04

Water conservation and efficiency measures are the cheapest, easiest, and least destructive ways to meet demand and extend supply. 05

Thank you for your attention to this matter.

Sincerely,

Doris Williams

Re: Protect the Tuolumne River

Dear Mr. Maltzer:

I am writing to you as a native San Franciscan who is concerned about the fate of one of our most valuable natural resources, the Tuolumne River. The river provides not only beauty but is a natural habitat to many fish as well. The conservation of the Tuolumne River is of the utmost important issue at hand right now.

I urge you to support a sustainable water plan that will protect our watersheds in the Bay Area and Sierras before this irreplaceable natural treasure is gone forever. We must conserve the river rather than increase water diversion. The results will be disastrous if we don't take action to preserve the Tuolumne River. Right now they are diverting close to 60% of the Tuolumne and any more diversion will threaten the entire ecosystem in the Bay Area. 01

Thank your for taking serious action to conserve and recycle this most precious natural resource for us now and for the future generations.

Sincerely,

Benita Zimmerman
1812 Devereaux Drive

P R O C E E D I N G S

ALFRED WILLIAMS: Ladies and gentleman, again, welcome. This is the public hearing on the Draft Program Environmental Impact Report on the San Francisco Public Utilities Commission's Proposed Water System Improvement Program.

Can you hear? You can hear. Okay.

With that, I'd like to introduce Diana Sokolove, who is with the San Francisco Planning Department.

DIANA SOKOLOVE: Good evening, and welcome again to tonight's hearing. My name is Diana Sokolove, and I'm a senior environmental planner with the San Francisco Planning Department, Major Environmental Analysis Division, and I will be the moderator for tonight's hearing.

And I also just want to introduce some people who are working on the program and on the environmental review process. Tonight, Kelly Capone, who is standing in the back of the room, is with the San Francisco Public Utilities Commission, or SFPUC. Heather Pohl, next to her, is also with the PUC working on the program.

Also here tonight is the project manager for the consultant team and the deputy project manager with the ESA + Orion consultant team, Leslie Moulton and Joyce Hsiao. And also here is Al Williams. And he's our public involvement coordinator for this program. So he'll be collecting speaker cards and can also assist you with anything you might need.

And this is one of five public hearings on the draft program environmental impact report. And we will be providing essentially the same information and opportunities for you to comment at each of the hearings.

12.6-3

So here's our agenda for tonight. We'll just take a few moments to introduce this process to you and give you some instructions on how you can comment. And then we'll open up the hearing for public comment.

So just some meeting reminders. Hopefully you signed in when you came into the room. If you didn't, please do so before you leave, and please sign your name clearly and legibly so that we can keep in touch with you throughout the process.

And if you do plan on speaking tonight, I hope that you filled out a speaker card. You can pick these up at the front table when you come in the door. And I think some of our folks have some extra ones that they

can be pass around.

I will be calling up speakers from these cards in the order I received them. So be sure you fill one out if you want to speak tonight.

Another item you may wish to pick up is a comment form so you can submit written comments on this comment form. You can hand them to me tonight, or leave them in the comment box at the back of the room, or you can mail or fax them later. And we will give you information where you can mail them later in the presentation.

Restrooms are located in -- restrooms are located in the back of the room, right back here [indicating]. And also, please turn off the ringer -- please turn off the ringers on your cell phones and pagers, and be sure to leave the room if you need to make a call. We really appreciate that.

Also, please note that we do have a court reporter present this evening here who is making a transcript of tonight's proceedings. And the transcript will become part of the public record of this environmental review process.

So the purpose of tonight's hearing: We are here to receive your comments on the environmental impact report on the Water System Improvement Program.

12.6-4

Staff are not here to answer your comments today. And comments will be transcribed, and your comments will be responded to in a comments and responses document that the San Francisco Planning Department will be preparing.

The comments and responses document, again, will respond to all verbal and written comments. And just to be really clear, this is not a hearing to consider approval or disapproval or modification of the proposed program. That hearing will be held by the San Francisco Public Utilities Commission following the final program environmental impact report certification hearing, which is held by the San Francisco Planning Commission.

So if you wish to submit written comments, you can do so, again, by submitting them to me tonight or you can drop off comments in the comment box at the back of the room. You can mail them or e-mail them at the address shown here on the screen. And also your agenda tonight, the address for mailing them or e-mailing them is on that.

And also, if you wish to get a copy of the document, the program environmental impact report, on CD, if you would when you fill out this comment card just leave a note for us asking us to send you a copy

of the CD.

And just to be clear, the Planning Department will accept public comments on the draft program EIR until 5:00 p.m. on Monday, October 1st.

So the draft program EIR is available for viewing at the San Francisco Planning Department and the San Francisco Public Utilities Commission and also at several libraries throughout the study area. And it's also available on line.

And again, you can find out the addresses of these libraries on your agenda or on the notice of availability. And all those materials are here tonight. Here's our schedule. We have a 90-day public review period which started on June 29th and ends at 5:00 p.m. on October 1st.

And we have a series of public hearings that we're going to be holding this month. This is the first of the public hearings tonight in Sonora. We'll be in Modesto, Fremont, Palo Alto, and also in San Francisco.

We will be, as I mentioned, responding to your comments in writing in a comments and responses document that we hope to publish next spring. And following publication of the comments and responses document, we will be holding a certification hearing in

12.6-5

front of the San Francisco Planning Commission.

So now we're ready to open up the hearing for public comment. And we ask that you just follow a few rules. First, as I've already noted tonight, this is a hearing for the PUC to receive your comments on the draft program environmental impact report. So please direct your comments to the adequacy and accuracy of the information in the environmental impact report.

Again, please submit a speaker card if you wish to speak. And I'll be calling out names from those cards in groups of three so you can get ready to come up and speak. And I'll call those names in the list as I received them.

And when you are ready to speak, step up to the microphone and state your name and address clearly and slowly for the court reporter to transcribe that information so that we can provide you with our responses to your comments.

In the interest of time, please keep your comments limited to three minutes. Al Williams will be keeping track of time tonight. We just want to make sure everybody has a chance to speak. And we also realize that you may have more than three minutes of information to share with us. We definitely respect that, so that's why we have our comment cards. And

there are certainly other ways that you can supplement your verbal comments with written comments.

Does anyone else want to submit a speaker comment card tonight?

Again, I'll be calling up your name in groups of three, so -- just so that you can get ready.

Stan Kellog, Dolores Boutin, and Cynthia King. And the microphone -- you can use this microphone up here, or you can use this microphone up in the front of the room.

STAN KELLOG: Somebody help me out. SI_TCFB

Thank you.

First of all, excuse me. I have never been known as a public speaker. So forgive me if I stutter, stumble, slip, or fall, but the bottom line -- my name is Stan Kellog. I'm the president of the Tuolumne County Farm Bureau.

SI_TCFB-01

And what we are here to say is that any time one drop of water leaves Tuolumne County, it has a negative impact on our county. Period.

On the flip side of that -- this is not Farm Bureau talking; this is me personally talking. This is not the avenue -- this is not the venue to distribute this kind of literature (indicating).

We need our water. We are facing major, major

12.6-6

water problems. And anything that gets taken from us will very much affect us in the future.

I talked to an individual today, expressing my concerns about this water taking. And he told me -- he is in development, construction. He says, "If we don't give them what they want, they will just move up here."

Well, how about just let them move down a little farther south?

We are opposed to taking any water from Tuolumne County.

SI_TCFB-01 cont.

Thank you.

DIANA SOKOLOVE: Before you sit down, could you please give us your address for the record? If you don't mind, if you could just say it for the record.

STAN KELLOG: Stan Kellog, Tuolumne County Farm Bureau, Box 675, Jamestown, California 95367, whatever.

DIANA SOKOLOVE: Thank you.

Dolores Boutin.

C_BoutiD

DOLORES BOUTIN: Why do we fill out cards if we do that?

Okay. I live in Tuolumne. I've lived here for 25 years or so. I'm going to read what I wrote so that I don't forget anything. The first question, main question is, why does San Francisco think it has a right to take any more water from the Tuolumne than it

C_BoutiD-01

already does? Almost 100 years ago, this fight was fought. They won; we lost.

Last fall during the salmon run, I was on the Tuolumne River. It was during salmon spawning time. There were only a few salmon that could be seen. Old-timers there told us that the river used to be thick, so thick you can almost walk across the river on their backs. Now, nothing.

Lack of natural river flows affect the whole ecology of the riparian habit, not just the salmon but everything else around it. We are part of that. If we don't see that all of that affects us, something is wrong with our viewpoint.

The river flow affects the delta and the bay and all the humans and human activities involved around those too. So it's not just the plants and animals. It's us.

The proposal from San Francisco is a taking from a national park that happened a long time ago. That's bad enough, but they're sending it through pipes and tunnels to a city far away for their benefit only. This was done through political pressure a long time ago as basically a theft of our local water. Now the San Francisco Public Utilities Commission wants to take even more, using our local resources for their own

C_BoutiD-01 cont.

economic benefit.

Already 6 percent is diverted. No more. Water, especially good water, is big business worldwide, not only for its direct use but also for its use in producing electricity and the money that that brings. It comes down to power and money instead of what's right.

Simply put, San Francisco Public Utilities Commission has no right to take more water from the Tuolumne River. Twenty-five million gallons a day is what they're proposing extra, beyond what they have. They must be pirates at heart. "Take whatever you can get away with," is the name of the game.

The population is growing in the San Francisco area, as everywhere else in California, including here. The need for water needs to be met through wise use and conservation. There's going to be less and less water through global warming and more and more people as people decide to move to California. Say no to these people.

C_BoutiD-01 cont.

DIANA SOKOLOVE: Would you mind stating your name and address for the record?

DOLORES BOUTIN: Dolores Boutin, P.O. Box 1450, Tuolumne 95379.

DIANA SOKOLOVE: Cynthia King.

CYNTHIA KING: Hello. Hi, everybody. It's great to see you all here tonight. My name is Cynthia King, and I'm the Sierra Nevada program director for the Tuolumne River Trust. The Tuolumne River Trust works to promote the stewardship of the Tuolumne River and its tributaries to ensure a healthy watershed. We have offices here in Sonora, Modesto, and San Francisco.

Thank you for coming to Sonora to listen to the concerns of Tuolumne County residents. Those of us in Tuolumne County who rely on the Tuolumne River for recreation, business, and personal renewal will suffer greatly if San Francisco pursues their plans to divert the additional 27 million gallons of water a day from the river.

With 50 percent of the Tuolumne already diverted for agricultural and urban uses, the Tuolumne is already an exceptionally hard-working river. As one of California's Wild and Scenic rivers and home to the largest run of Chinook salmon in the San Joaquin basin, the Tuolumne is an irreplaceable natural resource.

As the largest tributary to the San Joaquin River, the Tuolumne also contributes much-needed fresh water to the San Francisco Bay Delta upon which millions of Californians rely.

In our review of the draft PEIR, we found a

12.6-8

number of serious inadequacies that need to be addressed in the final report. I will touch on just a few of them here, and the Tuolumne River Trust will be submitting written comments before the public comment period ends.

The first problem is the lack of an adequate baseline of the Upper Tuolumne River. A comprehensive study of current conditions has not been conducted in over 15 years. Without knowing the condition of the river today, including its fisheries, riparian habit, and associated species, it's impossible to assess the impact that additional diversions might cost.

SI_TRT2-01

The second problem: The modeling used to estimate future water demands upon which the diversion proposal is based also contains a number of flaws. These flaws include using out-dated employment projections and ignoring the effect the expected price increase will have on future demands. San Francisco is planning to increase the price of water to the wholesale customers by three times, and they didn't take out its recount [sic] in modeling future demand.

These flaws led to inflated demand projections, and they need to be corrected in the final report.

SI_TRT2-02

Further, the mitigation measures proposed to

SI_TRT2-03

off-set impacts on juvenile Chinook salmon are inadequate. While the proposed restoration projects are worthy efforts, implementation of just one of these projects is inadequate to address the fishery impacts associated with the in-stream flow reductions and temperature increases expected for the Lower Tuolumne.

SI_TRT2-03 cont.

Finally, as a city and county that has greatly benefited from Tuolumne River water for generations, it is San Francisco's duty as it looks to the future to be a good steward and to pursue a water plan that will protect the Tuolumne for future generations.

Fortunately, San Francisco has an opportunity to adopt a sustainable water plan which does not rely on increased Tuolumne diversions.

If you're interested in learning more about those opportunities, please see our new report that was released called "From the Tuolumne to the Tap: Pursuing Sustainable Water Solutions for the Bay Area." We strongly encourage San Francisco to move in a sustainable direction before they cause any more harm to the Tuolumne River.

Thank you.

DIANA SOKOLOVE: If you could please add your name and your address.

CYNTHIA KING: My name is Cynthia King, P.O. Box

933, Sonora, California 95370.

DIANA SOKOLOVE: Thank you.

Fred Boutin. C_BoutiF

FRED BOUTIN: Yes. I am a resident of Tuolumne County and of Tuolumne. My primary objection to the draft environmental impact report is that it's misnamed. It's not a water system improvement program; it's a water system expansion program. That should be rightly named what it is. C_BoutiF-01

The environmental -- the final environmental impact report needs to include studies to show what potential there is, the maximum potential for water conservation within the San Francisco Public Utility Commission service territory. And really, they should be -- the report should be outlining where they're intending to market this water that they're planning to divert. C_BoutiF-02

Thank you.

I'm at P.O. Box 1450, Tuolumne, 95379.

DIANA SOKOLOVE: And please state your name for the record.

FRED BOUTIN: It's the same as I stated at the beginning, Fred Boutin.

DIANA SOKOLOVE: Nicole Sandkulla. L_BAWSCA3

NICOLE SANDKULLA: Good evening. My name is

Nicole Sandkulla. I'm with the Bay Area Water Supply and Conservation Agency. Our address is 155 Bovet Road, Suite 302, San Mateo, California 94402. I have a statement to read from Arthur Jensen, our general manager.

San Francisco's draft program environmental impact report for its Water System Improvement Program is undergoing careful review by the Bay Area Water Supply and Conservation Agency and its 27 member agencies that purchase water from San Francisco's regional water system for 1.7 million residents, businesses, and community institutions in Alameda, Santa Clara, and San Mateo counties.

While BASWCA's review of the draft PEIR continues, we find it to be a good, comprehensive document, analyzing the environmental impacts and program alternatives as required by law. BASWCA will submit written comments to correct apparent errors and expand the discussion of future water demands, alternative water supplies, and water conservation efforts.

One issue the PEIR should more clearly emphasize is the critical importance of completing the Water System Improvement Program to protect the public health and safety of the people who live in the Bay L_BAWSCA3-01

12.6-10

L_BAWSCA3-01 cont.

Area today.

Four active faults cross the major pipelines, tunnels, and reservoirs that provide water to 2.5 million people in our counties and San Francisco. There is a 60 percent probability that a major earthquake will occur in the Bay Area between today and 2032.

Following a major earthquake, the flow of water to communities could be disrupted for 30 to 60 days. The impacts to public health and safety would be catastrophic. The economic impacts, not counting injuries and loss of life, are estimated to be at least seven times the cost of rebuilding the aging water system.

L_BAWSCA3-02

The Water System Improvement Program includes projected uses for BAWSCA's agencies. These agencies in Alameda, San Mateo, and Santa Clara counties and their customers are dedicated to saving water and safeguarding the environment.

Today the average resident in the service area uses 15 percent less water per day than in 1986 and 23 percent less than in 1976.

In the Bay Area, residential water use per person is lower than the average for the State of California. And residential water use per person in

L_BAWSCA3-02 cont.

the BAWSCA area is lower than the average in the Bay Area.

BAWSCA and its agencies actively support implementation of additional conservation measures and water recycling to make the most effective use of limited water supplies. The water management issues addressed in the draft program environmental impact report --

UNIDENTIFIED SPEAKER: Time's up.

NICOLE SANDKULLA: -- are no longer issues. The projected growth is not going to happen tomorrow. The earthquake might.

L_BAWSCA3-02 cont.

Protecting existing people from a known catastrophe that could result from a highly probable earthquake is an urgent issue that the WSIP is designed to address.

Thanks.

DIANA SOKOLOVE: Just a reminder, thank you, Nicole, for stating your name and address when you came up. If everyone can do that before you come up, that would be great.

Also, I don't need any assistance in moderating the meeting. So if you would just leave that to me, that will be fine.

Bob Hackamack is the next speaker.

12.6-11

BOB HACKAMACK: I'm Bob Hackamack, P.O. Box 1886, Twain Harte, California. I'm a representative of the group Restore Hetch Hetchy. I'm their technical and engineering chairman.

It's apparent that the contractors and the planning staff have worked very hard on this document. And I compliment you for your work. There's some minor errors that are understandable. And I've learned several things about the Water Supply Project from reading your report. This is a good reference material. Thank you.

(Staff handing different microphone)

BOB HACKAMACK: Hmm. I feel like singing.

SI_RHH3-01

I want to explain how the preferred alternative called the WSIP is disconnected from reality, but that the combination of the alternatives that you presented, will make a workable plan.

You've correctly stated that John Freeman in 1912 projected that the Tuolumne River had a plan, and it might produce 400 million gallons a day.

But you failed to say that the San Francisco PUC did not build the project the way John had foreseen, that that has drastically reduced the amount of water availability, so you can't look forward to 400 million gallons a day but something drastically less.

SI_RHH3-01 cont.

Now, the reason the PUC did that was maximum profit from hydropower, not water supply.

I find that the yield of your project is 207 million gallons a day during your designed drought. But no prudent manager is going to follow the plan that you have in mind. The first year, no rationing; second year, full 25 percent, got-to-catch-up-type thing.

So I ask you, why would your board of supervisors approve this huge amount of money for a project that's going to triple the rates and now come back and have to tell them that, "Well, every 13 or 26 years or 41 years, you're going to have 25 percent rationing for the duration of the drought"? The rate payers deserve a better system than you're offering them.

DIANA SOKOLOVE: Sir, if you could wrap up your comments.

SI_RHH3-02

BOB HACKAMACK: Sure. Of the exports at 207 million gallons a day, you, for all the other needs that you have, go to the recycling, the aggressive conservation, the purchase of water, to avoid the Tuolumne diversion and the other things that you listed in the alternatives.

DIANA SOKOLOVE: Thank you.

Jerry Cadagan.

SI_RHH4

JERRY CADAGAN : My name is Jerry Cadagan. I reside at 13225 Sylva Lane, Sonora 95370. I am here speaking as an individual, but in the interest of full disclosure and for purposes of identification, I will acknowledge publicly and privately, I'm on the Board to Restore Hetch Hetchy. I'm a founder of an organization that nobody in this room's heard of probably called the Committee to Save Lake Merced. And I've dealt with the San Francisco Public Utilities Commission on environmental issues in San Francisco for 15 years. So I have a little experience. And I am a long-time member of the Tuolumne River Trust.

I'm probably the first speaker to really address the adequacy of the EIR. That's all right. I understand you.

The Chapter 10 lists 20 significant negative adverse environmental impacts resulting from the project proposed by San Francisco.

The EIR goes on to acknowledge that they can't eliminate those adverse impacts, and they can't limit them by any mitigation measures they've come up with.

SI_RHH4-01

I have a bold idea to improve the environmental impact report. And I mentioned being involved in the Restore Hetch Hetchy effort. I didn't hear any boos; I didn't hear any cheers. That's about

12.6-12

what I expected here.

I am not here proposing that San Francisco mitigate all the environmental impacts of its project by single-handedly restoring Hetch Hetchy Valley.

All I suggest is that San Francisco follow the accepted case law under CEQA in California and use as a mitigation measure a commitment to take a simple non-monetary step. That step would be to agree to cooperate in the restoration of the valley so long as certain conditions laid out by San Francisco were met.

And I'm not going the read the whole statement of commitment, but basically, reservoir removal would occur only after water and power currently supplied by the reservoir are fully replaced. Water and power replacement must take place without any increase in water or power rates or property rates for San Francisco residents and businesses and without any increase in the cost of delivering it to the city of San Francisco.

SI_RHH4-01 cont.

What I'm essentially saying is, have a mitigation measure -- add to the ones you've already got in here, which are inadequate to solve 20 of the major problems -- San Francisco saying, "We're okay with restoration, as long as we don't get hurt."

To date, they're unwilling to say that. "We

12.6-13

want 25 more million gallons of water, but we won't even think about possible restoration of Hetch Hetchy Valley."

SI_RHH4-01 cont.

That is a legitimate mitigation measure. Thank you.

UNIDENTIFIED SPEAKER: Could San Francisco --

DIANA SOKOLOVE: I'm sorry, ma'am. If you'd like to speak, can you fill out a speaker card, and we will certainly call you up to speak.

UNIDENTIFIED SPEAKER: This is a question about the very limited amount of time --

DIANA SOKOLOVE: Ma'am, I need you to fill out a speaker card in order to speak.

UNIDENTIFIED SPEAKER: -- a very limited amount of time that we're allotted for --

DIANA SOKOLOVE: I'm sorry. I really do need you -- just -- because everybody is here, they all want to speak. We need to give everybody a chance to speak. And I would --

UNIDENTIFIED SPEAKER: You need to give them more time and not try and do this in an hour and a half for your convenience. Just give us more time.

DIANA SOKOLOVE: So Galen Weston is the next speaker.

SI_TRT3

GALEN WESTON: Hello. Galen Weston, 21149 Lyons

Bald Mountain Road is my address.

I'm a Sonora resident and also work part-time for the Tuolumne River Trust. So it is -- and I grew up fishing, swimming, exploring, and rafting in the Tuolumne and its tributaries, so it's with great personal and professional connection with the river that I'm speaking tonight.

Looking over the program environmental impact report, I was very disappointed to see the preferred alternative called for increased diversions from the Tuolumne River by 27 million gallons a day, in addition to other important and non-controversial projects, such as seismic upgrades and general maintenance as the previous speaker mentioned, you know, there is great threat to the water system in San Francisco due to seismic activity.

Since the San Francisco Board of Supervisors has already clearly instructed the SFPUC to pursue a water plan that protects the health of the Tuolumne and does not include additional diversions from the river, I'm really unsure as to why you would want to risk holding up this entire project by burdening it with the controversial and unnecessary proposal to increase your diversions from the Tuolumne.

SI_TRT3-01

When the citizens of the United States,

SI_TRT3-02

through an act of Congress in 1913, granted San Francisco the unprecedented privilege of constructing a reservoir in the midst of Yosemite National Park, the city was given clear direction to fully utilize any current or future water supplies before tapping into the Tuolumne River.

Instead of honoring that pact with the nation, the City is now using wildly inflated demand projections to justify increased diversions from the Tuolumne.

SI_TRT3-02 cont.

Now I'll move on to some specific shortcomings in the environmental review. As Cynthia mentioned, the environmental impact report is inadequate in its evaluation of the potential impact because you guys don't have the studies to provide an adequate baseline of conditions on the river right now. Basically, we can't tell where we're going if we don't know where we are.

Much of EIR is base on a single, unfinished fish and wildlife study conducted back in 1992. And that study itself indicated that flows might need to be increased below Hetch Hetchy to ensure the health of the river's rainbow trout fishery.

SI_TRT3-03

But in any event, the City needs more than a handful of 15-year-old studies to convince me that

taking an additional 27 million gallons per day off the river won't significantly affect flows, fish, wildlife or recreation.

Now just cruising through a few more comments, because I'm going to run out of time.

San Francisco seems to expect other agencies to pick up their slack when it comes to water conservation. So this report is inadequate. for example, some of the mitigation measures this report discusses, in the event of drought years, include asking the Modesto and Turlock irrigation districts to conserve water in order to meet minimum fish flow requirements.

SI_TRT3-04

Similarly, the EIR indicates increased flows from the Bureau of Reclamation near the Stanislaus may be needed to mitigate for decreased freshwater flows into the Delta.

There are no contracts or agreements lined up to this effect, so these ideas are not in any way appropriate mitigation. And further, San Francisco should take responsibility for its own conservation instead of trying to farm out this responsibility to other water agencies.

SI_TRT3-05

And just in closing, by committing to meet increased levels of demand in the future, San Francisco

12.6-15

is foreclosing on opportunities to improve conditions on the Tuolumne and San Joaquin rivers and the Delta.

And one more thing: I'm encouraged to see that the report includes an alternative that calls for present conservation and recycling that can meet San Francisco's water needs without taking more water from the Tuolumne. And I really encourage you to come back with a final draft that has that as the option that you're going to go with. SI_TRT3-06

Thanks a lot.

DIANA SOKOLOVE: Darryl Bramlette.

C_BramlD3

DARRYL BRAMLETTE: Good evening. My name is Gerald Bramlette, 7700 Ruth Ridge Road, Jamestown, California.

I really represent Bramlette Consulting. And it has no connection at all with the water resource people here at all.

I attended this meeting last year and started doing some research. And I do see that there's really a problem that San Francisco has, but they're not addressing it at all. And with all the Ph.D.'s they have down there on their staff and with all the money they've put into this, they're totally lacking in solving their problem.

Their answer is to go get more water from a C_BramlD3-01

source that doesn't have more water. Their answer is to rebuild on technology that's 80-plus years old. They're ignoring we're in the 21st century. San Francisco can get water. They can do desalinization. Desalination. They have a nice large body of water which they can work on. They don't have to have the Tuolumne. They don't have to have all these other resources that they're trying to take from other communities. C_BramlD3-01 cont.

They can also go into conservation within their own city and, like the speaker before me said, not go out and ask our neighbors to do such. C_BramlD3-02

Also, looking at a little bit of research, they're not supposed to be selling the water to other communities. They are making money off of this also. If you take a look real carefully, they're making good money off of it. C_BramlD3-03

So I think if I look at this thing all the way back down, it's not the people of San Francisco's water demands. It's the demands of the pockets or the coffers of the San Francisco City.

With that, I'm going to rest my case.

Thank you very much for having us speak this evening. And I would like to have a response to my paper, though, that I wrote last year from the people.

12.6-16

C_Owen

DIANA SOKOLOVE: Ellie Owen.

ELLIE OWEN: Ellie Owen, 12098 Wards Ferry Road, Groveland.

I got a friend who just hiked up to the glacier at the Tuolumne River. He was going to camp on a stream -- there were several streams. He had an option -- on the way up, but they were all dried up. So he went up to the glacier. And the glacier was small.

C_Owen-01

So my question is, how do you calculate the yield from that glacier? Our GCSD manager from Groveland said there's an unlimited amount of water. Well, that's hard to believe.

My second question is, if we continue with drought years, how do we figure global warming into that? That's an unknown. I mean, isn't that part of the real equation right now? That's another question I have.

I would like it if these meetings were longer. And I also would like it if people would answer our questions because we need to know the answers to our questions. And we need to share that with everyone else. So I think that's a good idea.

C_EllioP

DIANA SOKOLOVE: Patricia Elliot.

PATRICIA ELLIOT: My name is Patricia Elliot. I

live at 12186 Bear Creek Road in Groveland, California, 95321.

I've been a resident of this county for four years. And I was instrumental in the Wild and Scenic move in 1984 for the Tuolumne River. I presently am the chair of the South Tuolumne County Planning Commission.

And my concern is the amount of activity we're seeing as people from the coast, and mostly from San Francisco, who are now able to sell their little cottages for a million dollars and racing up here to buy our acreage. And the demand for water and projects up here is of real concern to me as I see things coming across our board that will directly affect Groveland and Big Oak Flat.

For the past five years, we have been in a conflict over 400 homes that want the Hetch Hetchy water. And as Ms. Owen said, that the GCSD -- this is our governing body, now, four people -- we have no mayor. We're not a certified town -- but four people who are elected every two or three years -- and it's a controversial election -- can decide whether to route Hetch Hetchy water to homes behind Pine Mountain Lake.

C_EllioP-01

So I'm very, very concerned with what San Francisco draining more water out of Tuolumne and the

12.6-17

Tuolumne River will do to the future of our small community of 3,000 people in Groveland, 200 people in Big Oak Flat. But you will here a loud voice from us against taking the water out of the Tuolumne River.

C_EllioP-01 cont.

DIANA SOKOLOVE: Next speaker is Jimmy Gado.

C_Gado

JIMMY GADO: Good evening. My name is Jimmy Gado, and I'm a resident of Tuolumne County. I live in Columbia, California, P.O. Box 851, Columbia, 95310.

I've been a resident of Tuolumne County for 33 years, and I've been employed in the white water rafting industry for the last 27 years, part of those as an owner of a company that operated on the Tuolumne and now as an employee of a company that operates on the Tuolumne.

I'm concerned about the draft EIR's use of figures for average flow on the Tuolumne, which doesn't really mean anything when it comes to recreational use on the Tuolumne. There's a certain flow that's needed in order for rafting to occur on the Tuolumne River. And those flows were historically there while the Wild and Scenic was enacted and the recreational uses were protected on the Tuolumne. And I'm concerned that any additional taking of water by San Francisco and other Bay Area counties will cause an adverse impact to the rafting industry on the Tuolumne.

C_Gado-01

So I just would like to say that I'm opposed to any more water being taken from the Tuolumne, particularly before San Francisco and all of its water purchasers enact much better water conservation and recycling programs.

C_Gado-02

Thank you.

DIANA SOKOLOVE: Next speaker is Pete Kampa.

L_TUD3

PETE KAMPA: Pete Kampa, General Manager, Tuolumne Utilities District, 17245 Valley Okay Drive, Sonora.

I am here representing myself and also representing the Tuolumne Utilities District.

In some cursory comments, this document is huge. It's going to take us a long time to get through.

Number one, we request that there be a time extension on comments. It's really important for a small utility with significant potential impacts from any project constructed in this area.

L_TUD3-01

Tuolumne Utility District consumes most of the County of Tuolumne, from the Stanislaus in the north to the Tuolumne in the south, serving 44,000 in population. We currently recycle nearly a hundred percent of our wastewater. And when we look at the -- the fact that the EIR contemplates a very small percentage -- it's in the range of 4 million gallons a

12.6-18

day -- our current recycled water is about 1.8 million in Tuolumne County. So they're contemplating for the whole Bay Area 4 million.

I really think the EIR should look at maximum possible recycling of wastewater and use on parks and also new residential development. It's extremely important. L_TUD3-02

Also one of the major flaws in the EIR is the fact that it's based on contracts with major water utilities that are not yet completed. The contracts have not yet been developed, the terms and conditions. And it's not proven up whether these agencies in Turlock or Modesto have the right to divert that amount of water from the Tuolumne.

In addition, there's consideration being given to supplementing that water through the Stanislaus, which is our primary interest. I think that that needs to be much more closely analyzed -- and also the fact that those agreements should at least be detailed in some draft stage in some memorandum so that the PEIR can adequately address it because it's completely based on those transfers. L_TUD3-03

And if you have those needs and those needs are true, without the transfer from the Tuolumne, those other numbers need to be analyzed. So there's no way

to analyze it without the agreements. L_TUD3-03 cont.

The rationing of 20 percent is extremely small. That is not even an industry standard. It's something that we would -- we asked for it this year in just the typical dry years, Tuolumne Utilities. In the industry, it's not unusual to go up to 50 percent and then have provisions in there for different classes of users to restrict more, based on necessity. L_TUD3-04

I think you need to look more closely at industry standards in conservation, as well as the practices based on the water year. In Tuolumne County, if the water year is 50 percent, we target 50 percent reduction. You don't get what you ask for. If you say 20 percent, you get much less. L_TUD3-05

The last thing is the fact that Turlock and Modesto and Oakdale have vehemently opposed any new water sales of surplus water. And they just don't exist in those agencies.

DIANA SOKOLOVE: The next speaker is John Sturtevant.

C_Sturt

JON STURTEVANT: I'm Jon Sturtevant. I live at 18127 Apple Colony Road, Tuolumne, California 95379.

Back in the early '90s I worked for the Mono Lake Committee. And they worked very hard when they worked with L.A. Water and Power to have a win-win situation. Their main goal was to get L.A. to conserve more water. Everybody said, "Oh, yeah. That will happen."

But it did happen. People sweep their driveways, they don't wash their cars so often. They have 20 to 25 percent more population, and yet they use the same amount of water that they used 20 years ago. So if you guys would seriously address the issue of conservation, you might not need the 25 million gallons. That would be a win for us who live on the river because I canoe on it and hike around it with my Sierra Club friends. And it would also be a win for the folks in the Bay Area.

So be serious about conservation, and think "win-win."

C_Sturt-01

C_Picku

DIANA SOKOLOVE: Ron Pickup.

RON PICKUP: My name is Ron Pickup, Box 62 Soulsbyville, California. I was born, raised, and have lived in Tuolumne County most of my life. And as a fly-fisherman, writer, and photographer, I greatly value the unique recreation and beauty of our Wild and Scenic Tuolumne River.

As I testified at your last meeting with us, I believe taking any more water from the Tuolumne than presently used would be a real slap in the face of a

C_Picku-01

county of origin that has already provided you 20 million gallons a day from our river.

I ask you to respect and fully appreciate the important legacy the Tuolumne River provides our county. In addition to its considerable recreation and economic values, it provides us with a strong sense of place and identity. And we don't want to lose that identity.

I suggest the Commission take a three-day trip down the Tuolumne and experience this sense of place for themselves, firsthand. I also ask that you follow the San Francisco Board of Supervisors' recommendation, the Tuolumne River Trust advice, and the findings of your own studies to develop a more sustainable water supply through conservation, efficiency, and recycling as many other major cities have accomplished.

C_Picku-01 cont.

I thank you for coming up and taking our input.

C_GrinnD

DIANA SOKOLOVE: Doris Grinn.

DORIS GRINN: I'm a little disappointed that San Francisco is coming up here and giving us such a small sound byte of information when we're addressing an historic issue, the Tuolumne River, namesake county, all the concerns that the previous speaker just talked about.

12.6-20

We should be able to voice our opinion without little timers and have an hour and a half from San Francisco.

At what point does San Francisco stop impacting the riparian and water habitats of the river and the watershed that provides their domestic water source? At what point do they stop impacting it? At what point do they recognize the value of the natural world, the natural ecological habitat of rivers, the icon of life? At what point do they recognize that that is a value resource unto itself and stop taking more, taking landscapes with Hetch Hetchy and now taking more and more?

C_GrinnD-01

At what point is the riparian doctrine of water law implemented in this situation where we're looking at -- the riparian doctrine addresses in-stream flows for the ecological and aquatic health; at what point does the riparian doctrine allow priority over the extractions of water for domestic use?

I protest that the vestiges of civilization, that being San Francisco, continue to extract and degrade the natural ecological system and the rivers to maintain their expanding populations.

At what point does civilization -- and I'm not just talking about San Francisco and the Tuolumne

River; this is an age-old pattern. This is an archaic pattern of civilization destroying the upstream, the aquatic habitat to maintain and expand. At what point does San Francisco, which is some sort of vestige of environmental consciousness, when do they recognize this is -- this is the time to make a line and say, "Well, maybe we'll get into more water conservation. Maybe we'll be more conscious about what we're using," and stop degrading the upstream environment?

C_GrinnD-01 cont.

Thank you.

DIANA SOKOLOVE: Jim Grinnell.

C_GrinnJ

JIM GRINNELL: Thank you for the opportunity to speak. My name is Jim Grinnell. I live at 191 Elk Drive, Sonora. My great-great-grandfather had four sections of land in what is now Denair. And in 1904, San Francisco wanted to get water from what is now Hetch Hetchy. And Congress denied them.

In 1906 you had a great fire. After that, San Francisco got the right through Congress to take water and basically build the Hetch Hetchy system.

The deal that San Francisco was able to make -- well, let me say this. San Francisco became what it is because of Tuolumne County and the mining and all of this that was up in this area.

I'll be done in two minutes.

12.6-21

The deal, I think, was, a dollar and a half per acre foot is all San Francisco paid for that water. And San Francisco has sold over $150 million worth of water to the downstream Peninsula cities.

It seems to me that what San Francisco should do is stop selling water if they're short, because you're selling off the excess. You should be paying Tuolumne County, Merced County, Stanislaus County and these other counties that the water would have been used for. But now the water is gone because you've taken it.

It's time for conservation and reduction and reducing development in San Francisco if they're short of resources. But please don't take ours. C_GrinnJ-01

Thank you.

DIANA SOKOLOVE: Is there anyone who would like to speak who hasn't already spoken tonight? Can you please fill out a speaker card.

Robert Gelman.

NOAH HUGHES: Noah Hughes. Sorry.

C_Hughe1

DIANA SOKOLOVE: Okay. Just state your name and address.

NOAH HUGHES: My name is Noah Hughes. I'm at 20192 Gibbs Drive, Sonora, California 95370. I'm an earth science teacher down in Modesto. I grew up down

there in Modesto, and I've lived in Sonora for the last ten years or so. I'm a kayaker. I've spent a lot of the best moments of my life on the Tuolumne River.

So I'd like to make a couple of comments. First of all, about the draft program environmental impact report, a technical point: You based your flow projections, your future flow projections, off of monthly mean flows. Those are meaningless when it comes to environmental impacts. C_Hughe1-01

And monthly mean flows, monthly average flows don't mean anything to insects, humans or fish or kayakers. It's the amount of water that's in the river at that point in time. So your data is inadequate to make the projections that you're making. And it won't ever stand up in a court of law.

So given that fact, plus the fact that the board of supervisors do not support your preferred alternative, I really wonder where we're going with all this and what it's really all about. C_Hughe1-02

And in terms of water security for the communities in the Bay Area and customers of SFPUC, don't take more of our water so that you can sell it and make more money to make up for the money that was misspent back in the '90s that was supposed to go to all of the upgrades. That was documented in a series C_Hughe1-03

12.6-22

of articles in the San Francisco Chronicle that that money was squandered and misspent and didn't go to the upgrades that were supposed to be made.

C_Hughe1-03 cont.

Don't make it sound like it's going to be our fault if San Francisco gets in real trouble in an earthquake. This system, this alternative, is just demanding more and creating more demand. It's becoming less sustainable and less safe. Do what San Francisco's [sic] done. Do what Boston's done. Do what Seattle's done and reduce demand and put more slack in the system and make it safer.

Thanks a lot.

C_Gelma

DIANA SOKOLOVE: Robert Gelman.

ROBERT GELMAN: Good evening. My name is Robert Gelman. And I have dual residences, here in Tuolumne County and also in San Mateo County. My addresses are 321 Fuller Street, Redwood City and 240 Reservoir Road in Sonora.

So I have some questions about this. Why 25 million gallons? Why not 50 million gallons? 150? More? Why not? Well, I think we've heard a few good reasons why not tonight.

C_Gelma-01

Regarding the draft program EIR, many speakers have pointed out that the data it contains is fairly ancient; it doesn't take into consideration the climate

C_Gelma-02

science that we're now dealing with and many other environmental concerns.

C_Gelma-02 cont.

So as someone who can see both sides of this issue, I think it is incumbent upon the Commission to take another look at that EIR.

Thank you.

C_DayJ

DIANA SOKOLOVE: Joseph Day.

JOSEPH DAY: Good evening. My name is Joseph Day. I live at 716 Arbona Circle, Sonora, California. I grew up in the Bay Area. And I grew up on Hetch Hetchy water, so I know how good it is.

And I used to live in San Francisco. But I think you've got enough water coming from us. I think the real big problem is that, as populations grow on the coast, you're going to be demanding more and more of the water that originates in the Sierra Nevada watershed. And if you continue to take more, it's going to stifle the growth in the foothills or restrict what we currently are doing.

Pete Kampa already mentioned the potential transfers of water possibly from New Melones to make possible your plans. I find that very dangerous. We need to have that water supply. We have, I believe, 9,000 acre feet that is potentially usable for us here in Tuolumne County. And if our water rights are eroded

C_DayJ-01

12.6-23

by continued takings, I think that's a dangerous thing. C_DayJ-01 cont.

And as a speaker mentioned previously, there is a very large supply of water called the Pacific Ocean that you could use.

Looking at older numbers, I find that over $125 million is earned every year through sales of water and power generation by the SFPUC. An acre foot at the wholesale rate is over $500. When you start looking at the cost of de-sal, that's getting pretty close.

So I think the Bay Area could probably afford to invest in de-sal, and it really should start thinking about supplying their own water instead of taking more of ours. So that's essentially what I wanted to say. C_DayJ-02

DIANA SOKOLOVE: So is there anyone else who would like to speak tonight who has not spoken?

(No response)

DIANA SOKOLOVE: One of the main reasons why we do limit the number of minutes that you have is really just to make sure that everybody gets a chance to speak and that everybody gets home at a reasonable hour. But we do have some more time.

So if folks want to come back out and supplement your comments, you may do so. If you would

just -- you should probably get a sheet of paper and make sure that people just fill that out again.

For folks who are taking off, thanks for coming tonight. Thank you for speaking.

And folks who want to stay and listen to some more comments, please do so.

Take your seats. We do have a few more speakers. And if you need to have a conversation, if you could just take that outside the room, I'm sure people here who are speaking would greatly appreciate that. Thanks.

First speaker, Bob Hackamack. Bob again. Again, if folks want to take their conversations outside in respect to the people who are speaking again.

SI_RHH3 cont.

BOB HACKAMACK: Thank you, Diana, for letting folks come back. I was speaking before about the yield of the Hetch Hetchy system as only 207 million gallons a day. I wanted to go on to tell you that you're presently diverting north of 230 million gallons a day, and that gap is going to get you in trouble.

Now, it seems to me that, to make this project move forward smoothly, you're going to have to cap your diversions because it's obvious from the write-up that you're potentially building the fourth barrel of the

12.6-24

pipeline. At least in this iteration, you're going to build 46 percent of it, the miles of it. And those are the hardest 46.

So it's pretty obvious from what others have said that, once you hit that fourth pipeline, you're just going to continue taking more and more water without limit.

All you have in your mind are the words of John Freeman. "We can get 400 million, so let's go for it." But that's just not the way it is.

The reason that you can't do that is that you have ignored the feed to all these benefits in the first place.

In Section 9.(h) it says you have to develop all the water that you have in your city before you can take any from the Tuolumne. And you have not done that. Many people have referred to that already, and it's obvious that you have to develop the water in your service area, the bounds of the service area. And no one has spoken about that.

SI_RHH3-03

Diana spoke about the project, but she didn't say that they're going do anything to reduce their demand. And it's up to you to do that when you're contracting with them.

I wanted to say that the people who built this

system in the 20th century did a great job. And it's up to you, now, to build a good system, a serviceable system for the 21st century. And you're on the wrong track at this moment.

SI_RHH4 cont.

DIANA SOKOLOVE: Jerry Cadagan.

JERRY CADAGAN: Thank you for a second bite at the apple. I'm Jerry Cadagan, Sonora. I did prepare comments in case there was an overflow here. I've got another comment on the sufficiency of analysis, sufficiency of the information provided.

It is stated throughout the EIR and stated in newspaper articles, San Francisco said they need 35 million gallons more water between now and the year 2030. They say they are going to take 25 million gallons of that 35 million out of our Tuolumne River.

They say they're going to generate the other 10 million gallons a day through some combination of conservation of water recycling and groundwater resources.

And I cannot find in the 3,000-page EIR -- and I will confess, it may be buried in some appendices or some table -- a breakdown of that 10 million gallons a day. In other words, they're saying, "Tuolumne County, we want 25 million gallons a day more of your water. We're going to provide 10 million gallons a day through

SI_RHH4-02

some kind of recycling, conservation, and groundwater extraction," but I can't find where.

But what I can find on San Francisco's own Web site is their own recycled water master plan. Now, remember those 10 million gallons a day, they're going to do that -- in the aggregate, recycling, conservation, groundwater, presumably some of their customers are going to be contributing to that 10 million.

San Francisco's own recycled water master plan says, in San Francisco alone, there's feasible water recycling potential to the tune of 11.8 million gallons a day. That's almost 2 million gallons a day more than they are offering to contribute from the aggregate of the entire Peninsula, San Francisco, recycling, conservation, et cetera.

SI_RHH4-02 cont.

The EIR has got to address these issues. Thank you very much.

DIANA SOKOLOVE: Jim Grinnell.

JIM GRINNELL: Jim Grinnell. Just a follow-up on my previous comments.

I don't know what San Francisco is currently paying to Congress for -- to the United States government for this water that would otherwise be in the Tuolumne River, but in the early days, it was a

dollar and a half per acre foot. And that's around -- 300,000 gallons is an acre foot. It's 43,500 -- or anyway, it's a lot of water at a very low price per gallon.

Tuolumne County is so poor that this county, as of the 1st of July, had to close its county hospital because it doesn't have the money. Some of the money that San Francisco gets from selling the water should come to Tuolumne County.

Thank you.

DIANA SOKOLOVE: Doris -- sorry.

DORIS GRINN: It's Doris Grinn, P.O. Box 3053, Sonora.

And I want to commend all of the very informative, intelligent, and stimulating comments that are made today.

And I'm very disappointed that San Francisco was putting these time limits on, holding up the little cards, pressuring, forcing everybody to triage their presentation. And then we have all this extra time afterwards.

I really feel you people need to hear us, not cut us off with little timers. This is an issue for us. It's an issue that you folks should be listening to, not cutting us off, not saying, "Oh, sorry. It's time for you to stop." And then for us to have time left afterwards -- it's obviously poor planning for moderating.

So I think, if we have any more of these, you need to just listen to what people have to say.

Thank you.

DIANA SOKOLOVE: Anyone else who would like to speak tonight?

(No response)

DIANA SOKOLOVE: So again we'll be providing responses to your comments in writing.

I'm sorry. We do have one more speaker. Any others?

DOLORES BOUTIN: Dolores Boutin again.

12.6-26

Basically, it gets down to my wondering why is San Francisco asking for this extra amount of water? Because they can get it through the recycling; that's in the report. There are other alternatives. That's in the report.

The only thing I can figure out is, you ask for as much as you possibly can in hopes that you'll get something and that nobody will pay any attention. You ask for the extra amount of water so that you can sell it so you can make more money. You can sell the electricity; you can sell the water. That's it. Just

plain rip off.

Thank you.

DIANA SOKOLOVE: Anyone else?

(No response)

DIANA SOKOLOVE: Well, thanks again for coming, and thanks for those who spoke. And have a good evening.

(Whereupon, the proceedings concluded at 7:47 o'clock p.m.)

P R O C E E D I N G S

ALFRED WILLIAMS: Good evening, ladies and gentlemen. I'd like to ask you to take a seat, please. We want to get started with the program.

Good evening, and welcome to the public hearing for the San Francisco Planning Department on the Draft Program Environmental Impact Report on the San Francisco Public Utilities Commission's Proposed Water System Improvement Program.

The program this evening is going to be moderated by Diana Sokolove, who is a senior environmental planner for the San Francisco Planning Department.

DIANA SOKOLOVE: Hi. Good evening, and welcome to tonight's public hearing on the Water System Improvement Program. My name is Diana Sokolove, and I'm the senior environmental planner with the San Francisco Planning Department, and I'll be the moderator for tonight's hearing.

And I also just want to introduce some key folks who are working on the program and also on the environmental review process.

Kelly Capone, who's in the back over there, is with the San Francisco Public Utilities Commission. She's working on the program. And Heather Pohl is also with the PUC working on the program. And they are certainly available to answer any questions you may have after the formal portion of the hearing.

And I just want to introduce to you Joyce Hsiao, who is with the ESA + Orion consultant team. And she can help you navigate through the document a little bit if you have questions.

And there's some public involvement folks around to help you with speaker cards and help direct you in any other way. Al Williams is over here; he'll be collecting the cards.

Just so you know, this is one of five public hearings that we're holding on the Water System Improvement Program, Program Environmental Impact Report. We had one last night in Sonora and we're going to have a few more. And we'll be providing the same opportunity to comment and the same information at each hearing.

So here's our agenda for tonight. Sorry the screen might be a little hard to see because of the sun, but I'm just going to make a few opening remarks, and then we're going to open it up quickly for public comment.

Just some meeting reminders, hopefully when you came in, you signed in at the front table. That's really our only way to keep in touch with you. So hopefully you signed your name legibly and clearly.

And if you do plan on speaking tonight, please fill out a speaker card. They're available at the front table, and also folks around here have some more, so if you need one, please ask.

And another item you may wish to pick up is a comment form, just looks like this (indicating). So if you want to make comments on the document, you can drop this off with me tonight, or you can leave them at the front table where you came into the room, or you can always mail it in later. And also if you -- should you decide that you'd like to get a CD of the document, just write that on the bottom of the comment form, and we'll be sure to mail that to you.

Restrooms are located over here to my right, "boys" and "girls." And also, please, if you don't mind, turn off your cell phones and pagers. And if you do need to take a call, if you'd be so kind as to step outside the room, we'd appreciate it.

Also, we do have a court reporter here this evening who is transcribing the hearing, and the transcript will become part of the public record for hearing.

And so the purpose, why we are here tonight, this is a hearing to receive your comments on the adequacy and accuracy of the environmental impact report, or the EIR, for the Water System Improvement Program.

During the public comment portion of the hearing, we're not here to answer your comments or respond to your comments. We can help you and respond to comments and your questions after the hearing is over, but technically we're going to be taking your comments and responding to them formally in writing in a comment and responses document.

Also, this is not a hearing to consider whether the Public Utilities Commission should approve or disapprove or modify the proposed program. So please direct your comments to the adequacy of the environmental impact report.

Here is where you can submit written comments (indicating). And also, if you picked up an agenda for tonight's hearing, the address to submit written comments is on that agenda. So you don't have to take all this down, but here is the information for you. And the Planning Department will accept comments through close of business at 5:00 p.m. on October 1st.

The draft program EIR is available for viewing at the San Francisco Public Utilities Commission and also at the San Francisco Planning Department. It's also available at several public libraries throughout the study area, and it's also available on line. And the addresses of where you can view the Program Environmental Impact Report are also on the agenda.

Here's our schedule. We have a 90-day public review period from June 29th through October 1st of 2007. Several public hearings in September -- one tonight in Modesto, and then we'll been going to Fremont, Palo Alto, and then in front of the San Francisco Planning Commission in San Francisco.

Then we'll be preparing responses, written responses, to all of your comments. And that will be in the form of a comments and responses document, which we hope to publish in the spring of 2008. And we will been certifying the program environmental impact report in front of the San Francisco Planning Commission also in the spring.

So now, we are ready to open the floor for comments. Just a few notes, as I've already noted tonight, this is a hearing on the draft program environmental impact report, not necessarily here to decide whether to approve or modify the proposed

12.6-32

program.

Also, again, please submit a speaker card if you would like to speak tonight. And I'll be calling names off of those cards. So when I call your name, please step up to the microphone, state your name, and please state your address for the record as slowly and clearly as you can.

And also, we'll be keeping track of time. Although I realize that you may have more to share than three minutes will allow, please limit your comments to three minutes. If we have some more time at the end, we can call you back up. I just want to make sure everybody has a chance to speak and everybody gets home at a reasonable hour tonight.

And Al Williams will be holding up cards to let you know how much time you have left. So if he holds up a "2," you have two minutes left.

So anyone else who hasn't submitted a speaker card who wants to speak?

(No response)

DIANA SOKOLOVE: Well, I don't have that many speakers tonight, so I just want to offer, if you want to take a little bit more time than three minutes, I'm sure we'll be able to accommodate you.

So the first speaker I have on my list is Meg

Gonzalez.

SI_TRT4

MEG GONZALEZ: Okay. Meg Gonzalez, 1000 Wellington Drive, Modesto, California.

I'm the director of Community Outreach and Education Tuolumne River Trust. Since our organization is going to be submitting written comment on this proposal or on this draft PEIR and other staff here tonight are going to address some of the technical aspects of this report, I thought that I'd take the opportunity to highlight some of the positive actions that are take place along the Lower Tuolumne River.

These are locally supported initiatives designed to restore some of the ecological integrity of the river that has been lost over time and to preserve the qualities of this local gem that enhances the livability of surrounding communities.

SI_TRT4-01

Such efforts would inevitably be undermined and potentially derailed by the Water System Improvement Plan being considered tonight. So anyone that's been down to the river here in Modesto, you can tell just by looking at it that it's not in a pristine state. Indeed, spawning salmon populations are at an all-time low. Riparian habitat loss has been extensive and water quality compromised.

That said, the past decade has seen a flurry

12.6-33

of efforts to restore the river's natural environment and enhance recreational opportunities for surrounding communities.

The Lower Tuolumne River Parkway is collection of projects stretching from LaGrange Dam to the river's confluence with the San Joaquin River. The parkway combines private and public restoration activities to enhance habitat and provide public use opportunities that are compatible with existing private interests.

The Trust recently celebrated the completion of one of its projects on the lower river: a 250-acre floodplain restoration project at the river's Big Bend. The City of Modesto Parks, Recreation and Neighborhood Department is completing the first phase of the Tuolumne Regional River Park that will enhance the community's access to and enjoyment of the river as it runs through the park in Modesto.

The cities of Ceres and Waterford are also working on the development of their own river parkways. Such initiatives have caught the attention of local, state, and government officials. Senator Barbara Boxer, Congressman Dennis Cardoza and Assemblyman Tom Berryhill have all pledged political and financial support to this work.

Another exciting project is the Trekking the

Tuolumne Outdoor Education Program, a California science-standards-based initiative that teaches literally thousands of elementary school children about the Tuolumne River. One of the most important messages that we hope the students take away from this experience is that of stewardship of the river, a lesson that the San Francisco's Public Utilities Commission can benefit from.

The Trust has recently published a document called "From the Tuolumne to the Tap," which presents overwhelming evidence that San Francisco's proposal to take more water is unfounded and unnecessary.

We need to keep the water in the Tuolumne River for its health and for the health of our communities.

Thank you.

DIANA SOKOLOVE: Nicole Sandkulla.

L_BAWSCA4

NICOLE SANDKULLA: Thank you. Nicole Sandkulla, 1155 Bovet Road, Suite 302, San Mateo, California 94402. And I'm here on behalf of Art Jensen, General Manager of the Bay Area Water Supply and Conservation Agency, who has a statement for you.

The San Francisco Draft Program Environmental Impact Report for its Water System Improvement Program is undergoing careful review by the Bay Area Water

Supply and Conservation Agency and its 27 member agencies that purchase water from the San Francisco Regional Water System for 1.7 million residents, businesses, and communities in Alameda, Santa Clara and San Mateo counties.

While BAWSCA's review of the draft EIR continues, we find it to be a good, comprehensive document, analyzing the environmental impacts and program alternatives as required by law.

BAWSCA will submit written comments to correct apparent errors and expand discussion of future water demands, alternative water supplies, and water conservation efforts.

One issue the PEIR should more clearly emphasize is the critical importance of completing the WSIP to protect the public health and safety of the people that live in the Bay Area today. L_BAWSCA4-01

Four active faults cross the major pipelines, tunnels, and reservoirs that provide water to 2.5 million people in our counties and San Francisco. There is a 60 percent probability that a major earthquake will occur in the Bay Area between today and 2032.

Following a major earthquake the flow of water to communities could be disrupted for 30 to 60 days.

The impacts to public health and safety would be catastrophic. The economic impacts, not counting injuries and loss of life, are estimated to be at least seven times the cost of rebuilding the aging water system.

The WSIP includes projected use for the BAWSCA's member agencies. These agencies in Alameda, San Mateo, and Santa Clara counties and their customers are dedicated to conserving water and safeguarding the environment.

Today the average resident in the service area uses 15 percent less water per day than in 1986 and 23 percent less water than in 1976. L_BAWSCA4-02

In the Bay Area, residential water use per person is lower than the average for the State of California. And residential water use per person in the BAWSCA area is lower than the average for the Bay Area. BAWSCA and its agencies actively support water recycling to make the most effective use of limited water supplies.

The water management issues addressed in the draft program EIR are a longer term issue. The projected growth is not going to happen tomorrow. The earthquake might. Protecting existing people from a known catastrophe that could result from highly

12.6-35

probably earthquakes is an urgent issue that the WSIP is designed to address.

Thank you.

C_BramlD4

DIANA SOKOLOVE: Darryl Bramlette.

DARRYL BRAMLETTE: Darryl Bramlette, 7700 Ruth Ridge Road, Jamestown, California, Tuolumne County.

I spoke last night at the meeting up in Sonora. I didn't get a chance to compliment the team on their report because it is an excellent report, considering the task that they were given because, actually, if you take a look at it, they were given a task to do an environmental study on something that's basically impossible because there is no more water that people can get out of the Hetch Hetchy.

And the problem is, yes, San Francisco and the Peninsula needs more water. So the money would have been better spent if they'd have changed the project to look for alternative sources.

C_BramlD4-01

San Francisco Bay is a source for water. And the technology has moved out from about eight years ago when we were talking about restoring and making a principal supply for water in that area.

So I'm recommending very highly, and have done so in the past, that San Francisco Utility Commission actually do a study, environmental impact study, right

C_BramlD4-01 cont.

in San Francisco on putting in desalination so that they can have water for the future and Hetch Hetchy can remain maybe the way it is today or maybe even better because they would not have to have the flow of water from the Tuolumne River.

So in considering, I do appreciate their responses to the environmental impact. But I think it's against the wrong project, and I hope that they get the chance to turn it around and do it appropriately.

And I thank you for your time this evening, and I thank the committee.

C_Hughe2

DIANA SOKOLOVE: Noah Hughes.

NOAH HUGHES: My name is Noah Hughes, and I'm at 20192 Gibbs Drive in Sonora, California 95370.

And I'd like to start out by saying thanks again to you guys for allowing us to give our talk and, in some cases twice -- last night's meeting and tonight.

But I do have a little bit of dual citizenship. I live in Sonora. I grew up in Modesto, spent a lot of time on the Tuolumne River. And I work down here at Modesto Junior College, where I teach a class called "Earth Science."

C_Hughe2-01

One of the topics we talk about a lot in Earth

12.6-36

Science is natural resources and the acquisition of natural resources. And we sort of try to look at the natural resources through the lens of sustainability. So I would sort of like to echo the sentiment of a previous speaker, Nicole Sandkulla, that we need this -- this document to more accurately address public health and safety of the WSIP.

However, in my opinion, when you look at this through the lens of sustainability, by taking more water from a finite resource and allowing yourself more customers or more demand for that water, you have not moved toward sustainability. And therefore, you have not really addressed the long-term health and safety of a community by taking a step away from sustainability. By increasing demand and -- increasing demand on what's already a very hard-working river, we sort of moved away from that.

So examples of some cities that have actually moved towards sustainability would be, for instance, Seattle, where they have reduced withdrawals from local rivers by 15 percent in the last 20 years while serving 20 percent more people. That creates more slack in the system. That is safe. That is sustainability. It rewards itself.

I would like that type of thing to be

C_Hughe2-01 cont.

addressed in the environmental impact report.

C_Hughe2-01 cont.

And another comment, again, good job on what you guys have done, but it was sort of an impossible task to evaluate the environmental impacts with a poor data set to work with. One of the issues with data is the resolution of your data. And the resolution of the data that you are working with is too coarse. You are using monthly mean flows from the Tuolumne, a monthly average, if you will. And that cannot adequately address the needs of the ecosystem up there because it just takes a couple days without water to start to impact the ecosystem systems, riparian ecosystems, and the economy, based on recreation up there.

So even though you might get a big flow later on, so your monthly average looks pretty good, really from an ecosystem environmental impact perspective, your data is inadequate. So that is a serious flaw in the environmental impact report.

C_Hughe2-02

So, thank you so much.

DIANA SOKOLOVE: Patrick Koepele.

SI_TRT5

PATRICK KOEPELE: My name is Patrick Koepele, and I'm the Central Valley program director for the Tuolumne River Trust at 829 - 13th Street in Modesto, 95354. I'm also a rafter. I've rafted on the Upper

Tuolumne, and I like to canoe quite a bit on the Lower Tuolumne as well. And I wanted to thank you for coming to Modesto to listen to our comments.

Those of us who rely on the Tuolumne River for business, recreation, and personal renewal will suffer greatly if San Francisco pursues their plans to divert an additional 27 million gallons of water a day from the river.

I'll focus my comments on the impacts we feel the proposed withdrawals will have on the Tuolumne River below Don Pedro Lake. On the Lower Tuolumne River, many groups have come together to improve the habitat for many species, but most notably Chinook salmon. Several projects have been completed to date. SI_TRT5-01

The river is in a state of transition but is far from recovered. In fact, this past year saw only 625 Chinook salmon return to the Tuolumne, the lowest number since 1994. This is sad for a river that for a long time supported more than 60,000 fish annually and has been the focus of so much restoration work.

Taking water from the river would be like taking air from San Francisco. People need air, and fish need water. Furthermore, steelhead trout have been designated a threatened species by the National Fisheries Service, and the Tuolumne River is habit for SI_TRT5-02

these fish. Again, taking water from the Tuolumne would harm these fish by negatively impacting temperatures and reducing the frequency, duration, and magnitude of high flows. SI_TRT5-02 cont.

Finally, the riparian forest along the Tuolumne River will also be negatively impacted by reduction of flows. For example, cottonwood trees require periodic inundation to help them spread their seeds to germinate. Withdrawing more water from the Tuolumne will reduce the frequency and duration of inundation, thereby negatively impacting the riparian corridor. SI_TRT5-03

The proposed mitigation for this reduction of water in the lower Tuolumne is inadequate and, frankly, unmitigatable. While projects that add gravel and reduce sedimentation are needed, they aren't the same as fish and water. You can build miles of spawning gravels, but if those gravels don't have water running over them, they wouldn't produce more fish. SI_TRT5-04

Instead of increasing withdrawals, we encourage San Francisco and the entire Bay Area to show leadership by implementing significant water conservation measures. SI_TRT5-05

As Noah Hughes mentioned, the Bay Area lags behind other metropolitan areas, like Seattle and Los

12.6-38

Angeles, that are reducing water consumption even in the face of growth. As a region known for a strong environmental ethic, the Bay Area should be a leader in water efficiency and conservation. Thank you.

SI_TRT5-05 cont.

DIANA SOKOLOVE: Eric Wesselman.

ERIC WESSELMAN: Eric Wesselman, Executive Director of the Tuolumne River Trust, 5915 Thornhill Drive, Oakland, California, 95641.

SI_TRT6

As has been stated by other trust staff here tonight, we will be providing thorough written comments as well by the deadline date later this month, and we're working on those now with our attorneys and expert consultants and also provide I guess what we determine to be overarching problems, flaws, inadequacies with the draft EIR that -- I think point to a number of them, then follow-up, detailed comments that will be included in our statements.

No doubt -- at the outset, I would say that there's no doubt that there's a need for this project in the areas of repairs and retrofits and upgrades to the Hetch Hetchy system and the San Francisco water supply system and the infrastructure in the Bay Area. That is, no doubt needed.

And the problem -- and especially for seismic concerns. I think that the problem is that this poison

SI_TRT6-01

pill issue, increasing diversions from the Toulumne River by somewhere between 25 and 27 mgd -- which is, by the way, one of problems with the draft PEIR, there's different numbers there. And this poison pill of increased diversions threatens to delay the needed retrofits and upgrades to the system.

SI_TRT6-01 cont.

And speaking then specifically to the need for the increase in diversions, that is not adequately outlined or justified in the draft PEIR. And primarily, this is because the -- I would say three main -- well, because overall, the demand projections for water in the Bay Area are inflated. I mean, they're based on flawed data and analysis in three key ways.

One, it doesn't factor the relation between the price of water and demand for water. As price goes up, we all know that the consumption of a product tends to go down. And water is like that. It is elastic, or certainly not inelastic.

Yet in the analysis, rather than treating these demand projections, it has not considered the relation to the rising price of water tripling over 15 years and the corresponding decreasing demand for water. It didn't analyze that effect at all.

The second thing, it used allocated employment

SI_TRT6-02

projections that they -- they got from the Association of Bay Area Governments for employment projections that are inflated, and it's obvious they've sued the figures from '02 that were then updated in '05. And it showed, I think, it's 48,000 less or fewer jobs in the Bay Area. And that would result in another lower projected demand for water in that time period.

So that, in going from draft to final, they should incorporate the latest employment projections and then alter the water demand projections accordingly.

Third, there's an increase in per capita demand which is simply out of step. And it demonstrates inefficient use of water and of a resource that's held in public trust. So increase in per capita use, that's not a justifiable relief for the project specifically meaning the 25 mgd.

SI_TRT6-02 cont.

Second, and another category of problems is this analogy about known impact assessment for analysis. Looking at the baseline problems that Noah Hughes brought up, there hasn't been an adequate study of the watershed for years and years.

In fact, it's been 15 years since there was even a draft study of the status of the watershed put out. And the draft EIR references and relies on that

SI_TRT6-03

study a lot. And that's problematic because it's old, and it was never even finished. So you can't know what the impacts are. You can't adequately analyze the impacts of the project if you don't know your starting point. You don't know where you're going unless you know your history. So without adequate baseline data, the EIR is inadequate. End of story.

SI_TRT6-03 cont.

The third key point, the EIR didn't adequately factor in legal obligations. TID and MID have been covering fish recovery flows for years. The San Francisco PUC has been paying TID to do this. There's no -- the EIR assumes that this will continue. But to our knowledge, there's no written contract or no agreement between irrigation districts and San Francisco that this is going to continue. So that means San Francisco needs to provide this water, and that would cause a problem with taking even more water off the river.

SI_TRT6-04

Another one is the impacts in the Delta. The Tuolumne flows into the San Joaquin. The San Joaquin flows into the San Francisco Bay Delta, which we all know is in crisis. And the EIR doesn't adequately analyze the impacts to the Delta. And San Francisco likes to ignore that it has any relationship to the Delta, of course, because they don't want to get caught

SI_TRT6-05

12.6-40

up in that mess. But that's politics. This is supposed to be science.

It actually assumes -- it does find some impact in the EIR, but it assumes that the Bureau of Reclamation will mitigate for those impacts. But again, I'm not aware of any acknowledgment there that they will do that. So that's a problematic assumption that adds up inadequacy. SI_TRT6-05 cont.

Thanks for your time, and thanks for your work on this project.

L_MID

DIANA SOKOLOVE: Walt Ward.

WALT WARD: Good evening. Walter Ward, Modesto Irrigation District, 1231 - 11th Street, Modesto, California 95354. I only have some very general comments tonight. We will be providing specific written comments.

And towards that end, given the significance of the scope and range of this project, the magnitude of the documents under review, we would respectfully request that you extend the public comment period for at least another 30 days. I think it merits that kind of thorough understanding by the public. So I'll make that request. L_MID-01

More pointedly -- and again, we will provide written comments by the deadline if it isn't

extended -- but one comment that I do want to make tonight is to bring out the idea that the EIR, in our review, fails to clearly identify which projects will be subject to a subsequent, specific project-level EIR.

Some of the projects will probably be cure-all, programmatic, but in particular, the notion of a dry-year transfer from MID and TID to San Francisco is silent in the EIR. And we think, although that project has some intriguing ideas, it merits a very high-level of scrutiny and evaluation. And the EIR, as it now stands, does not identify that it would be extended to a project level. And we -- we have that concern. L_MID-02

C_TayloJ

DIANA SOKOLOVE: Jean Taylor.

JEAN TAYLOR: A few days ago, I sent a letter to the Modesto Bee regarding the condition of the Tuolumne River. I live on Santa Fe Avenue, Modesto, California. I've lived there 37 years. And I have never seen the river in this horrible condition it is now. It's green. It's slimy. And we have riparian rights. We can irrigate from the river, but it's a real problem. I have another hundred feet to even reach the river and constantly have to clean the slime off my foot path.

I just have a concern for the river. It's a real blessing for a community to have a river go C_TayloJ-01

12.6-41

through it. It's a recreational thing that -- you can't use it now. It's horrible. How can the fish survive in it? I'm just very concerned about the condition of the river and that something needs to be done that they don't take more water from it.

C_TayloJ-01 cont.

DIANA SOKOLOVE: Sandra Wilson.

SI_SierraC2

SANDRA WILSON: Hi. My name is Sandra Wilson, I live at 704 Tokay Avenue, Modesto 95350. I'm the chair of the local Sierra Club, and we'll be providing more detailed comments. But I did want to bring up a few things. I go to a lot of sprawl meetings. And I'm constantly told -- ask the question, "Why do we have to grow?"

And I'm constantly told that it's because San Francisco and the Bay Area has stopped growing. So it brings up the question, "Why do we need to give them 27 million gallons of water out of the Tuolumne when we stand to lose a great deal?"

As part of the Sierra Club, I lead hikes along the Tuolumne. And I also do a salmon walk. Last year, we were very hard pressed to find the salmon to show people. I think we found a dead one. But last year, there were record lows. So there's a lot of concern about the salmon and the rest of the wildlife. If the river dries up, what happens to the otters that you see

SI_SierraC2-01

up around LaGrange? There are so many things that depend on the river today.

Also, as a community, here in Stanislaus County, we have put a lot of time and money and energy into creating a regional park, a Tuolumne River Regional Park, a park that revolves around the river. And what do we lose? What is our environmental impact if we have the Tuolumne Ditch Regional Park because we don't have enough water left? I mean, it just doesn't seem like -- you know, what happens to all the years of planning and the time and the energy and money that we've put into building a park like this, if we're going to lose the river, and the benefits that it provides our community.

The river also flows down into San Joaquin Wildlife Refuge. And we've spent a lot of money there. And the wildlife refuge plans to grow. And one of its concerns is water. Losing more water is going to affect the marsh habitat that's need for migrating birds. That whole park was created for the Aleutian geese, which are going extinct because of losing migrating habitat for winter feeding. What happens to the birds in the park?

Those are all things that need to be addressed.

SI_SierraC2-01 cont.

12.6-42

And also, I think it's really unfair not to consider the Delta in this. Just last week we had a court case on Grant [phonetic] Damn upheld. We need to consider the water in the Delta because the water in the Delta provides the basic food that the salmon need before they swim upstream into the Tuolumne to spawn. So if you don't take that into account, you're really not addressing the salmon population on the Tuolumne River.

SI_SierraC2-02

So for us, another area that I think is important to consider is global warming. We've seen a lot of changes in our weather. You know, we're just not getting the snow pack that we used to get. How does that affect our overall water supplies running into Hetch Hetchy Reservoir? I still think you ought to be taking this further and looking at other ways of providing the needs of San Francisco.

SI_SierraC2-03

San Francisco is the wealthiest -- one of the wealthiest cities in the entire country. Yet here they are in this situation. They stand to take so much from us and Stanislaus County and the people living all up and down the Tuolumne River and, of course, all the wildlife and the animals that, for us -- you know, it's a limited resource. And once it's gone, it doesn't come back.

So I'd ask you to take all of these things into account.

DIANA SOKOLOVE: Is there anyone else who hasn't spoken who wants to speak tonight?

(No response)

DIANA SOKOLOVE: Anyone else who has spoken who wants to speak again?

(No response.)

DIANA SOKOLOVE: Okay. Well, thank you for coming tonight, and thank you for your comments, and thanks to everyone who spoke.

Again, here's where you can submit written comments (indicating). And have a good evening.

(Whereupon, the proceedings concluded at 7:06 o'clock p.m.)

Tuesday, September 18th, 2007 6:30 o'clock p.m.

---o0o---

P R O C E E D I N G S

DIANA SOKOLOVE: Okay. Folks, we're going to get started. Thanks for coming tonight. Good evening. My name is Diana Sokolove, and I'm a senior environmental planner with the San Francisco Planning Department. The Planning Department is the lead agency under CEQA for preparation of the environmental document on the Water System Improvement Program, and the San Francisco Public Utilities Commission is the project sponsor. We are two different departments in two separate entities.

I'm going to be the moderator for tonight's meeting, and I just want to introduce some other folks who are here with us tonight. Kelly Capone is the environmental project manager with the San Francisco Public Utilities Commission. She's at the back of the room. With her is Heather Pohl, also with the PUC. And they're available after the hearing to answer any questions you may have about the proposed program.

Leslie Moulton is the project manager for the ESA + Orion joint venture, the consultant team for the environmental impact report.

And we have some public involvement folks here, also with the San Francisco Public Utilities

Commission. Jim Marks is here in the audience, and there's some other folks here too.

Actually, if the public involvement folks -- you may want to stand up and just let folks know who you are.

And those folks can help answer questions after the hearing.

So this is one of five public hearings on the Water System Improvement Program, Program Environmental Impact Report. And we are essentially providing the same information at every public hearing, although you are more than welcomed to attend each one.

Here's our agenda for tonight (indicating). Just to provide some quick introductory remarks, and then we'll open up the hearing for public comment.

Some meeting reminders. Hopefully you signed in when you came in and you took some copies of our hand-outs, such as our meeting agenda, which has the information where you can submit comments on the environmental impact report. And please do submit a speaker card if you want to speak tonight. This is what it looks like (indicating). And you can submit them to Andrea here at the computer.

And also, you may also wish to pick up a comment form. And that's what this looks like. It's a comment card. If you want to submit written comments tonight, this is an opportunity for you to do that. And you can give them to me personally, or you can just leave them in the box here.

Restrooms are located out this door and to the right. And also, if you wouldn't mind please turning off your cell phones and pagers and just to make sure that, if you want to take a call, you step outside the room. I'm sure everybody would really appreciate that.

Again, be sure no food or drink other than water in this room. And as you see, we do have a court reporter here this evening who is taking a formal transcript of the proceedings. And the transcript will become part of the public record for this environmental impact report.

We are here tonight to receive your comments on the adequacy and accuracy of the environmental impact report and the Water System Improvement Program. Your comments will be transcribed and responded to formally in a comments-and-responses document prepared by the San Francisco Planning Department. And we are not here to answer your questions tonight as part of the formal public hearing, but we can try to answer some of your questions after the formal public portion of the meeting has closed.

Again, this is not a hearing to consider approval or disapproval of the proposed program. That hearing will be held by the San Francisco Public Utilities Commission following the final program environmental impact report certification hearing, which is presided over by the San Francisco Planning Commission.

Here's where you can submit written comments on the environmental impact report (indicating). And again, if you picked up an agenda, that information is also on the agenda. And a reminder that the Planning Department, my department, will accept comments by close of business on October 1st. The environmental impact report is available on line. It's also available in print at the Planning Department and at the Public Utilities Commission and at several libraries throughout the program study area, including the Fremont Main Library here.

And if you would like a copy of the environmental impact report on CD, that's something that you can put on this comment form and just let us know and we can mail you one.

Here is an overview of our schedule, our environmental review schedule (indicating). We are holding a 90-day public review period starting June

29th through October 1st of this year and, again, five public hearings. Tonight, we're in Fremont. We'll be in Palo Alto tomorrow night. And on Thursday we'll be at the San Francisco Public Utilities -- I'm sorry -- the San Francisco Planning Commission.

And if you haven't seen it already, the agenda for the Planning Commission hearing is up on the Web. It has been released, and there's a time certain for 5:00 p.m. And all that really means is that we won't be starting the hearing on the document before 5:00 p.m., but it could start later than 5:00. So it just means it won't start before 5:00.

We'll be preparing, as I mentioned, responses to all of your comments. And we will hopefully release that document, the comments and responses document, in the spring of next year. And then the San Francisco Planning Commission will hold a certification hearing to consider whether to approve the adequacy and accuracy of the environmental document.

So just some rules for the comments session tonight. Again, please comment on the environmental impact report, its accuracy, its adequacy. Please, again, submit a speaker card to speak. And I will call your names to come up to speak, and you can either speak at the microphone up here at the front of the

12.6-47

room or we have a portable microphone that we can give you. So wherever is most comfortable for you. And when you come up to speak, please state your name and your address for the record.

We do have a general standard of keeping your comments limited to three minutes, but we don't have that many speakers tonight. So just be as brief as you can and consider your comments to be a summary of your main verbal comments. And you can certainly submit additional comments, written comments, to me or to the environmental review officer through the 1st of October.

C_Cant

So is the first speaker I have is John Cant.

JOHN CANT: I am John Cant. I live in Fremont. And I seem to recall being in this room two years ago on a very similar topic. And perhaps I'll sound the same way as I did then.

C_Cant-01

My first major issue has to do with whether the SFPUC -- which we all understand has to maintain and improve a massive water supply system -- whether the Commission is paying sufficient attention to minimizing, insofar as possible, the demand for water in the overpopulated Bay Area.

And I would submit that this is not happening at all, that there is by far insufficient attention being paid to conservation and efficiency of water use. This can be done in metropolitan areas. It's being done in Los Angeles. And I know Los Angeles has a lot of guilt to atone for, but still, if Los Angeles can do something in terms of efficiency and conservation, then perhaps we, who are reputed to be more environmentally sensitive, should do even better.

Also, I might call attention to the example of Seattle, which has a much more enlightened approach to acquisition and use of water. So this can be done. As far as I can tell, the Commission is paying very little attention to it.

As a minor example, when I water my garden -- which I do, I confess -- I am using water which I believe 60 percent comes from the Sierra Nevada which, to me, is obscene that we here in Fremont can be watering our gardens, washing our cars, using a large amount of water from the Sierra Nevada with no recycling, no system for gray water. So that's my first point.

C_Cant-01 cont.

My second has to do with the proposed -- or I guess it's program environmental impact report. And Chapter 6 deals with the habitat reserve program.

Now, I'm not debating whether the Commission needs to pay attention to its facilities, make

C_Cant-02

improvements. There's going to be a lot of construction, earth moving, and so on. And those are bound to have negative environmental impacts. The issue is whether they -- the proposal suggests adequate mitigation.

And I'd like to call attention to, I think, an important letter by Jeff Miller of the Alameda Creek Alliance to Paul Maltzer of the San Francisco Planning Division [sic], dated August 28th -- it's available through the Alameda Creek Alliance website -- that explains in considerable depth just why the Habitat Reserve Program, whose aim is to mitigate impacts to habitats for sensitive species, comes nowhere near doing an adequate job. For one thing, the simple acreage is not sufficient.

C_Cant-02 cont.

So to summarize, it seems to me we in the Bay Area ought to figure out better ways and help the Commission push us into those ways, push our more recalcitrant neighbors into those ways of reducing water use in spite of growth, which can be done, and second, while working to maintain and safeguard the water supply system, obviously important, that the negative effects on the habitats that surround us in a very ecologically diverse area, those negative effects are dealt with properly.

C_Cant-03

12.6-49

C_Ellis

C_Ellis-01

Thank you.

DIANA SOKOLOVE: Dave Ellison.

DAVE ELLISON: Good evening. I live here in Fremont, and I recognize the need to upgrade our -- to give us all water and to make it seismically safe. But I have hiked the Tuolumne River, and I've rafted it and seen the flora and the fauna that it sustains. And I'm concerned about taking more water out of it, especially since this morning, as always, I was at my local health, club and after I swam, I went into the shower, and I lathered up. Then I turned on the water and turned the water off.

Meanwhile, when I walked in there were about eight people in the same room just standing there, leaving the water running. They were there when I arrived; they were still there when I left. I went out to the sinks to shave, and I sort of, you know, rinse off my razor, turn the water off, shave, rinse off my razor. Meanwhile, the gentlemen on either side just flipped the taps and let the water run.

I see when I go for walks in the evenings where water -- you know, gallons and gallons and gallons of water that was supposed to be irrigating grass is just going right down into the sewer because it's just left running or something is broken or what

C_Ellis-01 cont.

have you.

I guess I just echo my predecessor's comments. Before we go upsetting yet another pristine wilderness, maybe we should look at our own habits, and maybe part of this plan should be an outreach to us to educate us that water is not an unlimited -- in unlimited supply. And if we just changed our habits, we wouldn't need all that new water.

Thank you.

SI_TRT7

DIANA SOKOLOVE: Eric Wesselman.

ERIC WESSELMAN: Thanks. Hi, Eric Wesselman, executive director of the Tuolumne River Trust based out of San Francisco, Modesto, and Sonora.

I thought I'd start by saying the WSIP certainly includes a number of necessary projects -- seismic upgrades, retrofits, and repairs on the system -- that we've got to move forward on and move forward quickly.

SI_TRT7-01

Unfortunately, the WSIP also includes a proposal to take more water out of our natural environment for use here in the Bay Area; 25 million gallons per day would come from the wild and scenic Tuolumne River. So the Toulumne River already supplies more than half the river's volume for rural and urban uses. In other words, the majority of the river is

SI_TRT7-01 cont.

already diverted. So taking more water from this wild and scenic river will do more harm to the environment, which is simply unacceptable at this point. We should be talking about putting more water back into the environment.

And while I'm concerned about impacts to the Toulumne River, I'm also concerned about redirected impacts to other watersheds. If we don't take more water from the Tuolumne, where else does it come from?

SI_TRT7-02

Well, our answer is that it should come from conservation, recycling, and other efficient, sort of water-smart, sustainable measures, which are abundant and plentiful and cost effective in this day and age. We're not in the last century anymore.

SI_TRT7-03

More to the point, this draft EIR doesn't adequately define the need for this increased diversion. The science behind the increase in demand for the Bay Area, these 28 wholesale customers, is based on really flawed and flimsy and terrible science provided by the SFPUC and their 28 wholesale customers.

And to point out, and foremost, we're dealing with a situation where the relationship between price and demand wasn't analyzed at all. So as price goes up, which the SFPUC indicates will more than triple over the next 12 years, that's going to have an impact

SI_TRT7-03 cont.

on demand. There's a relationship between price and demand. It's not inelastic. So as price goes up, demand will go down. By how much? We don't know because it wasn't analyzed in the demand projections.

SI_TRT7-04

That's a technical flaw that makes this EIR inaccurate.

Secondly, the SFPUC conducted its own study just last year that found that the vast majority of their projected increase in demand could be met through efficiency, conservation, and recycling. Yet that study wasn't relied on at all in the draft EIR or in the reformulation of the new demand projections.

SI_TRT7-05

And thirdly, the demand projections rely on out-dated employment projections from the Association of Bay Area Governments. They used 2002 data for their job employment growth. Now, in 2005, ABAG re-released that data, and it was adjusted downward by tens of thousands of jobs. So if you have less jobs, you have less growth in water demand in the commercial sector. Ergo, the demand projections should be adjusted downward accordingly. Yet nothing was done when the draft EIR analyzed these inflated demand projections.

SI_TRT7-06

And fourthly, just out of principle, we're talking about an increase in per capita demand. So not only is the area's water use in the 28-wholesale-customer region projected to increase, SI_TRT7-06 cont.

it's projected to increase per person.

So this is unacceptable in this day and age. We should be becoming more efficient, using less water per person to do the same thing, through efficiency. It's like driving a hybrid car cross-country versus an SUV. You get the job done. You still get across the country. You just use less resources to do it. It's the same thing with efficiency. So we should be looking at decreasing per capita water use, not increasing it.

SI_TRT7-07

The DPEIR also failed to assess the environmental impacts of taking more water off the Tuolumne River. In a couple of key areas, this is true. First, there's no adequate baseline defined for the current environmental status of the Toulumne watershed. So there were no studies done or the studies were done more than a decade and a half ago and were never completed. So we don't know what the current status is.

So how can you forecast and figure out what the environmental implications or impacts will be taking of taking more water out of the system? If you don't know where you're coming from, you don't know where you're going. So that needs to be done. We need to have an adequate baseline first.

SI_TRT7-08

Secondly, we're dealing with a subjective definition of what constitutes a significant environmental impact in the draft EIR. Significant impacts should be defined with measurable and quantifiable criteria. And by having loosey-goosey, quite frankly, terms and a subjective definition of what constitutes a significant impact, the DPEIR fails in that area. It is inadequate. It needs to be quantifiable.

SI_TRT7-09

Thirdly, global warming was not -- was never really evaluated at all. It's mentioned in the draft document, but it was really -- it was a punt. It's hard to analyze, and a lot of things are hard to analyze. It's hard to analyze and project what future water demand is going to be in the year 2030. And if we think we can do that, then we need to also adequately analyze what we think is going to happen due to global warming. There's a lot of climate models out there. You run them a few hundred times, get some good data. And that wasn't done at all.

And instead, the Planning Department, SFPUC, and the wholesale customers relied on hydrologic data from the last 82 years. While that's necessary and important in a useful data set to include in models, it -- the planning document didn't look at the trends

12.6-52

in that data, didn't look at what happened over those 82 years. Were there trends towards decreasing Sierra snowpack at that time? What other trends should be noted about our water supply in the Sierras?

In addition, it doesn't look at climate change, because we know that in the last 82 years what happened is not what's going to happen over the next 82 years because of a whole host of things, most notably, I'd argue, due to global warming, which will have an impact on the Sierra snowpack. We all know it. It's going to change the hydrologic nature of this watershed.

And then on a subjective note, the SFPUC and the wholesale customers are now talking about increasing their reliance on the Sierra -- on the source out of the Sierra Nevada at a time when we know it's going to be less reliable, less sustainable because of global warming and a whole host of other issues.

SI_TRT7-09 cont.

So I'll stop there and look forward to providing written comments. Thanks for the extra time.

SI_ACA2

DIANA SOKOLOVE: Jeff Miller.

JEFF MILLER: Hi. Jeff Miller. I'm the director of the Alameda Creek Alliance, and we've been working since 1997 to restore Alameda Creek. And we now have

over 1400 members that live in and near the watershed. And I'm going to comment mostly on Sunol Valley projects that have to do with Alameda Creek and particularly the fishery issues.

And looking through the programmatic EIR, the main comment is that there's a couple projects in particular that we're concerned about, Calaveras Dam obviously being in largest one, that's the primary water source from Alameda Creek and the largest infrastructure project that's being contemplated.

Currently the PUC diverts, by its calculations, 86 percent of all stream flows in the Upper Alameda Creek Watershed into its water system. So that doesn't leave a lot for fish and wildlife. And under the Calaveras Damn project in the EIR, the PUC is claiming no impact to steelhead because they're not back in the system yet. Well, downstream, a couple agencies are working on fish passage projects. Our main barrier to steelhead in the flood control channel -- two agencies just signed an agreement to try complete that project by 2010, which is before construction of Calaveras Reservoir would begin.

So in our mind, looking at a long-term project like this and operation of Calaveras Dam, there has to be an analysis of impacts to steelhead in this EIR.

SI_ACA2-01

12.6-53

Also, there needs to be a commitment to adequate stream flows for steelhead trout. There's flows contemplated for resident fish which are not going to be adequate for migratory fish. They're certainly going to improve things for rainbow trout but are not going to adequately address flow needs for steelhead.

And another thing I'd point out, that obeying current laws, such as Fish & Game codes requiring minimum flows for native fish, is not an adequate mitigation measure. That's compliance, not mitigation. So the mitigation measures in there that merely contemplate complying with laws that haven't been complied with is not going to be adequate.

SI_ACA2-01 cont.

There's two projects in particular that are disturbing because they actually propose increasing diversion of water from Alameda Creek over what's currently diverted, and that's the Calaveras Dam project, where the Alameda diversion dam on Upper Alameda Creek is contemplated to be operated in such a way that it diverts nearly all of the flow from Upper Alameda Creek.

And I'd point out that that's illegal, for one thing, and also does not adequately analyze what the impact is, nor mitigate it. And we're calling on the

PUC to actually remove the Alameda diversion dam.

And the other is the fishery enhancement project, which is designed to recapture flows that are anticipated to be released from Calaveras Reservoir. This is the result of a legal settlement in the 1990s. And these are flows that are contemplated for instream fish -- so for rainbow trout. And the recapture project, unfortunately, also includes a clause that will have the PUC capturing their historic annual diversions, including water they used to divert from the Sunol filter galleries, which are no longer used, which would probably dry up Alameda Creek below the project site.

SI_ACA2-01 cont.

So these are both impacts that aren't analyzed. And then lastly, I just want to put a pitch in again for conservation, water recycling and efficiency. And this needs to be done so that additional water doesn't have to be taken from Alameda Creek or from the Tuolumne.

SI_ACA2-02

Thank you.

C_Means2

DIANA SOKOLOVE: Robert Means.

ROBERT MEANS: Okay. This is starting to feel a little bit like an experience I had nearly five or six years ago with the BART extension where the experts come in with their solution for how to do things and

12.6-54

they're not particularly interested in the public comment because they know the way they want to do it. But I'm here to give my public comment anyway.

The demand for this extra water coming from Tuolumne, apparently, seems rather unjustified. We've had a number of people talk about efficiency, conservation, and recycling being the best solutions. And my expertise comes from the energy and transportation realms. And these three values of efficiency, conservation, and recycling make so much sense there that that's actually being implemented by PG&E, who sells electricity. They're encouraging all of us to put in CFL's and cut back on our usage because they understand that, long-term, that's what makes the most sense economically for them.

C_Means2-01

And then we get into our environmental consequences and just the health effects from the pollution from generating electricity, et cetera, in this case, the health effects of the environment, of taking yet more water. We're already taking -- what is it 60 percent we're taking out? We're talking about jerking that up to 66 percent of the water when we could conserve and get that extra water that's projected on what sounds like, maybe, faulty projections.

I haven't had a chance to do the numbers, but it seems to me that projecting -- what are we talking -- 23 years out into the future is difficult to start off with. But given that we've got major changes coming down the pipeline, like global warming and possible population collapse -- I'd encourage all you folks to learn more about the 11th hour and some of the other crises that we're facing in addition to global warming -- we may not need all that water, especially since, if we're actually -- we're expecting the water use per capita to increase?

C_Means2-02

We're getting more efficient. We have been getting more efficient. And we will continue to get more efficient because it's cheaper to do it that way. So focus on conservation, not on stealing some more water from the river that -- who is that going to really benefit, large corporations again? Who is making these decisions? Is this another thing like the Cheney Energy Task Force, where the decisions are made by the corporations and then inflicted upon us?

Thank you for your time.

DIANA SOKOLOVE: William Noren.

C_Noren2

WILLIAM NOREN: Thank you for this time. I appreciate being able to stand up and talk to all my fellow citizens here about the situation we find

C_Noren2-01

12.6-55

ourselves in and again somebody trying to take our natural resources and use it in ways that we don't prefer to have them used. I hope a lot of you understand that we don't need to use nearly as much water as we do in our society, but because of the things our society believes we need to have, we just continue to use water the way we do.

There's been some experimental facilities for waste disposal, human waste disposal, that doesn't take any water. I lived that way in Australia for quite a while, in a city. This wasn't in the boonies in a hole in the ground or anything. And it's just a lifestyle change. It's an understanding. It's getting past our ignorance and "oh, it's going to smell." It's a place where water isn't that important to use for that particular thing. And also once you start doing that, you don't have to have these huge, massive facilities to clean the water because we didn't use it for that in the first place.

I grew up in Redwood City. And when I was a little boy, I used to go out in the creeks and catch frogs and look for snakes and all that kind of stuff. And I'd like for my son to do that. We live over in Niles, next to the creek. And right now, I don't feel comfortable him going in there, knowing what's floating

C_Noren2-01 cont.

around in the water, and knowing that there isn't adequate water flushed out of the system, what's being put on the land out there and what's being used.

So my big point is that, if we make decisions for ourselves and not let the people in charge who are making decisions downwards instead of coming upwards and looking towards the future, then we'll be allowing the future generations to use the resources the way that they'd like to see them instead of cutting them off now and not letting them have a say or even being able to participate in the wonderful nature that we have.

Over on the peninsula, they put almost all of the creeks underground. And where I grew up, there wouldn't be a chance for my son to play. So I think it's important that we do all that we can to make sure that the people making these decisions aren't doing it for the their own personal reasons or for the reasons of a very select few.

Thank you.

C_Noren-01 cont.

DIANA SOKOLOVE: Kristen Keith.

L_Menlo2

KRISTEN KEITH: Good evening. My name is Kirsten Keith, and I'm here from Menlo Park. I'm the chair of the Menlo Park Planning Commission. And we're just trying to make sure that our city is also represented

12.6-56

and that we attend all these meetings and have a say.

And I want to encourage anybody who has not read "Cadillac Desert" to go out and read it because it's a great historical perspective on water in California and across the West in our nation, and it's well worth the read.

L_Menlo2-01

WILLIAM NOREN: Are you suggesting that they might be doing another water grab, like they've documented in that book?

KIRSTEN KEITH: I'm just saying that, if anybody wants to get some background and information about water politics, that this is a good book to read. And it gives you a great overall perspective of water politics in California and across the Western states.

L_Menlo2-01 cont.

So thanks.

DIANA SOKOLOVE: Is there anyone else who wants to speak?

LECH NAUMOVICH: Sorry. I've come a little bit late.

SI_CNPS-EB2

My name is Lech Naumovich, and I'm representing the California Native Plant Society. I'm representing the East Bay Chapter, and we work in the two-county area of Alameda and Contra Costa counties as well as throughout the state of California. We have about 10,000 members that are very active in

conservation issues.

And although this doesn't immediately seem like a native plant issue, it's very germane to us. First of all, I know this has been echoed -- this has been said a number of times, and I want to echo it. There's an alternative out there that talks about aggressive conservation and water recycling and local groundwater alternatives. And we fully support this alternative.

SI_CNPS-EB2-01

We don't think there's -- we do want to see an upgrade to the system in terms of the delivery to the city and the folks there. We think they deserve to have clean, good water. But we didn't think there's any reason to have any additional diversions out of Tuolumne.

SI_CNPS-EB2-02

We don't think there's any reason to have any diversions out of Alameda Creek. There are a number of grass roots groups that have started from the ground up with a lot of hard work and working towards restoring our native fish out there -- fishes, actually, a number of species. Those efforts would be greatly undermined by this project.

And although that is also not, obviously, a native plant issue, the riparian corridor and its native plants and associated vegetation out there is.

SI_CNPS-EB2-03

12.6-57

So we don't think that's any sort of reasonable alternative.

SI_CNPS-EB2-03 cont.

In terms of the numbers here, it's pretty amazing. Take you back to a grad school class I took on international water policy, and folks may know these numbers.

But did you know on average in Israel they reuse their water four times? They withdraw it, and they recycle and use it four times. Do you know what it is in this state? About 10 percent of the water is reused a second time.

So in terms of aggressive conservation, recycling, in terms of the world and if you take a larger vision and a broader picture of how we utilize water resources, we are much lower on the spectrum.

Now, folks might argue, "Well, look, we're going to require a lot more energy to do that filtration, reuse that water." That's not necessarily true either. There are a lot of mechanisms which are very energy neutral in order to produce extra water at a minimal cost.

SI_CNPS-EB2-04

And finally, we think it's really important -- I know there are a number of previous water agreements, especially with Modesto and Turlock irrigation districts -- I think it would be really important for

SI_CNPS-EB2-05

the consultants and the agencies to flesh that out and understand what kind of parameters we're working with within there.

SI_CNPS-EB2-05 cont.

And then finally, we want to ask for adequate botanical surveys. We have these huge numbers of ecosystems that will be impacted and woodlands and vernal pools and serpentine and areas that are going to be inundated -- and we've seen all that. But we really want to see a really strong pitch for why we need to divert more water from Toulumne, from the Alameda Creek watershed and other watersheds on the peninsula.

SI_CNPS-EB2-06

Thank you.

DIANA SOKOLOVE: Anyone else?

(No response.)

DIANA SOKOLOVE: Okay. Well, thanks for coming tonight, and thanks to everyone who spoke. And you'll see, again, here is where you can submit written comments by October 1st (indicating).

Have a good evening.

(Whereupon, the proceedings concluded at 7:15 o'clock p.m.)

---o0o---

P R O C E E D I N G S

ALFRED WILLIAMS: Good evening, ladies and gentlemen. I'm going to ask you to take your seats, please. We'd like to get started for the hearing.

Good evening, ladies and gentlemen. Welcome to the San Francisco Planning Department's hearing on the Draft Program Environmental Impact Report of the San Francisco Public Utilities Commission's Water System Improvement Program.

Oh, I'm sorry. That was just a dry run.

Welcome to the San Francisco Planning Department's hearing on the San Francisco Public Utilities Commission's proposed Water System Improvement Program. Our facilitator for this evening's meeting is Ms. Diana Sokolove of the San Francisco Public Utilities Planning Department.

DIANA SOKOLOVE: Thanks, Al.

Hi. Good evening, and welcome to tonight's environmental hearing on the Draft Environmental Impact Report for the San Francisco Public Utilities Commission's Water System Improvement Program.

My name is Diana Sokolove, and I'm a senior environmental planner with the San Francisco Planning Department. And the San Francisco Planning Department

is the lead agency under the California Environmental Quality Act for environmental evaluation of projects that are sponsored by or within the City and County of San Francisco. And this project is sponsored by the San Francisco Public Utilities Commission, so we are separate entities in separate departments. And I do represent the Planning Department.

I will be the moderator for tonight's hearing, as Al mentioned. And I also want to just introduce some key folks who are here tonight to help answer questions after the public comments portion of the hearing. Tonight we have Kelley Capone, who is standing in the back of the room. And she is with the San Francisco Public Utilities Commission. And we have Jim Marks, who is with the San Francisco Public Utilities Commission Communications Department. We also have Joyce Hsiao, who is with the ESA + Orion joint venture. They are the consultant team who helped my department prepare the environmental impact report . And also some public involvement folks here tonight, who are here to collect comment cards and also help to answer any questions you may have. So feel free to chat with them as well later this evening.

And just so you know, this is one of five public hearings that we're holding on the environmental

12.6-61

impact report. And we are providing essentially the same information at every hearing. Last night we were in Fremont, and a couple weeks ago we were in Sonora and Modesto. Tonight we're here, in Palo Alto. Tomorrow we'll be at the San Francisco Planning Commission hearing.

And for those of you who may want to attend that hearing, the hearing normally starts at 1:30, but we have a time certain for the public hearing portion for this project, and that is at 5:00 o'clock. What that means is that it won't start before 5:00. It may not start exactly at 5:00, but it won't start before 5:00. So you won't have to be there from 1:30 on, waiting for the hearing.

So our brief agenda for tonight -- hopefully you signed in when you came in. We'll do sign-in, introductions, and I'll say a few remarks. Then we'll open up the hearing for public comment.

Some meeting reminders, again, hopefully you signed in and picked up a copy of the agenda for tonight's hearing. If you didn't sign in, please do so before you leave. It's our way to keep in touch with you throughout this process. And if you do plan on speaking tonight, I hope you filled out a speaker card. They look something like this, although mine's in

color. The ones we have here are black and white. And if you do plan to speak and you filled out a speaker card, please, as soon as you can, hand those in to Andrea over here. We just need to get a sense of how many people are going to be speaking tonight.

Another item you may wish to pick up is a comment card. This is a form that you can fill out if you want to submit comments tonight in writing. If you don't want to speak, you just want to submit some comments in writing, you can submit this card directly to me or you can put it in the written comments box at the back of the room, or you can always mail or fax this in later, and we'll give you our contact information.

Restrooms are located out this door here, and -- well, actually, there are some right here, but there are also another set out this door here and to the right.

And please, please turn off your cell phones and pagers. And if you need to take a call, please step outside the room and take your call outside.

And just so you know, we do have a court reporter here tonight. And she is transcribing this hearing, and that transcript will become part of the public record for the environmental review process for this program.

So we are here tonight to receive your comments on the adequacy and accuracy of the program environmental impact report on the Water System Improvement Program. We really want to get your thoughts on the quality of the document, the quality of the analysis.

We are not here to hear your comments on the merits of the program. We really want your comments on the adequacy of the environmental document. And all of your comments will be recorded, and we will respond to each and every one of them in a document called the "Comments and Responses Document."

And tonight, the comments that you make, again, we will respond to those formally in writing. But this is not a question-and-answer session, so we are just here to record and take your comments.

Also, this is not a hearing to consider approval or disapproval of the proposed program. That hearing will come after the hearing by the San Francisco Planning Commission, which will certify whether the environmental analysis is adequate and accurate. Then the San Francisco Public Utilities Commission will consider whether to approve, modify, or adopt the proposed program.

You can submit written comments in a variety of ways -- by e-mail, by fax. You can phone them in. You can mail them in. We have all that information, most of that information, up on the screen. We also have it on your agenda tonight so you can take that with you. And please note that the Planning Department -- that's my department -- will accept comments on the adequacy and accuracy of the environmental analysis by October 1st, close of business.

There are also several places where you can look at the draft program environmental impact report. We do have a copy in the back of the room here that you can look at right back here. And we also have the impact report in several libraries throughout the study area, so you can look at the impact report in any one of those places. You can also look at the environmental impact report at the San Francisco Planning Department or at the San Francisco Public Utilities Commission.

And if you'd like to receive a CD of the document, that's another way that you can use this comment card. You can request the CD, and we'll mail you one. So just let us know if you'd like one.

So this is just a brief overview of our

12.6-63

schedule. We have a 90-day public review period, which is twice as long as the mandated public review period, starting at the end of June and runs through October 1st, close of business. As I mentioned, several public hearings. Tonight we are in Palo Alto, and tomorrow in San Francisco.

We will prepare a comments-and-responses document, as I mentioned, and we hope to publish that in the spring of next year. And we also hope to have the documents certified as adequate and accurate in spring of 2008.

So again, anybody holding on to a comment card, if you wouldn't mind please submitting those right now.

Well, given that we only have about ten speakers, typically we limit your comments to about three minutes. That's if we have several speakers. And tonight I would just ask that you keep your comments as brief as possible, that you consider your public hearing comments or verbal comments as a summary of the overall comments on the document. And you certainly can supplement those in writing. So let's take about three minutes or so. We will generally keep track of time, but you can take up a little bit more time if you need it.

And what I'll do is, I will call your name up from the list of speaker cards that I have. You can step up to the microphone here at the front of the room, or I believe we have a mobile microphone. So if you feel more comfortable staying at your seat, you can certainly speak from there.

Please state your name clearly and your address when you walk up to the microphone to speak so that we have that for the record and we can get back to you with responses to your comments.

So again, take about three minutes, but you can take a little bit more time if you need it.

I have the first speaker, Anita Dippery.

ANITA DIPPERY: I'm passing.

DIANA SOKOLOVE: Okay. First speaker, Mary Jane Marcus.

C_Marcu

MARY JANE MARCUS: Hello. Sorry. I wasn't expecting to go first.

My name is Mary Jane Marcus. And I need to say my address?

521 Addison Avenue in Palo Alto, California, just down the street. This is the first time I've ever come to a hearing or spoken at a hearing. And I'm getting nervous. But the reason I'm here is that usually the actions we take here, our conceptions and

C_Marcu-01

12.6-64

so forth -- we don't really know where things come from and how we're effective. But this, in this recommendation, we know that we can do things here in Palo Alto, here in Silicon Valley that will prevent having to take 25 million extra gallons a day from the Tuolumne River where a lot of us go.

And I just think it's such an incredible opportunity to really let people know that what we do has a direct impact on the places we go. And so I guess I talked to you briefly beforehand, and she said that you got your information about conservation measures from talking to wholesalers. But I would suggest that you go to the public and say if we don't do these things, we're going to take this much more from Tuolumne, and what do we want to do?

C_Marcu-01 cont.

I mean, if I knew someone's sick, I'm probably going to give blood. If you don't know -- I mean, I think what wholesalers would recommend without the public being involved or knowing what the impact of what we're doing is, it would be different.

So I really want to get out there that what we're doing has an impact, and they see what we can do in terms of conservation. And I think people would take more action.

And I know -- I can give everyone my phone

number. I'm personally committed to do whatever it takes to not use the Tuolumne. You know, if I have to, like, shower in the rain or whatever. But -- I won't be that extreme because I want to represent the normal person. But seriously, I mean, I will rally as many people as possible, whatever is needed, not to increase our intake because I want to go in the opposite direction.

C_Marcu-01 cont.

And I think it's sending a really bad message right now, with global warming and everything, that the Bay Area, the forefront of the kind of "watt com" area, the green economy, that we're not able to reduce our water consumption.

So that's my comment. And like I said, anyone can come find me or -- (650)575-1945. You can call me any time. If you're not getting much success with other citizens, I'll go bang on their doors and help.

So that's it.

DIANA SOKOLOVE: Okay. The next speaker is Peter Drekmeier.

SI_TRT8

PETER DREKMEIER: Good evening. My name is Peter Drekmeier. I'm a Bay Area program director for the Tuolumne River Trust. And I just want to start by saying that our organization and every other conservation organization I'm aware of supports the seismic upgrades to the Hetch Hetchy system. That's not controversial. And we'd like to see that move forward as quickly as possible.

SI_TRT8-01

What we are adamantly opposed to is the proposal to divert another 25 million gallons of water a day from the Tuolumne River. And to put that in perspective, that's the equivalent of more than 1,000 large swimming pools pulled every day from this wonderful wild and scenic river.

SI_TRT8-02

First, I want to point out that the projected increase in demand for water in the -- for 2.4 million people who consume Hetch Hetchy water is inflated. The studies were very dated. They're looking at old technology. We are shifting from manufacturing to service and information, which uses considerably less water. And that wasn't taken into consideration. It also doesn't look at the impact of increasing prices on consumption.

In San Francisco, the cost of water is expected to more than triple. And we expect to see that in other areas of the consumer area. And that is definitely going to have an impact on consumption. One thing that's very telling is, in this report, they're projecting that per capita consumption of water is expected to increase in this area.

SI_TRT8-02 cont.

And that goes against everything we're seeing across the country. You look at places like Seattle or Los Angeles, they've grown without increasing consumption. And the Santa Clara Valley Water District, over the last 20 years, has remained flat despite the dot com boom. So that's something that we need to take into consideration. The Bay Area is very conservation minded, and there's a lot more potential for conservation and recycling here.

SI_TRT8-03

It also has not examined the full potential for water recycling and conservation in the area. It's only looking at 3 percent increase of recycling, of water recycling. Now, 60 percent of the water that's being demanded is for outdoor irrigation. That's a great opportunity for using recycled water and for conservation through drip irrigation systems.

SI_TRT8-04

Second, I want to point out that many of the studies are inadequate. They're dated. And we don't have adequate baseline data, especially for fish and other species that depend on the river. And it's really impossible to measure the impacts if we don't have that baseline data.

An example is, there's a study used from 1992 that was never completed, but it's used in the EIR. And one thing it did encourage was increasing minimum flows for fish, which was never done. So we have some information on Chinook salmon in the Lower Tuolumne. We've seen that species in decline, so already we know that the system is pushed beyond the limits that are good for the species. And we have very, very little information on steelhead trout, which is a threatened species. And that needs to be studied.

SI_TRT8-04 cont.

Another problem is, in the modeling, things are averaged in a way that really doesn't make sense for various species. For example, they're using monthly average flows versus daily flows. And for fish and other species, it's a daily flow that really has an impact. So that needs to be looked at.

SI_TRT8-05

The biggie here is that the EIR mentions global warming but doesn't discuss it. And that's going to have a huge impact on the ecosystem. What they do is they look at the last 82 years of data and assume that the level of water is going to remain the same over the next 82 years or so. But we know that global warming is going to have an impact on the snowpack. And the State of California actually predicts that the snowpack will decline by 33 percent by 2060. And so any water diversion is going to be a much higher percentage in the future than it is right now. And that's a fatal flaw in this EIR.

SI_TRT8-06

Last, I just want to mention there are some assumptions made that are really unfounded. One is that the Modesto Irrigation District and the Turlock Irrigation District will agree to water transfers. But in fact, those negotiations, as far as I know, last I heard, had not even begun. And in Modesto, the MID spokesperson said that they're opposed to this plan. And so it's going to be very difficult to get that water transfer for the Lower Tuolumne. And even if it did go through, there's still the potential problem of 25 million gallons of water per day less in the 25 miles of wild and scenic river between Hetch Hetchy and Don Pedro.

SI_TRT8-07

So I want to encourage anyone who would like to follow our work on this to come see me afterwards, and I'll make sure that I get your contact information.

And we will be submitting more complete comments on this by the October 1st deadline.

And great to see so many people here coming out in Palo Alto. It's a very conservation-minded community. I agree with the last speaker, that we have a lot of potential here to really make a difference. And again, looking forward to working with you on that.

Thank you all.

DIANA SOKOLOVE: Next speaker is Ramses Madou.

C_Madou

RAMSES MADOU: Well, going after Peter is a little bit hard. My name is Ramses Madou. My address is 3680 Bryant Street, here, in Palo Alto.

I'm here really to express my support for a conservation-minded plan. As it stands now, as Peter was just saying, 25 million gallons leaving the river, leaving it with -- leaving the biological species living there with much less resources than they need, seems that we could push our use of resources down to kind of keep the support for them there. C_Madou-01

And that's pretty much all I have to say. All the points have already been made by the last two speakers.

Thank you.

C_Dippe

DIANA SOKOLOVE: The next speaker is Dan Dippery.

DAN DIPPERY: Good evening. My name is Dan Dippery. I live in Menlo Park.

Couple of things that Peter left out that I think are quite relevant. Evidently, the Utility Commission had their own study on conservation and efficiency and recycling, and they found that the need to divert more money [sic] from the Tuolumne could be reduced by 74 percent. I think that's an important figure. So I think it should be very prominent in the EIR because it's obviously the critical need here. C_Dippe-01

The other thing that I'm proposing is that the PUC should conduct a study to determine the maximum technical potential for conservation efficiency, in other words, not just kind of a sketchbook thing but really go into details of what could be done so that we don't have to take this additional water from the river. C_Dippe-02

That's all. Thank you.

SI_SierraC3

DIANA SOKOLOVE: The next speaker is Bill Young.

BILL YOUNG: Thank you. My name is Bill Young. I'm the conservation coordinator with the Sierra Club Loma Prieta Chapter. Thank you for this opportunity to comment on the PEIR.

The Sierra Club believes that the draft PEIR ignores the risks that global warming presents for the Bay Area water supply. The PEIR also neglects to fully study the impacts of increased draw-down of the Tuolumne River and on local watersheds as well. The PEIR also fails to identify the sustainable water supply measures as alternatives. It encourages water waste instead of efficiency. SI_SierraC3-01

The PEIR fails to recognize that our rivers and creeks are finite and variable resources. Increased draw-down will have serious effects on these watersheds. The PUC needs to reduce reliance on the

12.6-68

Tuolumne River and local creeks, such as the Pilarcitos. A comprehensive watershed study should be completed to adequately assess the environmental impacts of the WSIP and to develop regional watershed protection and restoration programs.

SI_SierraC3-02

Climate change effects also were not adequately studied for the PEIR. The PEIR does not take into account the impact of climate change on precipitation in Tuolumne River watershed. As the Sierra Nevada snowpack shrinks due to the effects of climate change, Sierra rivers like the Tuolumne will become increasingly unreliable sources of water. By increasing dependence on the Tuolumne, San Francisco's proposal exposes the Bay Area to greater risk of water shortages.

Decreasing reliance on the Tuolumne is critical not only for protecting the health of the river but also for preparing for the future uncertainty of the Sierra snowpack as a result of global warming.

SI_SierraC3-03

The PUC's preferred alternative does not take advantage -- full advantage of the benefits of more efficient water use and water supply diversification. It ignores much-needed water conservation measures which would ensure a sustainable water supply and protect our watersheds instead of just taking more

SI_SierraC3-04

water from the wild and scenic Tuolumne River.

The Sierra Club believes that there are more cost effective and less environmentally harmful ways to secure and maintain a clean, reliable water supply. We support increased water efficiency in both urban and agricultural sectors, the use of groundwater storage, and the safe expansion of water reclamation and water recycling.

The PUC must invest in water resources in the most efficient way and reducing consumption. This would put the Bay Area on a path towards water sustainability, more efficient water use, and a more diverse mix of water supplies would also minimize the risk associated with shrinking snowpack that is expected as a result of climate change.

SI_SierraC3-04 cont.

Thank you.

Oh, also I have some petition sheets -- could I hand those in to you -- of signatures concerning the EIR.

DIANA SOKOLOVE: Let's talk after the hearing.

BILL YOUNG: Okay. Thank you.

DIANA SOKOLOVE: Richard Zimmerman.

SI_SierraC4

RICHARD ZIMMERMAN: Good evening. I'm Richard Zimmerman. I'm with the Water Sustainability Committee of the Loma Prieta Chapter of the Sierra Club.

I'd just like to say that the Sierra Club supports the seismic re-fit of the system.

SI_SierraC4-01

However, water conservation is the cheapest easiest, least destructive way to meet future demands and to extend our scarce supply or water. However, the PEIR preferred alternative ignores these measures in large part and simply asks for more water from the already overstressed Tuolumne River and therefore is inadequate.

The Bay Area lags far behind other metropolitan areas that are reducing water consumption even in the face of growth.

The Bay Area should be a leader in water efficiency and conservation. The SFPUC must provide strong leadership to make water conservation a fact in the Bay Area rather than a hope and must not simply give in to user demands for more water.

SI_SierraC4-02

Water usage in the United States has decreased by 20 percent since 1980. But the SFPUC projects an increase in water usage for the wholesalers represented by BAWSCA. That's an actual increase in the amount of water used as well as a per capita increase. The BAWSCA wholesalers forecast a 19 percent increase in water usage in 2030 over 2000, 2001. They also forecast a 19 percent population growth in the same

SI_SierraC4-03

period. However, the retail users are forecast to use less water in 2030 than they currently do, but with a population growth of almost 12 percent. Clearly we need to reduce the amount of water use by the wholesalers, not increase it. And it's certainly possible.

In Seattle, for example, while serving 20 percent more users, the regional water system there reduced water use by 15 percent from 1985 to 2005 and is currently committed to reducing water use by an additional 1 percent annually. We should do that too. The California Urban Water Conservation Council reported in 2003 that, quote, "Data on residential water use is currently showing that outdoor water usage is as much as 50 to 60 percent of residential consumption," end quote. Further, outside water usage according to the PEIR, is responsible for about 60 percent of the increase in demand. This represents an opportunity for water conservation not being addressed in the PEIR.

The best standard of practices used by many water companies do not include residential landscaping guidelines. We should immediately implement such a program throughout the SFPUC area. As an example, in Las Vegas, of all places, water users can get a rebate

SI_SierraC4-03 cont.

12.6-70

for replacing grass to zero-scape. Austin, Texas has a similar program, as do many cities in arid climates. We should do that here too.

SI_SierraC4-03 cont.

Thank you.

DIANA SOKOLOVE: Chris Sullivan.

CHRIS SULLIVAN [PHONETIC]: I have nothing to say at this time.

DIANA SOKOLOVE: The next speaker is Sidney Liebes.

C_Liebe

SIDNEY LIEBES: I'd like to endorse the remarks of Peter Drekmeier and his other conservation colleagues and add a comment which addresses perhaps a more global perspective, an overarching one. It's not much that the PUC can do anything about, but I have to clear my conscience.

Perhaps the greatest failing of our culture, I believe, is its failure to assume responsibility for the long-term future. If we had done so, we would not have an overpopulated planet, mass extinction of species, exhaustion of resources, and be debating global warming, proposing the Tuolumne be further diverted. It's past time to say "enough is enough."

C_Liebe-01

DIANA SOKOLOVE: Daniel Seidel.

L_PHWD2

DANIEL SEIDEL: Good evening. My name is Daniel Seidel. I'm the president of the Board of Directors of

Purissima Hills Water District, a public water district that serves 6,000 customers in Los Altos Hills with the pure water that we buy wholesale from the San Francisco Public Utilities Commission.

And I don't have any quarrel with the conservation measures that have been advocated and so forth previously because we have a very active water conservation program within our own district, and we live in a very conservation-minded community.

But I prepared some comments here to reinforce our interest not only conservation but in getting this program going so that the hazards and the risk that we are exposed to daily by not having an upgraded system can be ameliorated, corrected as soon as possible. That is our greatest risk right now.

So let me read my comments. I'll try to be brief.

For the past 73 years, water from Hetch Hetchy has flowed by gravity 140 miles to our taps, providing an economical and pure regional supply. The system draws less than 12 percent of the Tuolumne River's production and now serves over 2.4 million people in San Francisco and 27 Bay Areas cities and districts.

Fifty-one years ago, our direct was formed to connect into this high quality water supply. We, along

L_PHWD2-01

with Palo Alto, Hayward, Burlingame, Millbrae -- a whole raft of cities -- depend on this system and basically have no other alternative source of water supply that is natural.

In the 44 years that I have lived in Santa Clara County, I have seen Los Altos Hills transition from apricot and prune orchards, a one-room school house, to a vibrant conservation-minded residential community that parallels the economic growth of Silicon Valley. Our town hall, for example, is powered completely by solar power. Come out and visit. You would be impressed to see that.

The typical water, per capita water consumption values for our district that you read in the report and elsewhere are meaningless, mainly because of the 18,000 students we serve at Foothill College, which is basically three times the population we serve. That's not included in the calculations. So it looks like we're using all kinds of water, but basically, we have a lot of transient people, employees in the school district that we serve that doesn't get factored into that.

Let me just say that our district uses less than -- of all the water that's produced for the San Francisco -- we use less than 1 percent. We're small

L_PHWD2-01 cont.

potatoes, basically. But we're very interested in the seismic upgrades and the reliability of the system that we're so dependant on. So are all these other agencies and districts and cities that we've already mentioned. That's the big risk.

L_PHWD2-01 cont.

Now, the San Francisco WSIP has been a long time in the making. Immediately after Loma Prieta earthquake in 1989, the East Bay MUD, the sister utility in Oakland, big water utility, developed a plan for seismic improvements in their system. Right now, they're 95 percent complete and in operation. They've done it.

San Francisco, by comparison, guess where we are. 18 years later, we're still in the EIR stage. And we're going to continue to be in the EIR stage -- we've been it in for two years now. But I hear now we're going to be in it for another three to five years until we find finally get some construction going on and get these risks reduced.

But we can't wait any longer. Every day without the seismic improvements in place puts the life safety of 2.4 million people in jeopardy. Risks are catastrophic loss of property and wreckage of the local economy worse than Katrina imposed on New Orleans. Believe me.

L_PHWD2-02

12.6-72

Let me conclude by just saying that we eagerly support the Water Supply Improvement Program -- it's many years in the making -- the analysis in the programmatic EIR, and we hope it goes through without further modifications.

And we urge the Planning Department and the Planning Commission to proceed without delay to complete the PEIR process as expeditiously as possible and to work diligently to certify a document as required by CEQA so the critical improvements can be made posthaste.

L_PHWD2-02 cont.

Thank you.

DIANA SOKOLOVE: The next speaker is Claire Elliot.

C_EllioC

CLAIRE ELLIOTT: Hi. My name is Claire Elliot, and I'm a resident of Palo Alto at 271 Chestnut Avenue. And I have to agree with everybody who's commented about the importance of the seismic upgrades. It scared the heck out of me to read in the paper that we don't even have three days' supply of water if an earthquake were to remove our Hetch Hetchy supply. As a parent, that really makes me nervous. So the first time I really understood was tonight that these two things are linked together. I don't know if there's a possibility to separate them, but to me, it makes sense

C_EllioC-01

to separate it, given that the EIR will take another several years to process. I'd love to see the seismic upgrades happen sooner.

C_EllioC-01 cont.

But as far as the diversion from the Tuolumne, I think that would be a total travesty. And I don't think the EIR addresses all of the concerns of downstream water impact. I don't think it addresses something that a lot of people aren't aware of, which is that all the diversion we're currently doing into the San Francisco Bay through our treatment plant is converting many, many acres of salt marsh into fresh water marsh. And we have so little salt marsh left because of all the fill that's gone on in the bay. We really should not be diverting any more fresh water into this area.

C_EllioC-02

And as an environmental -- I was a water quality engineer for several years, and I have experience to know that we have technologies to treat water that's been used once before. And we are very spoiled in this area not to have experienced that. Most of the country is using re-used water because they bring their water from places like the Mississippi River, where there's outfall from the town above that is providing their water supply.

So we need to learn how to use these

C_EllioC-03

technologies to make our water that's been reused -- all of our water we're drinking, we're not creating new water. It's the water that Lincoln drank, that Cleopatra drank. So we should be able to drink the same water that we once used before. If not drink it, at least water our golf courses with it.

C_EllioC-03 cont.

And currently I'm an environmental educator. And I am seeing huge changes coming through the education of our children. And in the year 2030, which is what we're projecting for, most of these children that will be adults at that time will have gone through environmental education programs and will have learned the importance of conservation and will be able to plant native plants in their garden because they know it's the right thing to do to prevent 60 percent of our water -- this diversion that they're talking about, I read, is for outdoor use. And I do not want to see more lawns taking up this water that's coming from a beautiful wild and scenic river.

Thank you.

L_SCVWD2

DIANA SOKOLOVE: The next speaker is Amy Fowler.

AMY FOWLER: Good evening. I'm Amy Fowler, staff at Santa Clara Valley Water District. Thank you for the opportunity to provide comments on the draft programmatic EIR.

The Santa Clara Valley Water District -- which I'll shorten to call "the District" -- provides wholesale drinking water supply for 1.7 million residents and is the primary water resources manager for Santa Clara County. We manage the conjunctive use of surface and groundwater resources to make sure that water supply is reliable to meet current and future demands.

We actively manage the groundwater basin to optimize beneficial uses and aggressively protect the groundwater basin from contamination and minimize inelastic land surface subsidence.

As you all know, the San Francisco Public Utilities Commission and the District share the responsibility of providing a clean, safe, and reliable water supply to cities and entities in the northern portion of Santa Clara County. San Francisco PUC supply comprises 15 percent of the overall water supply in Santa Clara County and constitutes 100 percent of the water supply to some cities.

L_SCVWD2-01

We expect San Francisco PUC to continue providing this water supply in Santa Clara County and meet the projected 2030 purchase requests submitted by the wholesale customers. This expectation is described and documented in the District's and the City's 2005

L_SCVWD2-02

Urban Water Management Plans. The cities collaborated with San Francisco PUC on its demand projection and water-use efficiency studies and arrived at reasonable and defensible projections on future water needs. These water supply and demand projections constitute the foundation of water resources planning for the next 30 years for the cities, San Francisco PUC, and the Santa Clara Valley Water District.

We urge San Francisco to adopt the proposed water system improvement program and meet all the program goals and objectives. Any diminution in levels of service provided by San Francisco PUC could result in significant impacts to water resources in Santa Clara County with associated environmental and social, economical consequences.

Santa Clara Valley had a legacy of land subsidence in the 1920s and '30s due to over extraction of groundwater. Through water importation and conjunctive use management, land subsidence was halted by the late 1960s, and the District has been vigilant in preventing its reoccurrence. Understandably, we are very concerned with any potential redirected impacts on our groundwater basin and local or imported surface water resources due to San Francisco PUC's reduction in supplies or level of service provided to Santa Clara

L_SCVWD2-02 cont.

County.

We also urge San Francisco to address fully any potential redirected impacts on water supplies for the Safe Water Project and Central Valley Project users.

We support San Francisco PUC's goal to maximize water conservation, recycling, and desalination. The District has been very progressive in implementing programs to maximize water use efficiency and further diversify our sources of supply. We believe these program areas are ideal for San Francisco PUC and the District to partner with local cities and land-use entities in their implementation. However, there are practical limits in implementability of these programs. And they cannot be used as stand-alone substitute alternatives or variants because they fail to meet the overall program goals.

We look forward to San Francisco addressing our concerns adequately and adopting the current EIR and Water System Improvement Program expediently so that the critical work of securing the water supply for the Bay Area communities can begin.

L_SCVWD2-02 cont.

Thank you.

DIANA SOKOLOVE: The next speaker is Amy -- Adams? Sorry.

C_AdamsA

AMY ADAMS: It's Adams, like John Quincy.

I'm Amy Adams. I live in Palo Alto on Clark Way. I just want to make a couple comments. First, I grew up in Michigan, where there's lots and lots of water. And we had tornados. So when I moved here and I found out that much of our water comes from a gravity-fed place very far away and there's earthquakes and it's coming through big pipes, that made me a bit nervous. So I definitely agree that the seismic upgrade should be a priority.

C_AdamsA-01

However, I'm a little bit confused as to why that's related to the volume of water in the EIR. I think those should be two separate points that are addressed. It's, to me, like having a hole in your shoe and going into the store getting a new shoe and deciding you also need a belt or a hat. It's part of the same system. It's your clothing, something that needs to get fixed potentially, but I don't think it needs to necessarily be addressed at the same time or in the same process. So I hope that making those decisions would not delay the other.

C_AdamsA-02

The other point I wanted to make was just, I think that we need to look closely -- we had the Santa Clara Valley Water District representative speaking earlier. I think we need to look carefully at what the

C_AdamsA-02 cont.

district really has done since they're providing 15 percent of our district's total water supply. They have a number of amazing, both residential and commercial and agricultural, programs going on. And I think that part of it is actually citizens actually taking part and participating in these things.

There's rebates for using high efficiency clothes washers, high efficiency toilets going into commercial sites. There's, like, a list of 20 different things that they do that are either for residential or commercial conservation. And people, individual people, can get, actually, rebates for that.

And I think that we need to take a good look as citizens at what we're doing with our water. We can look at Arizona, and people have more arid landscapes. And do we need this many golf courses? Do we need this amount of fresh water out sprinkling -- sprinklers broken, sprinkling sidewalks, and et cetera?

And I just think that we as citizens and as a government -- because I don't think it's going to happen nationally. I don't think our national government is going to step forward with conservation issues and accept that global warming is a real issue. We have to take a step locally, regionally, and look at water conservation and not divert water away from a

12.6-76

C_AdamsA-02 cont.

river.

That's just an easy answer. I think we have to make some more harsh, difficult choices.

DIANA SOKOLOVE: The next speaker is Elliot Margolies.

C_Margo

ELLIOT MARGOLIES: Hi. I'm Elliot Margolies. I'm a resident of Palo Alto at 3858 El Centro Street.

And I have a lot of respect for the PUC's challenge of balancing human needs for water with preserving nature's sustainability and am fully appreciative of the seismic upgrades that are really needed. But I want to address the diversion of water from the Tuolumne River.

I know that the PUC has been long making these plans and studies, probably way before the movie "An Inconvenient Truth" came out, but I think that a lot of us have really shifted our sense of priorities in the last few years when global warming has now become a reality that most of us accept and feel very concerned about.

C_Margo-01

And I really feel that, to review the amount of conservation and recycled water that our community is willing to implement, it's really important to do that now because the figures are going to come out very differently. I'm very confident that our community is

C_Margo-01 cont.

ready to step up and to really change the equation much more so.

And there's no question that, over the coming years, there's going to be more and more reasons coming our way to do so. And so to refigure this -- and the day of putting our conveniences as cities and industries over and above the sustainability of the resources we depend on, those days are over.

And we now depend on our leaders, like the PUC, to put plans forward that reflect our own growth and awareness about these important issues.

thanks.

C_Beauj

DIANA SOKOLOVE: I know I'm not going to say the next name correctly, so please forgive me in advance. Cedric deLa -- sorry, sorry.

CEDRIC deLA BEAUJARDIERE: No worries. It's okay. I get that all the time.

My name is Cedric deLa Beaujardiere. You say it like it's spelled. I'm at 741 Josina Avenue in Palo Alto, 94306. And I'm here on behalf of myself as well as on behalf of my fiancee Susan Stansbury [phonetic], same address, who couldn't make it tonight. She's the director of a non-profit called Connections and also of a project called Valley of Hearts Delight, which seeks to protect local farmland which has been lost a lot.

12.6-77

And she bade me to mention some water conservation steps that we can all take individually and collectively as supported by our governments that we can do in the garden.

Some of them would be native and drought-tolerant plants which require less water, mulching to keep in moisture, using drip and micro-flow irrigation, also rainwater harvesting and gray water reuse. The City of Palo Alto, for instance, has a gray water system which they feed to large customers.

And there's many more in the home as well. There's things like re-circulating pumps that send water back to the hot water heater instead of running it down the drain when you're waiting for the shower to heat up or the faucet to heat up, just sending it back to the water heater. So those are available things.

So these sort of things can be incentivized by local governments and non-profits or businesses and residents taking it on their own. I think the cost that would be otherwise used to divert more water from the Tuolumne, that would be a great source of funding for such incentive programs and probably much more efficient for the long run.

C_Beauj-01

So I do support the seismic upgrades, but I think that we should actually not divert more water

C_Beauj-02

from the Tuolumne and, in fact, try to divert less over time.

C_Beauj-02 cont.

Thank you very much.

DIANA SOKOLOVE: The next speaker is Katherine Forrest.

SI_CI

KATHERINE FORREST: Hi, I'm Katherine Forrest, and I'm president of the board of Commonweal Institute, a progressive think tank in the Bay Area here.

One thing that concerns me is the interlinkage between the problems we're facing here because we're dealing with global warming, we're dealing with water problems, we're dealing with preservation of animal and plant species. And these are all interrelated to each other.

I certainly don't think that just trying to increase the amount of water flow that comes into -- to the ultimate end users is the way to go and that the State, if anything, should put a higher priority on the conservation ends of things. Predictions are we're going to have at least 55 million people in this state. So there's an incredible amount of continuing growth that we can anticipate.

In particular, I think that the State can play a role and -- whether it's through the PUC and then ultimately through the legislature -- in beginning to

SI_CI-01

12.6-78

work back and put some both carrots and sticks on local government. And the carrots and sticks would have to do with rules having to do with conservation at the local level, products -- I mean, there was mention of incentives for products like low-water-use toilets, low-water-use washing machines. But there could also be penalties. And so you have both an incentive to go for a more water-frugal way of living as also a disincentive for spending too much water out of the public, what's available to us.

And finally, also another thing that could happen potentially for local governments is to have incentives on them to change some of their permitting. And I'm thinking particularly in terms of construction permitting in allowing gray water systems for individual homes and also having constraints on the size of pipes that bring water into properties and the -- putting in irrigation systems for watering large lots of land instead of letting it go to native plants.

SI_CI-01 cont.

Thank you.

C_Roger

DIANA SOKOLOVE: Leah Rogers.

LEAH ROGERS: I'm Leah Rogers, a resident of Menlo Park and trained in groundwater hydrogeology. I've spent a lot of time over the last couple decades looking at a lot of water balances. And one thing that

C_Roger-01

always amazes me is how little of our water goes to thirsty people. And I think that so much of it goes to industrial and agricultural uses that are highly inefficient.

How many of us have driven through the Central Valley and seen open canals of water on a really hot day and wondered how much of that actually gets to the plants? I mean, there's a lot of wonderful technologies for drip irrigation. I think there's also a lot of wonderful technologies for reprocessing industrial and agricultural waters.

And so I guess my question is, how can we rob more money from our wild -- rob more water from our wild and scenic rivers when it's clearly a minor, minor part of what needs to be done. It's an interim solution, insignificant, with really negative results and probably irreversible results.

So I think we need to really look at where the deep pockets are in this equation and its agricultural and industrial use. All of us as end users pulling together, but we need to point the finger and really look at how our water is valued.

C_Roger-01 cont.

Thank you.

C_Eddy2

DIANA SOKOLOVE: The next speaker is Jeb Eddy.

JEB EDDY: Hi. I'm Jeb Eddy, 35-year resident

12.6-79

here of Palo Alto. Family name is Eddy, E-D-D-Y.

There's a street up in San Francisco by that exact same name. My family and I, we think we might be related to the guy William Eddy, who was the first civil engineer, city engineer, and surveyor for the City of San Francisco in 1849. And his map is the one that was sent up to Oregon to allow the State of California to become a state in the Union because that was the nearest place you could register a map.

So I've been interested in some planning issues for a long time, although personally I wasn't around back in those days. One of my sons has a master's degree in forestry. The other son has just started his graduate program at UC Berkeley in the energy and resources program.

Our family has been interested in, concerned about stuff like this for a long time. And we live here because I struggled my way through a well-known business school down the street.

C_Eddy2-01

One of this things that really struck me as I was looking over some of the material for the planning that's been done so far is that a six-letter word, one of my favorites, doesn't show up in the document at all, M-A-R-K-E-T.

There's almost no discussion of using the

C_Eddy2-01 cont.

dynamic -- we're going into one of the greatest periods of trying to figure out markets in human history, exactly as the speaker from Commonwealth just said, the integrated complexity of all this stuff is tremendous. And we need to introduce some serious influence of markets.

As you perhaps know, those of you who read the San Francisco Chronicle, what's the lead story in today's paper? "Congestion Pricing For Traffic." What a great idea. Bloomberg is stirring around this pot in New York City. It is already a fabulously profit-making activity in London. Traffic is down. The London program made something like 100 million pounds of profit last year.

C_Eddy2-02

If we are smart -- let's -- the thing that bothered me so much about looking over the way some of the demand forecasting was done is, okay, we're going to do our sort of per capita estimates, multiply that by the number of capitas, and that becomes the target for supply.

I don't think that's the way market works. If we have market influences in the decision process here, we could have different kinds of water supply for different kinds of users and different kinds of needs, determined on more of an open-market basis, changing

12.6-80

the market structures over time, but not simply saying, "Yeah, it's going to be this much demand. We have to fill it." I think it's a profound mistake.

One of the few things I remember from going to this business school 35 years ago, a great question, "What business are you in?"

Meeting fixed demand based on numbers that were invented, you know, five or more years ago is not a reflection of the conditions that we are in now.

C_Eddy2-02 cont.

So the seismic upgrade stuff, absolutely, yes.

But failing to adapt our consumption to the realities of global warming and other supply issues I think is a significant mistake.

Last point, anybody here from Sacramento?

Guess not. I've heard multiple times that the metropolitan statistical area of Sacramento has basically been built with no water meters. I see some nods. Is that possibly true? No water meters, don't have any idea how much water they use.

If we use prices and significant measures of our personal consumption, our industrial consumption, we can do a lot better than I think the plan proposed so far.

Thank you.

L_Menlo3

DIANA SOKOLOVE: Next speaker is Kelly Fergusson.

HONORABLE KELLY FERGUSSON: Good evening. I'm Kelly Fergusson. I'm the Mayor of Menlo Park. And Menlo Park is a wholesale water purchaser from SFPUC. And I'm just here tonight with Kent Stephans, our public works director, to listen to comments and to absorb the comments and your remarks.

L_Menlo3-01

Thank you.

C_Mater

DIANA SOKOLOVE: The next speaker is Len Materman.

And if you wouldn't mind giving us your address either before you speak or if you could fill this out, we need to be able to get back in touch with you to respond to your comments.

LEN MATERMAN: Sure. Thank you. I'm in San Carlos.

Really just two points on the adequacy of the document. The PEIR states that there is no clear scientific consensus on how global warming will affect water supplies, yet it also states that predicted changes are within the range that occurs under existing and proposed operations.

I've found their conclusion that there's no clear consensus yet they can estimate kind of the effect of global warming and how this will shake out over the next 30 years to be both inconsistent and inaccurate.

C_Mater-01

12.6-81

And I also found the fact that they devoted three whole pages to the topic of global warming and its influence on the snowpack out of the hundreds or probably more than hundreds of pages over there to be inadequate.

C_Mater-01 cont.

So I'm trying to use those words up there.

Second point, in terms of the assessment of the document on natural resources and species, I felt that they did take a look at species, yet they didn't take a look the ecosystems within which those species operate adequately. And that there are real and knowable negative economic impacts of projects that don't look at ecosystems and the services and the economic values they provide.

And because those things are knowable and because those things are real, I found this document to be inadequate in its assessment of on the environmental impact on the species involved.

C_Mater-02

I guess my last point is, earlier this week, the State PUC came out with a document related to energy. But I thought it would be instructive for us here because what that document says, among other things, is, quote, "We need to have our utilities thinking long-term and strategically to make energy efficiency business as usual, a part of everyday life

in California."

And of course, we're talking about water here today, but I think the idea still hold for this document. In so many ways, the Bay Area and San Francisco is at the forefront of thinking nationally on so many topics. I wish that in the context of water it would do the same.

Thanks very much.

DIANA SOKOLOVE: Is there anyone else who wants to speak who has not submitted a speaker card?

(No response)

DIANA SOKOLOVE: Okay. Well, that closes the public comment portion of this hearing. Thank you for coming tonight. Again, here up on our screen is where you can submit written comments if you wish to further supplement your verbal comments tonight. Thank you, and have a very good evening.

(Whereupon, the proceedings concluded at 7:33 o'clock p.m.)

P R O C E E D I N G S

SECRETARY AVERY: Commissioners, you're now going to take Item No. 21, Case No. 2005.059E, Water System Improvement Program. This is a public hearing to receive public comment on the draft environmental impact report.

DIANA SOKOLOVE: Good evening --

COMMISSIONER SUGAYA: Excuse me, before you start.

I'm going to have to recuse myself on this item. The company that I work for prepared the historic resources evaluation for the Water System PEIR. So I have a conflict of interest.

COMMISSIONER BILL LEE: I move to recuse Commissioner Sugaya.

SECRETARY AVERY: On the motion to recuse Commissioner Sugaya, Commissioner Moore?

COMMISSIONER MOORE: Aye.

SECRETARY AVERY: Commissioner Sugaya?

COMMISSIONER SUGAYA: Aye.

SECRETARY AVERY: Commissioner Bill Lee?

COMMISSIONER BILL LEE: Aye.

SECRETARY AVERY: Commissioner Antonini?

COMMISSIONER ANTONINI: Aye.

SECRETARY AVERY: Commissioner Alexander?

PRESIDENT ALEXANDER: Aye.

SECRETARY AVERY: Commissioner Olague?

COMMISSIONER OLAGUE: Aye.

SECRETARY AVERY: Commissioner Sue Lee?

COMMISSIONER SUE LEE: Aye.

SECRETARY AVERY: Thank you. Commissioner Sugaya is excused.

DIANA SOKOLOVE: Okay. Good evening, President Alexander, Members of the Commission. My name is Diana Sokolove. And I'm a senior environmental planner with the Major Environmental Analysis Division of the San Francisco Planning Department.

This is a hearing to receive comments on the draft program environmental impact report for the San Francisco Public Utilities Commission's Water System Improvement Program. It's Case No. 2005.0159E.

The public comment period for the draft program environmental impact report began on June 29th of 2007 and will end on October 1st, also in 2007. The Planning Department also held four other public hearings this month for the Water System Improvement Program, Program Environmental Impact Report throughout the program study area to take public comment on the EIR. And the proceedings from those hearings will be

included in the comments and responses document.

This is not a hearing to consider approval or disapproval of the proposed program. That hearing will be held by the San Francisco Public Utilities Commission following certification of the program environmental impact report by this commission.

Therefore, comments today should be directed to the adequacy and accuracy of the information contained in the environmental impact report rather than the merits of the proposed program. Also as you know, staff is not here to -- generally not here to answer public comments today. Comments will be transcribed and responded to in writing in the comments-and-responses document, which we hope to publish in the spring of 2008.

Members of the public who would like to speak this evening should speak slowly and clearly so that the court reporter who we have here tonight can produce an accurate transcript which will become part of the public record for this environmental review process. Also, commentors should state their name and address so that they can be properly identified and so that they can be sent a copy of the comments-and-responses document when completed.

After comment from the general public, we will also take any comments that the Commission may have on the draft program environmental impact report. This concludes the presentation on this matter.

Unless the Commissioners have any questions, I respectfully request that you open up the hearing for public comment.

PRESIDENT ALEXANDER: Thank you. We are now open for public comment, and I do have speaker cards.

John Sarbie [sic] followed by Steven Miller and Gwynn MacKellen.

C_Barbe2

JOHN BARBEY: Excuse me. My name is John Barbey, with a "B." I live at 50 Liberty Street, San Francisco, California 94110.

C_Barbe2-01

My concerns are very simple. I have not seen the documentation. This was not tremendously well noticed. I understand there was a tiny notice in the Examiner, which is nearly impossible to obtain in its paper form, a paper ad on September 10th. The full documentation, I understand, fills a book box, which is 12 by 16, and fills the box right up to the lid. It's 3,000 pages. You know, there's a matter of time that we have to peruse this information.

C_Barbe2-02

And my concern is very simple. I hope that you are safeguarding the water supply into San Francisco and the future water supply, as I believe in

C_Barbe2-02 cont.

increasing housing here in the city. I think it's a big priority for us. We have to remain a competitive destination as we have somehow managed to be.

And I think in the past, we simply assumed that we would receive priority on this system and that our supply would be safeguarded. I'm hearing amazing stories about conservation being the solution. Certainly conservation has to be prioritized too, but my brother lives in Durango, Colorado. They have no water. Even the Animas River is drying up. He gets water delivered to his house every week.

We are an enormous, huge city. Imagine a similar catastrophe if we had a serious water shortage or if we had to help our neighbors in the East Bay because they had a serious water shortage.

This is of tremendous huge priority for San Francisco, the city itself, never mind all the other cities that depend on this. But I think we're the ones who made this system. We're the ones who should be safeguarded. We're a very vulnerable big city, and I think this is, in some ways, a simple problem. And I certainly hope this report addresses that correctly.

We simply cannot take baths in Sparkletts water. It's just too horrible to consider. Thank you very much.

L_BAWSCA5

PRESIDENT ALEXANDER: Thank you.
Steven Miller.

STEVEN MILLER: Good evening, Commissioners. I'm Steven Miller. I'm a lawyer for the Bay Area Water Supply and Conservation Agency, BAWSCA. And I'm here representing BAWSCA and its general manager, Arthur Jensen. BAWSCA is an independent special district whose board of directors represents 27 long-term contact customers of San Francisco. BAWSCA members purchase over two-thirds of the water which the SFPUC distributes and pays over two thirds of the cost of the regional water system.

BAWSCA will shortly be submitting extensive written comments. Today we'd just like to highlight three key issues.

L_BAWSCA5-01

First, the PEIR should more clearly emphasize the critical importance of completing the WSIP to protect the public health and safety of the 2 1/2 million people that live in the Bay Area. We must not lose site of why the WSIP is necessary and the urgency with which it should be prosecuted.

This is not the world's greatest -- many of the regional water system's facilities are located on or cross one or more active faults. There's a greater than 60 percent chance of a major earthquake before the

L_BAWSCA5-01 cont.

year 2032. It is not a question of if such an earthquake will happen but when. Following such an earthquake, the flow of water to communities could be disrupted for 30 to 60 days. The WSIP is necessary to protect the millions of people who live in this area from the catastrophic consequences of the water system's failure.

L_BAWSCA5-02

Second, BAWSCA member agencies and their customers are dedicated to conserving and recycling water. Residential members of BAWSCA members use less water than residents of all other regions of the state. Indeed, residential use in San Francisco's neighboring communities is lower than the average for the Bay Area as a whole. As population grows, BAWSCA, its member agencies and their customers, will implement additional conservation measures and water recycling, so the residential per capita water use is actually expected to decline, despite the forecasted population growth.

L_BAWSCA5-03

Third, contrary to recent public statements, San Francisco and BAWSCA are not the most significant users of Tuolumne River water. Almost half of the Tuolumne River runoff is used for agricultural production.

While BAWSCA actively pursues additional conservation efforts in its own service area, it also

12.6-88

makes sense, good sense, to encourage further conservation from agricultural users of Tuolumne River water. The modified WSIP, identified in the PEIR as the environmentally superior alternative, suggests a partnership with agricultural interests to conserve Toulumne River water while keeping agricultural stakeholders whole so that water delivered to the Bay Area would be offset by agricultural water conservation.

BAWSCA supports such a partnership. It hopes in its written comments to support and enlarge upon the ideas presented in the PEIR, and will suggest ways to achieve a net savings on the river while still providing the water necessary to accommodate environmentally sound in-fill growing plans for San Francisco.

L_BAWSCA5-03 cont.

PRESIDENT ALEXANDER: Thank you.

STEVEN MILLER: Thank you. I have copies of these slides if anybody would like them.

PRESIDENT ALEXANDER: Thank you.

Gwynn MacKellen.

SI_SierraC5

GWYNN MacKELLEN: Hello. My name is Gwynn MacKellen, and I live at 143 Howth Street in San Francisco. I work for the San Francisco Bay Chapter of the Sierra Club, and I want to thank the Planning

Commission for letting me speak.

I also wanted to let you know that the public truly cares about this issue. It's concerned with the PUC's plans to withdraw more water from Yosemite and the Tuolumne River.

A bunch of Sierra Club members were here earlier and left all these public comments. And this is a picture of them.

Also, many Sierra Club members and San Francisco residents sent cards indicating their support for water conservation and recycling to protect the Toulumne. Here are those cards (indicating).

There are a total of 800 comments. So clearly many people are not pleased with the current plan to allow more water-heavy landscaping at the expense of our wildlife and natural treasures. We have a chance to meet our water needs in an environmentally responsible way. Please take these public comments into account. Thank you.

SI-SierraC5-01

PRESIDENT ALEXANDER: Tony Gantner.

SI_D3Dem2

TONY GANTNER: Commissioners, good evening. Tony Gantner, President, District 3 Democrat Club. I live at 235 Chestnut Street, San Francisco, 94133.

Our club is deeply concerned about any action taken by the PUC that would allow more water to be

SI-D3Dem2-01

12.6-89

diverted from the Tuolumne River. We believe that the rights of the environment are equal to human civil rights and that compassion for the environment is as impassioned as for our fellow human beings.

SI-D3Dem2-01 cont.

Within that belief system, the proposed diversions on their face are presumptively harmful to fisheries and sensitive riparian habitats. It is our understanding that the draft EIR released by the PUC does not properly identify and address the impacts of taking more water from the Tuolumne and that such diversions would be for customers outside of San Francisco.

SI-D3Dem2-02

We realize that growth projections for the Bay Area over the next generation are pressuring the PUC to allow these increased diversions, but the rights of and compassion for the environment must be acknowledged. There must be limits to gross impact on the environment. Conservation and recycling are one solution.

SI-D3Dem2-03

In this city which can rightly be called the cradle of environmentalism, do not betray your heritage. The Toulumne fisheries are as much entitled to help the ecosystems as each of you is entitled to live in a clean and green urban environment. Thank you.

SI_GWWF2

PRESIDENT ALEXANDER: Thank you.

Cindy Charles.

CINDY CHARLES: Good evening. My name is Cindy Charles, and I live at 403 Willard Street, San Francisco, 94117. I'm a conservation chairperson for the Golden West Women Fly Fishers. And I'm also a member of the Steelhead Committee of the Northern California Council-Federation of Fly Fishers. I'm a native San Franciscan, and the Tuolumne River is really very special to me. I fish all over California, and it's my favorite river.

And one of the reasons why is that's where I caught my first fish as a kid. I caught my first fish on a fly, an artificial lure, there. I also caught the largest trout I've landed to date. I brought you a picture of it because I like showing pictures of my fish.

That's a 19-inch brown trout. It was caught below the Hetch Hetchy Dam in Pupino [phonetic] Valley. So I'm here to represent anglers of Northern California. We are very concerned that the plan as it stands increases the water diversion to extremely high levels. Already the Tuolumne River has diversions in the range of 70 to 80 percent. And I know irrigation further down contributes to that.

SI-GWWF2-01

12.6-90

But this water system is already compromised. And to further divert more water is just unthinkable. Also, further down the road is the Sacramento Delta. And everyone knows it's suffering. It needs every bit of fresh water that it can get in order to help turn that fishery around.

SI-GWWF2-01 cont.

The anglers are also very concerned about the proposed increased diversions on the Alameda Creek watershed. My club and several other clubs are working to restore steelhead passage so the fish can go from the ocean back up to where they were born and spawn. And we're working on removing dams. And if you're taking more water out of there, that's not helping the fish any either.

SI-GWWF2-02

So we will be submitting a more detailed comment letter, and I thank you for your time.

PRESIDENT ALEXANDER: Thank you. Tomer Hasson followed by Eric Wesselman and Jennifer Clary.

TOMER HASSON: My name is Tomer Hasson. I live at 2191 - 21st Avenue in the Sunset.

C_Hasso

First of all, I want to put my support behind the seismic upgrades and most of the Water System Improvement Plan. I think it's about time that the Bay Area has a secured source of water. And I commend all of you guys for taking on that larger project.

C_Hasso-01

I do take issue, though, with the water diversion from the Tuolumne River. We're talking about a wild and scenic river in which 60 percent of its flow is already diverted for urban and rural use. And as you know, you're threatening an additional 25 million gallons a day from the river. And basically, most of that will be going for outdoor use to increase lawns and our parks, the green of our lawns and parks, which basically says to me that we're more -- we have much more -- I'm sorry.

We view the green of our lawns and parks much more important than we do actually a federally protected wild and scenic river. The simple fact that the PEIR equates an increase in population to an increase in water is exactly wrong -- or increase in use of water is exactly wrong. Other major metropolitan areas, such as Seattle and Los Angeles, have been able to decrease water usage in the face of population growth by focusing on conservation and recycling measures.

C_Hasso-02

The draft PEIR also uses flawed modeling to determine anticipated water demand. The anticipated 14 percent increase in demand is excessively large and out of step for the Bay Area. And let me point out to you that, not only do we have flawed methods in our

C_Hasso-03

population projections for the Bay Area, but our increase in demand, that increase in demand of 14 percent is reflected in per capita use, which is also set to increase over the next 20 years.

I fail to understand why a person 20 years from now is going to be using more water than I do today. But that's besides the point because that per capita increase will supposedly increase, even though the price of water is expected to triple in the next decade, according to the SFPUC.

But even if that 14 percent increase in demand does hold, then a majority of that demand can be met by conservation, efficiency building, and recycling measures.

The SFPUC's own studies indicate that such measures, which I remind you are the cheapest, easiest and least destructive ways to meet demand and extend supply, could eliminate the need to divert more water from the Tuolumne by 74 percent.

My simple point here is that other large metropolitan areas have been able to do this with little effort. The Bay Area, the leader in the environmental movement and environmental ethic, should be ahead of everyone, not far behind. I also invite you to please revisit the studies and new methodology

C_Hasso-03 cont.

within the draft PEIR.

C_Hasso-03 cont.

And please revisit the concept of global warming. The State of California projects that global warming will reduce the Sierra snowpack by 5 percent by 2030, and by 33 percent by 2060.

C_Hasso-04

PRESIDENT ALEXANDER: Thank you. Eric Wesselman.

TOM MARASAN: Thank you. I appreciate your time.

SI_TRT9

ERIC WESSELMAN: Good evening. My name is Eric Wesselman. I'm the executive director of the Tuolumne River Trust.

For over 25 years, the Tuolumne River Trust has been working to protect and restore this wild and scenic river. But now, the San Francisco Public Utilities Commissioners and their wholesale customers are proposing to take an additional 25 million gallons of water out of this river each and every day.

And as I stand here in San Francisco, I think it's important to note that it's not even for San Francisco. This is being [sic] for sales to the wholesale customer, which projects demand increase of 25 million gallons from the Tuolumne alone.

The Toulumne, as I said, is a wild and scenic river, and more than half of the river is already diverted. And while much of that is for rural or agricultural uses or urban uses in other parts of the

SI_TRT9-01

12.6-92

state, the increase in demand is coming from the Bay Area. So the single largest threat to the Tuolumne River is the San Francisco plan to divert an additional 25 million gallons per day.

SI_TRT9-01 cont.

And I think more to the point, the draft EIR does not adequately justify or define the need for more water. For instance, the draft is based on the fundamentally flawed analysis that didn't look at the relationship between the price of water, moving into the future, and the demand for water. It's not inelastic. It's elastic. As price goes up, as has been mentioned, a tripling of price over the next decade or two will lead to a decrease in demand.

So that was not analyzed or looked at in the analysis done by the SFPUC, the wholesale customers, or the Planning Department. So I'd recommend that that be reevaluated, and that that would reduce demand projections in the future.

SI_TRT9-02

Second, the SFPUC's own study wasn't used that found that much of the demand increase could be met through sustainable sources, such as recycling and conservation. And that should be looked at and incorporated.

SI_TRT9-03

Finally, there is a use of outdated employment projections from the Association of Bay Area

SI_TRT9-04

Governments that used '02 data. And '05 data became available which decreased the job -- the employment projections moving into the future, which means less growth in the commercial sector, which means less water use.

While it's not great for the region's economy, it's a reality, and we ought to be looking at that in terms of planning for the future use of our resources.

SI_TRT9-04 cont.

Additionally, there's an increase in per capita use. And as an objective note, it's simply not acceptable in this day and age to project an increase in water use per person.

SI_TRT9-05

And I think -- my time is running short. By that, while the bulk of the WSIP is focused on needed repairs and seismic upgrades -- and we whole-heartedly endorse that and support that -- we're concerned that it includes this poison pill of taking more water off of a wild and scenic river that is already largely diverted. And that threatens to delay these needed seismic improvements and retrofits and repairs. So that should be looked at. And I think it would be of concern to the wholesale customers.

SI_TRT9-06

Thank you for your time.

PRESIDENT ALEXANDER: Thank you. Jennifer Clary.

JENNIFER CLARY: Thank you. Excuse me.

SI_CWA2

My name is Jennifer Clary. I'm here in my professional capacity today as the water policy analyst for Clean Water Action. And I just want to thank you all for listening to this. All of us folks back here, we've been soaked in this for five years. And we just come in and talk about stuff. And I know that you all read the five-volume report overnight before you came here. And I just want to thank you for listening to us. And we're trying to keep our comments brief, but there's a whole lot of detail that will be going into in our written comments. And I hope you'll have a chance to look at that.

Clean Water Action has been tracking this program for more than five years. We supported the bond to rebuild the system. We think it's vital that we have a reliable water supply. But of course, your job here is, in ensuring that we have a viable water supply, to ensure sure that this document is adequate.

SI_CWA2-01

And we have lots of serious concerns about the adequacy of document. One concern that I'd like to note today is the four pages -- the four-page review of the impact of climate change on the program. And in -- I understand that it's a difficult, new science but the fact of the matter is that, if this report does not adequately asses the process of climate change, it's

SI_CWA2-01 cont.

not going to be an adequate document, and it's going to be challenged.

They did take a look at the impact of temperature increase and found that it could result in a 7 percent decrease in run-off, but they said that's within the range of expected -- the range of historic data. The difficulty with this is it's not part of the range. It's additive. And how do you create -- how do you measure the cumulative effect of climate change?

And in addition, there's other impacts of climate change that aren't looked at here. In the local reservoirs, you have more evaporation, you have increase in algae blooms, which is a big concern for water agencies. You have an increase in temperature in the river which could require more flow releases for fish.

So there are things that aren't really studied and aren't even referred to in the document that really have to be taken care of. If we have a snow melt -- or if we have a snow, that means the timing of the run-off changes, and that changes the way you operate a reservoir. And that's something that should be looked at and estimated here.

And of course, there could be an increase in environmental water demand, and, as I mentioned, not

12.6-94

just for the middle fork of the Tuolumne but below Don Pedro. And the PUC will have a responsibility for that as well. Remember that the Tuolumne feeds into the San Joaquin River and goes down into the Delta. So don't think that this project isn't part of that whole mess.

And finally, there is another good silver lining to this, which is the most cost-effective way to reduce greenhouse gas emissions is through water conservation. So these demand numbers don't take into account that we're going to be looking for cheap ways to save energy before 2030.

SI_CWA2-01 cont.

Thank you.

C_Olsen

PRESIDENT ALEXANDER: Thank you. Jenna Olsen.

JENNA OLSEN: Hello. My name is Jenna Olsen. I live on Vallejo Street in San Francisco. My full address is on my speaker card.

I imagine all of you Commissioners and most of the people in this room, everyone in this room, walked by the house that is on display right in front of City Hall today. It is MKlotus House. It has a green roof. It has native landscaping on the outside. It has a gray water system. It has a rainwater catchment system to use that rainwater for the little bit of water that is needed for the landscaping. It's part of West Coast Green, which is a conference going on in Bill Graham

C_Olsen-01

Center this week and this weekend. If you haven't had a chance to look at the house, I encourage you to go there tomorrow or Saturday.

Mayor Newsom gave one of the keynote speeches this morning at that conference. And he talked about San Francisco's leadership on the environment and sustainability. He talked about San Francisco's leadership on greenhouse gasses, transportation, waste diversion.

Did he talk about San Francisco's leadership on water? No. He did not.

That's a problem.

Is the PEIR that's in front of you the document of a leading city in environmental sustainability? No. It's not. It's inadequate for all the reasons you've heard tonight. It did not even consider an option that would have not taken more water out of the Tuolumne River. San Francisco should be a leader. It should be showing the way in water use efficiency, water conservation, and environmental restoration, sustainability.

I encourage you to do this right, do it over so that a year or two from now Mayor Newsom can give another speech where he talks about what a leader San Francisco is in water and in finishing the earthquake

C_Olsen-01 cont.

12.6-95

C_Olsen-01 cont.

retrofits as well.

And thank you for that. I also would like to submit to the record the appalling nature with which this hearing was publicized. I have printouts from both the Planning Department and the SFPUC Web sites from yesterday. I had a very hard time finding out what time this hearing was going to be. It was listed as 1:30 on the SFPUC Web site, even though it was apparently for 5:00 o'clock today.

So I just would like to say that I think more people would have been interested in this if it had been better noticed. Thank you.

SI_SierraC6

PRESIDENT ALEXANDER: Thank you. John Rizzo.

JOHN RIZZO: John Rizzo, 1621 Waller Street, 94117, San Francisco. I'm here today, Commissioners, in my capacity as former chair of the Sierra Club's San Francisco Bay Chapter. I'm a current executive committee member. I'm also representing Sierra Club California.

SI_SierraC6-01

And we are opposing the 25-million-gallon-per-day additional water grab from the Tuolumne River, and we'll be submitting comments in conjunction with the other environmental groups in the package.

SI_SierraC6-02

But I'm just going to talk about one very

SI_SierraC6-02 cont.

small aspect of the EIR, and that's on growth, the impacts of the additional water on growth. Additional review is necessary to bring the impacts of the growth numbers up to 2030 and also to review the impacts of the ABAG projects which only go 2025.

The expanded water supply would accommodate a 28.8 increase in employment and 16.8 increase in population between 2005 and 2030 in the service area. This is about 5 percent more jobs and 5 percent less population than what the EIR estimates that the general plans would allow.

The document cites the environmental analysis done by the general plans for the service areas. It doesn't do it itself, doesn't do the analysis itself. But none of the plans has a time horizon that extends to 2030. So it is speculative to make conclusions about consistency.

It is also speculative to assume that the local jurisdictions will plan for a continuing rate of growth beyond their horizontal years as assumed in the EIR. So it cannot be concluded that the EIRs done for the general plans adequately cover the growth allowed by the increased water supply. The EIR acknowledges this fact on Page 7-35 and Page 7-69.

The EIR finds that the water supply growth is generally consistent with ABAG projections to the year 2025, but ABAG projections are not subject to environmental review. So this area is completely inadequate. They have done no work in this. This EIR is full of this.

SI_SierraC6-02 cont.

Another big area, which I don't have time to go into, is the water flows. They simply do not have any idea of what the impact of taking this water will do to the river flows and what it will do to the fish. They don't have enough of a baseline -- they don't have the science; they don't have the numbers. We need a much more multi-year longer study to get that. And we're not there.

SI_SierraC6-03

So there's many other areas. I just wanted to point out this one on sprawl.

Thank you.

SI_SFNeigh

PRESIDENT ALEXANDER: Thank you. Joan Girardot.

JOAN GIRARDOT: Joan Girardot, Coalition for San Francisco Neighborhoods. My home address is on my speaker card. Because an EIR is an informational tool for decision makers, besides being accurate, adequate, and complete, it should be clear. And I would like to offer some points that I think need to be clarified.

The benchmark year that is chosen is 2001, as far as demand. And it is stated that 261 million

SI_SFNeigh-01

gallons a day were delivered in that year. And we're going to a goal of 300 mgd.

However, if you review the historic tables, which I have here, the average going back over the years is around 240 million gallons a day that has actually been delivered. So it's a big jump from 240- to 300-. It puts everything in a different perspective from 261- to 300-. I think that should be clarified and the historic table should be included in the document.

SI_SFNeigh-01 cont.

Number two, the growth outside of the city -- it has been stated -- I think it should be clarified in the document -- the 25 million gallons a day proposed to be extracted from the Tuolumne is going to the suburbs, not for use by San Franciscans who planned, designed, engineered, built, and paid for this system.

A next point of clarification is the discussion of conservation. We're looking at our whole customers as a whole. But within the city itself according to PUC documents, the average resident of San Francisco uses 61.19 gallons of water per day. That is lower than any of our customers.

And 61.19 gallons per day is 12 percent below what the EPA recommends for indoor water usage. And we have negligible outdoor usage. The outdoor usage in

SI_SFNeigh-02

12.6-97

the city is from our Rec and Park Department. And I think it would be helpful to have a table in the document that listed the per capita water usage per day of all of the 28 customers in comparison with the citizens of San Francisco. I think it would be very helpful.

SI_SFNeigh-02 cont.

The other thing is -- so we need to clarify where we're going with conservation within the city. Of course there is room for plumbing fixtures, et cetera, but 61 gallons per person per day is so low -- I want this clarified. And this nonsense about further conservation by the residents of the city -- we are already doing our job.

Then the last point is I want clarification about recycled water. Because the document presumes that we're freeing up --

SI_SFNeigh-03

PRESIDENT ALEXANDER: Thank you.

I have no other speakers cards. Is there anyone else deciding to comment on this item?

BERNIE CHODEU: Now you have a speaker card for Bernie Chodeu.

C_Chode

I would just underscore what Jennifer Clary has indicated, that I am a believer in global change. And the inadequacy of the EIR in recognizing that issue is an issue for you as a Planning Commission and as

C_Chode-01

staff. And that is, the 30 percent less snowpack and so forth will affect the ability of this city to meet its future water needs, especially with regard to the now discredited housing element, as Kathy Devencenzi indicated at the State appeals court, others, that states that we have adequate water supply and infrastructure.

C_Chode-01 cont.

Until there is mitigation with our conservation measures and a change in city's political policy to accommodate its 200,000 proposed growth and commercial expansion, this Commission and its staff needs to be directed to mitigate its issuance of permits that allows further growth.

Thank you, and I hope I've directed you in some truthful expansion of your meeting.

PRESIDENT ALEXANDER: Thank you. State your name.

BERNIE CHODEU: I did. But I'll repeat it. Bernie Chodeu in case you didn't remember me secretary secretary thank you.

ANN CLARK: Mr. Chair, I have a respectful question because I'm new to this. I have copies of written comments. Do I need to give one to each of you?

PRESIDENT ALEXANDER: You can just place it on the rail. If you have one for each of us, that's great.

12.6-98

If not, the single is fine.

ANN CLARK: But it will get submitted?

PRESIDENT ALEXANDER: It will get submitted.

ANN CLARK: I'll do that.

C_Clark2

I'm Ann Clark. And my name and my address is on the card. And I'm living in San Francisco. I'll speak very quickly as being your last person.

The comment cards that -- the report that you have is going to address actually three main issues. One has to do with the Hetch Hetchy water delivery infrastructure costs and finance. We do thoroughly support, by the way, the work that's being done in order to protect the Hetch Hetchy and its infrastructure.

C_Clark2-01

This is about the cost and the finances, whether you have enough money to do this project. And if you don't have enough money, what's going to happen? And usually the knee jerk reaction is to cut mitigations. That, of course, I think, would cause some legal concerns.

The SFPUC Commissioner last week said he is betting on the over, if he went to Las Vegas, on this project. And I think we'd all bet on the over, that this is going to go over cost. So we are asking that there be an environmental impact study in terms of what

C_Clark2-01 cont.

will be done as a result of however this develops in the future.

C_Clark2-02

Secondly -- and I don't know if I'm saying this right, the gentleman from BAWSCA -- is that the one? Bay Area Something -- I'm new, so I don't know that -- mentioned something about general promises from wholesale cost customers and working out agreements with the agricultural group. Remember the W-S-I-P, the WSIP, is directly connected to the 2009 contract. That's directly connected to the WSIP, so there's an integral connection between the two.

When you do contracts, that's going to have to be looked at in an environmental, stable way. You need a review of that contract because that is an integral part of the plan. So if they are coming forward agreements that are in the contract, not good faith agreements but contractual agreements with agricultural users or contractual agreements with promises to do more conservation, contractual agreements with definitive terms, they have got to be in the contract. If they're not there, they are not there, and they shouldn't be considered.

C_Clark2-03

Second point is drought and climate change and global warming. You've already heard that the study of that is really limited and narrow. There is a study of

12.6-99

drought. But what's really bothering us is there's not a study of what happens if there's drought, climate change and global warming, what would be the exponential effects from now to 2030 if those coalesce.

And in a drought cycle state, which we are, we are going to see some effects come through. And these need to be carefully studied.

C_Clark2-03 cont.

PRESIDENT ALEXANDER: Thank you.

ANN CLARK: So I'll leave you with the rest of the report.

C_Goken

SHAWNA GOKENER [phonetic]: Good evening, Commissioners. Shawna Gokener. My address is 667 O'Farrell, Apartment 10, 94109.

"Compassion" means understanding and action. And it seems that we don't have the understanding necessary of how to preserve our water supply, which is one of the most sacred things that a city's duty is to do. So I really think we need to step back and really look at this very carefully and know that there's a great deal of public concern. And we need to think far into the future before we take answer actions and be compassionate about water supply.

C_Goken-01

PRESIDENT ALEXANDER: Thank you. Next speaker, please.

C_Kalma

EMERIC KALMAN: Thank you. My name is Emeric

Kalman, member of the public. And my address is on my speaker card.

On September 19, yesterday, the San Francisco Landmarks Preservation Advisory Board has on the on the agenda an announcement on this item, which is today, on agenda at the Planning Commission.

And says here, that, "The draft environment impact report was published on August 31st, 2007. The Planning Commission will hold a public hearing to receive comments on the draft EIR to submit to the Planning Department. Written comments on the draft EIR will be accepted in the Planning Department until 5:00 p.m. on until Tuesday, October 16."

The public didn't know about this documentation. And the first time appeared in the newspaper was published in the Examiner on September 10, ten days ago and said that this hearing will be September 20, which is today.

So the public was given ten days to read the material, which I think is -- I don't know 30 points something like that, a bit of material, and maybe 3,000 pages; I'm not sure. So the public needs more time to read it study it and have comment on it. It's unbelievable that the City gives ten days of this crucial documentation to make comments on it. I think

C_Kalma-01

12.6-100

it's a joke. And I will ask whoever can forward this within ten days to study, to give an answer, why is just ten days on it?

C_Kalma-01 cont.

PRESIDENT ALEXANDER: Thank you.

Is there anyone else desiring to speak on this item?

C_JohnsSil

SILVIA JOHNSON: Those who -- my name is Silvia Johnson. I live at 1230 Market Street, 94102, San Francisco, California.

And I don't think that this water and distance is greatly allowed study on it. And other people at the environmental, that resource is needed and know where there's water already. That we don't have anything to worry about in the mountain of the -- over here. And I've written stories on the water that been in revisions.

And I think that also an environmental control is -- you know, more time it needs for this to be read because not only that, thinking of when the inclusion that I have a -- what you call anxiousness to be able to handle all this kind of -- stop Silvia's, you know, progress. And I'm going to change that.

I found that it don't do much to get this whole life back together. And I'm sorry if I do, you know, that -- because of environment that is -- I'm

C_JohnsSil-01

fighting every day. And I'm going to proceed. And my idea is what is going on where we can see the results, and that I'm going -- been through a lot. And I am glad -- you know, learn about more about the conversation.

And I reviewed a lot of this [unintelligible]. And I think this is what their's scared of, you know, for environment. And I don't -- the police -- I didn't give a report on what should be done. They've already told that. The police have already, you know, made an arrangement that needs to be solved.

But I don't want what why they're scared of somebody that can, you know, show you in the future, to keep everything whole. And because this advantage of that's speeding things too fast. I've only been out of jail now for four months. And you know, I've suffered enough. I think that this will be reviewed a whole lot more. Thank you.

C_JohnsSil-01 cont.

PRESIDENT ALEXANDER: Is there anyone else desiring to comment on this item?

C_Bug

JUNE BUG [phonetic]: Hi. My name is June Bug, and I'm 31-year San Francisco native. And I live at 618 Buchanan Street, over in the Western Addition.

I am here to really express importance as somebody who's worked with the Conservation Corps. I

12.6-101

worked with the Conservation Corps back in 2000. I'm also somebody who dealt with homelessness as a child, eight years old, and dealt with a different strategy in water and public systeMs. And I'm also somebody that, on a spiritual level, really identifies with water.

All of these things combined, my concern would be "improvement" doesn't usually mean taking something away. "Improvement" usually means something that you want to preserve. And even if we're at a certain percentage, as people living in San Francisco being really conservative with the water, that doesn't mean we stop there. That means we keep moving forward. That should be an encouragement for us to continue making that even a more amazinger [sic] percentage.

I don't see how taking water out of a river is going to improve a water program -- to improve a water system. So I really have a lot of concerns about what the San Francisco Public Utilities Commission is trying to propose here as somebody who is very, very concerned about our water, due to the fact that -- I mean, there's rumors that one day we'll be fighting L.A. for our water.

C_Bug-01

So I think that we really need to take a look at this. Thank you.

PRESIDENT ALEXANDER: Thank you.

Is there anyone else deciding to comment?

C_Dough

DENISE DOUGHERTY [phonetic]: Hello. I'm 52-year resident of California. My name is Denise Dougherty. And I live at 216 Eddy in San Francisco. I was born in Castro Valley, which -- and I never left the Bay Area unless I went overseas for a while.

And I learned they had a few different approaches to their water usage. And they used old water to water their lawns. Even when I was a child, I could never understand, why would they use drinking water to water their lawns? You know, water is such a precious resource.

I think we need to restructure our water usage as well as our energy usage. Our resources are becoming less and less as the population grows. So we need to restructure a lot of things. Our lifestyles need to be restructured. And I can go on and on about that, but I have only three minutes.

So we need to make use of, like, old water they call it gray water, reclaimed water. I'm sure you know all about that.

C_Dough-01

But the Tuolumne River, it's just the most obvious choice because it's so clean. But there's so many other ways to get water than taking it from the Tuolumne. There really are.

And that's about all I have to say. I thank you very much for listening. I'm against this.

PRESIDENT ALEXANDER: Thank you.

Is there anyone else desiring to comment on this item?

(No response)

PRESIDENT ALEXANDER: Seeing none, public comment is closed. The Department will continue to take comments on this item until 5:00 o'clock, October 10th, I believe the date is? Oh, October 1st. So I encourage you to submit your written comments to the Department.

Commissioner Olague?

L_SFCPC1

COMMISSIONER OLAGUE: I think my comments are related more to the process than the contents of the draft EIR at this point.

I feel a little bit -- I'm sorry. I want to apologize to members of the public who are here. We had about 40 people in blue T-shirts that were here to speak to the issue, and we're down to one now.

Thank you for sticking around and providing us with that documentation, the 800 signatures of people who have concerns about this draft EIR.

L_SFCPC1-01

But I wanted to point out exactly what we're commenting on today. For the benefit of the public, I

wanted to sort of point out the size of the document the people are commenting on today [indicating]. It's like close to 4,000 pages of documentation, this draft EIR. And basically, I think we waited a little long to have this hearing. I know what we did what was legally required, but sometimes I think we do need to go above and beyond that.

It's a 4,000-page document. This is one of -- four of five volumes that we're required to review. And to have only one period of public comment, and we're -- what's today's date? September -- 20th. So people are basically being given, what, 10 or 11 days to respond.

And I know that this document has been out there for a long time, but I think in the future, when we have this size of a document to really review and to expect the public to comment on, we need to provide more than one public comment period about it. I think this is just too important to just sort of rely on only one public comment period ten days before the date that these comments are due.

L_SFCPC1-01 cont.

L_SFCPC1-02

One of my concerns also is that this is a project that's ultimately going to be decided by the Public Utilities Commission, I believe. So it's not even a project that we're ultimately going to be

12.6-103

approving.

L_SFCPC1-02 cont.

And I have serious concerns about the fact that we're being asked to judge the adequacy of an EIR without the benefits of any real briefing from the PUC about the project itself. I think that I -- I think that that's just irresponsible.

So before I actually am able to adequately evaluate and fairly evaluate the accuracy of an EIR, I need to understand the project. I need to understand it within some context. And I think that it's going to be necessary to understand exactly what the project is.

L_SFCPC1-03

And I'd like to have some information from the PUC, maybe a hearing, a briefing; I don't know. But I think that it's important for us to understand that before actually giving -- you know, actually fairly evaluating the adequacy of the EIR sort of in a vaccum without the benefits of understanding deeply what the project is.

So I'm going to -- I'm requesting that a hearing be held about the project itself before this Commission, so we can be evaluating this EIR within the context of the project.

DIANA SOKOLOVE: Thank you for your comment. I'll certainly talk to the PUC about that.

COMMISSIONER OLAGUE: Thank you.

And again, thanks to the members of the public. And I hope that there's some written things. I'd like to understand a little bit more, too, the concerns of the Sierra Club and others. I know that three minutes isn't enough time to really state all that needs to be stated.

L_SFCPC2

PRESIDENT ALEXANDER: Commissioner Antonini.

COMMISSIONER ANTONINI: Thank you all for coming and testifying. And again, my apologies for the fact that we didn't hear this at the time that it was announced.

I think that what -- I've read this over, and I think it is -- you know, in my estimate, it is an adequate statement. However, I understand some comments were made tonight.

L_SFCPC2-01

I guess the first thing is, we didn't get a lot of discussion on, is the fact this is moving forward. And that's very important because, you know, the system does need to be upgraded, seismically improved. And this is probably something that I think everyone agrees upon.

And we have a huge fiduciary responsibility because of the size of the system. It goes far beyond just the city and county of San Francisco. It's a huge area and part of the Bay Area. So what we do here is

12.6-104

L_SFCPC2-01 cont.

extremely important.

L_SFCPC2-02

I think there were comments made about the per capita usage and that perhaps the projections were overly high. And I think that that is something that could be looked at here. However, to the extent that they are lower if there is conservation or there are factors that make the per capita consumption lower than is projected, it's probably a good thing.

So I think that it's important that the study err on both -- to both sides and examine all the different possibilities that might exist. I think it was interesting to hear that the per capita consumption in San Francisco is 61 gallons per day. I think that that's pretty low. It's interesting that -- you know, I don't know that it's realistic that the rest of the the Bay Area is going to be that low, given the fact that there's a lot less pavement in a lot of those other parts of the Bay Area, and their consumption for outdoor use is probably a lot higher.

But anyway, I appreciate the work here, and I'm interested in, you know, going forward and getting as much information as I can from PUC on this.

PRESIDENT ALEXANDER: Thank you.

Commissioner Moore.

L_SFCPC3

L_SFCPC3-01

COMMISSIONER MOORE: I want to weigh in on the

L_SFCPC3-01 cont.

side of not finding enough forward-leading concepts in this entire document. If we are moving into greener sustainability, which has been talked about now for quite some time, I believe that this document shows very little. It is, I think, an engineered response.

L_SFCPC3-02

And while I strongly support the idea of seismic safety and a healthy, deliverable system in all circumstances, I question how we look at projections of growth, how we look at projections of increased water consumption, the effect on scenic resources, and not looking at how we are transforming the urban environment.

Just coming back from Europe, where the cities are not as over-asphalted as we are -- certain sidewalks have partially pervious surfaces. All of our surfaces are hermetically sealed. All of our streets do not allow the repercolation of rainwater into the groundwater, and on and on and on and on -- I think this is a backward-looking document in its own right.

And I hope that there is a way of, at least at this moment, opening up to those concerns which we're currently celebrating across the street. There's a Green Conference across the street. We are trying to be the greenest city in the country. And we're subscribing to a document which really does not address that at all.

At least there should be a chapter in here which tries to create a horizon or a future by which we are moving ourselves away from conventional concepts.

PRESIDENT ALEXANDER: Thank you, Commissioners.

SECRETARY AVERY: Okay. Thank you very much. That concludes the public hearing for this item.

(Whereupon, the proceedings concluded at 7:51 o'clock p.m.)

P R O C E E D I N G S

SECRETARY AVERY: Okay. The Planning Commission is back the session.

Commissioners, I had just called into the record Item No. 10, the informational presentation on the Water System Improvement Program.

DIANA SOKOLOVE: Good afternoon, President Alexander and Members of the Commission. My name is Diana Sokolove. I'm a senior environmental planner with the San Francisco Planning Department, Major Environmental Analysis Division.

The item before you is a hearing to receive comments on the Draft Program Environmental Impact Report on the San Francisco Public Utilities Commission's Water System Improvement Program. The case number is 2005.0159(E). The public comment period for this environmental report began on June 29th, 2007 and extends to 5:00 p.m. close of business on October 15th, 2007.

The Planning Department also held five other public hearings throughout the Water System Improvement Program study area to take public comment on the Draft Program Environmental Impact. One of those hearings

was held before this Commission on September 20th. The proceedings from all of those hearings will be reported in the comments and responses document.

So prior to opening up the hearing for public comment, Susan Leal, with the San Francisco Public Utilities Commission, will make a few remarks, and then Tony Irons will give a presentation on the proposed program. And then I'll provide an overview of the Program Environmental Impact Report.

SUSAN LEAL: Good afternoon, Commissioners. Susan Leal, General Manager, San Francisco Public Utilities Commission.

We're pleased to be here today, pleased to have an opportunity to give a brief presentation on our water system. We understand, as we are in the comment period, it is just that, a comment period, but it does provide us with an opportunity to give you Commissioners a better understanding of how our system works. So with that, I will turn it over to my deputy general manager, Tony Irons, and he will walk you through how this system works and what we're up against in the seismic repairs of that system.

PRESIDENT ALEXANDER: Thank you.

TONY IRONS: Thank you, Susan, Commissioners. Tony Irons, Deputy General Manager, SFPUC.

12.6-108

Over here (indicating) there are some boards that you might reference. And I believe the information on these is also in the executive summary of the PDIR, but I'll kind of walk you through a brief history of this program and why we're doing it.

Susan and I have both been at the PUC since -- for three years, a little over three years. And when we came there, the City and the PUC had been working on this program intermittently for a long time. What we found was a series of projects, approximately 77 projects, each one with a brief outline of what its characteristics were.

My first stop, actually, the day I got -- came to the PUC to work with Susan was to see Paul Maltzer in the Environmental Review office and ask him how far along the environmental review had progressed. He said, "It has not because the PUC has not given the City Planning a program." That, in large part, was true.

So the first task before us was to create a program that could be reviewed for its environmental impacts and commented on by the public. That involved figuring out what all -- why all of these projects were being done.

So I went to individual project managers and

said, "You're in charge of X, Y, and Z projects. Why are we doing those?"

And they gave an answer, but the answers, when you aggregated them, didn't define a system; they didn't define an overarching purpose. So we delegated ourselves to go to Public Utilities Commission and asking them if they would adopt level-of-service goals such that we might be able to then have a design basis and an integrated system that related to goals that the Commission had adopted relative to this whole program.

Those goals are outlined here, and they're also in the executive summary of the PEIR. In essence, there are four categories: seismic reliability -- and I'll touch on a brief history of that in a moment -- delivery reliability -- which is very important -- water quality, and water supply.

In the first instance, back in the I believe early '90s, the Bay Area Economic Forum published documents that basically stated in the event of a major earthquake on any one of the three major faults that this system crosses, the economic impact of that, of a cessation of water of up to 60 days in the Bay Area, would be catastrophic.

And the State kind of responded by passing three pieces of legislation. One stipulated that these

12.6-109

certain major projects would be done and certain moneys would be spent and outlined a time table for those -- not statutorily but a time table at the inception of the project.

The next was that the suburban customers who receive water from us are incorporated as an agency; whereas they had been a loose amalgam beforehand, they are a State-authorized agency. So the State acted, basically saying to the City, "You need to do this, and you need to do it now because there is great danger to the health and well-being of the Bay Area if you don't do it."

We have established a time table, a goal, which is, the end of 2014, to have this program completed. And the reasons for that are the danger to the public health and safety in this entire area should a major earthquake occur.

So the seismic reliability goal was established as, after a major event, there would be basic water service. And that is defined as 215 million gallons of water a day to the customer base within 24 hours. And there would be full water service restored within 30 days.

Those are very aggressive goals. And they are, frankly, more aggressive than other jurisdictions

have. But we cross three earthquake faults so that the likelihood of a major event occurring is far greater in our system, which is essentially a linear system from Hetch Hetchy Reservoir to Fisherman's Wharf.

The delivery reliability kind of harkened to the notion that this system had to have this major program done for it because there has been inadequate maintenance in the system for 70 years, that the revenues generated by the Public Utilities Commission were routinely delivered to the City's general fund instead of repairing the water system.

So that criteria was that this system needs to be maintained, and we need to be able to deliver average-day water while one major either pipeline or storage system is out of service and another one concurrently in an unplanned outage of some sort. So that's the criteria for the maintenance component.

The water quality stipulates that we will comply with all present and known future water quality regulations, either from the federal, state, or local governments. And the water supply identifies two overarching issues. One is a delivery capacity of an average of 300 million gallons of water a day to the overall surface area and that, during a drought, there would be a maximum rationing of 20 percent of average

12.6-110

delivery of water. And that would be incrementally imposed.

Now, those guidelines, Commissioners, provide us, as management to this program, the ability to actually design all of these individual projects as an interwoven continuum. And they establish the design basis for each one.

You can see here (indicating) -- and I don't know how I'm going to do this. When I was actually managing the City Hall project, I worked really, really hard to get the podium over there and the Commissioners here so the public could see the same documents the Commission could see. But I failed in that effort.

In any event, the system stretches 167 miles from the Hetch Hetchy Reservoir in Yosemite National Park, behind the Hetch Hetchy Dam, which is wholly owned by the City and County San Francisco -- and the authority to do so derives from the Raker Act, which was passed by an act of Congress. It's federal legislation passed in 1914, I believe -- '13, which gave the City of San Francisco the authority to collect the waters behind the O'Shaughnessy Dam and deliver them to the Bay Area.

Michael O'Shaughnessy, whose bust is in the Van Ness entry to City Hall and in the International

Water Hall of Fame, was the engineer. And he was a brilliant, brilliant man. It was entirely constructed, the entire system constructed, by City employees. And that includes the dam, all of the tunnels, all of the treatment plants that actually were not originally constructed, but subsequently -- the entire delivery system, constructed by City employees.

This program starts at the Tesla Portal. This program does not have work to the north or to the east of the Foothill Tunnel. All of the components are to the west of the Foothill Tunnel. And that is -- these improvements would have to be done irrespective of what water is delivered to whom, when, or how much. All of the improvements are a result of deterioration of the system and the necessity to provide for earthquake protection.

As we go down through the system, San Francisco is at the very end, and so the water that we get is a measure of the vitality of the system. And San Francisco -- actually, San Franciscans use per capita less water than any of the other customers. And there are good reasons for that. It's a very dense urban environment, there are very few lawns. I mean, there are good reasons.

But I think one thing that's important to note

12.6-111

is that, after the severe drought of the late '80s early '90s, the water consumption throughout the entire customer base dropped precipitously and did not rise again. Unlike power -- after the blackouts, there was a reduction of use of electrical power, but it has risen back up to its pre-blackout levels. That's not the case with water, and that's very heartening to us.

So that's -- the level of service established for us the design basis for going forward with this and the criticality of the system as it relates to the likelihood -- which is from today, I believe, 62 percent likelihood of a major event on either the Calaveras Fault, the Hayward Fault or the San Andreas Fault within the next 15 years. It gives us a time frame that we have to respond to.

So with that, what I'll do is walk you through some of the very large projects. I won't bring you through every project. Some are larger; some are smaller. But the very large ones kind of encompass the notion of the criticality and the size of the program.

The program is the largest capital undertaking the City has ever endeavored. It's $4.3 billion worth of work. And Commissioners, it is a City-run, City-managed program, which is highly unusual for an infrastructure program of this sort. Typically cities

or counties or states would hire a consultant -- a Bechtel or a Flour or whatever -- to come in and run their program.

The City is has elected not to do that by agreement between the Mayor and the unions who represent folks that I'm in charge of. And that agreement is that it is a City-run, City-managed program. I feel very comfortable with that. It's extremely difficult. It presents us with very difficult challenges. And we do need to bring in professional consultants to design the dams, the wastewater -- the water treatment plants, the major infrastructure because our city engineers, they are very, very good, but they have never designed those massive infrastructure things.

But it kind of harkens back to the days of Michael O'Shaughnessy. It was originally built by City employees, 100 percent, the entire system.

So with that, let's walk through a few of the major projects.

Uh-oh. Technological glitch.

There it is. This shows the project development cycle. And I wanted to touch on this, because there's a component here that I think is of great interest to us, to the City, and perhaps to this

12.6-112

Commission.

We have chosen to design 100 percent concurrent with the environmental review. And we are very aware that there is substantial risk involved in doing that, that at the end of the environmental review, the project may be different than the project that was being designed during that concurrent process.

We are willing to take that risk because we have very little time to enact this program. Doing $4 billion worth of work over principally a six-year time span is extremely challenging. So we've decided to take the risk on designing concurrent with environmental review.

This -- this cycle description here shows where the planning phase is and those elements of planning that then allow us to drop down into the environmental review and where, during the environmental review, we feel comfortable then beginning the design work.

Now, in every instance it shows the design phase ending before construction begins. That, in fact, may not be the case in some of these. We may opt to do a bridging design build on some of the very large projects. We haven't made that determination yet.

We do know that our biggest challenge is

actually getting contractors to bid on these projects. These are different contractors than work in San Francisco now. These are contractors that have to post a 3- or $400 million bond and build dams and tunnels and water treatment plants.

Okay. This is one of the major projects (indicating). This is the farthest major project to the east. This is the San Joaquin pipeline system. I think many of you may recall that three years ago -- two years ago, this -- the program called for an entirely new fourth barrel on the San Joaquin pipeline. That is what had been proposed by the folks running the program for a number of years.

Susan asked for a top-to-bottom review of the efficacy of that proposal because the potential existed for the diversion of a great amount of water from the Tuolumne River. Whether the PUC chose to or not, the physical infrastructure would be there to accomplish it. And it would be also, from my viewpoint, extremely expensive and very intrusive. So we developed an alternative to that that did not necessitate a fourth barrel on the San Joaquin pipeline system. We're very happy with that.

It was modified to install a number of crossovers along the three existing pipes and two stubs

12.6-113

on either end to relieve the hydrostatic pressure so that the amount of water that can pass through there does meet the level-of-service goals but does not exceed them. And that is the case with each one of the major projects that we are going to be developing, that we will meet in the most cost-effective way, the most efficient way, the minimum requirements of the level-of-service goals.

This shows -- this is a photograph of a failure in the San Joaquin pipeline system that took place in I think it was the mid '80s. Those pipes are pre-stressed concrete pipes, one whole reach of them. They are subject catastrophic failure because they are concrete with pre-stressed wire inside the concrete. The wire corrodes over time. And when it gives -- concrete has no tensile strength -- the entire pipe blows outwards. Actually, above this photograph, there is a cow on top of the water plume. That didn't make it in there. That is out in the Central Valley. When those things go, it's really, really catastrophic. There's an enormous amount of water that goes out. So there is a program to rehabilitate those three existing pipes.

This is the Calaveras Dam. I think about seven or eight years ago, the Division of Safety of

Dams which oversees the -- has jurisdiction over the Calaveras Dam, the Crystal Springs Dam, and also the terminal reservoirs in San Francisco which are considered, in effect, dams -- they have jurisdiction. They determined that there was a seismic -- potential for seismic failure at the Calaveras Dam and ordered us to reduce the volume of water behind it by 60 percent. There is now 30 percent of its original carrying capacity [sic]. So we've been operating the system for a number of years now with no reserve in the Calaveras Reservoir, which, in terms of drought, is extremely dangerous for us.

So one of the major programs here is to build a new Calaveras Dam just slightly downstream of the existing one to maintain the same amount of water behind the dam that preexisted before the Division of Safety of Dams ordered its reduction. And that project is a very expensive project. That's a $230-or-40 million dam construction project. And the significance there to us pertains to our overarching obligation to defend the natural environment. And the watersheds around the Calaveras Reservoir, the Alameda Creek watersheds are very, very important to the health of that entire area.

This is a photograph of a portal on the

12.6-114

Irvington Tunnel. Now, all the waters come down from the Hetchy Reservoir. And there's an obligation in the federal act, the Raker Act, that stipulates that first we must use water from local runoff. And that's the Calaveras Dam and the Crystal Springs Reservoir -- the Calaveras Reservoir being a much more productive reservoir in terms of runoff than Crystal Springs. But the Raker Act stipulates that we have to use local water first.

That local water constitutes about 15 percent of all the water we deliver to our customers, 85 percent coming from the Hetch Hetchy Reservoir through this single aqueduct, down to the entire southern reach below us in Santa Clara, Alameda County, San Mateo County and into San Francisco.

All the water coming from there passes through the Irvington Tunnel. No one has been able to inspect that tunnel for 40 years because, in order to get into it, you have to shut the water off to 2 1/2 million people. That's not tenable. Therefore, the conclusion was it's absolutely necessary to have a redundant tunnel.

The other component here that was of overriding concern, that portal that you see there is subject to failure and landslides following a

significant earthquake. Were that to happen, millions of people would have no water because it would not be able to go through the Irvington Tunnel. So we are -- one of our major projects is the construction of a new tunnel.

This project is not particularly large in the scale of a number of our projects. It's about $65 million. It is, however -- or $80 million. It is, however, critical. The Alameda siphons are just north of the Calaveras Reservoir, just to the west of the Irvington Tunnel. The fault, the Calaveras Fault, passes directly underneath the existing three siphons of the Alameda siphons as the water progresses to the Irvington Tunnel. So we're building a fourth siphon which is earthquake resistant and can withstand the maximum earthquake on that fault.

Next. This is the largest project in the collection of projects that we have, Commissioners. This is a total of $572 million. And it is the amalgam of water transport facilities including a new tunnel across the southern region of San Francisco Bay. The tunnel option is, for us, a much, much better option. It is environmentally far superior to any other option. The existing water pipes go through very, very sensitive wetlands. We can't get out to them to maintain them because we can't pass through the waters. We can't get permission to pass through the waters. And therefore we've determined to build a new tunnel under the southern reach of the San Francisco Bay.

The whole project, the pipeline repairs, the seismic renovation to the pipelines and the tunnel, is nearly $600 million. It is absolutely critical to our ability to deliver water to the Peninsula and to San Francisco to the Harry Tracy Water Treatment Plant to be able to get it safely across the bay and to be able, in the future, to maintain those conveyance facilities.

12.6-115

This project is Crystal Springs-San Andreas Transmission Upgrade. And I'm kind of now bringing you up the Peninsula. The Crystal Springs Reservoir and Pillarcitos Reservoir -- well, the Crystal Springs Reservoir feeds water into the Harry Tracy Water Treatment Plant. And we bring water from Hetchy to recharge Crystal Springs when there is a surplus of Hetchy water that is ours.

Approximately between 1- and 1.8 billion gallons a day of water comes out of the reservoir on an average day. And of that, 300 million gallons is water that is diverted for the use of this entire system of customers. The rest of the water goes to the irrigation districts -- Modesto and Turlock Irrigation

Districts. They have senior water rights. They get first call on it. And they get far more water than the San Francisco system.

But it is imperative for us to be able to deliver water safely out of the Harry Tracy Water Treatment Plant, which is located down at the Crystal Springs Reservoir off 280, up through the Peninsula. And that transmission system is in serious need of repair. So this project addresses the repair of that delivery system.

And finally, in San Francisco, there are three terminal reservoirs. It's kind of like the question of in-city generation of power. When we reviewed the water system, we concluded it was absolutely necessary to have in-city storage of major water facilities. In the event that the system went out, there is a period of time in which there is sufficient water to fight fires and to provide basic water needs. That's what those three terminals, Sunset Reservoir, University Mound Reservoir, and Summit Reservoir are our terminal reservoirs as part of the regional project.

And finally, the recycled water component of this is a $200 million effort to build recycled water plants on the western side of the city and deliver those for use to all of the green spaces in Golden Gate

12.6-116

Park and to be able to reduce our reliance on waters from the Tuolumne River. And that is a very aggressive program. It will, in my view, the recycled water program, expand.

We're looking, Commissioners, very hard in our Wastewater Master Plan at significant opportunities to recycle water on the wastewater side so they may be combined into a much more aggressive recycled water program in San Francisco.

It, to me, is kind of a sad testimony; San Francisco doesn't have nor ever has had one drop of recycled water in it. And we're the most progressive city in the country. So we're working really hard to radically change that in the near future.

So with that, that's a brief overview of our system and some of the major projects. I didn't, in the interest of time, go into all 27, but that should give you a fairly broad view of what we're doing with our staff of approximately 300 city employees and a variety of internationally renowned consultants over at the PUC.

So if you have questions on the system, I'd be happy to answer them.

PRESIDENT ALEXANDER: Thank you very much --

TONY IRONS WITNESS: You are very welcome.

PRESIDENT ALEXANDER: -- for a thorough presentation.

DIANA SOKOLOVE: Hi. This is Diana Sokolove of the San Francisco Planning Department. And I'm just going to give an overview of the Program Environmental Impact Report that we released at the end of June on the Water System Improvement Program.

So this is just an overview of the organization of the Program EIR -- if we can get this up. I guess it takes a moment.

There we go. Volume I includes a summary of the program, and it includes major findings, summary of the program description, and a summary of the alternatives that we evaluated in the Program Environmental Impact Report.

Volume II includes the impacts of the facilities projects, the projects that Tony Irons just mentioned earlier. Most of the projects that are listed there are included in the impact assessment in that volume.

Volume III looks at the impacts of the water supply strategy that the SFPUC is proposing, bringing more water into the area to serve customer demand through 2030.

And Volume IV looks at mitigation measures,

12.6-117

growth inducement impacts, and also the alternatives to the proposed program. Volume IV also looks at variants to the program, which is a little different than CEQA alternatives. The variants are variations on the water supply strategy that the Public Utilities Commission actually specifically asked that Planning look at the impacts of, even though they're not necessarily CEQA alternatives. So it's a little bit different.

So again, we do have an analysis, a very thorough analysis, of the environmental effects of the facility improvement projects. And those projects are located in five regions as we've kind of chopped the entire PUC Water System area into five different regions -- San Joaquin, Sunol Valley, Bay Division, Peninsula, and San Francisco regions.

We looked at construction impacts that may begin in 2008 through 2015. And we looked at mostly the fact that a lot of these projects are going to result in construction impacts. So there's impacts related to noise and air quality and traffic and those kinds of things and they're -- air quality, they're all -- those kinds of things are addressed in that section.

Here's all the areas, the environmental resource areas that we looked at for impacts related to

facility improvement projects, all of the standard areas that you look at in a CEQA document -- noise, air quality, recreation, energy, hazards, et cetera.

So we found, just to give you a summary of the key findings of the Environmental Impact Report, that many of the impacts would be less than significant because the PUC would be complying with existing regulations. They have adopted watershed management plans that ensure that they're complying with regulations and their own policies and regulations, and that also the PUC has a set of standard construction measures that it's going to apply for every construction project in the WSIP.

So that's why you'll see those findings -- for the most part, it's less than significant, although I do feel as though the analysis is pretty conservative. If we didn't feel like a regulation or some sort of -- or an existing measure could reduce impacts to less than significant or ensure that impacts would be less than significant, we would certainly call it significant. And a lot of those impacts that are called as significant can be reduced to less than significant with mitigation.

We do have -- in terms of mitigation, we do look at measures to avoid impacts entirely or at least

12.6-118

to minimize the significant effects. And you can see the kind of range of mitigation measures that we look at. We look at making sure that the projects are sited properly, that if there's any way to site a facility to avoid impact on a wetland, we're putting that in the document.

We're talking about controlling noise through different -- there's different ways that you can control noise -- and making sure that erosion and sedimentation doesn't occur with implementation of these projects. And we also look at doing surveys and making sure that we are protecting the resources the best that we can through this environmental process.

So we also look at the environmental effects of the water supply strategy that the PUC is proposing. And the Water System Improvement Program, as you know, does propose to increase diversions from the Tuolumne River and would modify system operations to meet customer purchase requests through 2030. And some of the effective resources would be the different watersheds throughout the study area, including the Tuolumne River Watershed, Alameda Watershed, Peninsula Watershed, including Pillarcitos Watershed, and the West Side Groundwater Basin.

Actually, you can see these watersheds on the

screen here. Here's the Tuolumne Watershed. It's hard to see with the text on there, but down here is the Alameda Watershed and Peninsula Watershed. And West Side Groundwater Basin is near San Francisco.

So in our water supply impact analysis, we do look at how the PUC is proposing to change system operations, and that can cause changes in the water levels in the reservoirs. And it could cause changes in the amount of water that's released from the reservoirs. And we looked at how those changes would impact our resource areas such as biological resources, recreational resources, aesthetics, et cetera. And we did use what's called a Hetch Hetchy local simulation model to determine impacts in the study area.

So here are our water supply impact areas that we looked at: stream flow and reservoir levels, geomorphology; we looked at surface water quality and surface water supplies; we looked at impacts on fish, impacts on biological resources, and also of course recreational and visual resources.

So I'll just quickly go through the different impacts, the key impacts, that we came up with in the different watersheds. We found impacts on biological resources in the Poopenaut Valley below Hetch Hetchy Reservoir. We do have impacts on fisheries and

12.6-119

riparian resources also along the Tuolumne River. So we certainly called those out in the document.

In Alameda Creek, as Tony mentioned, one of the major projects is the Calaveras Dam replacement project. And that has a bearing upon many of the impacts that are included in the Alameda Creek Watershed analysis. So we looked at the changes in stream flow because the PUC will -- after -- since the DSOD restriction on Calaveras Dam, the PUC has not been taking water off of Alameda Creek to fill the dam. So the PUC would resume that process and restore the existing capacity in the Calaveras Dam through the Calaveras Dam project. So we looked at stream flow below Alameda Creek and the Alameda Creek diversion dam.

We looked at fisheries and riparian resources and the effects of diverting water off the creek on those resources and, of course, the effects on riparian habitat and recreational visual resources.

In the peninsula as, again, as Tony mentioned, some of the major projects are the Lower Crystal Springs Dam Project, repairing that dam, and also the Crystal Springs-San Andreas Pipeline Project. So in that watershed, we looked at water quality and fishery resources, the effects on those resources by repairing

the dam. And we also looked at biological resources and looked at the effects on the different creeks in the watershed.

In the Westside Groundwater Basin, the proposed project includes conjunctive use program that looks at developing groundwater resources. So we looked at impacts in the north Westside Groundwater Basin and also the south Westside Groundwater Basin, in terms of saltwater intrusion and any way that any of these projects could cause overdraft in the groundwater basin. So we certainly looked at all of those effects.

And as you can see, we do have -- we do show impacts in the Program EIR on basin overdraft, seawater intrusion due to increased pumping in that basin. We look at changes in water levels in Lake Merced, potential contamination of drinking water due to groundwater pumping.

And we do propose a wide range of system operations mitigation measures, in other words, ways that the PUC can operate its system a little differently to try to avoid these impacts. We look at managing releases from reservoirs. And also the PUC is proposing a habitat conservation program that we're looking at and using that to reduce impacts on resources, specifically biological resources and fisheries. And we look at revised operations for Pillarcitos and also just making sure that, in the groundwater basin, that we're not causing overdraft or seawater intrusion.

The Program EIR also includes an analysis of the growth inducement effects of the proposed program. And we are concluding that, removing an obstacle to growth by providing this water to serve future demand, that the Water System Improvement Program would remove water supply limitations as an obstacle to growth. So we do show that there would be a growth-inducing impact in the service area or in the area that's served by the PUC.

12.6-120

In our CEQA Alternatives Analysis, we identify alternatives that would reduce our less-than-significant impacts of the proposed program and also meet most of the basic project objectives, program objectives, as required by CEQA. So the program alternatives that we look at address the water supply and the demand level served and also the number and scale of the facility improvement projects that are proposed by the PUC.

So here is the range of alternatives that we looked at. We have the No-Program Alternative, which is required by CEQA. And we have the No Purchase

Request Increase Alternative, which looks at not increasing the water supply to meet customer purchase requests through 2030. We look at an aggressive conservation and water recycling alternative. We look at changing the diversion of water supply to the Lower Tuolumne River. We also look at -- a couple alternatives look at de-sal, one at Oceanside, which is in San Francisco near the zoo, and then there's another one that is a regional de-sal plant that involves a consortium of water purveyors in the Bay Area.

And then we look at what we call the Modified Water System Improvement Program, which we identify as the environmentally preferable alternative. And it really incorporates a lot of the mitigation measures we have in the document and also incorporates some additional revised operations of the Water System.

These (indicating) are just some other alternatives that we considered since we heard from a lot of folks, members of the public, during the scoping. So we were careful to look at all the alternatives that were suggested to us during scoping and anything else that the PUC may have looked at through developing its Water System Improvement Program. And in the document, we discuss very carefully why we rejected these alternatives from

12.6-121

detailed consideration in the environmental report.

So that concludes my presentation. And are there any questions from the Commission on either my presentation or for the PUC?

PRESIDENT ALEXANDER: Thank you.

Commissioner Moore?

L_SFCPC4

COMMISSIONER MOORE: I have a question for Mr. Irons, please.

I think the report is terrific. I'm totally impressed by your daring step to work with local people and not outsource this project, which is typically done, and we all know about it. I hope you will not have the overruns that many of the large nationally important projects have shown. I'm sure you will manage it in a way that will not have it.

L_SFCPC4-01

I'm interested of why Region 6, Hetch Hetchy Region, did not have any problems -- because it's unusual.

L_SFCPC4-02

TONY IRONS: The facilities that are in the Hetch Hetchy Region are the O'Shaughnessy Dam and then a series of tunnels and penstocks and powerhouses. There are three hydroelectric powerhouses up there, which are not relative to the delivery of water but more relative to the generation of power. And then the water goes through a series of tunnels.

Those tunnels are granite tunnels. And while they do need periodic lining, they are maintenance rather than capital projects. So there were no capital projects that needed attention in that area.

COMMISSIONER MOORE: You have a couple of smaller reservoirs, but they do not show any impact from seismic activity. You have, like, the Priest, the Moccasin reservoirs -- which I assume are part of the system.

L_SFCPC4-03

TONY IRONS: That's right. There are no major earthquake faults there.

PRESIDENT ALEXANDER: Thank you.

Commissioner Antonini?

L_SFCPC5

COMMISSIONER ANTONINI: Yeah, Mr. Irons, I have a couple of questions. Thank you for an excellent presentation.

I guess as we talk about some of the parts of the project and the fourth pipeline option, which was not -- or fourth barrel, I guess, more properly, was -- in the San Joaquin system was not chosen, one issue I guess I have in terms of seismic was, by having an alternate pipeline at some other location a distance away, would you prevent, you know, a seismic event from taking the whole system out because you have, you know, two different pipelines; you've got the existing

L_SFCPC5-01

pipeline and then you have an alternate pipeline? I mean, I know that was probably considered as a safety measure perhaps.

L_SFCPC5-01 cont.

TONY IRONS: Yes, Commissioner, it was. There is no active major fault in the San Joaquin Region. They're all to the west of that; the first one is the Calaveras and then the Hayward and then the San Andreas Fault. There are splinter faults that are through there, but there has never been major activity on them.

The issue of the San Joaquin pipelines is that they traverse 50 miles, 47 miles of the Central Valley. They are principally underground. And it's necessary -- when we say the average water delivered on an average day is 300 million gallons a day, that is average on a year-round basis. During the summertime, there are demands upwards above 400 million gallons a day when the water is -- the usage is the greatest.

The San Joaquin pipeline system needs to be able to deliver water that is normally used during the high periods without the potential of failure. So it was concluded -- and I think a number of our Commissioners really kind of agreed with the general manager that the importance, the real importance, in the San Joaquin system was to have three existing pipelines in a state of good repair rather than simply

leaving them in a bad repair and putting a brand-new pipeline in, that it was more prudent to have three in a state of good repair.

COMMISSIONER ANTONINI: Thank you. And in keeping with that, I would assume that the new pipe you talked about -- the concrete having no tensile strength -- would the new pipes be non-concrete or something with greater tensile strength?

L_SFCPC5-02

TONY IRONS: We are in the process of investigating and repairing two of the pipelines. They were incrementally put in from 1934, 19- -- early 1960's and 1970's. The 1970, the most recent pipeline, is the reinforced concrete, pre-stressed concrete pipe. That is the most vulnerable. The newest one is the most vulnerable. The others are steel pipelines and riveted steel. And they were put in as population grew.

And I think -- you know, I think it's right to say that the vision of this -- this is truly a remarkable water system because of the way O'Shaughnessy designed it. It's known internationally as an incredibly special system. It uses no energy to pump water all the way from the Sierras to San Francisco. The issue through the San Joaquin pipelines was to make sure that there was sufficient head,

12.6-123

sufficient water to go through.
So I think that really was the driving force in adding additional pipelines was the additional water needs. Our feeling is that we do not need to create a conveyance facility that is capable of conveying more water than we actually need.
COMMISSIONER ANTONINI: And finally in regards to the Bay Division pipeline and you talked about the tunnel options would replace the lines that currently, I believe, go above water and are on stilts or something above the bay -- L_SFCPC5-03
TONY IRONS: That's right.
COMMISSIONER ANTONINI: -- would those remain or those would be removed? L_SFCPC5-03 cont.
TONY IRONS: Those pipelines -- there's a set that is above the water and some are submarine. The ones that are submarine we would probably leave, we are going to leave. And I actually don't know if we are right now still considering -- still considering removing the above-grade ones --
(Sotto voce discussion)
TONY IRONS: No. We're decommissioning them but not removing them.
And you can see those water pipes when you drive over the Dumbarton Bridge. They're directly to

the south. The issue with doing any work on them is really the wetlands that are on both sides. It's very, very sensitive wetlands. So I believe the final analysis was, from an environmental point of view, it is better simply to leave them than to try and tear them out from the subsoils.
COMMISSIONER ANTONINI: Well, my other point being sort of similar to the other discussion is you have an alternate line there if you needed it in an emergency that might be available were something to happen. You could run it through there. L_SFCPC5-04
TONY IRONS: Absolutely. And I did briefly mention, but I'd like to reiterate, the San Joaquin pipeline system, the addition of the redesign in place of an additional fourth barrel includes a series of three crossover valves. One exists right now. It's being renovated and expanded. But what that basically does for that entire water conveyance system is allows us to take certain reaches of one pipe out of service without taking the entire pipe out of service so that at no point in time do you have only two pipes. You have in essence 2 2/3 or 2 1/2 or whatever is necessary to allow the volume of water to continue. So the crossovers are a good solution to that problem.
COMMISSIONER ANTONINI: Thank you, Mr. Irons.

12.6-124

TONY IRONS: You're welcome.

PRESIDENT ALEXANDER: Thank you, Ms. Leal, Mr. Irons, and Ms. Sokolove. Thank you very much for an excellent presentation. I think it gives us a good framework in which to the review the Draft EIR.

We want to now open for public comments. I do have some speaker cards. Peter Drekmeier?

SI_TRT10

PETER DREKMEIER: Good afternoon, Chair Alexander and Commissioners. Thank you for the opportunity to address you today.

My name is Peter Drekmeier. And I'm the Bay Area Program Director for Tuolumne River Trust, and we appreciate the opportunity to comment on the Draft PEIR, also appreciated the presentations by Mr. Irons and Ms. Sokolove and appreciate the good work they're doing.

Our organization is 100 percent supportive of the seismic upgrades to the Hetch Hetchy system. However, we're very, very concerned about the proposal to divert up to 25 million gallons of water per day additionally from the Tuolumne River. And to put that in perspective, that's the equivalent of 1,000 large swimming pools every day in addition to what's already being withdrawn. SI_TRT10-01

So we have worked with the Sierra Club and

Clean Water Action to provide comments, over 60 pages. I don't know if you'll get to read them all. But we also have a short executive summary. And unfortunately, I don't have enough copies for everyone, but I do have a few copies that I'll leave here for you.

I'm not going to talk so much about our comments right now, but I want to address an issue that's going to be coming up. And it's the proposal to work out a water transfer agreement with Modesto Irrigation District and Turlock Irrigation District, or MID-TID. And it sounds great on the surface, "We'll pay farmers to conserve water so that there's no net loss of water in the Tuolumne system." But there's two problems to this.

First of all, SFPUC withdraws water at Hetch Hetchy, and any conservation would take place 30 miles downstream at Don Pedro Reservoir. So we have impacts to 30 miles of river, about seven miles in Yosemite national park, 18 miles of world class white-water rafting, and home to a number of species, some rare and some threatened. SI_TRT10-02

And the problem is, we don't have a lot of information on the biological resources because many of the studies are dated, some 15 years old or more, never SI_TRT10-03

12.6-125

completed. So our comments were focused mainly on the lack of baseline data, on flawed modeling and faulty assumptions.

SI_TRT10-03 cont.

I see I don't have a lot more time. I was going to read a few things from the MID-TID letter and from the Fish and Game letter, but I'll just sum those up.

First of all, MID-TID have a lot of concerns with this project. And they're not sure there's enough water to do a transfer agreement, and they're uncertain about future releases below Don Pedro. And that's because Fish and Game has pointed out the current flows are inadequate for the Anadromous fish there -- Chinook salmon and the federally threatened Steelhead trout.

And what's probably going to happen in 2016, when the FERC relicensing takes place, is they're going to decrease the flows at LaGrange Dam below Don Pedro. So you're in a tricky position -- I don't envy you -- when it comes time to certify the EIR.

SI_TRT10-04

PRESIDENT ALEXANDER: Thank you.

PETER DREKMEIER: We hope you'll do your best. Thank you.

PRESIDENT ALEXANDER: Art Jensen?

L_BAWSCA6

ART JENSEN: Art Jensen, General Manager, Chief Executive Officer of the Bay Area Water Supply and

Conservation Agency.

Mr. President, Members of the Commission, the Bay Area Water Supply and Conservation Agency, or BAWSCA, represents 27 agencies in Alameda, San Mateo, and Santa Clara counties that purchase water from San Francisco's regional water system and serve it to 1.7 million residents and businesses and community institutions in those counties. They in turn pay two thirds of the costs, roughly, for the operation, maintenance and construction of the regional system.

We've carefully reviewed the PEIR, and overall we believe that it's a well-crafted document. Your staff did an excellent job. It's a very conscientious effort and largely successful, we believe, in meeting CEQA's requirements.

There are two areas where we believe it can be improved. First, the Draft PEIR does not convey the great risk which we all face, nor the urgency for rebuilding the regional water system without delay.

Mr. Irons' presentation, I think, introduced you to the issues associated with the water system traversing four earthquake faults. And those earthquakes could occur at any time. The impacts to public health and safety would be dramatic. The Bay Area Economic Forum study which he cited cites figures

L_BAWSCA6-01

12.6-126

of $20 billion worth of damage. So obviously the investment is a well-centered one.

L_BAWSCA6-01 cont.

Second, the draft PEIR does not describe or analyze the environmentally superior alternative in the detail to which it's warranted. We believe it's an excellent alternative which your staff has come up with in their analysis of the alternatives proposed.

L_BAWSCA6-02

The moderate-city-growth employment forecast for both San Francisco and the BAWSCA area will create a need for additional water over the coming decades. Unlike the urgent problem with the earthquakes, the growth problem will occur over decades, and we have time to solve it.

Our agencies are already committed to meeting a portion of their demands by conserving and recycling 23 million gallons a day worth of water. Those are in the baseline projections that were examined.

The environmentally superior alternative includes an ambitious, legally feasible request for an additional 5 to 10 percent MGD of water conservation and recycled water from our agencies, above and beyond the 23 to which they're already committed.

The centerpiece of the environmentally superior alternative is for Bay Area water customers to financially support water conservation in the

L_BAWSCA6-03

agricultural areas adjacent to the Tuolumne River equal in amount to any additional diversions to the Bay Area. This could avoid net reductions in the Lower Tuolumne River, a portion of the river most important to the salmon and to the other endangered species in the lower part of the river.

L_BAWSCA6-03 cont.

We believe it's an excellent opportunity, has great promise. And our board of directors recommends that you would explore an even greater possibility, and that is, a larger investment in agricultural water conservation to create a net increase in flow in the Lower Tuolumne River, in other words, conserve more than we intend to divert -- we might need to divert to the Bay Area.

L_BAWSCA6-04

PRESIDENT ALEXANDER: Thank you.

ART JENSEN: Thank you.

PRESIDENT ALEXANDER: John Rizzo.

SI_SierraC7

JOHN RIZZO: Good afternoon. I'm John Rizzo with the Sierra Club.

We fully support the critical earthquake upgrades. Our comments to the PEIR focus on the inadequacy of the environmental review of the proposal to divert an additional 25 million gallons a day from the Tuolumne River, a federally designated wild and scenic river.

SI_SierraC7-01

Our comments include some of these points: Inadequate analysis of the impacts inside Yosemite National Park due to changes of releases; faulty urban growth statements that rely on published studies that don't cover the time period up to 2030 and have not undergone environmental review; inadequate baseline data for river flows and fish populations, inadequate mitigations for impacts to rivers and fish, lack of consideration for the effect of global climate change on future snow packs and river flows; for faulty demand projections -- there are many other inadequacies as well.

SI_SierraC7-02

SI_SierraC7-03

SI_SierraC7-04

SI_SierraC7-05

SI_SierraC7-06

SI_SierraC7-07

But other organizations have also pointed out similar problems with the proposed diversion. The San Luis & Delta Mendota Water Authority, Westlands Water District, and Kern County Water agencies were critical. They opposed the proposed diversions from Tuolumne River, saying that there isn't enough data to show the effect on the San Joaquin River watershed and the Delta ecosystem.

I quote, "The failure of the Draft PEIR to consider impacts with the San Joaquin River and Delta is made more egregious by discussions in the Draft PEIR that suggest proper analysis of the impacts which show potentially significant effects."

SI_SierraC7-08

These water agencies also quote the San Francisco Board of Supervisors' resolution that expresses serious concerns with the proposed diversion.

SI_SierraC7-09

The California Fish & Game Department said, "In this context, we believe that the proposed project has the potential to cause Anadromous fish populations to drop below self-sustaining levels, and restrict the range of federally threatened Central Valley Steelhead. Therefore, we respectfully request the SFPUC use alternative water sources other than the Tuolumne River system to meet the purchase request of 2030."

SI_SierraC7-10

They also have a statement about the -- Yosemite that I referred to before. They recommend that the 1987 Instream Flow Agreement be re-evaluated.

SI_SierraC7-11

The Tuolumne County Board of Supervisors has passed a resolution opposing the proposed diversion and threatening legal action to San Francisco.

SI_SierraC7-12

The increased diversion puts this much-needed project at risk. The best way to correct this inadequate Draft PEIR is to drop the proposed increased diversion from the WSIP project. Thank you.

SI_SierraC7-13

PRESIDENT ALEXANDER: Thank you. Is there anyone else desiring to comment on this item?

(No response)

PRESIDENT ALEXANDER: Seeing none, public comment is closed. Written comments can be submitted up until October -- 5:00 p.m., October 15 at the Planning Commission offices. Thank you.

(Whereupon, the proceedings concluded at 4:42 o'clock p.m.)

Public Comments Needed by October 1st to PROTECT THE TUOLUMNE RIVER!

Take action to stop the San Francisco Public Utilities Commission (SFPUC) from harming the Tuolumne River by signing this comment letter. Please send it to the Tuolumne River Trust in the enclosed envelope so we can deliver it before the October 1st deadline. You can find more information and take action on our website: www.tuolumne.org Thank you for your support!

To: Paul Maltzer, Environmental Review Officer
Water System Improvement Program PEIR
San Francisco Planning Department

Dear Mr. Maltzer:

Your environmental review of the SFPUC's plan to take more water from the Tuolumne River fails to adequately identify and address all of the environmental impacts to the River. I urge you to undertake additional studies of the Tuolumne River before finalizing this document. 01

I support the alternatives identified in your draft document that protect the Tuolumne River from new diversions. Requiring more water conservation, efficiency, and recycling is the best way to lessen impacts to the Tuolumne River while promoting a sustainable water solution for the San Francisco Bay Area. 02

Only by ensuring that healthy amounts of water continue to flow into the Tuolumne River can we protect this irreplaceable natural wonder.

Sincerely,

Name: Mary Louise McDonnell
Address: 7 Aquavista Way
City, State, Zip: San Francisco, CA 94131

C_FORM2

Protect the Tuolumne River!

To: Commissioner Ryan L. Brooks, President
San Francisco Public Utilities Commission

With its headwaters in Yosemite National Park, the Tuolumne River is a national jewel that is home to an outstanding native trout fishery, bald eagles, black bears, and thrilling whitewater.

Unfortunately, instead of increasing water conservation and recycling efforts, the San Francisco PUC plans on meeting future water demand by taking more water out of the Tuolumne, a federally designated Wild and Scenic River. 01

I urge you to meet our water needs and protect the Tuolumne River for future generations through conservation and recycling rather than withdrawing more water and depleting the Tuolumne River.

The fate of the Tuolumne River rests in your hands.

Sincerely,

Name: Elise Vaccarest
Address: 1640 Vallejo St. #6

13. Introduction to Responses and WSIP Revisions

CHAPTER 13
Introduction to Responses and WSIP Revisions

13.1 Overview of Responses to Comments

Organization

This is Volume 7 of the Program Environmental Impact Report (PEIR) on the San Francisco Public Utilities Commission's (SFPUC) Water System Improvement Program (WSIP or proposed program) and presents the responses to comments received on the Draft PEIR. Copies of the comments are contained in Volume 6, and appendices to the Comments and Responses are contained in Volume 8; together, Volumes 6, 7, and 8 make up the Comments and Responses document. The Draft PEIR, published on June 29, 2007, consists of Volumes 1 through 5, and when combined with the Comments and Responses document (Volumes 6, 7, and 8), constitutes the Final PEIR on the WSIP.

The Comments and Responses document is separated into three volumes. Volume 6, Comments, consists of two chapters. Chapter 11 in Volume 6 is an introductory chapter that describes the purpose of the Final PEIR as well as the organization and coding of the comments; it includes a list of all agencies, organizations, and individuals that submitted comments on the Draft PEIR and describes the coding system used to identify individual comments. Chapter 12 contains copies of all comments received on the Draft PEIR and identifies each comment by alphanumeric code.

Volume 7, Responses, consists of Chapters 13 through 16. This chapter, Chapter 13, describes the organization of the responses to the comments received on the Draft PEIR and also describes changes in the WSIP that have been proposed by the SFPUC since publication of the Draft PEIR. The SFPUC has proposed revisions to the WSIP in three areas, either in response to comments received on the Draft PEIR or as part of its ongoing system operations and planning. These revisions include: (1) changes in the project descriptions of two WSIP facility improvement projects (both of which help reduce impacts associated with the projects as originally proposed) which affect overall system operations; (2) updated water system assumptions and corresponding updates in the system modeling and results; and (3) development of the Phased WSIP Variant, a "hybrid" program that is a combination of the proposed program and one of the alternatives analyzed in the Draft PEIR. As described below, none of these changes to the WSIP affect the impact conclusions presented in the Draft PEIR; they do not result in new or more severe environmental impacts than those previously disclosed in the Draft PEIR.

Chapter 14 contains master responses, which provide comprehensive discussions to respond to select sets of issues that received multiple comments, and it includes cross-references to the individual comments being addressed using the alphanumeric codes shown in Volume 6, Chapter 12. Chapter 15 presents the individual responses directed specifically to each comment; in some cases, the reader is referred to a master response in Chapter 14 or to another individual response that addresses the same issue. Chapter 16 contains text changes to the Draft PEIR that resulted from: (1) changes made in response to comments received on the Draft PEIR; (2) changes that reflect the WSIP revisions; or (3) changes to correct errors or to clarify information presented in the Draft PEIR. Volume 8, Appendices, provides supporting documentation for information presented in the Comments and Responses document.

Responses

As required by Section 15132 of the Guidelines for the California Environmental Quality Act (CEQA Guidelines), the responses in this volume address significant environmental issues raised by commenters during the review period. They are intended to provide clarification and refinement of information presented in the Draft PEIR and, in some cases, to correct or update information in the Draft PEIR. In some instances, the text of the Draft PEIR has been revised in response to a comment, and the revised text is included as part of the response. The reader is referred to Volume 6, Chapter 11, Tables 11.2 through 11.7, for a complete list of commenters and the alphanumeric comment identification codes.

Due to the repetitiveness of many issues raised by commenters, Chapter 14 includes master responses that provide a more comprehensive discussion of related issues. Chapter 15 includes responses to every individual comment, although sometimes a response refers the reader to either a master response or another response. The responses to the individual comment letters in Chapter 15 are organized by commenter type (federal, state, or local/regional agency; special interest group; or citizen) and referenced by the alphanumeric code corresponding to the comment. Responses to oral comments received during public hearings (see Section 12.6, Public Hearing Transcripts, in Vol. 6, Chapter 12) are integrated with the responses to written comments and are included in Chapter 15 by commenter type.

Many comments received on the Draft PEIR did not address the adequacy or accuracy of the environmental analysis or did not identify any other significant environmental issue requiring a response; rather, these comments were directed toward the perceived merits or demerits of the proposed WSIP, provided information, or expressed an opinion without specifying why the Draft PEIR analysis was inadequate. The San Francisco Planning Department, as the CEQA lead agency, acknowledges the receipt of these types of comments; however, limited responses are provided to these comments as they do not relate to the adequacy or accuracy of the Draft PEIR or otherwise raise significant environmental issues.

Where a response to a comment includes a change to the text of the Draft PEIR, the text changes are shown in <u>underline</u> for additions and ~~strikethrough~~ for deletions.

Some issues received a substantial number of comments from numerous commenters, demonstrating common concerns among agencies, special interest groups, and members of the public. For these issues, a comprehensive discussion of the issue and related topics is presented as a master response in Chapter 14 of this document. Each master response provides an integrated and comprehensive response to a particular issue and related concerns. The master responses are listed below:

- 14.1 Master Response on WSIP Purpose and Need
- 14.2 Master Response on Demand Projections, Conservation, and Recycling
- 14.3 Master Response on Proposed Dry-Year Water Transfer
- 14.4 Master Response on PEIR Appropriate Level of Analysis
- 14.5 Master Response on Water Resources Modeling
- 14.6 Master Response on Upper Tuolumne River Issues
- 14.7 Master Response on Lower Tuolumne River Issues
- 14.8 Master Response on Delta and San Joaquin River Issues
- 14.9 Master Response on Alameda Creek Fishery Issues
- 14.10 Master Response on Modified WSIP Alternative
- 14.11 Master Response on Climate Change

13.2 Program Description Changes Affecting System Operations

Since publication of the Draft PEIR in June 2007, the SFPUC has modified the project descriptions of two of the facility improvement projects—the Alameda Creek Fishery Enhancement (SV-1) and Calaveras Dam Replacement (SV-2) projects—and these proposed changes would affect overall system operations (SFPUC, 2008a). These modifications were made due to the numerous comments received on the potential impacts on future steelhead fishery resources in the Alameda Creek watershed as well as to actions taken in July 2007 by other agencies in the watershed. The SFPUC has incorporated project revisions and protective measures into these two projects to reduce the WSIP's potential to affect habitat conditions for potential future-occurring steelhead in the upper watershed. The project revisions would occur regardless of steelhead presence or absence in the upper watershed, while the protective measures were designed to reduce the WSIP's potential to affect habitat conditions for potential, future-occurring steelhead in the Alameda Creek watershed in the event that man-made barriers in Alameda Creek are removed and steelhead gain access to the upper watershed.

The proposed project revisions and protective measures would provide both a long-term strategy to ensure habitat protection as well as interim measures in the event that regulatory agencies have determined steelhead to be present above the BART weir, construction of the Calaveras Dam Replacement project is complete, and the Alameda Watershed Habitat Conservation Plan is yet to be finalized. Please refer to **Section 14.9, Master Response on Alameda Creek Fishery Issues** (Vol. 7, Chapter 14) for further description of the project revisions and protective measures.

In summary, the following project revisions have been incorporated into the Alameda Creek Fishery Enhancement (SV-1) and Calaveras Dam Replacement (SV-2) projects:

- The Calaveras Dam Replacement project would include facility modifications at the Alameda Creek Diversion Dam (ACDD) to construct a new bypass structure needed to implement bypass stream flows.

- If a structural alternative involving construction of a recapture facility is selected under the Alameda Creek Fishery Enhancement project, the recapture facility would be located at the downstream end of the reach of Alameda Creek between the lower Sunol Valley and the confluence with Arroyo de la Laguna. As an alternative to the recapture facility, the SFPUC may coordinate with other water agencies to develop and implement other means of recapturing fishery enhancement flows consistent with the 1997 California Department of Fish and Game Memorandum of Understanding (CDFG MOU).[1]

The project components designed to provide protective measures for future-occurring steelhead in the upper Alameda Creek watershed would include the following:

- An operational plan to provide minimum stream flows to support steelhead spawning below the ACDD to the confluence with Calaveras Creek when precipitation naturally generates runoff and flow in the creek, including the site-specific studies needed to determine the specific minimum stream flow requirements to support steelhead spawning in this reach of the creek.

- A detailed monitoring plan to survey and document steelhead spawning, subject to review and comment by the appropriate resource agencies.

- Interim minimum flows would be implemented consistent with the 1997 CDFG MOU, with the additional requirement that these flows would be achieved through bypass flows at the ACDD at all times when flows are available in upper Alameda Creek, rather than through releases at Calaveras Dam, and with the following conditions:

  – The SFPUC would provide seasonal flow bypasses at the ACDD and/or flow releases from Calaveras Dam, either (1) without recapture or (2) with recapture at a point approximately at the downstream end of the reach of Alameda Creek between the lower Sunol Valley and the confluence with Arroyo de la Laguna, below critical riffle locations or lower in the creek, between December 1 and June 30 (combined adult and juvenile migration period) in an amount equivalent to the flow release schedule provided in the 1997 CDFG MOU.

  – As an alternative to the recapture facility, the SFPUC would coordinate with other water agencies to develop and implement other means of recapturing enhancement flows consistent with the 1997 CDFG MOU at a location downstream of the reach of Alameda Creek between the lower Sunol Valley and the confluence with Arroyo de la Laguna.

---

1 Under the 1997 CDFG MOU, the SFPUC and CDFG reached agreement on the magnitude and timing of flows to be released from Calaveras Reservoir for the purposes of improving fishery habitat conditions. The MOU includes provisions for the SFPUC to divert flows from Alameda Creek to the SFPUC regional system at a suitable downstream location equivalent to the magnitude and timing of these releases; the MOU refers to this as "recapture."

In Draft PEIR Tables S.2 and 3.10 (Vol. 1, Summary, p. S-12, and Chapter 3, p. 3-50), the following text related to the location and description of these two facility improvement projects is revised to incorporate information about these recently initiated planning efforts:

No.	Project Title	Location of Preferred Project	Project Description
SV-1	Alameda Creek Fishery Enhancement	Structural Alternatives: Alameda Creek in Sunol Valley, downstream of Calaveras Dam	This project would recapture the water released as part of the Calaveras Dam project (SV-2) and return it back to the regional system for use. A number of structural and non-structural recovery alternatives are under consideration for this project, including: a water recapture facility downstream of the Sunol Valley WTP, conjunctive groundwater use, horizontal collector wells, or other groundwater recovery systems yet to be defined. Other alternative designs for this project could be developed. If a structural alternative involving construction of a recapture facility is selected, the recapture facility would be located at the downstream end of the reach of Alameda Creek between the lower Sunol Valley and the confluence with Arroyo de la Laguna. As an alternative to the recapture facility, the SFPUC may coordinate with other water agencies to develop and implement other means of recapturing fishery enhancement flows consistent with the 1997 CDFG MOU.
SV-2	Calaveras Dam Replacement	Sunol Valley, immediately downstream of existing dam and at the Alameda Creek Diversion Dam	This project would provide for the planning, design, and construction of a replacement dam at Calaveras Reservoir to meet seismic safety requirements. The new dam would provide for a reservoir with the same storage capacity as the original reservoir (96,800 acre-feet), but the replacement dam would be designed to accommodate enlargement of the dam in the future. The preferred project would include construction of: • New earthfill dam • New intake tower and new outlet valve for water releases for instream flow requirements • New or rehabilitated outlet works for seismic safety and improved operations and maintenance • New bypass structure at the Alameda Creek Diversion Dam As part of this project, Calaveras Reservoir and the proposed bypass structure at the diversion dam would be operated to release up to 6,300 acre-feet per year (5.5 mgd) of water to Alameda Creek in support of fisheries in compliance with the 1997 CDFG MOU. When flow is available in Alameda Creek, releases would be made through the proposed bypass structure at the Alameda Creek Diversion Dam and would be supplemented as necessary with releases from Calaveras Dam.

These project description modifications would generally reduce the impacts identified in the Draft PEIR, and, in some cases, would reduce impacts from potentially significant to less than significant (i.e., Impacts 5.4.7-1 and 5.4.7-2). The refined impact analyses associated with these project description modifications, including the discussions on Impacts 5.4.7-1 and 5.4.7-2, are presented in Chapter 16, Staff-Initiated Text Changes (Vol. 7).

13.3 Updated Water System Assumptions and Modeling

As described in the Draft PEIR (Vol. 3, Chapter 5, p. 5.1-9), the SFPUC utilizes a computerized water supply planning model to assist in the evaluation of its water systems operations—the Hetch Hetchy/Local Simulation Model (HH/LSM). Data from the HH/LSM were used in the Draft PEIR to evaluate the impacts of WSIP water supply and system operations on resources in the Tuolumne River, Alameda Creek, and Peninsula watersheds (Vol. 3, Chapter 5). In 2008, subsequent to publication of the Draft PEIR, the SFPUC conducted updated model runs using more recent input assumptions for several model parameters as part of its ongoing system planning and management. The revised input assumptions included the following:

- Adjusted capacity for Crystal Springs Reservoir based on recent survey data
- More accurate assumptions for Pilarcitos facilities operations
- Improved data regarding the historical hydrology in the Alameda Creek watershed
- Updated agricultural demands in the service areas of the Modesto Irrigation District (MID) and Turlock Irrigation District (TID) to be consistent with data used in recent statewide planning documents
- Refinement in the water release protocols at Don Pedro Reservoir

Review of the 2008 model output indicated that the results are generally consistent with the 2007 results used in the Draft PEIR impact analyses of water supply and system operations, and that the analyses and impact determinations presented in the Draft PEIR remain valid. With one exception, no changes in the Draft PEIR impact approach, analysis, or conclusions are necessary for the water supply and system operations impact assessments. The sole exception is the approach to the analysis of impacts on Pilarcitos watershed resources, for which only semi-quantitative data were previously available. Therefore, the 2008 data were used to conduct a refined impact analysis of the Pilarcitos watershed resources; no new impacts were identified in the refined analysis. The results of the refined impact analysis for the Pilarcitos watershed are summarized below, and the complete refined impact analysis is presented in Chapter 16, Staff-Initiated Text Changes.

In select instances, the Draft PEIR text and tables presenting the 2007 results have been updated with the 2008 results where useful to reflect this more current information; it should be noted that there are no changes in any of the impact analyses or conclusions as a result of the revised model data. In addition, review of the 2008 HH/LSM data provided additional insight in understanding the potential range and magnitude of impacts, and some revisions to the Draft PEIR text based on the updated HH/LSM modeling are included in Chapter 16, Staff-Initiated Text Changes, to provide refinement and clarification of the impact discussions. However, no staff-initiated text changes are provided in Chapter 16 to replace 2007 results with the updated 2008 results if the impact approach, analysis or conclusions are unaffected by the updated modeling.

One of the notable outcomes of the updated HH/LSM output is a refinement in the estimated magnitude of dry-year water transfers that would be required under the WSIP. The 2007 model results used in the Draft PEIR indicated that an equivalent of 23 million gallons per day (mgd) (annual average over the 8.5-year design drought) of supplemental Tuolumne River water obtained through water transfer agreements with TID and MID would be required to meet the WSIP level of service objectives (see Vol. 1, Chapter 3, p. 3-36). The updated 2008 analysis indicates that this number would be 26 mgd. Please refer to **Section 14.3, Master Response on Proposed Dry-Year Water Transfer** (Vol. 7, Chapter 14) for further explanation of this updated information.

Refined Pilarcitos Watershed Impact Analysis

The refined impact analysis for the Pilarcitos Creek watershed involved updated modeling using the HH/LSM as well as biological field reconnaissance. The refined analysis enabled a more precise identification of the potential impacts of the WSIP in that watershed. No new impacts were identified that were not documented in the Draft PEIR, but several impacts identified as potentially significant in the Draft PEIR were reevaluated and determined to be less than significant. Analysts were able to reclassify terrestrial biological and fishery impacts at Pilarcitos Reservoir and terrestrial biological impacts at Pilarcitos Creek between the reservoir and Stone Dam as less than significant. The revised impacts are reflected in Chapter 16, Staff-Initiated Text Changes.

In the Draft PEIR, a mitigation measure was proposed that would lessen or eliminate all potentially significant adverse impacts of the WSIP in the Pilarcitos Creek watershed (Measure 5.5.3-2, Revised Operations Plan for Pilarcitos Watershed Facilities). Under the revised operations plan identified in this measure and with the WSIP in place, the SFPUC would develop protocols that would enable it to operate its Pilarcitos Creek watershed facilities just as it does under the existing conditions. Future operations would mimic existing operations as closely as possible and, consequently, there would be little or no change in environment impacts. However, an attempt to develop the protocols led to the conclusion that the revised operations plan envisaged under Measure 5.5.3-2 would be technically challenging and that other more practical solutions are available.

More practical mitigation measures to replace Measure 5.5.3-2 were developed subsequent to publication of the Draft PEIR and are included in Volume 7, Chapter 16. The replacement mitigation measures would reduce the potential impacts of the WSIP in the Pilarcitos Creek watershed to a less-than-significant level. They include:

- Measure 5.5.3-2a, Low-Head Pumping Station at Pilarcitos Reservoir, which would lessen fishery and water quality impacts in Pilarcitos Creek between Pilarcitos Reservoir and Stone Dam
- Measure 5.5.5-5, Establish Flow Criteria, Monitor and Augment Flow, which would lessen fishery impacts in Pilarcitos Creek below Stone Dam

Because Measure 5.5.3-2a could itself result in potentially significant water quality, fisheries, and terrestrial biological impacts at Pilarcitos Reservoir, two additional measures were developed to mitigate these impacts. The potential water quality and fisheries impacts in Pilarcitos Reservoir would be reduced to a less-than-significant level through implementation of Measure 5.5.3-2b, Aeration System at Pilarcitos Reservoir; this measure also addresses potentially significant impacts on fisheries in Pilarcitos Creek below the reservoir. The potential terrestrial biological impacts at Pilarcitos Reservoir due to Measure 5.5.3-2a would be reduced to a less-than-significant level through implementation of Measure 5.5.3-2c, Habitat Monitoring and Compensation.

13.4 Phased WSIP Variant

Introduction

In March 2008, the SFPUC determined that it would like the option to consider approval and implementation of a variation of the WSIP called the Phased WSIP Variant (SFPUC, 2008b; SFPUC, 2008c). The SFPUC identified this variation in order to consider a program scenario that would involve *full implementation of the proposed WSIP facility improvement projects* to ensure that the public health, water quality, seismic safety, and delivery reliability goals are achieved as soon as possible, but a *phased implementation of water supply delivery through 2030*. Phasing the water supply element of the WSIP would allow the SFPUC and its wholesale customers to focus first on implementing additional local recycled water, groundwater, and demand management actions while minimizing additional diversions from the Tuolumne River. Under this variant, the SFPUC would establish an interim, mid-term planning horizon—the year 2018. If the SFPUC adopts this variant, it would make a decision about future water supply to its customers through 2018 *only* and defer a decision regarding long-term water supply until after 2018. All WSIP goals and level of service objectives that are not related to 2030 water supply levels would be achieved under this variant, and all individual WSIP facility improvement projects proposed by the SFPUC would be constructed.

Under this variant, the SFPUC would limit average annual water deliveries supplied from its watersheds to 265 mgd. This generally represents the base-year level of supply delivered from the SFPUC watersheds through the regional water system to both the retail and wholesale customers analyzed in the Draft PEIR.[2] The SFPUC would maintain the 265 mgd average annual delivery of surface water from the SFPUC watersheds to existing levels through 2018. At the same, through 2018, the SFPUC would implement the delivery and drought reliability element of the WSIP, including proposed dry-year transfers from MID/TID coupled with the Westside Basin conjunctive use program, which would increase average annual diversions from the Tuolumne River by about 2 mgd over the existing conditions.

[2] The SFPUC watersheds that supply surface water to the regional system include the local watersheds—the Alameda Creek and Peninsula watersheds—and the Tuolumne River watershed. Under this variant, similar to existing conditions, the Tuolumne River watershed would provide approximately 85 percent and the local watersheds would provide approximately 15 percent of the water supply delivered to customers.

By 2018, the demand on the SFPUC regional water system is projected to be 285 mgd, consisting of 91 mgd for the retail customers and 194 mgd for the wholesale customers, based on the purchase requests developed by the wholesale customers as part of the WSIP planning process. To satisfy the remaining 20 mgd of demand on the regional system through 2018 while holding deliveries from the SFPUC watersheds to 265 mgd, the SFPUC proposes development of local conservation, recycled water, and groundwater projects within its service area. As proposed under the WSIP, the Phased WSIP Variant would develop 10 mgd of local supply and supply offsets through conservation, recycled water and groundwater projects in San Francisco. The SFPUC also proposes to develop an additional 10 mgd of local conservation, recycled water, and groundwater within the service area under this variant through one of the following three approaches:

- The SFPUC, wholesale customers, and Bay Area Water Supply and Conservation Agency (BAWSCA) partner to develop an additional 10 mgd in local conservation, recycled water, and groundwater within the service area; or
- BAWSCA and the wholesale customers develop an additional 10 mgd in local conservation, recycled water, and groundwater within the wholesale customer service area, independent of the SFPUC; or
- Individual wholesale customers develop 10 mgd of additional conservation, recycled water, and groundwater on their own within their individual services areas.

The SFPUC has initiated discussions with BAWSCA and the wholesale customers to determine the best approach to develop the additional 10 mgd of local supply/conservation needed under this WSIP variant to fully meet the wholesale customer needs through 2018.

By 2018, the SFPUC would reevaluate the wholesale customer delivery amount and consider whether to maintain these delivery limitations from the SFPUC watersheds through 2030 or increase them, and whether and how to provide additional supply to the wholesale customers. In the years approaching 2018, the SFPUC would update demand projections for its wholesale and retail customers and reevaluate customer water delivery needs and water supply options. As part of the process, the City and County of San Francisco (CCSF) would conduct additional environmental studies and CEQA review as appropriate to address the SFPUC's recommendation regarding water supply and proposed water system deliveries after 2018.

The following subsections describe the Phased WSIP Variant in more detail and summarize the environmental impacts associated with this variant based on the analysis in the PEIR. In summary, this variant includes the following key program elements:

- Full implementation of WSIP facility improvement projects.
- Water supply delivery to wholesale and retail regional system customers through 2018 of at least 275 mgd average annual target delivery, and up to an additional 10 mgd of conservation, recycled water, and groundwater developed in one of the three approaches described above. This includes 91 mgd for the retail customers and 184–194 mgd for the wholesale customers.

- Water supply sources include: 265 mgd average annual delivery from the SFPUC watersheds (i.e., the Tuolumne River watershed and the local watersheds), 10 mgd of conservation, water reuse, and groundwater developed by the SFPUC within San Francisco but used to meet regional system delivery needs, and up to an additional 10 mgd of conservation, water reuse, and groundwater developed in one of the three approaches described above.

- Dry-year water transfer from MID/TID of about 2 mgd coupled with the Westside Groundwater Basin conjunctive-use project to meet the drought-year goal of limiting rationing to no more than 20 percent on a systemwide basis.

- Reevaluation of 2030 demand projections, potential regional system demand (purchase requests), and water supply options by 2018, and SFPUC decision in 2018 regarding regional water system deliveries after 2018.

As further described below, the potential environmental effects of the Phased WSIP Variant fall within the range of impacts already evaluated in the Draft PEIR for the WSIP and the alternatives. This program variation is similar to the No Purchase Request Increase Alternative analyzed in the Draft PEIR. That alternative also limits average annual regional water system deliveries from the SFPUC watersheds to approximately 265 mgd, but it does so through 2030, while the Phased WSIP Variant only establishes this limit through 2018. Although the Phased WSIP Variant does not include a specific water supply proposal beyond 2018, for purposes of environmental impact analysis and comparison to the proposed WSIP and other alternatives evaluated in the PEIR, the following discussion assesses the range of water supply that could be provided under this variant through 2030. On the low end of the range, after 2018 and through 2030 under the Phased WSIP Variant, deliveries from the SFPUC watersheds could continue to be limited to 265 mgd, similar to the No Purchase Request Increase Alternative. On the high end of the range, after 2018 and through 2030, the SFPUC could propose to increase surface water deliveries from the watersheds and meet the additional projected 2030 demands of up to 15 mgd on the regional water system for a total demand of 300 mgd, which could include average annual deliveries from the SPFUC watersheds of up to 280 mgd coupled with up to 20 mgd of local conservation, recycled water, and groundwater previously implemented in the first phase by 2018. This would provide the retail customers with 91 mgd and the wholesale customers with 209 mgd in average annual deliveries. This high-end scenario would be similar to the Modified WSIP Alternative, which assumes 10 mgd of conservation, recycled water, and groundwater in San Francisco and 10 mgd of conservation, recycled water, and groundwater in the wholesale service area.

The No Purchase Request Increase Alternative is discussed in Draft PEIR Section 9.2.3 (Vol. 4, Chapter 9, pp. 9-40 to 9-47) and Section 9.3 (pp. 9-84 to 9-96). Also relevant are the analyses of the No Program Alternative (Section 9.2.2, pp. 9-23 to 9-40), the Aggressive Conservation/Water Recycling and Local Groundwater Alternative (Section 9.2.4, pp. 9-47 to 9-59), and the Modified WSIP Alternative (Vol. 4, Chapter 9, Section 9.2.8, pp. 9-78 to 9-84; and Vol. 7, Chapter 14, Section 14.10, Master Response on Modified WSIP Alternative).

Description of SFPUC and Wholesale Customer Actions

SFPUC Actions

Water Delivery

Table 13.1 summarizes the SFPUC average annual water deliveries to its retail and wholesale customers under the WSIP, the No Purchase Request Increase Alternative, and the Phased WSIP Variant. Under the Phased WSIP Variant, the SFPUC proposes to establish an interim delivery amount through the year 2018, and then to either maintain this same delivery amount through 2030 or increase it, possibly up to the level proposed under the WSIP.

TABLE 13.1
SFPUC AVERAGE ANNUAL WATER DELIVERIES UNDER THE PHASED WSIP VARIANT

Supply Source	SFPUC Regional System Average Annual Water Deliveries (mgd)		
	Existing Condition 2005	WSIP (Proposed Program) 2030	Phased WSIP Variant 2018
SFPUC Watersheds			
Retail customers[a]	91	81	81
Wholesale customers	174	209	184
Total	**265**	**290**	**265**
Local Conservation, Recycled Water, and Groundwater (not included in purchase requests)			
Retail customers	0	10	10
Wholesale customers	0	0	0 – 10 [b]
Total	**0**	**10**	**10 – 20**
Total from all sources	**265**	**300**	**275 – 285**

a The SFPUC retail customer deliveries include 1 mgd delivered to Castlewood in the Pleasanton area that is supplied by local groundwater rather than from the regional system. Thus, although this delivery amount is included in the SFPUC retail customer delivery total, 90 mgd represents the current and future deliveries to retail customers that are and will continue to be made from the regional system.
b A range is provided because 10 mgd may be provided by SFPUC in partnership with BAWSCA and wholesale customers or BAWSCA and wholesale customers may choose to separately develop this 10 mgd.

The 2030 regional system water deliveries shown in Table 13.1 for the WSIP reflect wholesale customer purchase requests of 209 mgd (see the Draft PEIR, Vol. 1, Chapter 3, pp. 3-16 to 3-22 for a discussion of the wholesale customer purchase requests developed for the WSIP). Under the WSIP, the 2030 combined retail and wholesale customer purchase requests of 300 mgd would be met with up to 290 mgd of supply from the SFPUC watersheds and 10 mgd from local conservation, recycled water, and groundwater projects developed in San Francisco and used to meet the overall regional system needs. Under the Phased WSIP Variant, the regional system target delivery for the wholesale customers in 2018 would range from 184 mgd to 194 mgd, depending on how BAWSCA and wholesale customers elected to develop the required additional

10 mgd of local conservation, recycled water, and groundwater needed. If the SFPUC and BAWSCA partnered to jointly develop the additional 10 mgd of local supply and conservation and made it part of the regional system supply portfolio, then the wholesale customer delivery target for the regional water system would be 194 mgd to match their purchase requests. If BAWSCA and/or the wholesale customers decided to develop the additional 10 mgd of conservation, recycled water, and groundwater independent of the SFPUC and not make it part of the regional system supply portfolio, then the wholesale customer delivery target from the regional system would be 184 mgd.

Although the SFPUC would only make a decision regarding water supply through 2018 under the Phased WSIP Variant, after 2018 and through 2030 it is possible that average annual deliveries to the wholesale customers could range from 184 mgd to 209 mgd, as shown in Table 13.1 (or 199 mgd, on the high end if it is an assumed additional 10 mgd of local conservation, recycled water and groundwater programs is implemented by 2018). If after 2018 the SFPUC decides to maintain the 184 mgd average annual limit on SFPUC watershed deliveries to the wholesale customers, then by 2030 the SFPUC regional water system deliveries to the wholesale customers could be up to 25 mgd less than their 209 mgd purchase request amount, although it is possible that, in combination with the additional local conservation, recycled water, and groundwater already developed during the first phase of this variant, the wholesale customers could receive up to their full 2030 purchase request amount of 209 mgd with no shortfall.

Table 13.2 (which is similar to Draft PEIR Table 9.4) summarizes the key characteristics of the Phased WSIP Variant in comparison to the WSIP and other select alternatives considered in the Draft PEIR. Under the Phased WSIP Variant, the SFPUC would continue to rely on water supply sources from local watersheds and the Tuolumne River for up to 265 mgd average annual deliveries and would continue to implement the proposed 10 mgd of conservation, water recycling, and groundwater projects in San Francisco that is included in the WSIP through 2018. An additional 10 mgd of local conservation, water recycling, and groundwater projects could be developed by the SFPUC and/or BAWSCA/wholesale customers. Information on retail and customer purchase requests after 2018 would be confirmed, and target deliveries and water supply sources would be determined.

Table 13.3 (which is similar to Draft PEIR Table 9.5) compares average annual Tuolumne River diversions and drought-year shortages for the Phased WSIP Variant and the proposed program. Under the Phased WSIP Variant, by 2018 only 2 mgd of additional water diversion from the Tuolumne River over existing levels would be needed (on an average annual basis). This limited additional diversion over existing levels would occur in order to meet the WSIP delivery and drought reliability objectives, but no additional Tuolumne River diversions would be made through 2018 for the purpose of serving demand increases.

One objective of this program variant is to minimize increased diversions from the Tuolumne River and to maintain SFPUC deliveries from its watersheds as close to current levels as possible for the near term through 2018, at which time supply delivery needs and the need for additional Tuolumne River deliveries would be reevaluated. To meet the total projected customer water

TABLE 13.2
DESCRIPTION OF PHASED WSIP VARIANT IN COMPARISON TO WSIP AND NO PURCHASE REQUEST INCREASE ALTERNATIVE
(SIMILAR TO DRAFT PEIR TABLE 9.4)

Program Element	Existing Condition	Proposed Program	No Purchase Request Increase Alternative	Phased WSIP Variant	
Planning Year	2005	2030	2030	2018	2030
Retail Customer Purchase Request (2018 / 2030)	91 mgd / NA	91 mgd / 91 mgd	91 mgd / 91 mgd	91 mgd	91 mgd (to be reevaluated by 2018)
Wholesale Customer Purchase Request (2018 / 2030)	174 mgd / NA	194 mgd / 209 mgd	194 mgd / 209 mgd	194 mgd	209 mgd (to be reevaluated by 2018)
SFPUC Regional System Target Delivery Level (annual average)	265 mgd	300 mgd	275 mgd	275 to 285 mgd	To be determined
Target Delivery from SFPUC Watersheds	265 mgd	290 mgd	265 mgd	265 mgd	To be determined

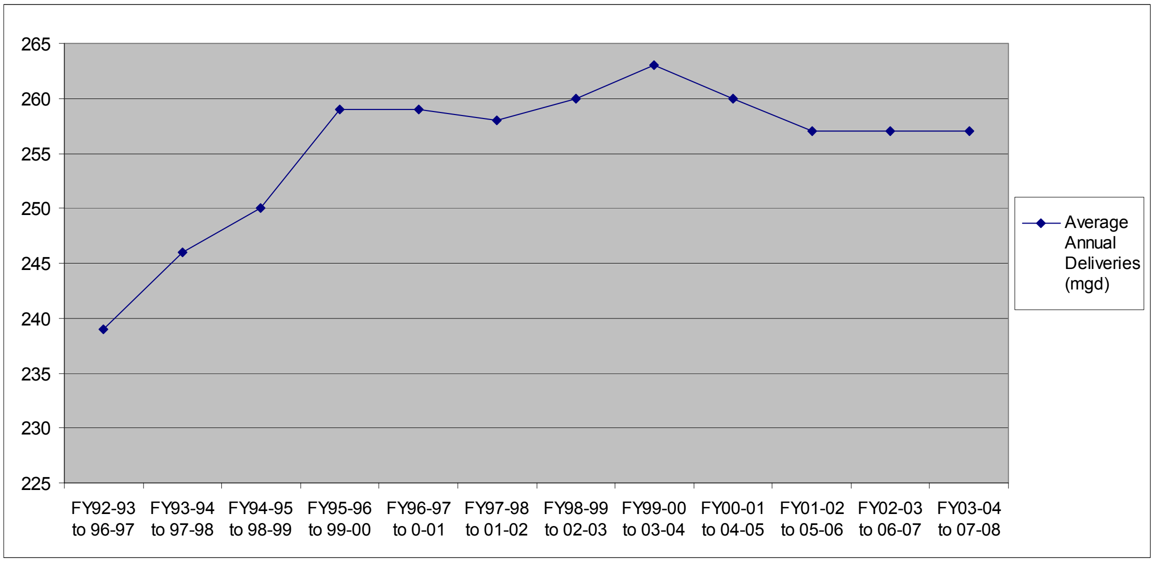
[a] Results from 2008 HH/LSM analyses using updated and refined modeling assumptions. The numbers are not directly comparable to those in Draft PEIR Table 9.5, which are based on 2007 HH/LSM analyses.
[b] Diversion levels represent the average annual amount modeled over the 82-year historical hydrology. Even with a zero average annual increase in diversions, there would still be year-to-year variations in diversions compared to the existing condition due primarily to modified system operations for maintenance and implementation of the conjunctive-use program.
[c] Represents the difference in average annual diversions modeled over 82-year historical hydrology, but does not represent year-to-year variation. Thus, even with zero average annual increase in diversions, there would still be year-to-year variations in diversions compared to the existing condition due primarily to modified system operations for maintenance and implementation of the conjunctive-use program.

delivery needs through 2018 and maintain Tuolumne River diversions at or close to current levels, the SFPUC would implement its proposed 10 mgd of in-city recycled water and groundwater projects and conservation actions plus work with BAWSCA and the wholesale customers to implement another 10 mgd of local recycled water, groundwater, and conservation actions (or BAWSCA and wholesale customers might elect to implement this additional local conservation and supply development themselves without the SFPUC). The SFPUC plans to implement projects to achieve its in-city 10 mgd by 2014 (see Draft PEIR Vol. 1, Chapter 3, p. 3-55 for a description of the proposed Groundwater Projects [WSIP project SF-2]; p. 3-56 for a description of the proposed Recycled Water Projects [WSIP project SF-3]; and Figure 3.6, p. 3-62 for the proposed implementation schedule). Since publication of the Draft PEIR, the wholesale customers have also taken steps to develop the necessary local projects (see the discussion below under the heading Wholesale Customer Actions for further information). The SFPUC will determine with BAWSCA the best way to develop the additional 10 mgd of supply (supply offsets) needed to meet the full wholesale customer needs by 2018.

In implementing the Phased WSIP Variant, the need could arise to temporarily increase deliveries from the Tuolumne River and local watersheds over the 265 mgd average annual target levels to meet customer water delivery needs in the near term, because it might not be possible to implement all of the local projects and actions in time to meet increasing customer demands. The impact analysis for the Phased WSIP Variant recognizes that, between now and 2018, deliveries from the Tuolumne River and local watersheds might increase above the 265 mgd average annual level (to a possible 275 to 285 mgd average annual) for up to a few years. By 2018, and perhaps well before, it is expected that local projects would provide sufficient local supply and conservation to bring SFPUC watershed deliveries back down to current levels, close to 265 mgd.

Under the Phased WSIP Variant, the SFPUC would monitor sales to ensure that annual average sales delivered from the SFPUC watersheds are limited to an average annual of 265 mgd through 2018. The SFPUC would measure and review annual average sales at the close of each fiscal year. **Figure 13.1** presents the five-year rolling average for the past 15 years of actual deliveries from the SFPUC watersheds (from fiscal year 1992/1993 through fiscal year 2007/2008) for the combined retail and wholesale customers. As shown on the graph, the highest five-year rolling average water delivery from the SFPUC watersheds via the regional water system to date was 263 mgd between fiscal year 1999/2000 and fiscal year 2003/2004. Since that time, this average has declined and leveled at 257 mgd for each of the past three years.

In consideration of public health and safety, the SFPUC would not cease water deliveries to customers in the event that total sales in water deliveries from the SFPUC watersheds exceed 265 mgd. However, in the event that sales from the SFPUC watersheds go above the 265 mgd average annual restriction, the SFPUC would provide financial incentives as a mechanism to encourage customers to develop the necessary local supply and conservation programs and discourage additional use of supply from the SFPUC watersheds.



SFPUC Water System Improvement Program . 203287

Figure 13.1
SFPUC Regional Water System Deliveries – Five-Year Rolling Average

Facility Improvement Projects

Under this variant, the SFPUC would implement the same 22 facility improvement projects as proposed under the WSIP. There would be no difference in the proposed facility sizing, design, siting, or operation between this variant and the WSIP. Although the total average water deliveries from the regional water system would be less under this variant (275 to 285 mgd) than those under the WSIP (300 mgd), the facilities design and sizes would remain the same. Facility design and size are determined by several factors, and reducing the water supply delivery target alone would not reduce the required size of the proposed facilities. The SFPUC determined that individual facilities throughout the regional water system must be designed and sized to meet overall system performance objectives for seismic reliability, water delivery reliability, maintaining high water quality, and meeting water supply goals (SFPUC, 2008d). Sizing for many system components is primarily driven by the need to replenish local storage following a drought, seismic event, unplanned outage, or maintenance shutdown period such that the local system has enough stored water to meet 90 days of demand strictly from the local system; facility sizing is also determined by the need to meet water delivery demand while performing maintenance or in the event of an emergency outage.

Wholesale Customer Actions

The wholesale customers have obligations, through laws, contracts, and other legal instruments, to provide water service to their customers. As described in the Draft PEIR (Vol. 1, Chapter 3, pp. 3-16 to 3-22), the wholesale customers, in conjunction with the SFPUC, conducted a comprehensive assessment of future water use within their service areas and identified the amount of water needed from the SFPUC, in addition to increased water conservation, to meet customer needs through 2030. The SFPUC wholesale customer purchase requests for 2030, developed as part of the WSIP, total 209 mgd. By approximately 2018, wholesale customer demand on the SFPUC regional system is projected to increase to 194 mgd.

Under the Phased WSIP Variant, the wholesale customers would receive 184 mgd on an average annual basis from the SFPUC watersheds until 2018. The SFPUC is proposing to obtain the remaining 10 mgd needed to meet the projected 194 mgd wholesale customer demand through the development of additional local conservation, recycled water, and groundwater projects. As described above, this additional 10 mgd increment of supply/conservation could either be developed jointly by the SFPUC and BAWSCA and become part of the regional system supply portfolio or it could be developed independently by BAWSCA and/or the wholesale customers and remain separate from the regional system supply portfolio. The SFPUC is meeting with BAWSCA to discuss the best way to develop this additional increment of supply.

How the 265 mgd Limit on Deliveries from the SFPUC Watersheds Could Affect the Wholesale Customers

The ability of each individual wholesale customer to implement additional demand management and/or secure additional water supplies varies. Sixteen of the 27 wholesale customers rely on the SFPUC for 100 percent of their supply (see **Table 13.4**). Only eleven of the 27 wholesale customers have other sources of supply in addition to the SFPUC deliveries: nine have other sources of surface water, groundwater, and/or local recycled water supply and two others have only local recycled water supply. **Table 13.5** (which is the same as Draft PEIR Table 7.2) indicates which agencies have sources of supply other than the SFPUC. The Alameda County Water District (serving Fremont, Newark, and Union City) has a combination of local groundwater (including direct pumping and use of groundwater resources as well as desalination of brackish groundwater from its salinity intrusion barrier well system along the bay shoreline), imported surface water supply from the Delta delivered through the State Water Project (SWP), and local recycled water, in addition to its SFPUC supply. California Water Service Company (three districts), Coastside County Water District, Daly City, and Mountain View each have one or more local resources, including groundwater, surface water, and/or recycled water. Palo Alto and Redwood City both have some local recycled water.

In the South Bay, eight of the SFPUC wholesale customers also lie within the Santa Clara Valley Water District (SCVWD), and some of these customers receive supply from both the SCVWD and the SFPUC. The SCVWD is a special district under state law and is required to serve the inhabitants of its service area. SCVWD is both a state water contractor receiving imported water from the Delta via the SWP and a federal water contractor receiving Delta water from the Central Valley Project (CVP). In addition, the SCVWD manages local surface and groundwater resources for its customers and actively manages a conjunctive-use program that includes groundwater replenishment with imported surface water to manage groundwater use. SFPUC wholesale customers that also receive water from the SCVWD include Stanford University (which also has some local surface water resources), Mountain View, Sunnyvale (which also has local groundwater and recycled water), Santa Clara (which also has substantial local groundwater

TABLE 13.4
SFPUC WHOLESALE CUSTOMERS – SUPPLY SOURCES

SFPUC Wholesale Customers	
Customers Relying on the SFPUC for 100% of Supply	**Customers with Other Supply Sources**
California Water Service (Mid-Peninsula)	Alameda County Water District
City of Brisbane	California Water Service (Bear Gulch and South San Francisco)[a]
City of Burlingame	Coastside County Water District [a]
City of East Palo Alto	City of Daly City
Estero Municipal Improvement District	City of Milpitas
Guadalupe Valley Municipal Improvement District	City of Mountain View [a]
City of Hayward	City of Palo Alto [a]
Town of Hillsborough	City of Redwood City [a]
City of Menlo Park	City of Santa Clara
Mid-Peninsula Water District	Stanford University
City of Millbrae	City of Sunnyvale
North Coast County Water District	
Purissima Hills Water District	
City of San Bruno	
City of San Jose (North)	
Skyline County Water District	
Westborough Water District	

[a] These wholesale customers receive 25 percent or less of their supply from other sources; the SFPUC provides 75 percent or more.

resources and recycled water), and Milpitas (which also has local recycled water). Palo Alto and Purissima Hills Water District lie within the SCVWD service area but do not receive water from the SCVWD. In total, the SFPUC provides about 54 mgd, or 56.4 percent, of the supply to meet the demand of these eight SCVWD customers.

In summary, for five of the 11 customers who have other sources of water supply in addition to the SFPUC supply, the other supply sources make up 25 percent or less of their supply and the SFPUC provides the remaining 75 percent of supply or more. Hence, only a few of the wholesale customers have other substantial sources of supply besides the SFPUC.

Supply shortfalls from the SFPUC regional water system could also affect individual wholesale customers differently because of differences in their supply agreements with the SFPUC. As discussed in the Draft PEIR (Vol. 1, Chapter 2, pp. 2-43 and 2-44, and Vol. 4, Chapter 7, pp. 7-13 and 7-14), the SFPUC currently holds individual agreements with its wholesale customers. A Master Water Sales Agreement between the CCSF and each of the wholesale customers establishes wholesale water rates, cost allocation, water supply allocation, and use of local water. Under the Master Sales Agreement, the CCSF has agreed that the wholesale customers may collectively purchase up to 184 mgd on an average annual basis, subject to reductions in the event

TABLE 13.5
SUMMARY OF 2030 DEMAND PROJECTIONS, WATER SUPPLY ASSUMPTIONS, AND SFPUC PURCHASE ESTIMATES
(SAME AS DRAFT PEIR TABLE 7.2)

Customer	A	B	C	D	E	F	G	H	I	J

NOTE: Numbers may not sum due to rounding.
a mgd = million gallons per day.
b CWS = California Water Service Company.
c CWS–Bear Gulch District includes the former Los Trancos County Water District.
d The upper range purchase estimate assumes loss of all local water sources (surface water and groundwater) and the lower range estimate assumes continuation of local sources; both estimates assume Level B water conservation.
e The purchase estimate range reflects a range of potential groundwater usage established under a pilot project, from the sustainable yield (3.76 mgd) to the lowest annual production yield (1.34 mgd), according to Daly City's best estimate of 2030 water purchases (SFPUC, 2004).
f MID = Municipal Improvement District.
g 2030 conservation savings is based on URS 2004c and the City's UWMP as confirmed by the City (Popp, 2007).
h 2030 demand and conservation savings are based on information provided by the City of Palo Alto to the SFPUC (City of Palo Alto, 2005a).
i In November 2005, Redwood City informed the SFPUC that it would be purchasing its low-range estimate of 11.6 mgd due to anticipated implementation of 1 mgd of recycled water in 2030 (City of Redwood City, 2005a). The high-range purchase estimate total of 300 mgd published in URS 2004b remains the SFPUC 2030 purchase estimate total for planning purposes, to be consistent with the previous and ongoing WSIP studies. The purchase estimate range originally submitted apparently reflects the average of the City's estimated conservation savings range plus the originally estimated range of recycled water use.
j Portion of north San Jose only.
k Demand and purchase estimates are based on Westborough Water District's 2005 UWMP, as requested by the District in a letter to the SFPUC (Westborough Water District, 2007). The UWMP discusses ongoing and planned future demand management programs but does not quantify conservation savings in relation to the demand and purchase estimate. The District's original estimate of water purchases indicated conservation savings of 0.020 mgd (SFPUC, 2004).
l The low range of the SFPUC retail customer purchase estimate reflects the identified groundwater, recycled water, and conservation programs totaling 10 mgd in San Francisco that are included as part of the WSIP proposed water supply option.

SOURCES: URS, 2004a; URS, 2004b; URS, 2004c; URS, 2006; SFPUC, 2004; SFPUC, 2007; City of Palo Alto, 2005a; Popp, 2007; City of Redwood City, 2005a; Westborough Water District, 2005 ; Westborough Water District 2007.

of a drought, water shortage, earthquake or other natural disaster, or rehabilitation and maintenance of the system; the 184 mgd amount is referred to as the “supply assurance.” The agreement also requires that the wholesale customers employ best efforts to use all sources of water owned or controlled by them, including groundwater. The terms of individual agreements vary among the wholesale customers. In general, there are individual supply assurances for each wholesale customer with two exceptions (see Vol. 5, Appendix E, Table E.1.1, p. E.1-2 for each customer’s existing supply assurance from the SFPUC regional water system). The wholesale customers have varying amounts of their individual supply assurance remaining. All but two wholesale customers are under their current supply assurance by some amount, and two agencies have exceeded their individual supply assurance caps; however, collectively, the wholesale customers remain below the 184 mgd supply assurance cap established by the Master Sales Agreement.

The first exception to the SFPUC’s supply assurance contracts involves the City of Hayward and the Estero Municipal Improvement District (Estero MID) (serving primarily Foster City and some portions of San Mateo County). Contracts with these two agencies do not specify a limit on purchases from the SFPUC. For these two agencies, the CCSF has agreed to meet all of their water needs in excess of other water sources owned or controlled by them. The agreement with Estero MID expires in 2011, while the agreement with the City of Hayward has no termination date. A specified amount (28 mgd) of the total 184 mgd wholesale customer supply assurance has been set aside by the wholesale customers to meet the long-term supply needs of Hayward and Estero MID. However, Hayward alone projects that it will need to purchase up to 28 mgd from the SFPUC by 2030 (just under 10 mgd more than its fiscal year 2001/2002 delivery purchase). Estero MID has requested purchase of up to 6.8 mgd by 2030. Thus, the combined usage for these two agencies is projected to exceed the 28 mgd reserved for them. If this occurs, then the other wholesale customers would have to reduce their purchases in order to accommodate Hayward and Estero MID deliveries. The Master Sales Agreement provides a method for proportional reduction in the other wholesale customers’ supply guarantee in the event that Hayward and Estero MID exceed the supply amount reserved for them.

The second exception to the SFPUC supply assurance contracts involves the Cities of San Jose and Santa Clara. The SFPUC sells water to these two entities on a temporary, interruptible basis; neither city has a supply assurance contract with the SFPUC. As a result, deliveries to these two cities are not accounted for in the 184 mgd supply assurance cap established in the Master Sales Agreement. In fiscal year 2001/2002, these two cities purchased a combined total of 8.26 mgd from the SFPUC system. As part of the WSIP planning and development process, they submitted a request to purchase an additional 2.98 mgd, for a combined total 2030 purchase request of 11.24 mgd. The SFPUC serves northern San Jose, while the remainder of San Jose is served by the SCVWD. The City of Santa Clara receives less than 20 percent of its supply from the SFPUC. Within Santa Clara, however, the SFPUC supply constitutes nearly 90 percent of water supply to the northern part of the city (north of Highway 101), which is largely isolated from the rest of the city’s water system. For Santa Clara to serve this area from a source other than the SFPUC, it would not only need to secure the additional supply but also to extend major new infrastructure. Similarly, in San Jose, the SFPUC supply serves the northern San Jose area. Although San Jose and Santa Clara lie within the SCVWD, the District does not have available supply or the necessary treatment plant capacity or infrastructure reaching these areas that could provide service to compensate for a reduction in SFPUC deliveries; major new facilities would need to be constructed to serve these areas.

In the future under the Phased WSIP Variant through 2018, the Cities of San Jose and Santa Clara could face partial or complete SFPUC water delivery reductions as the other wholesale customers with supply assurance contracts increase their deliveries up to their supply assurance limits and Hayward and Estero MID continue to increase their purchase requests beyond a combined 28 mgd. The San Francisco Planning Department received letters from the SCVWD, the City of San Jose, the City of Santa Clara, and BAWSCA concerning the proposed Phased WSIP Variant (see Vol. 8, Appendix M for copies of these letters). Each of these agencies expressed concern that neither San Jose nor Santa Clara have good alternative treated water supply sources, and that increasing local groundwater pumping would have environmental consequences associated with over-pumping. Historically, over-pumping of groundwater was an issue for these communities and resulted in appreciable land subsidence that was remedied through a combination of actions, including the use of surface water supplies from the SFPUC to reduce the need for pumping. (Refer to the discussion below under the heading Environmental Effects of the Phased WSIP Variant for further information on the potential environmental effects of groundwater pumping increases by San Jose and Santa Clara.)

If SFPUC supplies to San Jose and Santa Clara were interrupted due to increased demand among the remaining wholesale customers, these entities could rely entirely on the SCVWD to meet the portion of their existing demand now being met by the SFPUC. As noted in the SCVWD water supply planning documents, the District relies on the SFPUC to continue to meet the supply needs of these two customers in the future. The SCVWD has not made plans to serve these customers from the supplies that they manage. Similarly, if any of the other customers do not have their demand increases met through the SFPUC, then these customers could increase their reliance on the SCVWD to meet that portion of increased demand.

Water Supply Options

As discussed in the Draft PEIR for the No Purchase Request Increase Alternative (and the No Program Alternative), if the SFPUC does not fully meet the wholesale customer purchase requests, it is assumed that the wholesale customers, either individually or collectively, would pursue supplemental supply sources and/or additional conservation and/or water recycling projects to make up the shortfall in SFPUC water deliveries under this scenario. BAWSCA represents the SFPUC wholesale customers and has the authority to pursue and secure water supplies on behalf of the wholesale customers as well as to coordinate recycled water and conservation projects to benefit its members.

Local Options

Draft PEIR Section 9.2.4, Aggressive Conservation/Water Recycling and Local Groundwater Alternative (Vol. 4, Chapter 9, pp. 9-47 to 9-59) and Section 9.2.8, Modified WSIP Alternative (Vol. 4, Chapter 9, pp. 9-78 to 9-84) provide a discussion of the additional, potential conservation, recycled water, and groundwater projects that could be implemented by the wholesale customers beyond those projects accounted for in their 2030 purchase request. This information is summarized below. These projects could potentially be implemented to develop the additional 10 mgd of local supply and/or conservation required under the Phased WSIP Variant by 2018, assuming these projects are feasible (see **Table 13.6**, below, which is the same as PEIR Table 9.11). Most of the projects have been developed on a very conceptual level and have technical, institutional, and financial issues to overcome prior to implementation; and contain uncertainties with regard to water quality issues, end-users, long-term sustainable yield, and production rates. The SFPUC is interested in working with BAWSCA and the wholesale customers in the further development of local conservation, recycled water, and/or groundwater projects to meet the full customer supply needs through 2018. The SFPUC is considering the creation of financial mechanisms to support actions in the wholesale customer service areas as well as direct participation in local projects (SFPUC, 2008c).

In March 2008, BAWSCA authorized a study, called the BAWSCA Water Conservation/Recycling Implementation Plan, to identify the specific conservation actions needed to secure an additional 10 mgd of supply savings through conservation savings and reclamation by 2030, as was indicated to by BAWSCA in its comments on the Draft PEIR (see Vol. 6, Section 12.3, Comment L_BAWSCA1-53). BAWSCA moved in August 2008 to secure a consultant to prepare the plan, which is scheduled to be completed by the end of June 2009. The plan will include a 10-year implementation plan showing proposed actions, schedules, costs, and funding alternatives to achieve the combined commitments shared by BAWSCA and its member agencies to achieve a total of 58 mgd of water conservation and recycling between 2001 and 2030 (BAWSCA, 2008b). The commitment to develop 10 mgd of local recycled water and conservation is in addition to the amount the wholesale customers previously committed to in the development of their 2030 purchase requests as part of the WSIP planning process (BAWSCA, 2008a).

As discussed in the Draft PEIR analysis of the Aggressive Conservation/Water Recycling and Local Groundwater Alternative (Vol. 4, Chapter 9, pp. 9-47 to 9-59), studies to date suggest that it would be difficult for the wholesale customers to develop sufficient local conservation, reuse, and groundwater projects to meet their full 2030 needs. Thus, after 2018, if the SPFUC decides to continue limiting deliveries from its watersheds to 265 mgd, it could be difficult for the SFPUC, BAWSCA, and the wholesale customers to develop sufficient additional local supply through groundwater, recycled water, and conservation to satisfy projected 2030, long-term demands. With respect to the potential for additional local groundwater development, the wholesale customers with appreciable groundwater resources (i.e., Daly City, Santa Clara, Sunnyvale, and Alameda County Water District) are already maximizing or planning to maximize their use of this supply, while other customers have no or only a limited potential for groundwater development. As shown on Table 13.6, the wholesale customers identified potential groundwater projects totaling just under 3 mgd. The wholesale customers with groundwater resources risk the potential for overdrafting their local aquifers if they increase the use of this resource. This is a particular concern for South Bay communities such as San Jose and Santa Clara that have a history of over-pumping groundwater, land subsidence, and loss of aquifer storage capacity.

TABLE 13.6
POTENTIAL REGIONAL RECYCLED WATER, GROUNDWATER, AND CONSERVATION PROJECTS
(SAME AS DRAFT PEIR TABLE 9.11)

Location/Jurisdiction	Type of Supply	Description	Low-Range Yield (mgd)	High-Range Yield (mgd)
Category 1 – Projects Likely to be Implemented				
City of Daly City	Recycled Water	Expansion of recycled water uses from an existing facility to irrigate an additional park and landscape medians	-	0.01
North Coast County Water District/San Francisco	Recycled Water	Various irrigation uses for school grounds and highway uses	0.15	0.58
		Subtotal Category 1	**0.15**	**0.6**
Category 2 – Eligible Projects in Early Planning Stages				
Mountain View	Recycled Water	Irrigation and industrial usage – joint project with City of Palo Alto	-	1
Various	Conservation	Eight conservation measures to be implemented by a regional body	2.3	5.7
Various	Conservation	Seven additional conservation measures to be implemented by a regional body	0.6	1.5
Palo Alto	Recycled Water	Irrigation in Palo Alto and East Palo Alto	-	1
Cal Water–Mid-Peninsula	Groundwater	New well in Mid-Peninsula District for potable use	-	1
Cal Water–Bear Gulch	Groundwater	New well shared with Menlo Park for potable use	-	1
East Palo Alto	Groundwater	Reestablish use of existing well	-	0.5
Redwood City	Recycled Water	Expand recycled water system for use by additional customers outside of service area	2.2	4.5
South San Francisco and San Bruno	Recycled Water	Replace current groundwater irrigation uses with recycled water	-	0.3
		Project Overlap Adjustment[1]		(1.5)
		Subtotal Category 2	**5.1**	**15**
Category 3 – Potentially Eligible Projects for Future Consideration				
Menlo Park	Groundwater	Groundwater well for emergency use	Unknown	Unknown
Sunnyvale	Recycled Water	Extend existing recycled water project	-	0.7
Various	Conservation	Eight additional conservation measures to be implemented by a regional body	0.5	1.4
Burlingame	Groundwater	Rehabilitate existing well	-	0.02
Burlingame	Recycled Water	Irrigation of commercial landscaping	-	0.25
		Project Overlap Adjustment		(0.14)
		Subtotal Category 3	**0.5**	**2.23**
Total			**5.75**	**~19**

1 Project overlap adjustment represents the amount of potential conservation program savings overlap with respect to other projects to avoid double counting.

SOURCE: SFPUC, 2007b.

Imported Supply and/or Desalination Options

Other options for potential supplemental water sources that the wholesale customers could pursue to make up for the SFPUC water delivery shortfall that could occur under this variant are seawater or brackish water desalination and surface water transfers, potentially coupled with conjunctive groundwater use and/or additional surface water storage. These potential supplemental supply options are discussed in the Draft PEIR, primarily in Section 9.2.2, No Program Alternative (Vol. 4, Chapter 9, pp. 9-25 to 9-40), but also in Section 9.2.3, No Purchase Request Increase Alternative (Vol. 4, Chapter 9, pp. 9-40 to 9-47).

Regarding water purchases or transfers, statewide trends indicate that while urban water use is increasing, agricultural water use is decreasing, in part because agricultural water users are selling water rights or contracts to urban agencies (DWR, 2005). Potential sources of supplies for the wholesale customers include water-rights holders north of the Delta, in the Delta, or south of the Delta. The agencies with the rights to the greatest quantities of water in the state—the U.S. Bureau of Reclamation (USBR) and California Department of Water Resources (DWR)—would not be sources of new water supply contracts/agreements because of their commitments to existing contractors and to the protection, restoration, and enhancement of fish and wildlife habitat. The wholesale customers and/or BAWSCA could face challenges to water purchases and transfers pertaining to restrictions associated with entitlements, contracts, and water rights; permitting requirements; effects caused by the cessation of water application to an area (e.g., land fallowing, economic impacts); Delta pumping restrictions; and wheeling arrangements[3] (Johnson and Loux, 2004). Existing water delivery infrastructure could theoretically be used through agreements with other agencies (such as the DWR, USBR, SFPUC, SCVWD, East Bay Municipal Utility District, or Alameda County Water District) to convey water to the wholesale customers, if and when system capacity is available. Construction or expansion of interties or connecting pipelines in urban areas would likely be required.

Since the Draft PEIR was released in June 2007, a series of events has affected the feasibility of executing water transfers that involve moving water from or through the Sacramento–San Joaquin River Delta. These events are primarily related to endangered species issues and include: the DWR's 10-day shutdown of the State Water Project (SWP) Delta diversions in the summer of 2007 to protect delta smelt; the Judge Wanger decision in late 2007 regarding delta smelt("Wanger 2007 Decision"), which imposed interim export pumping restrictions tied to flow conditions on Old and Middle Rivers in the Delta; the Judge Wanger decision to invalidate the Biological Opinion for the coordinated operations plan for the CVP and SWP known as the OCAP (Operations Criteria & Plan) on anadromous fish, including steelhead, winter-run and spring-run salmon, and green sturgeon (Wanger Decision 2008); the Endangered Species Act reconsultation now in progress for the OCAP, which will establish revised long-term operating requirements for the CVP and SWP operations to protect endangered species (replacing both the Wanger 2007 and Wanger 2008 decisions); and the proposed Bay Delta Conservation Plan, which includes alternatives for substantially modifying conveyance facilities and operations for the state and federal water systems that now use the Delta for conveyance, and for which the state and

[3] Wheeling arrangements are agreements to use existing infrastructure owned by a third party to transport/convey water from a source to a customer.

federal environmental review processes have recently been initiated (spring 2008). This series of events has made the potential for securing a water transfer from an entity north of the Delta less feasible now than it was when the Draft PEIR was published.

Another potential source of supplemental water for the wholesale customers could be increased agricultural water conservation in the San Joaquin Valley such that surface water conserved in these agricultural areas could then be delivered to the Bay Area. BAWSCA and some of its member agencies have proposed the implementation of additional agricultural water conservation beyond that included in the Modified WSIP Alternative (refer to Vol. 7, Chapter 14, **Section 14.10, Master Response on Modified WSIP Alternative**). According to these proposals, the water saved would accumulate in Don Pedro Reservoir and could be used to increase flows in the Tuolumne River below La Grange Dam or could be conveyed to water users in the Bay Area via a water exchange agreement with TID and MID. The SFPUC regards any project intended to increase agricultural water conservation beyond the level needed to reduce the impacts of the WSIP to a less-than-significant level to be separate from the WSIP. Any such agreements would be undertaken independently of the WSIP. If the Modified WSIP Alternative, or this element of it, is selected as the preferred course of action, the SFPUC would work with TID, MID, or another water agency to develop the transfer of conserved water that is included in the Modified WSIP Alternative. BAWSCA could choose to pursue a separate agricultural water conservation project to augment this transfer, but if the SFPUC were to participate in the project, it would be considered a distinct action from the WSIP or any alternative/variant of the WSIP. This is one option BAWSCA and its member agencies could pursue in order to secure a supplemental supply.

Use of seawater or brackish water desalination technologies to supplement supplies would involve the construction and operation of a desalination plant and related infrastructure. Such a project could occur on a local or regional level. For example, the Alameda County Water District has developed a local desalination facility to treat brackish groundwater pumped from local wells to blend with other drinking water supplies. The SFPUC is currently participating in a study on a potential regional desalination facility that might serve multiple Bay Area communities. The Draft PEIR includes a description of the facilities and environmental impacts of desalination in Section 9.2.6, Year-round Desalination at Oceanside Alternative (Vol. 4, Chapter 9, pp. 9-66 to 9-74) and Section 9.2.7, Regional Desalination for Drought Alternative (Vol. 4, Chapter 9, pp. 9-74 to 9-78). Desalination represents a potential new local source of water.

Ability to Meet Program Objectives

Table 13.7 (similar to Draft PEIR Table 9.6) summarizes the ability of the Phased WSIP Variant to meet the program objectives as compared to the WSIP and select other alternatives. Through 2018, the Phased WSIP Variant would meet many, but not all, of the program objectives. Given the proposed 265 mgd annual average limitation on deliveries from the SFPUC watersheds, the wholesale customers would receive up to 184 mgd from the SFPUC watersheds and would need to quickly develop an additional 10 mgd of local supply and conservation by 2018. Because the Phased WSIP Variant has not already identified specific local projects for implementation to secure the additional 10 mgd needed to fully meet the wholesale customer demand through 2018,

TABLE 13.7
SUMMARY OF ABILITY OF ALTERNATIVES TO MEET PROGRAM OBJECTIVES[a]
(SIMILAR TO DRAFT PEIR TABLE 9.6)

Objectives	Proposed Program	No Program Alternative	No Purchase Request Increase Alternative	Phased WSIP Variant
Water Quality				
Design improvements to meet current and foreseeable future federal and state water quality requirements?	Yes	Yes	Yes	Yes
Provide clean, unfiltered water originating from Hetch Hetchy Reservoir and filter all other surface water sources?	Yes	Yes	Yes	Yes
Continue to implement watershed protection measures?	Yes	Yes	Yes	Yes
Seismic Reliability				
Complies with current seismic standards?	Yes	No	Yes	Yes
Capable of delivering basic service to all regions in the service area following a major earthquake?	Yes	No	Partial	Partial
Facilities restored to meet average-day demand within 30 days of a major earthquake?	Yes	No	Partial	Partial
Delivery Reliability				
Provides operational flexibility to allow for planned maintenance without service interruptions?	Yes	No	Yes	Yes
Provides operational flexibility and system capacity to replenish local reservoirs, as needed?	Yes	No	Yes	Yes
Capable of minimizing risk of service interruption due to unplanned facility upsets or outages?	Yes	No	Yes	Yes
Capable of serving average 2030 demand of 300 mgd with one planned shutdown of a major facility and one unplanned facility outage?	Yes	No	Partial	Partial
Water Supply				
Meets average annual purchase requests of 300 mgd during nondrought years for system demands through 2030?	Yes	Partial	No, 275 mgd	No, 275–285 mgd
Meets 20% systemwide rationing limit during droughts?	Yes	No	Partial	Partial
Meets system firm yield of 256 mgd?	Yes	No	No	No
Diversifies water supply options during nondrought and drought periods?	Yes	No	Yes	Yes
Improves use of new water sources and drought management, including use of groundwater, recycled water, conservation, and transfers?	Yes	No	Yes	Yes

TABLE 13.7 (Continued)
SUMMARY OF ABILITY OF ALTERNATIVES TO MEET PROGRAM OBJECTIVES[a]
(SIMILAR TO DRAFT PEIR TABLE 9.6)

Objectives	Proposed Program	No Program Alternative	No Purchase Request Increase Alternative	Phased WSIP Variant
Sustainability				
Manages natural resources and physical systems to protect watershed ecosystems?	Yes	Yes	Yes	Yes
Meets current and anticipated legal requirements for protection of fish and other wildlife habitat?	Yes	Yes	Yes	Yes
Manages natural resources and physical systems to protect public health and safety?	Yes	No	Yes	Yes
Cost-effectiveness				
Ensure cost-effective use of funds?	Yes	No and likely greater cost	Unknown, but greater cost	Unknown, but greater cost
Maintains gravity-driven system?	Yes	Yes	Yes	Yes
Implement regular inspection and` maintenance program for all facilities?	Yes	No	Yes	Yes

NOTES:

a This assessment is based on SFPUC actions under each alternative only and does not account for the actions that BAWSCA and/or the wholesale customers might take in order to make up for any shortfall in the regional system's ability to meet the program objectives. See text for a discussion of the ability of each alternative to meet the objectives. In general, the terms in the table are used as follows:

Yes: Indicates that the alternative would fully meet the sub-objective at an equivalent level to the WSIP.

Partial: Indicates that the alternative could meet the objective in part, but it would not fully meet the objective at an equivalent level to the WSIP due to variation associated with the alternative, such as the reduced delivery targets, additional facility requirements, and associated issues. Both the No Purchase Request Increase Alternative and the Phased WSIP Variant would include the full set of WSIP facilities. Thus, the facilities would be capable of delivering and managing supplies to fully meet the 2030 WSIP objectives, but the proposed supply scenarios under these alternatives would not; as a result, these alternatives/variants would only partially meet the full WSIP objective.

No: Indicates that the alternative would not meet the sub-objective.

there is less certainty that this variant could meet the SFPUC's water supply objective compared to the WSIP. It appears feasible to develop additional local conservation, recycled water, and groundwater to provide another 10 mgd, but there is substantial additional work to be completed in order to develop, review, approve, and implement these local actions and projects by 2018. Thus, due to this uncertainty, the table indicates that Phased WSIP Variant would only *partially* achieve those objectives associated with fully meeting customer purchase requests. The Phased WSIP Variant would meet the drought reliability objective at the reduced water supply delivery level.

The Phased WSIP Variant would fully meet the WSIP level of service goal for water quality (although the SFPUC would not be responsible for the quality of any supplemental water supply pursued by the wholesale customers under this scenario). Seismic reliability would be improved over existing conditions; however, because this variant would limit water supply to the SFPUC customers through 2018, this option would not meet the WSIP objective of providing 300 mgd average-day demand through 2030.

Delivery reliability of the regional system would be similar to that under the WSIP; however, this variant would only partially meet those objectives because it would not meet the average annual projected demand of 300 mgd in 2030 under maintenance or outage conditions but instead would meet a reduced target delivery set for 2018. Similar to the WSIP, comprehensive and regular repair and maintenance of the regional system would occur under this variant without service interruptions, and the risk of service interruptions due to unplanned facility upsets or outages would be minimal. Facilities would be in place to replenish local reservoirs as needed to prepare for drought, and the system would remain predominantly gravity-driven.

The Phased WSIP Variant would achieve the WSIP's water supply level of service goal during nondrought periods through the year 2018, but would not achieve the 2030 WSIP program goal. This variant would meet the WSIP objective of limiting drought-year rationing to a maximum of 20 percent systemwide, but it would achieve this objective at the reduced delivery level only.

Environmental Impacts of the Phased WSIP Variant Compared to those of the WSIP

The environmental effects of the Phased WSIP Variant would be similar to those described for the No Purchase Request Increase Alternative if the SFPUC decides to continue limiting average annual water deliveries from the SFPUC watersheds to 265 mgd beyond the year 2018. If the SFPUC decides in 2018 to increase water deliveries from the SFPUC watersheds to the wholesale customers, then the environmental impacts would be the same or similar to those evaluated for the WSIP or the Modified WSIP Alternative.

Facility Construction and Operation Impacts

WSIP Facility Improvement Projects

The Phased WSIP Variant would have the same impacts associated with proposed facility construction and operation as the WSIP. The 22 facility improvement projects proposed under the WSIP would also be implemented under the Phased WSIP Variant to meet the intent of the water quality, seismic reliability, delivery reliability, and water supply goals of the WSIP. All four of these goals are factored into the decision on how to size the WSIP's individual facility improvement projects. Even if the average annual diversions from the Tuolumne River were to remain within the current historical levels, the SFPUC would move forward with all projects as identified and sized under the WSIP in order to provide improved reliability and operational flexibility to perform the maintenance that has been deferred in the past and that is necessary in the future (SFPUC, 2008d).

Other Facilities Potentially Developed by the Wholesale Customers

The types of projects that the wholesale customers might pursue to reduce demand and/or supplement the surface water supplies delivered by the regional water system from the SFPUC watersheds, and the potential facility and operations impacts associated with such projects are discussed in the Draft PEIR in Section 9.2.2, No Program Alternative (Vol. 4, Chapter 9, pp. 9-34 to 9-37) and Section 9.2.4, Aggressive Conservation/Water Recycling and Local Groundwater Alternative (Vol. 4, Chapter 9, pp. 9-55 to 9-57).

In general, certain types of impacts are common to water supply transfers/acquisition and include: the cessation of water application to lands irrigated by the water being transferred; changes related to flows, fisheries, and water quality; and impacts caused by the use of existing or the construction of new infrastructure. Typically, the water-rights holder previously applied the water to agricultural land. If water is taken from agricultural customers, rather than implementing agricultural conservation measures, the transfer can result in the conversion of agricultural land to nonagricultural land. Beneficial environmental effects (related to retiring drainage-impaired lands, reducing the application of pesticides, etc.) can also occur. The need for new facilities and/or changes in the operations of existing facilities depend on the source of supply (e.g., the Tuolumne River through transfers with TID and MID, water-rights holders north of the Delta, in the Delta, or south of the Delta), the quantity of supply, the means of conveyance, and any additional storage requirements. Construction or expansion of interties or connecting pipelines could be required, potentially resulting in impacts similar to those described for the WSIP pipeline projects. The types of impacts associated with water supply acquisition projects are summarized in **Table 13.8** (which is the same as Draft PEIR Table 9.10). Depending on the facilities needed to convey the supplemental supplies to the wholesale customer service areas, the construction and operation of such facilities could result in a full range of construction and operational impacts similar to those described in Chapter 4 (Vol. 2) for the WSIP facilities in the South Bay and Peninsula areas (such as traffic, air quality, noise, energy use, waste disposal, and vibration).

TABLE 13.8
SUMMARY OF POTENTIAL IMPACTS AND MITIGATION STRATEGIES ASSOCIATED WITH REPRESENTATIVE WATER SUPPLY ACQUISITION PROJECTS
(SAME AS DRAFT PEIR TABLE 9.10)

Actions Associated with Water Supply Acquisition Projects	Potential Impacts	Mitigation Strategy
Supplemental Water Supply Source		
Increased Water Use Efficiency/Conservation (e.g., conversion to drip irrigation); tiered water pricing	Reduced groundwater recharge. Exposure of soils to wind erosion leading to air quality impacts. Could lead to increased groundwater pumping.	None required. See below regarding increased groundwater pumping.
Conversion of More Water-Intensive to Less Water-Intensive Crops, Land Fallowing	Land fallowing could create pressure to convert land to urban uses and loss of agricultural land. Economic impacts to community.	Include consideration of farming interests in decision-making process for transfer.
Increased Groundwater Pumping/Conjunctive Use of Groundwater	Groundwater level reductions and overdraft if there is insufficient sustainable yield to accommodate increased pumping. Water quality issues include decreased aesthetic quality in drinking water (hardness, tastes, odors), health risk from potential contaminants in groundwater basin.	Determine sustainable yield of the basin, implement monitoring program, regulate groundwater pumping to preserve safe yield, provide treatment and/or blending if necessary to remove contaminants and control taste and odor. Local assistance programs for remediation of affected wells.
Delta Diversions	Potential impacts on sensitive Delta fisheries including: winter-run, spring-run Chinook salmon, Delta smelt, steelhead trout, and Delta splittail.	Compliance with existing and future pumping requirements related to threatened and endangered species protection.
	Changes in Delta inflow, outflow. Potential impacts on flows associated with wheeling Delta transfers through the Delta, resulting in secondary impacts on Delta fisheries and other biological resources.	Transfer would require review/approval by applicable regulatory agencies. Analysis of flow impacts and commitment to minimize adverse secondary impacts on biological resources (e.g., through transfer timing, pumping restrictions).
	Water quality for the Delta and downstream water users (including salinity, bromides, potential contaminants from agricultural and industrial runoff, taste and odor problems, disinfection byproducts, and temperature).	Compliance with existing and future applicable water quality control. Regulations. Treatment to bring up to water quality equitable to Tuolumne River.
	Water quality for the Delta and downstream water users (including salinity, bromides, and temperature).	Transfer would require review/approval by applicable regulatory agencies. Analysis of flow impacts and commitment to minimize adverse impacts on other water users (e.g., through transfer timing, pumping restrictions).

TABLE 13.8 (Continued)
SUMMARY OF POTENTIAL IMPACTS AND MITIGATION STRATEGIES ASSOCIATED WITH REPRESENTATIVE WATER SUPPLY ACQUISITION PROJECTS

Actions Associated with Water Supply Acquisition Projects	Potential Impacts	Mitigation Strategy
Facilities Required		
Conveyance	Mostly temporary impacts from construction of pipelines, valves, and pumps (disturbance of soils, surface water quality, biological resources, cultural resources, air quality, traffic, noise, land use, hazardous materials, aesthetics).	Most impacts associated with facility construction could be mitigated to a less-than-significant level with the types of measures identified in Chapter 6. As is the case with the proposed WSIP facilities, some impacts (e.g., short-term noise and traffic) could be unavoidable.
Pumping	Noise, energy consumption, air pollutant emissions from energy consumption.	Muffle noise. Use energy-efficient pumps and alternative energy sources.
Treatment	Temporary construction impacts, including land use, traffic, noise and air quality impacts. Potential long-term impacts could include increase in energy consumption, air pollutant and greenhouse gas emissions from energy consumption.	Use standard construction mitigations. Use energy-efficient pumps and alternative energy sources.
Groundwater Basin Storage of Surface Water	Potential degradation of groundwater quality, hydrofracturing (injection).	Pretreatment, groundwater quality monitoring, groundwater basin modeling, modifications to recharge and pumping practices.
Storage – Development of New Offstream Storage	Temporary and long-term impacts from construction of dam, pipelines, pumps, and appurtenant features (direct and indirect impacts on wetland and upland fish and wildlife and attendant habitat; impacts related to cultural resources, air quality, traffic, noise, land use, aesthetics, etc.).	Most impacts associated with facility construction could be mitigated to a less-than-significant level with the types of measures identified in Chapter 6. Some impacts would likely be unavoidable.

If desalination technologies were used to supplement supplies, implementation of a desalination project to augment wholesale customer water supplies would result in the full range of construction impacts at the proposed facility location (such as traffic, air quality, noise, and vibration) as well as operational impacts related to aquatic resources, water quality, energy consumption, air quality, visual resources, land use and planning, traffic, and greenhouse gas emissions. The programmatic impacts of construction and operation of a desalination facility are described in the Draft EIR under WSIP Variant 2, Regional Desalination for Drought (Vol. 4, Chapter 8 (pp. 8-24 to 8-32).

Similar to the Aggressive Conservation/Water Recycling and Local Groundwater Alternative, the Phased WSIP Variant could also result in construction and operation of extensive additional recycled water and groundwater facilities in the wholesale customer service areas; thus, collective impacts in the Bay Division and Peninsula Regions and associated cumulative effects would occur. The types of impacts associated with implementation of the local recycled water and groundwater projects are summarized in **Table 13.9** (which is the same as Draft PEIR Table 9.12) and generally relate to construction of new infrastructure, water quality, and groundwater resources, and operational uses of energy and long-term air quality emissions.

Water Supply and Systems Operations Impacts

Tables 13.10, **13.11**, and **13.12** show the significance of the environmental impacts of the Phased WSIP Variant in the Tuolumne River, Alameda Creek, and Peninsula watersheds compared to the potentially significant impacts identified for the WSIP. Under the Phased WSIP Variant, the SFPUC would limit deliveries from the SFPUC watersheds to 265 mgd on an average annual basis, which would include 184 mgd to the wholesale customers and 81 mgd to the retail customers. In 2018, the SFPUC would decide whether to continue this limit on deliveries from the SFPUC watersheds or to increase it after completing further demand and supply option studies. The impact summary tables show the significance of impacts for the Phased WSIP Variant as the SFPUC proposes to implement it through 2018, and also for a potential 2030 implementation scenario that includes an increase in deliveries from the SFPUC watersheds up to the full level provided under the WSIP. The effects of the Phased WSIP Variant through 2018 would be similar to those described for the No Purchase Request Increase Alternative. For the 2030 scenario, while the SFPUC plans to reconsider water demand and water supply and make a later decision about the appropriate amount of SFPUC watershed deliveries after 2018, this 2030 scenario represents a potential “worst-case” impact assessment with respect to the potential level of effect on the SFPUC watersheds, particularly the Tuolumne River watershed, that might occur under the Phased WSIP variant. For this 2030 scenario, the impacts of the Phased WSIP Variant are the same as those of the Modified WSIP Alternative, since it assumes that 20 mgd of local conservation, recycled water, and groundwater projects would be implemented by 2018.

Tuolumne River Watershed

The significant impacts of the WSIP and the Phased WSIP Variant in the Tuolumne River watershed are shown in Table 13.10. Overall, the impacts of the Phased WSIP Variant through 2018 would be less than the impacts of the WSIP.

TABLE 13.9
SUMMARY OF POTENTIAL IMPACTS AND MITIGATION STRATEGIES FOR RECYCLED WATER AND GROUNDWATER PROJECTS
(SAME AS DRAFT PEIR TABLE 9.12)

Potential Impact	Mitigation Strategy
Groundwater Resources. Potential for increased groundwater pumping, groundwater level reductions, and overdraft if there is insufficient sustainable yield to accommodate increased pumping.	Determine sustainable yield of the basin, implement monitoring program, regulate groundwater pumping to preserve safe yield.
Surface Water, Groundwater Quality, and Public Health Issues. Recycled water applied to the irrigated lands would infiltrate through the subsurface levels, potentially affecting surface and groundwater quality. Groundwater may have contaminants with potential health effects. Groundwater lowers the aesthetic quality of the water through increased hardness, and potential for tastes and odors.	Comply with Title 22 Water Recycling Criteria. Groundwater may require disinfection, treatment and/or blending.
Energy use. Operation of both recycled water and groundwater projects would require increased energy use for treatment and distribution, and pumping. Increased energy production to support these activities along with plant operation would, in turn, generate additional air pollutant emissions, including greenhouse gases emissions.	Energy efficiency measures.
Treatment. Temporary construction impacts (disturbance of soils, surface water quality, biological resources, cultural resources, air quality, traffic, noise, land use, hazardous materials). Potential long-term impacts could include odor, depending on treatment processes and location relative to sensitive receptors. Plant operations could also generate long-term noise, traffic, and visual impacts depending on facility site location(s)and increased energy consumption and air pollutant emissions. **Pumping.** (groundwater pumping station)	Most impacts associated with facility construction could be mitigated to a less-than-significant level with the types of measures identified in Chapter 6. As is the case with the proposed WSIP facilities, odor control features (scrubbers) could reduce any odor impacts to a less-than-significant level.
Conveyance. Mostly temporary impacts from construction of pipelines, valves, and pumps (disturbance of soils, surface water quality, biological resources, cultural resources, air quality, traffic, noise, land use, hazardous materials, aesthetics).	Most impacts associated with facility construction could be mitigated to a less-than-significant level with the types of measures identified in Chapter 6. As is the case with the proposed WSIP facilities, some impacts (e.g., short-term noise and traffic) could be unavoidable.
Storage. Temporary construction impacts (disturbance of soils, surface water quality, biological resources, cultural resources, air quality, traffic, noise, land use, hazardous materials) and potential long-term impacts based on site-specific characteristics (e.g., slope stability, location within a scenic viewshed).	Most impacts associated with facility construction could be mitigated to a less-than-significant level with the types of measures identified in Chapter 6. As is the case with the proposed WSIP facilities, some impacts (e.g., short-term noise and traffic) could be unavoidable. Prepare and implement recommendations from a geotechnical study, implement measures to reduce visual contrast with surroundings (e.g., backfilling, earth-tone paint).

TABLE 13.10
SUMMARY OF SIGNIFICANT WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR PHASED WSIP VARIANT – TUOLUMNE RIVER WATERSHED

Impact	Impact Description	Proposed Program – 2030	Phased WSIP Variant – 2018[a]	Phased WSIP Variant – 2030 Scenario[b]
Section 5.3.6, Fisheries				
Impact 5.3.6-4: Effects on fishery resources along the Tuolumne River below La Grange Dam.				
	In wet or above-normal years when Don Pedro Reservoir is being filled, changes in the timing and duration of releases from the reservoir would decrease average monthly flows along the lower Tuolumne River beneath La Grange Dam. The greatest average flow reductions would occur during June and could result in elevated water temperatures. Changes in stream flow and water temperature would result in a reduction in the linear extent of suitable habitat for rearing Chinook salmon and oversummering steelhead/rainbow trout, potentially causing adverse affects on these fish populations in the lower Tuolumne River.	PSM	LS when average annual deliveries from the watersheds are maintained at 265 mgd or less; PSM if deliveries exceed 265 mgd	PSM
Section 5.3.7, Terrestrial Biological Resources				
Impact 5.3.7-2: Impacts on meadow/alluvial features along the Tuolumne River below O'Shaughnessy Dam.				
▪ Sensitive habitats	Delayed snowmelt releases, reductions in flow, and the resulting reduction in groundwater recharge would result in an incremental reduction in the extent and diversity of wetland and riparian habitats, including sensitive wetland and riparian habitats in the Poopenaut Valley.	PSM	PSM	PSM
▪ Key special-status species	A reduction in wetland and riparian habitat would reduce suitable breeding habitat for key special-status species potentially occurring along this reach (e.g., foothill yellow-legged frog, California red-legged frog, and willow flycatcher), the populations of which are already critically reduced in the Sierra Nevada.	PSM	PSM	PSM
▪ Other species of concern	A reduction in the extent and diversity of wetland and riparian habitats would reduce habitat quality and extent for animal and plant species of concern.	PSM	PSM	PSM
▪ Common habitats and species	All habitats affected by the WSIP are considered sensitive. The WSIP could affect a large number of common animal species that depend on sensitive meadows and larger riparian areas for food and cover.	PSM	PSM	PSM
Impact 5.3.7-6: Impacts on biological resources along the Tuolumne River below La Grange Dam.				
▪ Sensitive habitats	Delayed spring releases and reductions in average and total flow (particularly during and following an extended drought) below La Grange Dam would reduce or eliminate suitable conditions for the recruitment of some riparian species along the river.	PSM	LS when average annual deliveries from the watersheds are maintained at 265 mgd or less PSM if deliveries exceed 265 mgd	PSM

TABLE 13.10 (Continued)
SUMMARY OF SIGNIFICANT WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR PHASED WSIP VARIANT – TUOLUMNE RIVER WATERSHED

Impact	Impact Description	Proposed Program – 2030	Phased WSIP Variant – 2018[a]	Phased WSIP Variant – 2030 Scenario[b]
Section 5.3.7, Terrestrial Biological Resources (cont.)				
▪ Key special-status species	Because of the known presence of key special-status species and the very limited amount of remaining suitable habitat along this reach of the Tuolumne River, this incremental impact would be potentially significant.	PSM	LS when average annual deliveries from the watersheds are maintained at 265 mgd or less PSM if deliveries exceed 265 mgd	PSM
▪ Other species of concern	Species of concern that would be adversely affected by changes in the extent and quality of suitable riparian habitat include western pond turtle, several bat species, and a wide variety of riparian- and marsh-associated bird species.	PSM	LS when average annual deliveries from the watersheds are maintained at 265 mgd or less PSM if deliveries exceed 265 mgd	PSM
▪ Common habitats and species	The populations of common species that depend on riparian habitat could be adversely affected by the alteration of habitat.	PSM	LS when average annual deliveries from the watersheds are maintained at 265 mgd or less PSM if deliveries exceed 265 mgd	PSM

LS = Less than Significant, no mitigation required
SM or PSM = Significant or Potentially Significant, can be Mitigated to less than significant
SU or PSU = Significant Unavoidable or Potentially Significant Unavoidable, cannot be mitigated to less than significant

[a] Under the Phased WSIP Variant through 2018, the SFPUC would limit the average annual SFPUC watershed deliveries to 265 mgd (approximately current levels).
[b] While the SFPUC would not make a decision about regional system deliveries for 2030 until 2018, for purposes of impact analysis a potential "worst-case" 2030 scenario was evaluated for the Phased WSIP Variant that assumes SFPUC watershed deliveries would increase after 2018 up to the 280 mgd level proposed under the Modified WSIP Alternative.

TABLE 13.11
SUMMARY OF SIGNIFICANT WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR PHASED WSIP VARIANT – ALAMEDA CREEK WATERSHED

Impact	Impact Description	Proposed Program – 2030	Phased WSIP Variant – 2018[a]	Phased WSIP Variant – 2030 Scenario[b]
Section 5.4.1, Stream Flow and Reservoir Water Levels				
Impact 5.4.1-2: Effects on flow along Alameda Creek below the diversion dam.				
	In all year types, system operations under the WSIP would increase diversions from Alameda Creek to Calaveras Reservoir between the months of December and May, nearly eliminating low and moderate (1 to 650 cubic feet per second) flows in Alameda Creek downstream of the diversion dam and substantially reducing many higher (greater than 650 cubic feet per second) flows that have occurred since 2002. The resultant reduction in stream flows and alteration of the stream hydrograph is considered an adverse effect.	SU	SU	SU
Section 5.4.5, Fisheries				
Impact 5.4.5-3: Effects on fishery resources.				
	Following implementation of the Calaveras Dam Replacement project (SV-2), operation of Calaveras Reservoir and the Alameda Creek Diversion Dam would be restored to pre-2002 conditions. A substantial increase in diversions from Alameda Creek to Calaveras Reservoir would reduce flows in this stretch of the creek, despite proposed bypass flows at the diversion dam. Diversion of most or all flows during late winter and spring months would reduce the ability of resident rainbow trout to spawn and for eggs to incubate; additional monitoring would be needed to determine the effectiveness of proposed bypass flows. In addition, the increased diversion of flows to the reservoir would divert fish from Alameda Creek to the reservoir, prevent fish passage to downstream reaches of the creek, and increase the potential for fish entrainment since there are currently no screens on the diversion.	PSM	PSM	PSM
Section 5.4.6, Terrestrial Biological Resources				
Impact 5.4.6-1: Impacts on riparian habitat and related biological resources in Calaveras Reservoir.				
▪ Sensitive habitats	Increased reservoir storage elevations would result in inundation and permanent loss of seasonal wetlands, seeps, perennial freshwater marsh, and riparian habitat that have established since 2002.	PSM	PSM	PSM
▪ Key special-status species	Since 2002, foothill yellow-legged frogs have occupied approximately 10,000 linear feet of stream channel along Arroyo Hondo between the maximum reservoir elevation mandated by the Division of Safety of Dams and the spillway elevation. Higher maintained reservoir levels would reduce the length of this high-quality habitat along the creek and adversely affect existing populations of foothill yellow-legged frog.	PSM	PSM	PSM
Impact 5.4.6-2: Effects on riparian habitat and related biological resources along Alameda Creek from below the diversion dam to the confluence with Calaveras Creek.				
▪ Key special-status species	A reduction in the frequency, duration, and magnitude of flows below the diversion dam would reduce the total available aquatic breeding habitat and food sources for California red-legged frog and foothill yellow-legged frog populations that currently occupy this reach of Alameda Creek.	PSM	PSM	PSM

TABLE 13.11 (Continued)
SUMMARY OF SIGNIFICANT WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR PHASED WSIP VARIANT – ALAMEDA CREEK WATERSHED

Impact	Impact Description	Proposed Program – 2030	Phased WSIP Variant – 2018[a]	Phased WSIP Variant – 2030 Scenario[b]
Section 5.4.6, Terrestrial Biological Resources (cont.)				
Impact 5.4.6-3: Effects on riparian habitat and related biological resources along Calaveras Creek from Calaveras Reservoir to the confluence with Alameda Creek.				
▪ Key special-status species	Future outlet works at Calaveras Dam would have the capacity to make higher-volume releases than under existing conditions. Depending on the timing and volume of operational releases, they could adversely affect the reproductive success of special-status amphibian species along this reach (e.g., California red-legged frog and foothill yellow-legged frog).	PSM	PSM	PSM
Impact 5.4.6-4: Effects on riparian habitat and related biological resources along Alameda Creek from Calaveras Creek to San Antonio Creek.				
▪ Key special-status species	Depending on annual rainfall and localized site conditions along this creek segment, changes in winter and summer flows along this reach could result in both beneficial and adverse impacts on habitat for California red-legged frog and foothill yellow-legged frog populations.	PSM	PSM	PSM
Section 5.4.7, Recreational and Visual Resources				
Impact 5.4.7-1: Effects on recreation.				
	Operations under the WSIP would substantially reduce flows along Alameda Creek in the Sunol Regional Wilderness during winter and early spring months and adversely affect the recreational experience for hikers. *(Note: The Draft PEIR determined this impact to be PSM, but due to the change in the project description of the Calaveras Dam Replacement project (SV-2), this impact determination is revised to LS.)*	LS	LS	LS
Impact 5.4.7-2: Visual effects.				
	WSIP-induced reductions in stream flows along Alameda Creek would substantially change the quality of visual resources in the Sunol Regional Wilderness. *(Note: The Draft PEIR determined this impact to be PSM, but due to the change in the project description of the Calaveras Dam Replacement project (SV-2), this impact determination is revised to LS.)*	LS	LS	LS

LS = Less than Significant, no mitigation required
SM or PSM = Significant or Potentially Significant, can be Mitigated to less than significant
SU or PSU = Significant Unavoidable or Potentially Significant Unavoidable, cannot be mitigated to less than significant

[a] Under the Phased WSIP Variant through 2018, the SFPUC would limit the average annual SFPUC watershed deliveries to 265 mgd (approximately current levels).
[b] While the SFPUC would not make a decision about regional system deliveries for 2030 until 2018, for purposes of impact analysis a potential “worst-case” 2030 scenario was evaluated for the Phased WSIP Variant that assumes SFPUC watershed deliveries would increase after 2018 up to the 280 mgd level proposed under the Modified WSIP Alternative.

TABLE 13.12
SUMMARY OF SIGNIFICANT WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR PHASED WSIP VARIANT – PENINSULA WATERSHED

Impact	Impact Description	Proposed Program – 2030	Phased WSIP Variant – 2018[a]	Phased WSIP Variant – 2030 Scenario[b]
Section 5.5.3, Surface Water Quality				
Impact 5.5.3-2: Water quality in Pilarcitos Reservoir and along Pilarcitos Creek.				
	Proposed operations would generally be within the same range as existing conditions, although replacement Measure 5.5.3-2a would cause Pilarcitos Reservoir to be drawn down earlier in the summer compared to existing conditions. Water temperature could increase and dissolved oxygen content could be reduced. *(Note: The Draft PEIR determined this impact to be PSM, and with the refined impact analysis for the Pilarcitos Creek watershed, this impact determination remains PSM due to impacts resulting from implementation of a replacement mitigation measure.)*	PSM	LS	PSM
	During dry years, summertime releases from Pilarcitos Reservoir to Pilarcitos Creek would be reduced to reservoir inflow at an earlier date than they are under the existing condition. This would increase the temperature of instream flows between Pilarcitos Creek and Stone Dam and reduce the creek's ability to support designated cold freshwater habitat along this reach.	PSM	LS	PSM
	During wet and above-normal years, the volume of spills over Stone Dam would be reduced compared to the existing condition.	LS	LS	LS
Section 5.5.5, Fisheries				
Impact 5.5.5-1: Effects on fishery resources in Crystal Springs Reservoir.				
	Elevated water levels in Crystal Springs Reservoir would inundate approximately 1,500 linear feet of trout spawning habitat upstream of the reservoir along Laguna and San Mateo Creeks.	PSU	PSU	PSU
Impact 5.5.5-4: Effects on fisheries resources in Pilarcitos Reservoir.				
	Proposed operations would be within the same range as existing conditions, although replacement Measure 5.5.3-2a would cause Pilarcitos Reservoir to be drawn down earlier in the summer compared to existing conditions. This would reduce the volume and quality of coldwater habitat available for resident fish species. *(Note: The Draft PEIR determined this impact to be PSM, and with the refined impact analysis for the Pilarcitos Creek watershed, this impact determination remains PSM due to impacts resulting from implementation of a replacement mitigation measure.)*	PSM	LS	PSM
Impact 5.5.5-5: Effects on fisheries resources along Pilarcitos Creek below Pilarcitos Reservoir.				
	Under the WSIP, the extended period of no or very little flow in Pilarcitos Creek below Pilarcitos Reservoir during summer months of dry years would result in significant impacts on resident trout, other resident fish species and aquatic resources, and habitat quality and availability for anadromous steelhead. Increased drawdown of Pilarcitos Reservoir would increase the temperature of releases in summer and fall and reduce the quality and availability of habitat for coldwater fish species.	PSM	LS	PSM

TABLE 13.12 (Continued)
SUMMARY OF SIGNIFICANT WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR PHASED WSIP VARIANT – PENINSULA WATERSHED

Impact	Impact Description	Proposed Program – 2030	Phased WSIP Variant – 2018[a]	Phased WSIP Variant – 2030 Scenario[b]
	A reduction in the frequency and magnitude of spills over Stone Dam would reduce flows along the lower reach. Reduced instream flows during winter months would adversely affect migratory fish habitat.	PSM	LS	PSM
Section 5.5.6, Terrestrial Biological Resources				
Impact 5.5.6-1: Impacts on biological resources in Upper and Lower Crystal Springs Reservoirs.				
▪ Sensitive habitats	Implementation of the Lower Crystal Springs Dam Improvements project (PN-4) would raise average monthly water levels in Crystal Springs Reservoir and result in a short-term reduction in the overall extent of freshwater marsh as the reservoir fills. Proposed changes in operations would maintain maximum reservoir levels during summer for longer periods than under existing conditions, which could affect the composition and structure of riparian habitats. In addition, sensitive upland habitats that are unable to tolerate these longer periods of inundation would be lost.	PSM	PSM	PSM
▪ Key special-status species	Elevated reservoir levels would inundate existing populations of special-status plant species, including serpentine-associated fountain thistle and Marin western flax, and their habitat could be permanently lost. The extent of available habitat for San Francisco garter snake and California red-legged frog would be temporarily reduced during reservoir refill, but wetland habitat that would establish at higher elevations could be more extensive. Raised reservoir levels would provide greater opportunities for largemouth bass and other predators to access frogs and snakes. Periodic drawdown during planned maintenance could adversely affect San Francisco garter snake foraging habitat.	PSM	PSM	PSM
▪ Other species of concern	Changes in wetland habitat due to reservoir refill and proposed operations would adversely affect reptile and bird species of concern, particularly if permanent changes in the composition of wetland vegetation occur. Permanent loss of upland habitat, including upland trees, grassland, and coastal scrub, would result in significant impacts on several bird and mammal species of concern. Serpentine- and grassland-associated plant species unable to tolerate extended periods of inundation would be lost.	PSM	PSM	PSM
▪ Common habitats and species	Due to the extent of area involved, impacts on common habitats and species would be significant.	PSM	PSM	PSM
Impact 5.5.6-4: Impacts on biological resources in Pilarcitos Reservoir.				
▪ Key special-status species	Proposed operations would be within the same range as existing conditions, although replacement Measure 5.5.3-2a would cause Pilarcitos Reservoir to be drawn down earlier in the summer compared to existing conditions. This would affect the extent of suitable habitat for California red-legged frog and San Francisco garter snake due to earlier reservoir drawdown in some years. Special-status species that utilize adjacent upland vegetation would not be affected. *(Note: The Draft PEIR determined this impact to be PSM, and with the refined impact analysis for the Pilarcitos Creek watershed, this impact remains PSM due to impacts resulting from implementation of a replacement mitigation measure.)*	PSM	LS	PSM

TABLE 13.12 (Continued)
SUMMARY OF SIGNIFICANT WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR PHASED WSIP VARIANT – PENINSULA WATERSHED

Impact	Impact Description	Proposed Program – 2030	Phased WSIP Variant – 2018[a]	Phased WSIP Variant – 2030 Scenario[b]
Impact 5.5.6-5: Impacts on biological resources along Pilarcitos Creek.				
▪ Sensitive habitats	In summer months of dry years, an extended period of no or little flow in Pilarcitos Creek between Pilarcitos Reservoir and Stone Dam could stress riparian vegetation, but existing vegetation appears to be adapted to periods of dryness. *(Note: The Draft PEIR determined this impact to be PSM, but due to the refined impact analysis for the Pilarcitos Creek watershed, this impact determination is revised to LS.)*	LS	LS	LS

LS = Less than Significant, no mitigation required
SM or PSM = Significant or Potentially Significant, can be Mitigated to less than significant
SU or PSU = Significant Unavoidable or Potentially Significant Unavoidable, cannot be mitigated to less than significant

[a] Under the Phased WSIP Variant through 2018, the SFPUC would limit the average annual SFPUC watershed deliveries to 265 mgd (approximately current levels).
[b] While the SFPUC would not make a decision about regional system deliveries for 2030 until 2018, for purposes of impact analysis a potential "worst-case" 2030 scenario was evaluated for the Phased WSIP Variant that assumes SFPUC watershed deliveries would increase after 2018 up to the 280 mgd level proposed under the Modified WSIP Alternative.

The WSIP would result in a reduction in the average annual volume of water released from O'Shaughnessy Dam and a change in the pattern of monthly and daily releases to the Tuolumne River below the dam (Draft PEIR, Vol. 3, Chapter 5, Section 5.3.1). The reduced release volume and altered flow regime would affect fisheries and terrestrial biological resources in the river below O'Shaughnessy Dam. Various quantitative factors or metrics were considered in determining the significance of the WSIP's impacts on fisheries and terrestrial biological resources. Several of the metrics relate to conditions in May, the month in which the effects of the WSIP would be the greatest in the reach of the river below O'Shaughnessy Dam. The following factors were evaluated over the 82-year hydrologic record:

- WSIP-caused reduction in average annual releases from O'Shaughnessy Dam
- Average WSIP-caused delay in May releases (in days)
- Maximum WSIP-caused delay in May releases (in days)
- Frequency of more than two-day delay in May releases caused by the WSIP
- Percentage reduction in May releases in all hydrologic years due to the WSIP
- Percentage reduction in May releases in dry years due to the WSIP
- Increase in the number of months when only minimum required releases are made as a result of the WSIP

These factors were considered together to arrive at significance conclusions with respect to the WSIP's impacts on fisheries and terrestrial biological resources in the Tuolumne River below O'Shaughnessy Dam, as shown in Table 13.10.

The WSIP would also result in a reduction in the average annual volume of water released from La Grange Dam and a change in the pattern of monthly and daily releases to the Tuolumne River below the dam. The reduced release volume and altered flow regime would affect fisheries and terrestrial biological resources in the river below La Grange Dam (see Vol. 3, Chapter 5, Section 5.3.1). A similar procedure (as was described above for the reach of the river below O'Shaughnessy Dam) was used to determine the significance of WSIP impacts on fisheries and terrestrial biological resources in the reach of the river below La Grange Dam. However, several of the metrics used in the analysis relate to conditions in June, because June is the month in which the effects of the WSIP would be greatest in this reach of the river.

Under the Phased WSIP Variant, while average annual deliveries from the SFPUC watersheds would be limited to 265 mgd such that there would be no increase in diversion from the Tuolumne River to serve additional demand, there would be a small increase in average annual Tuolumne River diversions of 2 mgd in order to implement the WSIP delivery and drought reliability elements for system customers through 2018. As a result of this small increase in average annual Tuolumne River diversion, like the WSIP, the Phased WSIP Variant with the 265 mgd delivery limitation from the SFPUC watersheds would result in a reduction in the average annual volume of water released from O'Shaughnessy Dam to the Tuolumne River, potentially affecting monthly and daily release patterns, (Vol. 3, Chapter 5, Section 5.3.1). Under the WSIP, the reduced volume and changed release pattern would have a potentially significant impact on the terrestrial biological resources of streamside meadows and other alluvial features in the reach of the river between Hetch Hetchy and Don Pedro Reservoirs, particularly in the sensitive Poopenaut Valley (Vol. 3, Chapter 5, Section 5.3.6). Although flow changes would be much less with the Phased WSIP Variant through 2018 than with the WSIP, the impacts of the Phased WSIP Variant on terrestrial biological resources was still determined to be *potentially significant* because of the sensitivity of biological resources in the Poopenaut Valley. Accordingly, under the Phased WSIP Variant with the 265 mgd delivery limitation from the SFPUC watersheds, the SFPUC would still need to implement Mitigation Measure 5.3.7-2, Controlled Releases to Recharge Groundwater in Streamside Meadows and Other Alluvial Deposits (Vol. 4, Chapter 6, pp. 6-49 and 6-50) to reduce potentially significant impacts on biological resources.

As described in the previous paragraph, under the Phased WSIP Variant there would be a small increase in average annual diversions from the Tuolumne River of 2 mgd in order to implement the delivery and drought reliability elements of the WSIP through 2018. As a result, like the WSIP, the Phased WSIP Variant would result in a reduction in the average annual volume of water released from La Grange Dam to the Tuolumne River and a change in monthly and daily release patterns, although again, it would be a much smaller reduction. Under the WSIP, the reduced volume and changed release pattern would have a potentially significant adverse impact on fisheries and terrestrial biological resources in the Tuolumne River below La Grange Dam. Flow changes with the Phased WSIP Variant with the 265 mgd delivery limitation from the SFPUC watersheds would be much less than those under the WSIP, and the impacts of the Phased WSIP Variant on fisheries and terrestrial biological resources were determined to be less than significant. However, as previously discussed in the description of the Phased WSIP Variant, while the SFPUC proposes to limit average annual deliveries from its watersheds to 265 mgd (approximately the current level), it recognizes that it might be necessary to allow a short-term increase in watershed deliveries beyond 265 mgd (up to 275 mgd) while the SFPUC and/or BAWSCA and the wholesale customers implement the local conservation, recycled water, and groundwater projects needed to meet increasing demands through 2018. For the purpose of impact analysis, it was assumed conservatively that watershed deliveries could increase above 265 mgd for a few years until all of the local projects needed to generate the required 20 mgd of local supply and conservation have been fully implemented. In addition, a conservative, worst-case assumption of a short-term increase in watershed deliveries to 275 mgd was used. If the 265 mgd limit on watershed deliveries were exceeded, then there could be potentially significant impacts on the lower Tuolumne River during that time, until average annual diversions were reduced to 265 mgd (representing existing conditions). Although the impacts on the lower Tuolumne River would be of lesser magnitude than those of the WSIP (which assumed a watershed delivery level of 290 mgd) and would be temporary (on the order of a few years), the potential effects of the Phased WSIP Variant on fisheries and terrestrial biological resources in this reach of the river are conservatively considered to be *potentially significant*. The SFPUC would monitor annual water deliveries from its watersheds, and, if average annual deliveries from the SFPUC watersheds exceeded the 265 mgd limit, the SFPUC would implement Mitigation Measure 5.3.6-4a, Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water, or 5.3.6-4b, Fishery Habitat Enhancement and Measure 5.3.7-6, Lower Tuolumne River Riparian Habitat Enhancement. The SFPUC would continue to implement the necessary measure(s) until the average annual SFPUC watershed deliveries are 265 mgd or less. Similar to the WSIP, implementation of Measure 5.3.6-4a is the preferred mitigation approach, and for the Phased WSIP Variant, the amount of conserved water required to reduce the impact to less than significant would be proportional to the amount of increased diversions from the Tuolumne River contributing to exceeding the 265 mgd restriction.

Alameda Creek Watershed

The significant impacts of the WSIP and the Phased WSIP Variant in the Alameda Creek watershed are shown in Table 13.11. The impacts of the Phased WSIP Variant, both with and without the 265 mgd limitation on SFPUC watershed deliveries, and the impacts of the WSIP would be the same or very similar. The reason the impacts in the Alameda Creek watershed would be the same or similar is that they would result primarily from facility improvements and restoration of the historical reservoir capacity at Calaveras Reservoir rather than from demand increases. Facility improvements would be the same for the WSIP and the Phased WSIP Variant.

Peninsula Watershed

The significant impacts of the WSIP and the Phased WSIP Variant in the Peninsula watershed are shown in Table 13.12. The impacts of the Phased WSIP Variant, both with and without the 265 mgd limitation on SFPUC watershed deliveries, and the impacts of the WSIP in the San Mateo Creek watershed would be the same or very similar. The reason the impacts in this watershed would be the same or similar is that they would result primarily from implementation of the facility improvement projects and restoration of Crystal Springs Reservoir capacity rather than from demand increases. Facility improvements would be the same for the WSIP and the Phased WSIP Variant.

With both the WSIP and the Phased WSIP Variant under the “worst-case” 2030 scenario (without the 265 mgd delivery limitation from the SFPUC watersheds), Pilarcitos Reservoir would be drawn down at an earlier date in some summers than it is under the existing condition (Vol. 3, Chapter 5, Section 5.5.1). As a result, releases to Pilarcitos Creek from the reservoir would be reduced to reservoir inflow earlier in the year than under the existing condition. The flow reduction in the creek between Pilarcitos Reservoir and Stone Dam would have a significant adverse impact on water quality and fisheries. In addition, under the WSIP and the 2030 Phased WSIP Variant scenario, the volume of wintertime spills over Stone Dam would be reduced compared to the existing condition. The reduction in the volume of spills would have an adverse impact on fisheries in Pilarcitos Creek below Stone Dam. These same phenomena would occur with the Phased WSIP Variant through 2018 with the 265 mgd delivery limitation, but their magnitude would be much less than with the WSIP. Consequently, the impacts of the Phased WSIP Variant through 2018 on water quality and fisheries in Pilarcitos Creek were determined to be less than significant. Under the Phased WSIP Variant through 2018, no mitigation measures would be needed in the Pilarcitos Creek watershed.

Secondary Effects of Growth

The Phased WSIP Variant would have the same growth-inducement potential through 2018 as the WSIP because the SFPUC (possibly with the cooperation of BAWSCA and the wholesale customers) would provide the additional water supply to meet 2018 purchase requests. However, depending on the decision on water supply in 2018, this variant could result in less growth inducement if the SFPUC decides to maintain the 265 mgd restriction on deliveries from the SFPUC watersheds, or on the high end, it could result in the same growth-inducement potential as the WSIP if it decides to fully meet a 2030 purchase request of 300 mgd. Similar to the WSIP, any growth-inducement increment attributable to this variant would be considered significant and unavoidable.

14. Master Responses

14.1 Master Response on WSIP Purpose and Need

14.1.1 Introduction

Overview

This master response addresses the issues commenters raised on the need for and objectives of the WSIP. Commenters were concerned with the overall combination of goals and objectives of the WSIP as well as with the level of detail provided in the Draft PEIR on these issues. Many commenters expressed an opinion that the Draft PEIR did not adequately describe the needs and deficiencies of the regional water system and the importance for improving the seismic and delivery reliability of the system.

The Draft PEIR provides background information on the purpose and need for the WSIP but does not discuss these issues in great depth; however, these issues do factor into the decision-making process (i.e., project approval), the WSIP bond measure, and the selection of the CEQA alternatives. This master response emphasizes and expands on the benefits of the proposed program but does not address comments related to the program's environmental effects; those comments are bracketed and responded to separately in Chapter 15 and/or in other master responses as appropriate.

This master response is organized by the following subtopics:

14.1.2 Purpose of the WSIP
14.1.3 Need for Seismic Reliability
14.1.4 Need for Water Supply and Drought Reliability
14.1.5 Seismic Improvements and Water Supply
14.1.6 Economic Evaluation of the Need for the WSIP

Summary of Issues Raised by Commenters

- Requests for a more detailed discussion of the overall need for the WSIP and of the potential consequences of not implementing the proposed program.
- Requests for a more detailed discussion of the importance of the WSIP to public health and safety.
- Requests for an expanded description of the needs and deficiencies of the existing regional water system.

Response

As described in the Draft PEIR (Vol. 1, Chapter 2, p. 2-1), the SFPUC developed and designed the WSIP to increase the overall reliability of the regional water system which services 2.4 million people in San Francisco, San Mateo, Santa Clara, Alameda, and Tuolumne Counties. The reliability of the water infrastructure system is of vital importance to the public health, safety, and drinking water needs of the Bay Area, including the welfare of residents, universities, state institutions, health care facilities, businesses, commercial and industrial complexes, and research and development facilities. The San Francisco Bay Area employs millions of Californians and generates billions of dollars in exports and tax revenues to the state. Catastrophic failure of the regional water system would be disastrous for public health and safety, and for the regional and state economies. Failure of the regional water system would present serious implications for Bay Area communities, including for the most vulnerable segments of the population—homebound elderly, children, hospital and nursing home patients, and families that could be displaced from their homes—particularly if failure of the regional system were to happen concurrent with earthquakes and fire. In addition, damage to water supply infrastructure in the event of an earthquake could result in uncontrolled releases of water from pipelines, tunnels, and reservoirs and create severe flood damage and environmental harm to fish and wildlife habitat in the communities in which water facilities are located, which stretch 160 miles from Yosemite National Park to San Francisco.

Existing Needs and Deficiencies

Maintenance Needs

Regular maintenance of regional facilities is needed to maintain the seismic and delivery reliability of the overall system. As described in the Draft PEIR (Vol. 1, Chapter 2, p. 2-1), the regional water system is comprised of over 280 miles of pipeline, over 60 miles of tunnels, 11 reservoirs, 5 pump stations, and 2 water treatment plants. Many of these components were built in the 1800s and early 1900s using now-outdated construction materials and/or methods, and were not designed to meet modern seismic engineering standards. Pipelines, tunnels, treatment and pumping facilities, and other related facilities all require maintenance (see Draft PEIR, Vol. 1, Chapter 2, Section 2.3.6). Maintenance of these facilities, which includes inspections and minor repairs/upkeep as well as major repairs, replacement, and/or rehabilitation, is a fundamental part of regional system operations and often requires that these facilities be completely shut down for up to 45 days or more. The most important facilities to maintain are also the most critical for system operations, making it inherently difficult to take them out of service for extended periods of time for inspection or repair. As a result, several key components of the system, including tunnels, dams, and other critical regional water system facilities, have been poorly maintained or have not been not maintained at all for decades.

Deferred Maintenance Has Reduced Overall System Reliability

As described in the Draft PEIR (Vol. 1, Chapter 2, pp. 2-27 and 2-28), unplanned outages have occurred periodically throughout the regional system for various reasons, including aging and deteriorating infrastructure. Specific examples of facility outages that have recently occurred include:

- In August 1996, a rupture in San Joaquin Pipeline No. 3 due to failure of the pipeline material resulted in a reduction of water delivered from the Hetch Hetchy system to the Bay Area, from 230 million gallons per day (mgd) to 150 mgd for a period of three weeks. The pipeline failure caused an unplanned discharge of over 10 million gallons of water at a rate of 200 to 400 cubic feet per second, flooded the surrounding cattle range land, and created a 1,000-foot-long erosion gully. In November 2002, there was another similar rupture in a different location on the same pipeline.

- In 1990, the 60-inch-diameter San Andreas No. 3 prestressed-concrete pipeline ruptured violently in an urban area of South San Francisco, sending waves of water across a schoolyard and turning cars over.

- During the 1996/1997 rainy season, a landslide originating on the hillside above the Crystal Springs Bypass Pipeline buried a 350-foot segment of the roadway in which the pipeline is aligned. The pipeline was taken out of service for several months to prevent a potentially disastrous discharge if the pipeline were to break. This incident revealed the vulnerability of the Crystal Springs Bypass Pipeline to seismically induced landslides.

Because funding has not been provided to replace facilities at the end of their service life, a tremendous amount of resources go into repairing broken equipment, which in turn causes facility outages, delays in operational schedules, and a shift of resources away from scheduled maintenance programs. Aging pump stations, such as the Baden, Crystal Springs, and San Antonio Pump Stations, are particularly susceptible to equipment failures and could result in outages or decreased operating capacity. Deteriorating valves that operators use to control pipe flow are critical links that affect the SFPUC’s ability to isolate facilities for maintenance; some valves were historically installed without a redundant line or isolation valves, making them difficult or impossible to exercise and maintain without shutting down the system.

Pipelines are particularly susceptible to leakage or failure along segments where there is prestressed-concrete cylinder piping; leakage or failure has occurred in recent years on parts of the San Joaquin No. 3, San Antonio, Bay Division No. 4, Crystal Springs No. 2, and San Andreas No. 3 Pipelines, the repair of which has taken from several days to several months. Seismic safety and flooding issues at Calaveras Dam and Lower Crystal Springs Dam (described below under the heading Reduced Storage Capacity) have restricted the normal operating capacity of the system. The deferred maintenance and inspections of key infrastructure, such as the Irvington, Pulgas, and Crystal Springs Bypass Tunnels, have increased the susceptibility of the system to failure and unplanned outages. The frequency and magnitude of unplanned outages would be substantially reduced with increased replacement at the end of service life, increased operating flexibility, and regular maintenance and inspection, thereby substantially improving overall system reliability.

Seismic Vulnerability

Many of the key components of the regional water system are located in a seismically active region. The Draft PEIR (Vol. 2, Chapter 4, pp. 4.4-4 to 4.4-13) describes the regional faulting and seismic hazards along the SFPUC regional water system. The major faults in the vicinity of the regional water system are shown in Figure 4.4-1 (pp. 4.4-7 and 4.4-8). As shown in Figure 4.4-1, several key storage, transmission, and treatment facilities are traversed by, or located very near to, one or more active faults. All four of the major transmission pipelines that carry water from the East Bay to the South Bay, Peninsula, and San Francisco communities are intersected by one or more active faults. Calaveras Reservoir (in Alameda County), and San Andreas and Crystal Springs Reservoirs (in San Mateo County) are traversed by the Calaveras and San Andreas faults, respectively. Further, as described in the Draft PEIR, the U.S. Geological Survey Working Group on California Earthquake Probabilities concluded that there is a 62 percent probability of a magnitude 6.7 or greater earthquake, capable of causing widespread damage, occurring in the San Francisco Bay region in the 30-year period between 2003 and 2032 (Vol. 2, Chapter 4, p. 4.4-5). Although the San Joaquin region is relatively seismically inactive compared to the Bay Area, earthquakes on any of the active faults in the greater Bay Area could also produce groundshaking and associated seismic hazards in this region. The combination of outdated building methods, aging infrastructure, lack of deferred maintenance, and regional seismicity place several of the key facilities at a high risk of catastrophic failure in the event of a major earthquake. As discussed in the Draft PEIR (Vol. 1, Chapter 3, pp. 3-27 and 3-28), the results of seismic reliability studies conducted by the SFPUC indicate that a major earthquake on the San Andreas, Hayward, or Calaveras fault under existing conditions could result in unplanned outages and a drastic disruption of service to all SFPUC customers for more than 14 days and possibly more than 30 days. Refer to Section 14.1.3 below for additional information regarding the vulnerability of the regional water system to seismic hazards.

Need for Drought Planning and Preparedness

Past experience with droughts has reinforced the critical importance of planning for future drought events. The term “drought event” refers to all years or sequences of years when hydrological/meteorological conditions indicate that water supplies may not be adequate to fully meet customer demands and the SFPUC needs to modify its operating procedures and implement drought response actions (Draft PEIR, Vol. 1, Chapter 3, Section 3.5.4). As described in the Draft PEIR (Vol. 1, Chapter 2, Section 2.3.5), the regional water system has experienced drought periods in the last 30 years, most notably the droughts from 1976 to 1977, and from 1987 to 1992. As the 1987–1992 drought progressed, the SFPUC was forced to adopt a mandatory rationing program to impose rationing on customers that resulted in a near 25 percent annual systemwide reduction in water deliveries. Due to the wide variation in types of water users in the regional service area, the program resulted in a wide variation in cutbacks experienced by different customers, ranging from about 20 percent in areas with cooler climates to 40 percent in areas with warmer climates. In the later stages of the six-year drought, the SFPUC initiated programs to achieve a 45 percent reduction in systemwide deliveries, but these programs were averted when a series of storms in March 1991 provided relief.

The potential impacts of a severe drought are based on the frequency, duration, severity, and spatial extent of the drought, and the degree to which a population, water user, or sector of the economy is vulnerable to the effects of a drought (e.g., rainfall/runoff, amount of water in storage, availability of supplemental dry-year supplies). As discussed below, a reduction in the overall storage capacity due to reservoir restrictions imposed by the Division of Safety of Dams (DSOD) has reduced the system firm yield of the regional water system and further impaired the ability of the system to meet water deliveries to current customers during a prolonged drought. Major droughts (such as the 1987–1992 drought) can have substantial direct and indirect impacts on the state and regional economy, environment, and society as a whole. Direct impacts of drought are characteristically biophysical and include reduced water levels, increased fire hazards, a reduction in agricultural production and forest productivity, and adverse impacts on wildlife and fisheries, among others. Indirect impacts are consequential and can include impacts on public health and safety, increased food prices, reduced quality of life, reduced income for water-intensive industries, and increased unemployment. Studies indicate a 30 percent chance that the regional water system will experience a drought in the next 75 years that is equal to or more severe than the 1987–1992 drought, the most extreme recorded drought to affect the regional system (see Draft PEIR, Vol. 1, Chapter 3, p. 3-14). As described below, the future storage capacity and system firm yield of the regional water system are two factors affecting the vulnerability of the system to future drought impacts.

Reduced Storage Capacity

The regional water system is highly dependent on storage to be able to serve water under a variety of meterological/hydrological and operating conditions. While the Hetch Hetchy system provides the majority of water to the regional system, local Bay Area reservoirs are operated to maximize the yield for water deliveries and carryover storage and to provide critical backup or redundancy in the event of water quality problems, transmission disruptions in the Hetch Hetchy system, emergencies, critical maintenance, and droughts. In 1983, the DSOD placed operating restrictions on Lower Crystal Springs Dam due to concerns regarding the ability of the dam to retain water during major flood events, reducing the historical water storage capacity of Crystal Springs Reservoir by approximately 10,900 acre-feet, or about 15 percent (see Draft PEIR, Vol. 1, Chapter 2, Table 2.2, p. 2-6). In terms of operating storage capacity, the DSOD restrictions on Crystal Springs Reservoir are equivalent to 1 mgd of water (annual average over 8.5-year design drought) (Vol. 1, Chapter 3, p. 3-36).

In 2001, the DSOD also placed interim operating restrictions on Calaveras Dam due to the dam's inability to meet current seismic stability criteria at normal operating levels. The restrictions on

Calaveras Dam reduced the total storage capacity of the reservoir by 60 percent and the total, combined working storage capacity of the SFPUC's local reservoirs by over 30 percent. From the perspective of emergency preparedness, the DSOD restriction on Calaveras Dam has reduced the SFPUC's total reservoir storage, including its emergency storage capacity, by over 58,000 acre-feet (see Vol. 1, Chapter 2, pp. 2-10 and 2-11). The loss of operating storage capacity at Calaveras Reservoir resulting from the DSOD restrictions represents an equivalent of 7 mgd of water (annual average over 8.5-year design drought) (Vol. 1, Chapter 3, p. 3-36). Thus, the DSOD restrictions and related decreases in reservoir storage capacities currently impair the ability of the regional system to adequately serve customer water demands in the event of water quality problems, transmission disruptions in the Hetch Hetchy system, emergencies, critical maintenance, and droughts.

Reduced System Firm Yield

"System firm yield" refers to the average annual water delivery that can be sustained throughout an extended drought. As described above, DSOD operating restrictions on Lower Crystal Springs and Calaveras Dams have reduced system firm yield, impairing the SFPUC's ability to serve water deliveries to current customers during an extended drought (Vol. 1, Chapter 2, p. 2-25). In normal and wet years, when there is a system upset such as unusual water quality conditions in any of the SFPUC reservoirs, the regional system includes a number of operational bypasses and backup facilities that allow the SFPUC to modify normal operations in order to serve existing water demand and continue to meet water quality standards. The DSOD operating restrictions placed on Lower Crystal Springs and Calaveras Dams have reduced the system firm yield such that, under the existing condition, the regional water system is even more constrained in its ability to meet existing water demand during a prolonged drought. Without supplemental dry-year water supplies and the restoration of historical water storage capacity in Bay Area reservoirs, the SFPUC cannot meet current demand at its desired goal of no greater than 20 percent rationing in any single year of a drought. These conditions would be further exacerbated by future increases in water demand, resulting in potentially disastrous effects on the communities, businesses, and economy of the Bay Area.

Background and Development of the WSIP

The overall need for and objectives of the WSIP are described in the Draft PEIR (Vol. 1, Chapter 3, p. 3-5). The need for a comprehensive, systemwide program to address the existing needs and deficiencies described above, as well as to plan for future needs, is predicated on the basic mission of the SFPUC, which is in part:

> To serve San Francisco and its Bay Area customers with reliable, high-quality and affordable water, while maximizing benefits from power operations and responsibly managing the resources entrusted to its care.

The WSIP would address the existing needs and deficiencies of the regional water system; that is, decreased seismic and delivery reliability and increased risk of failure due to aging and deteriorating infrastructure; increased vulnerability to seismic hazards due to proximity to active earthquake faults and because certain facilities were historically constructed with building materials that do not meet current seismic standards; the need for system upgrades to improve the

SFPUC's ability to maintain compliance with current water quality standards and to meet anticipated future water quality standards under a range of operating conditions without reducing system reliability; the lack of adequate infrastructure redundancy, which would remove constraints to maintenance and improve delivery reliability in the event of an emergency or system failure; and insufficient water supplies to satisfy current water demand in drought years. In addition, implementation of the WSIP would address the ability of the regional water system to serve projected 2030 demand (purchase requests) in all hydrologic year types and improve overall system reliability.

Reliability, Hydraulic, and Hydrologic Models

The SFPUC began planning for major system improvements over a decade ago and has conducted numerous planning and engineering studies of the regional water system with respect to its vulnerability, reliability, performance, operations, water supply, watershed management, and water quality. As described in the Draft PEIR (Vol. 1, Chapter 3, Section 3.4), the SFPUC primarily used three models—reliability, hydraulic, and hydrologic models—to determine the appropriate performance objectives and level of service goals and to develop the scope of the WSIP facility improvement projects.

- *Reliability Model*. This statistical model was used to evaluate the ability of the system to meet identified targets when subjected to earthquakes on the San Andreas, Hayward, and Calaveras faults, as well as to quantify the risk of system components to failure when subjected to earthquake hazards under both existing and improved conditions.

- *Hydraulic Model*. The hydraulic model was used to determine transmission pipeline and tunnel capacities, which were then used as input to the hydrologic model (see below) to analyze system operations under existing and potential alternative future conditions. This model was used to analyze the hydraulic characteristics of the existing water system and to assist in determining facility sizing for WSIP facility improvement projects.

- *Hydrologic Model*. This model, referred to as the Hetch Hetchy/Local Simulation Model (HH/LSM), was used to simulate the monthly operation of all major water transmission and storage facilities in the regional water system under existing conditions, and to predict system operation under various alternative future conditions using historical hydrology for the 82-year period from July 1920 to September 2002. For additional information on the HH/LSM, see Draft PEIR Section 5.1 (Vol. 3, Chapter 5) and Appendix H (Vol. 5) as well as **Section 14.5, Master Response on Water Resources Modeling** (Vol. 7, Chapter 14).

Water Supply Studies

To provide guidance on addressing the needs of the regional water system through 2030, the SFPUC prepared several studies that evaluated various water supply options based on facilities requirements, costs, environmental effects, water quality impacts, and institutional and regulatory issues (described in Draft PEIR Vol. 1, Chapter 3, Section 3.4.1). The water supply studies provided guidance on demand management strategies and needed improvements related to system infrastructure. The studies also examined drought-related strategies for meeting customer demand during extended periods of drought. The water supply options analyses resulted in the proposed water supply strategy described in the Draft PEIR (Vol. 1, Chapter 3, pp. 3-33 to 3-39).

System Performance Studies

To evaluate the vulnerability and reliability of the regional water system, the SFPUC conducted extensive engineering analyses and studies as described in the Draft PEIR (Vol. 1, Chapter 3, pp. 3-15 and 3-16). The studies used a statistical, risk-based approach to examine hazards and deficiencies at existing facilities, assessed their reliability, and determined the risk to the overall system presented by hazards such as earthquakes, landslides, flood, fire, and general wear and tear under a range of conditions. The SFPUC conducted system assessment and performance analyses of the WSIP with respect to seismic and delivery reliability over the identified range of conditions, and developed level of service objectives for seismic and delivery reliability. The results of the engineering studies indicated that the existing system would fail to meet the WSIP seismic and delivery level of service objectives under most operating conditions, and that the performance of the system would continue to decline in the future if no improvements were made. These results were used to develop the numerous facility improvement projects that address the identified system deficiencies, particularly with respect to aging infrastructure and seismic hazards. Refer to the discussion under the heading Need for Seismic Reliability, below, for more detailed information regarding the seismic analyses conducted by SFPUC and the level of service objectives used to develop WSIP facility improvement projects.

Water Demand Studies

To assess future water needs in the SFPUC service area through 2030, the SFPUC, in collaboration with its wholesale customers and the Bay Area Water Supply and Conservation Agency (BAWSCA), conducted comprehensive planning studies to assess future water demands as well as the potential for water conservation programs and the use of recycled water to offset demand for potable water supplies in retail and wholesale customer areas (Vol. 1, Chapter 3, Section 3.4.4). Upon completion of the demand, conservation, and recycled water studies, the wholesale customers and the SFPUC (for the retail service area) submitted their best estimates of purchases from the SFPUC regional system in 2030. A high-range estimate of 300 mgd was used for planning purposes to establish the delivery reliability and water supply objectives for the proposed program. This 300 mgd accounts for a level of customer-committed conservation/recycled water programs and use of other supplies, as summarized in the SFPUC planning studies in Draft PEIR Table 3.3 (Vol. 1, Chapter 3, p. 3-18) and Table 7.2 (Vol. 4, Chapter 7, p. 7-15). Refer to **Section 14.2, Master Response on Demand Projections, Conservation, and Recycling** (Vol. 7, Chapter 14) for a detailed description of customer demand projections as well as the conservation programs and recycling projects proposed by the SFPUC in San Francisco and by the SFPUC's wholesale customers in their respective service areas.

WSIP Goals and Objectives

The goals and objectives of the WSIP are founded on two fundamental principles pertaining to the existing regional water system: (1) maintaining a clean, unfiltered, water source from the Hetch Hetchy system, and (2) maintaining a gravity-driven system. The WSIP goals and objectives are presented in Table 3.2 of the Draft PEIR (Vol. 1, Chapter 3, p. 3-9). In summary, the overall goals of the WSIP for the regional water system are to:

- Maintain high-quality water and a gravity-driven system
- Reduce vulnerability to earthquakes
- Increase delivery reliability and improve maintenance of facilities
- Meet customer water supply needs in nondrought and drought conditions
- Enhance sustainability
- Achieve a cost-effective, fully operational system

Proposed WSIP Levels of Service

To achieve the these goals and system performance objectives, the WSIP also identifies level of service goals that describe and, in many cases, more specifically quantify what the regional water system proposes to achieve under the WSIP, and that thereby guide the water supply actions, facility improvements, operations, and maintenance requirements included in the proposed program. The proposed changes in levels of service with implementation of the WSIP as compared to existing conditions are shown in Table 3.5 of the Draft PEIR (Vol. 1, Chapter 3, p. 3-26). The WSIP level of service goals can be summarized as follows:

- *Water Quality Level of Service*. Ensure compliance with all existing and anticipated federal, state, and local drinking water requirements under a range of operating conditions, including catastrophic events such as a major earthquake.

- *Seismic Reliability Level of Service*. Reduce the regional system's vulnerability to earthquakes; provide basic service to at least 70 percent of customer turnouts in each region within 24 hours after a major earthquake; and restore facilities to meet average-day demand within 30 days after a major earthquake.

- *Water Delivery Reliability Level of Service*. Address the overall operations of the regional system with respect to its ability to deliver water to customers under a variety of conditions, such as reservoir replenishments during planned maintenance, unplanned outages, and loss of any one water source.

- *Water Supply Level of Service*. Assure an adequate supply of water to deliver to customers through the 2030 planning horizon during both nondrought and drought periods, and provide drought-year delivery with a maximum systemwide rationing of 20 percent.

In addition to program goals and objectives in the areas of water quality, seismic reliability, delivery reliability, and water supply, the WSIP includes program goals and objectives in the areas of sustainability and cost-effectiveness.

WSIP Facility Improvement Projects

The WSIP facility improvement projects and proposed water supply option and associated modifications in system operations have been designed to meet the level of service objectives and to ensure the water delivery needs are served in the SFPUC service area through 2030 while reducing impacts on the environment and on existing resources. Table 3.10 of the Draft PEIR (Vol. 1, Chapter 3, pp. 3-49 to 3-56) describes the WSIP facility improvement projects that are necessary to improve the regional water system to meet the goals and objectives of the WSIP with respect to seismic reliability, water quality, delivery reliability, and water supply. The table also shows the objectives to which each individual facility project contributes.

Proposed Water Supply Option

As described in the Draft PEIR (Vol. 1, Chapter 3, Section 3.6), under the WSIP the SFPUC would serve its customers in nondrought years through increased diversions of Tuolumne River and local watershed sources to supplement current Tuolumne River diversions and local watershed supplies in combination with 10 mgd of groundwater/recycled water/conservation projects in San Francisco. During drought periods, the SFPUC would augment the nondrought water supplies with implementation of a groundwater conjunctive-use program in the Westside Groundwater Basin, water transfers with the Turlock and Modesto Irrigation Districts, and restoration of the capacities of Calaveras and Crystal Springs Reservoirs; dry-year delivery assumes a maximum 20 percent systemwide rationing in any one year of a drought.

Management and Asset Management Strategy

As described in the Draft PEIR (Vol. 1, Chapter 3, Section 3.7.4), as part of the proposed changes in system operations, the WSIP includes implementation of a Management and Asset Management Strategy that includes provisions for regular maintenance, repair and replacement, and renewal. The plan uses a 20-year timeline and focuses initially on the major transmission pipelines and tunnels of the regional water system under the WSIP, but can be expanded to a more comprehensive maintenance program to cover the maintenance needs for other facilities in the regional system, including dams, powerhouses, chemical stations, pump stations, treatment plants, balancing reservoirs, valve lots, and other pipelines. The improvements to the transmission system under the WSIP would allow the SFPUC to meet its maintenance goals. System operations under the WSIP would allow planned facility inspection, repair, and maintenance without interrupting customer service, and the SFPUC could schedule planned facility shutdowns to accommodate ongoing system demand. Overall, the proposed program would enable the SFPUC to conduct previously deferred maintenance and repair work throughout the regional system, thereby extending the useful life of facilities and improving overall system reliability.

14.1.3 Need for Seismic Reliability

Summary of Issues Raised by Commenters

- The Draft PEIR does not adequately describe the urgent need for seismic repairs and catastrophic consequences of system failure in the event of an earthquake.

Response

The Draft PEIR clearly identifies seismic hazards as one of the fundamental driving forces in the development of the WSIP. The Draft PEIR (Vol. 2, Chapter 4, pp. 4.4-4 to 4.4-13) describes the regional faulting and seismic hazards along the SFPUC regional water system. Figure 4.4-1 (pp. 4.4-7 and 4.4-8) shows the major active and potentially active faults in the vicinity of the system. One of the WSIP's overall goals for the regional water system is to reduce vulnerability to earthquakes, and the system performance objectives for seismic reliability indicate that the WSIP facility improvement projects would be designed to meet current seismic standards, to deliver basic service to the service area within 24 hours after a major earthquake, and to restore facilities within 30 days after a major earthquake (Vol. 1, Chapter 3, pp. 3-8 and 3-9). These goals and objectives recognize the need to improve the system's ability to prepare for and withstand an earthquake as well as to restore services following an earthquake.

WSIP System Assessment for Level of Service Objectives

As described in the Draft PEIR (Vol. 1, Chapter 3, Section 3.4.2), the SFPUC conducted an extensive series of seismic reliability analyses to evaluate the delivery reliability of existing facilities and the performance of the overall system following a major earthquake event on the San Andreas fault (magnitude 7.9), Hayward fault (magnitude 7.3), and Calaveras fault (magnitude 6.9). The seismic analyses accounted for all of the hazards associated with these earthquakes, including groundshaking, surface fault rupture, liquefaction, and landslides. The results of the analyses were used to estimate the underlying questions posed by each of the level of service objectives:

- **Delivery After a Major Earthquake** – How much water would be delivered by the regional water system after a major earthquake?
- **Percentage of Turnouts that Receive Water** – What percentage of the turnouts in each customer group would receive water after an earthquake?
- **Post-Earthquake Recovery** – How would the regional system recover after an earthquake? After 30 days, how much would the system be able to deliver?

The seismic reliability analysis identified the ability of the existing system to meet quantitative level of service objectives, identified and described the deficiencies in the existing system, and identified the WSIP projects that are needed to meet the level of service objectives. Delivery reliability following a major earthquake was evaluated on a customer group basis, and delivery to individual turnouts within a customer group could vary. The three customer groups in the service area consisted of the South Bay (Alameda/Santa Clara/southern San Mateo County), Peninsula (northern San Mateo County), and San Francisco. Because seismic hazards and damage to facilities following an earthquake cannot be predicted in an exact manner, the uncertainty inherent in the analysis is estimated at 10 percent, meaning that there is a 10 percent or less chance that the actual delivery or percentage of turnouts that receive water would be less than shown.

The post-earthquake delivery analysis estimated how much water the regional system could deliver after a major earthquake to each customer group, and the percentage of turnouts within each customer group that would receive water. **Table 14.1-1** shows the estimated volume of water the

TABLE 14.1-1
DELIVERY WITHIIN 24 HOURS AFTER A MAJOR EARTHQUAKE

Customer Group	Level of Service Objective (mgd)	San Andreas Fault		Hayward Fault		Calaveras Fault	
		Existing System (mgd)	With WSIP (mgd)	Existing System (mgd)	With WSIP (mgd)	Existing System (mgd)	With WSIP (mgd)
South Bay	104	27	122	10	131	0	145
Peninsula	44	3	54	3	61	3	64

Total System	229	30	267	24	278	3	297

SOURCE: SFPUC, 2006.

system could deliver, expressed in million gallons per day (mgd), following a major earthquake. The results of the analysis indicate that the existing system falls drastically short of meeting the level of service objective of delivering a systemwide total of 229 mgd and providing basic service to at least 70 percent of the turnouts within each customer group within 24 hours after a major earthquake on any of the three major regional faults. For example, the studies estimated that after a major earthquake on the Calaveras fault, the existing system would only deliver a total of 3 mgd to all customer groups, which falls 226 mgd short of the systemwide WSIP level of service objective, and would not be capable of delivering any water to the South Bay and San Francisco customer groups. In fact, the analysis estimated that under any of the three earthquake scenarios, no water would be delivered to San Francisco. After completion of the WSIP, the analysis indicated that the regional system would be capable of meeting the delivery level of service objective systemwide and individually for each customer group (SFPUC, 2006).

Table 14.1-2 shows the estimated percentage of turnouts within each customer group that would receive water within 24 hours following a major earthquake. The results of the analysis indicate that the regional water system without implementation of the WSIP would deliver basic service to an estimated 0 to 14 percent of the turnouts in each customer groups, compared to the 70 percent WSIP level of service objective. After full implementation of the WSIP, the percentage of turnouts under each customer group that would receive water would exceed the level of service objective (SFPUC, 2006).

The post-earthquake recovery analysis determined the percentage of water the regional water system would be capable of delivering 30 days after a major earthquake. This analysis included a facility outage scenario that assumed that facilities with a probability of failure greater than 25 percent would be out of service after the occurrence of a major earthquake, and used estimated repair times as a basis for determining how many of the damaged facilities would be brought back to service after 30 days. The delivery capability of the system was then estimated based on the facilities that could be returned to service in 30 days. As shown in **Table 14.1-3**, 30 days after a major earthquake on the San Andreas fault, the regional system would only be capable of delivering 8 mgd to San Francisco; 31 mgd would be delivered to San Francisco following a major earthquake

TABLE 14.1-2
PERCENTAGE OF TURNOUTS THAT WOULD RECEIVE WATER WITHIN 24 HOURS AFTER A MAJOR EARTHQUAKE

Customer Group	Level of Service Objective	San Andreas Fault		Hayward Fault		Calaveras Fault

on the Hayward fault, compared to the 86 mgd level of service objective for San Francisco. The critical outages under the San Andreas earthquake scenario include the Harry Tracy Water Treatment Plant (WTP), Bay Division Pipelines Nos. 1 and 2, and Sunset and University Mound Reservoirs. For the Hayward earthquake, the critical outages include the Irvington Tunnel, Bay Division Pipelines Nos. 1 and 2, Bay Division Pipelines Nos. 3 and 4, and Harry Tracy WTP (SFPUC, 2006).

Table 14.1-4 shows the most critical WSIP projects that help address the seismic reliability deficiencies and contribute to meeting the seismic reliability objectives. The table also indicates the seismic event for which the project is critical and the seismic benefits provided. As indicated in Tables 14.1-1 through 14.1-3, following completion of all WSIP facility improvement projects, the reliability of deliveries that would be achieved immediately after a major earthquake, the percentage of turnouts that would receive basic water service immediately after an earthquake, and the level of delivery that could be restored after 30 days would meet or exceed the WSIP level of service objectives.

TABLE 14.1-4
KEY WSIP PROJECTS FOR SEISMIC RELIABILITY

	WSIP Facility Improvement Project	Earthquake Scenario			Seismic Reliability Benefits and Deficiencies Addressed

14.1.4 Need for Water Supply and Drought Reliability

Comment Summary

This section of this master response responds to all or part of the following comments:

S_CSA-01	L_BAWSCA1-11	L_LosAltosH-01	L_Milpts-01
L_BAWSCA1-03	L_BAWSCA1-112	L_PHWD1-01	L_MtnVw-01
L_BAWSCA1-04	L_LAHCFD-01	L_PHWD2-02	L_SClara2-01

Summary of Issues Raised by Commenters

- The Draft PEIR does not adequately describe the impacts on public health and safety that would result from disruption of water service following an earthquake.
- Requests for additional discussion of the importance of drought reliability.

Response

Importance of Water Supplies Following an Earthquake

The SFPUC recognizes that the dependability of public utilities and infrastructure following an earthquake is a major concern with respect to public health and safety. Strong groundshaking produced by a major earthquake on the San Andreas, Hayward, or Calaveras fault could cause serious damage to water transmission and distribution facilities and rupture gas mains and fuel lines. Interruption of water supplies resulting from damage to distribution or transmission infrastructure could disrupt the delivery of vital emergency and government services, threatening public health and safety as well as the environment. The ability of the regional system to deliver water immediately after an earthquake would be especially important for firefighting if ruptured gas mains and fuel lines were to start fires, as occurred following the San Francisco earthquake of April 18, 1906, which toppled buildings and caused gas and water mains to twist and break, crippling the city's water supply. The loss of water in the San Francisco distribution and transmission system following the earthquake caused 4.5 square miles of San Francisco to burn to the ground, left over 200,000 people homeless, and caused hundreds of deaths (USGS, 2008).

As stated in the Draft PEIR (Vol. 1, Chapter 3, p. 3-28), the results of the SFPUC's seismic reliability studies indicated that, under existing conditions, a major earthquake on the San Andreas, Hayward, or Calaveras fault would result in unplanned outages and a drastic disruption of service to all SFPUC customers for more than 14 days and possibly more than 30 days. During the first days following an earthquake, most people in areas with water outages could likely obtain drinking and cooking water from bottled water suppliers. Within a day or two, water for sanitation, personal hygiene, and food cleaning and preparation could become scarce, resulting in an increased risk of infection and gastroenteritis. Disruptions in the delivery of potable water through the municipal distribution system could impair the ability of hospitals and health care institutions to provide services, and these facilities could be overwhelmed by the need for additional services.

As described in the Draft PEIR (Vol. 1, Chapter 3, pp. 3-27 and 3-28), implementation of the WSIP would greatly reduce the regional system's vulnerability to earthquakes and would enable the SFPUC to ensure water service to customers within a defined period following a major earthquake. Critical facilities would be upgraded to meet current seismic standards to improve the system's ability to withstand seismic damage, and construction of redundant facilities and backup/standby power would improve the SFPUC's ability to restore service following a major earthquake.

Impacts of Drought

As evidenced by the 1987–1992 drought, reductions in water supplies during a prolonged drought event can result in impacts on residential users, businesses, industry, and government. Severe and prolonged rationing can limit the use of water supplies to serve basic human needs and can increase fire risk. As described above in Section 14.1.2, the regional system is currently operating at a reduced system firm yield due to DSOD restrictions on local dams and reservoirs, and, in the event of an extended drought, the SFPUC would have to impose systemwide rationing similar to that imposed during the historical droughts, possibly up to 25 percent.

As described in the Draft PEIR (Vol. 1, Chapter 3, pp. 3-31 and 3-32), implementation of the WSIP would greatly reduce the regional system's vulnerability to droughts and would enable the SFPUC to reduce both the frequency and magnitude of systemwide rationing. The system firm yield would be increased to 256 mgd, and there would be supplemental dry-year water supplies, which would increase overall system reliability and reduce the potential hardship on customers during droughts. Although a maximum systemwide rationing of 20 percent could still be imposed, the frequency of this level of rationing would be greatly reduced, estimated to occur approximately once every 41 years over the 82-year hydrologic record (Vol. 4, Chapter 9, Table 9.5, p. 9-13).

14.1.5 Seismic Improvements and Water Supply

Summary of Issues Raised by Commenters

- The San Francisco Planning Department, as lead agency, should use a two-tiered approach for CEQA review that separates the seismic improvements from the WSIP water supply and additional Tuolumne River diversions.

Response

California case law, statutory requirements by the state and federal governments, and the SFPUC's contractual obligations to its wholesale customers require that the SFPUC develop a comprehensive plan that ensures the provision of water supplies in a manner that addresses demand and water supply availability under various hydrological/meteorological scenarios as well as in the event of natural disasters and catastrophes. These regulatory provisions and contractual obligations require the SFPUC to secure a reliable water supply capable of serving demand, implement the necessary facility upgrades, construct new facilities to meet future conditions, and design such facilities with sufficient capacities to meet future conveyance needs. Particularly with a complex system such as the SFPUC regional water system, these components must be developed through an integrated planning process in order to effectively achieve level of service goals and objectives and to avoid wasteful expenditures through improper design. Because full implementation of these components is necessary to achieve the level of service goals and objectives, a programmatic approach to CEQA compliance is needed to capture the full spectrum of environmental impacts and to ensure that appropriate CEQA alternatives are developed based on the same level of service goals and objectives.

As a public water utility, the SFPUC is vested with a public interest to provide services considered vital for public health and welfare. The SFPUC is granted special rights (e.g., the right to pursue eminent domain and acquisition of water rights under state law, rights-of-way under the Raker Act) by the government and is heavily regulated to ensure public safety. Under the common law doctrine,[1] the SFPUC, like other public water utilities, holds several obligations to the public, including a "duty to serve" and continuity of service. The "duty to serve" principle requires that the SFPUC adequately and efficiently serve all members of the public located within its service area in a reasonable, non-discriminatory manner. Beyond this obligation, the SFPUC must ensure continuity of service in a safe and reliable manner, which requires that the SFPUC maintain excess capacity to ensure spikes and seasonal peaks in demand can be accommodated and do not drain existing supplies (Monte de Ramos, 2004).

The SFPUC, like all major urban water suppliers, must look ahead many years in order to secure new water supplies to meet growing demands and undertake the capital programs required to meet that demand. The California Urban Water Management Planning Act (California Water Code, Division 6, Part 2.6, Sections 10610 through 10656), as amended in 2001, was passed in response to the California legislature's concern that the state's water supply agencies might not be engaged in adequate long-term planning. The act requires water suppliers generally, and the SFPUC and its wholesale customers, to prepare and update urban water management plans at five-year intervals that describe and quantify, to the extent practicable, future water demand, water supplies, and water reliability in five-year increments, to a minimum of 20 years or as far as data are available. The projected 20-year water supply must account for three scenarios: a normal or average water year; a single dry water year; and multiple dry water years.

1 Common law refers to the body of laws not currently expressed in statutes or previously codified; these types of laws are created by precedent and are upheld by past precedential decisions in relevant courts.

In predicting 20-year water demands, urban water agencies must rely on "data from the state, regional, or local service agency population projections." Thus, for example, to the extent that any of the wholesale customers with land use planning authority served by the SFPUC (chiefly cities) anticipate large population increases in their adopted general plans, those customers are required to identify how existing and planned water sources meet planned development. General plans (prepared by the local land use agency) and the urban water management plan (prepared by the urban water supplier) design a blueprint of the municipality's growth over the next 20 years and ensure the water supplies are sufficient to serve the zoning actions of the local land use agency. Within the regional water system, in some cases the local land use agency and the urban water supplier are the same entity, and in many cases they are not. Under California Water Code Sections 10910 through 10912, as amended in 2001 (also known as Senate Bill [SB] 610), an urban water supplier must consult with the cities and counties in its service area when those entities propose development projects of a certain magnitude (e.g., residential projects with more than 500 dwelling units or a retail or business establishment employing more than 1,000 persons or having more than 250,000 square feet). The water supplier must accommodate future development projects either by identifying the water sources available to serve such development or by identifying the plans it would follow to obtain new water supplies for such development, unless the water supplier "finds and determines that the ordinary demands and requirements of water customers cannot be satisfied without depleting the water supply of the distributor to the extent that there would be insufficient water for human consumption, sanitation, and fire protection" (also see California Water Code Section 350).

Urban water suppliers are also subject to 2001 state legislation commonly known as the "Kuehl Bill" (SB 221), after its author State Senator Sheila Kuehl (see Government Code Section 66473.7). SB 221 requires any city or county considering the approval of a proposed subdivision map for more than 500 units to consult with the relevant water supply agency to determine whether adequate water is available for the proposed subdivision, as well as for "existing and planned future uses" (including agriculture) over the next 20 years, under "normal, single-dry, and multiple-dry year" scenarios. If water supplies are inadequate, SB 221 expressly allows a developer to work with the urban water supplier to pursue new supplies. This legislation prohibits local land use agencies from approving a project if supplies are insufficient and, like the Urban Water Management Planning Act, requires urban water suppliers to constantly consider and take the necessary steps to address the growth planned for the next 20 years by the cities and counties within the supplier's service area.

Existing contractual agreements between the SFPUC and its wholesale customers, which are represented by BAWSCA, obligate the SFPUC to supply an annual average of 184 mgd to its wholesale customers, subject to reductions in the event of a drought, water shortage, earthquake, or other natural disaster, or rehabilitation or maintenance of the system. The 184 mgd is referred to as "the supply assurance" and remains effective following termination of the 1984 Settlement Agreement and Master Sales Water Contract (Master Water Sales Agreement) held between the SFPUC and each of its wholesale customers. In addition to the Master Water Sales Agreement, the SFPUC holds individual wholesale water contracts that specify the SFPUC's obligations to each customer (see Draft PEIR Vol. 1, Chapter 2, Section 2.5.5).

In addition to the SFPUC's obligations to provide water to its retail and wholesale customers in consideration of future growth within its service area, the state legislature has mandated that the SFPUC rebuild and seismically retrofit the regional water system. California Assembly Bill (AB) 1823, known as the Wholesale Regional Water System Security and Reliability Act, imposes various requirements on wholesale regional water systems and applies directly to the City and County of San Francisco (CCSF) and the SPFUC regional water system. Designed to protect the health, safety, and economic well-being of the 2.4 million people that depend on the regional water system, AB 1823 provides a process to ensure that the system is rebuilt and retrofitted as soon as possible. AB 1823 includes the requirement that the regional water system be retrofitted so as to distribute water on an equitable basis during an interruption of supply after an earthquake or other catastrophe (California Water Code, Division 20.5, Section 73500).

For the reasons described above, the SFPUC addressed future growth and water demand and could not disregard supply augmentation issues during the formulation of the WSIP. Further, facility improvements designed in accordance with future capacity requirements avoid wasteful expenditures and improper design. As described in the Draft PEIR (Vol. 1, Chapter 3, pp. 3-1 to 3-9), the WSIP establishes program goals for improvements to the regional system and level of service objectives for system performance in the areas of water quality, seismic reliability, delivery reliability, and water supply. The proposed facility improvement projects and water supply and system operations under the WSIP are an integrated whole designed to meet the program objectives and enable the SFPUC to continue to fulfill its basic mission of providing reliable, high-quality water to its customers. Thus, the SFPUC developed the WSIP as a comprehensive program to improve the regional system, and the San Francisco Planning Department determined that the collection of WSIP facility improvement projects combined with the water supply and system operations modifications should be treated as a single, integrated program during CEQA analysis. Only this programmatic approach was capable of capturing the full spectrum of environmental impacts and ensuring that appropriate CEQA alternatives were developed based on the same level of service goals and objectives.

The PEIR has been prepared as a program EIR in compliance with CEQA Guidelines Section 15168(a), which specifies that a program EIR may be used to evaluate a plan or program that has multiple components (projects and actions) or to address a series of projects or actions that cover a broad geographic scale. The PEIR addresses the environmental effects of the WSIP as a *whole program*, the purpose of which is to improve the ability of the regional water system to deliver water to the SFPUC service area through the year 2030 and to increase the overall reliability of the system.[2] To accomplish this goal, the Draft PEIR includes a combination of program-level and project-level analyses. The PEIR provides a program-level analysis of the major environmental effects of implementing the WSIP facility improvement projects, including those related to seismic improvements, and identifies programmatic mitigation measures to

2 Although implementation of all of the WSIP projects is required to fully meet the program objectives, the San Francisco Planning Department has determined that several of the WSIP projects have independent utility for CEQA purposes and can undergo environmental review independent of the PEIR. The independent utility projects would not: increase SFPUC water supplies, increase the normal operating capacity of the regional water system, change the manner in which water is dispersed, increase the storage capacity of the system, or increase or alter the nature of the treatment capacity of the system.

reduce the impacts of these projects. The program-level analysis in the Draft PEIR frames the nature and magnitude of these effects and assumes that more detailed, project-level review of the individual projects will be conducted separately as provided for under CEQA. In addition to the program-level analysis of the proposed improvements, the Draft PEIR also evaluates the overall effects associated with implementing the WSIP as a whole. This evaluation includes an analysis of the combined impacts resulting from construction of all of the WSIP facility improvement projects (Vol. 2, Chapter 4, Section 4.16) as well as a project-level impact analysis of implementing the proposed water supply option through 2030 (Vol. 3, Chapter 5). By evaluating the environmental effects of both the facility improvement projects and the proposed water supply option, the PEIR provides a more comprehensive analysis of environmental effects and alternatives than would be practical on a project-by-project basis and allows for the consideration of broad-policy alternatives and program-wide mitigation measures early in the process. In addition, preparation of a program EIR has ensured the consideration of cumulative impacts that might not have been evident in the separate, project-level analyses.

The SFPUC takes seriously its duties to provide sufficient water supplies to its customers when such supplies are needed to serve planned growth and to meet its contractual obligations. As a prudent water system manager, the SFPUC chose to consider future demand at the same time it identified necessary seismic upgrades. From an engineering and design standpoint, it would have been imprudent, impractical, and inefficient for the SFPUC to conduct an overall assessment of how to make the system stronger and more reliable without also considering future demand during the 20-year planning period imposed by law.

Finally, CEQA does not preclude the CCSF from considering supply augmentation components together with seismic retrofit and upgrade components. No provision of CEQA prevents an agency from combining various elements together as one project. In fact, agencies have broad discretion to define projects as they see fit, and thus have substantial leeway in selecting the components of a project analyzed in a single EIR. Therefore, it is entirely within the CCSF’s discretion to combine components related to seismic safety and reliability as well as water supply augmentation into a single, long-term project (i.e., the WSIP).

As described in Section 13.4 (Vol. 7, Chapter 13), subsequent to the publication of the Draft PEIR, the SFPUC requested that the PEIR include environmental review of a variation of the WSIP referred to as the Phased WSIP Variant. This variant, developed in response to comments received on the Draft PEIR, would consist of full implementation of the proposed WSIP facility improvement projects together with phased implementation of the water delivery component. This variant would achieve the WSIP goals and level of service objectives for water quality and seismic and delivery reliability, but it would defer a decision regarding long-term water supply until after 2018. Nonetheless, as discussed in Section 13.4, the PEIR analyzes the potential environmental effects of the Phased WSIP Variant as an integrated program and describes the range of potential effects that could occur by 2030 under this variant. Consistent with CEQA guidelines for a program EIR, this PEIR addresses the Phased WSIP Variant as a whole program and determined that the environmental effects fall within the range of alternatives already evaluated in the Draft PEIR. Please refer to Section 13.4, Phased WSIP Variant (Vol. 7, Chapter 13), for further discussion.

14.1.6 Economic Evaluation of the Need for the WSIP

Comment Summary

This section of this master response responds to all or part of the following comments:

Summary of Issues Raised by Commenters

- The economic impacts of mandatory rationing should be addressed in the PEIR.
- An economic analysis of the environmental effects on Tuolumne County residents, businesses, and tourism should be conducted prior to approving additional diversions from the Tuolumne River.

Response

Under CEQA, the economic impacts of a proposed project are not treated as significant impacts on the environment (CEQA Guidelines Section 15131[a]). While economic evaluations are beyond the scope of this PEIR, CEQA Guidelines Section 15131(b) states that the "economic or social effects of a project may be used to determine the significance of physical changes caused by the project."

CEQA requirements aside, with respect to the economic impacts of mandatory rationing on wholesale customers, it is not clear that the WSIP level of service objective of a maximum 20 percent systemwide rationing would result in physical changes sufficient enough to warrant an analysis of its economic effects. With implementation of the WSIP, the regional system firm yield would increase to 256 mgd, and the overall system reliability with respect to delivery to customers during droughts would improve substantially over existing conditions. The results of the HH/LSM modeling of the proposed program indicate that the frequency of 20 percent systemwide rationing would be about 2 out of the 82 years, or 1 in 41 years (Vol. 4, Chapter 9, Table 9.5, p. 9-13). This infrequent rationing would not result in substantial physical environmental effects.

Furthermore, the possibility that a lower rationing objective (e.g., 15 percent) might result in a different future economic scenario than the 20 percent objective does not translate into an adverse environmental effect of the 20 percent rationing objective proposed under the WSIP. For CEQA purposes, the key comparison is between existing conditions and future conditions with the WSIP (and its 20 percent rationing objective), and this comparison shows a very considerable improvement over current conditions rather than any adverse effects. This improvement would in part take the form of reduced economic consequences compared with those that would occur in the event of a major earthquake or similar disaster under the No Program Alternative. Any economic impacts under a future 20 percent rationing scenario and a future 15 percent rationing scenario cannot be characterized as an adverse effect or consequence of adopting the 20 percent rationing objective.

The 20 percent maximum systemwide rationing objective proposed under the WSIP is lower than the maximum rationing objectives of other large water agencies in California. For example, the East Bay Municipal Utility District (EBMUD), which serves a population of approximately 1.3 million in parts of Alameda and Contra Costa Counties, and the Metropolitan Water District of Southern California, which serves a population of 14.8 million, both maintain a maximum rationing reduction goal of 25 percent during critical water supply shortages (EBMUD, 2005; Metropolitan Water District of Southern California, 2005). Most importantly, however, is the fact that implementation of the WSIP would also improve the performance of the regional water system under both drought and nondrought conditions, thus resulting in an overall benefit to retail and wholesale customers compared to the existing condition by reducing the magnitude and frequency of significant water shortages.

While economic evaluations are beyond the scope of the PEIR, the Draft PEIR does analyze the environmental effects that some commenters perceive could cause economic impacts for Tuolumne County residents, businesses, and tourism. The Draft PEIR analyzed the effects of the WSIP on Tuolumne River stream flows to identify any consequent impacts on recreational as well as other resources, and determined that the WSIP would not substantially alter stream flows such that they would be outside the range of pre-project conditions (Vol. 1, Chapter 5, pp. 5.3.1-21 to 5.3.1-39). The Draft PEIR (Vol. 3, Chapter 5, Section 5.3.8) also evaluated the effects of the WSIP on recreational resources, including whitewater rafting in the Tuolumne River and Cherry Creek. The analysis concluded that impacts on recreation would be less than significant, and that no mitigation was required. The impact of the WSIP on whitewater rafting was determined to be typically limited to a delay in releases from Hetch Hetchy Reservoir by an average of two days (and up to eight days) in May or June of most years. Thus, the impact analysis suggests that, because the alteration of stream flows under the WSIP would be within the range of pre-project conditions, and typically limited to a delay in releases by an average of two days, the economic effects would be very modest, if noticeable at all. The Draft PEIR analysis indicates that the WSIP would not result in economic effects that would in turn result in a significant degradation of the physical environment.

14.2 Master Response on Demand Projections, Conservation, and Recycling

14.2.1 Introduction

Overview

This master response addresses comments and questions about water demand projections, water use patterns, and the effectiveness and extent of conservation measures and recycled water programs within the SFPUC service area to offset demand for potable water. Commenters raised questions about the water demand models used in the wholesale and retail service areas and the differences between the two models, the levels of employment growth assumed in the demand models, the efforts of the SFPUC and its wholesale customers to implement conservation and recycled water programs, and whether more could be done in these areas to limit the increase in future demand for potable supplies. The demand projections and estimates of 2030 purchases necessarily entail the use of assumptions about factors that cannot be known or predicted with absolute certainty. With respect to forecasting, CEQA Guidelines Section 15144 states the following:

> Drafting an EIR or preparing a Negative Declaration necessarily involves some degree of forecasting. While foreseeing the unforeseeable is not possible, an agency must use its best efforts to find out and disclose all that it reasonably can.

The analysis in the Draft PEIR is consistent with CEQA Guidelines Section 15144. The Draft PEIR analysis describes in detail the demand methodology (Vol. 5, Appendix E.2) and presents a detailed review and comparison of the demographic projections used in the demand models with more recent projections (Vol. 4, Chapter 7, p. 7-22, and Vol. 5, Appendix E.3).

The comments addressed in this master response largely critique the SFPUC's demand projections as too high and the conclusions regarding conservation and recycled water potential as too low. As discussed in this response, the SFPUC and its technical consultants relied on reasonable assumptions and used accepted methodologies to forecast demand and conservation and recycled water potential within the service area, and the Draft PEIR reflects the City and County of San Francisco's (CCSF) best efforts at analysis and disclosure. Even if the SFPUC overestimated demand and underestimated conservation and recycled water potential, the likely effect would be a reduction in the use of water from the Tuolumne River and local watersheds, which could result in a reduction in impacts on those watersheds. Also, to the extent the SFPUC has overestimated demand based on growth projections, the PEIR may overestimate the impacts associated with induced growth. The comments regarding the accuracy of conservation and recycled water potential may be taken into account by decision-makers in evaluating the feasibility of alternatives, but do not indicate that the PEIR underestimated the impacts of the WSIP.

This master response is organized by the following subtopics:

14.2.2 Demand Projections and Methodology
14.2.3 Conservation and Recycling

Commenters

Table 14.2-13, presented at the end of Section 14.2, lists the commenters that submitted comments on water demand projections, conservation, and recycling.

PEIR Section Reference

The Draft PEIR addresses demand projections, conservation, and recycling in the following locations: Vol. 1, Chapter 3, Section 3.3 (introduction) and Section 3.4.4, pp. 3-8 and 3-16 to 3-22; Vol. 4, Chapter 7, Sections 7.1.2, 7.2.2, 7.3 (introduction), 7.3.1, 7.3.2, 7.3.3, 7.3.4, and 7.3.6, pp. 7-6 to 7-8, 7-14 to 7-33, and 7-34 to 7-58; and Vol. 5, Appendices E.2 and E.3.

Summary of Issues Raised by Commenters

Numerous comments asserted that the modeling used to project future water demand was flawed. The more specific comments asserting that "the demand analysis is flawed" or that the analysis results in "inflated demand" stem from three main criticisms of the demand methodology: (1) the use of the Association of Bay Area Government's (ABAG) *Projections 2002* as the source of nonresidential (employment) growth rates; (2) the use, in the wholesale customer service area, of ABAG's forecasts of total jobs rather than industry-specific projections, which (commenters assert) (a) fails to capture differences in growth rates of different nonresidential sectors, and (b) fails to account for different water use rates by different sectors; and (3) the fact that the future price of water is not included as a factor in the demand models. Other comments focused on the results of the demand projections. On the whole, the comments fell into the following categories:

- Employment projections – use of ABAG's *Projections 2002*
- Use of total jobs projections for the wholesale customer service area
- Effects of the future cost of water on projected demand
- Per-capita demand
- Substantiation of the need for sizable water supply increases
- Outdoor water use
- Requests that demand projections be reevaluated

This master response presents an overview of the demand projections and related studies conducted for the WSIP, followed by a discussion of each of the topics listed above; specific comments addressing these issues are summarized, followed by a response.

Overview of Demand Projections Conducted for the WSIP

As described in the Draft PEIR (Vol. 1, Chapter 3, p. 3-16 and 3-17, and Vol. 5, Appendix E.2), the SFPUC, in collaboration with its wholesale customers and the Bay Area Water Supply and Conservation Agency (BAWSCA), conducted comprehensive planning studies from 2002 to 2006 to assess future water demands as well as the potential for water conservation programs and the use of recycled water to offset demand for potable water supplies in its retail and wholesale customer service areas. These studies, which provided a basis for 2030 water purchase estimates from the SFPUC regional water system, include the following:

- SFPUC Wholesale Customer Water Demand Projections Technical Report (URS, 2004a)
- SFPUC Wholesale Customer Water Conservation Potential Technical Report (URS, 2004b)
- SFPUC Wholesale Customer Recycled Water Potential Technical Memorandum (RMC, 2004)
- City and County of San Francisco Retail Water Demands and Conservation Potential (Hannaford and Hydroconsult, 2004)
- City and County of San Francisco Recycled Water Master Plan (RMC, 2006)
- SFPUC 2030 Purchase Estimates Technical Memorandum (URS, 2004c)

The studies established total demand for the 2000/2001 base year in the entire SFPUC service area from all water sources (about 366 million gallons per day [mgd]), of which about 261 mgd was purchased from the SFPUC regional water system. SFPUC wholesale customers met the balance of their supply needs from other water sources and conservation. The demand studies project that total service area demand in 2030 is approximately 417 mgd.[1] Of this total, approximately 300 mgd would be purchased from the SFPUC system; the remaining 117 mgd would be met through other supply sources available to customers, primarily water purchases from other agencies, customers' local groundwater sources, additional water recycling, and conservation. For the water conservation and recycled water potential studies, the SFPUC and its technical consultants worked in close consultation with the wholesale customers to identify suites of theoretically feasible and cost-effective conservation programs for each customer and to determine each customer's potential to develop recycled water projects that might replace part of their demand that would otherwise be met by potable supplies. Based on this information, the customers submitted their best estimates of 2030 water purchases from the SFPUC. Each customer's estimates of conservation savings and the use of recycled water, groundwater, and other supply sources as well as its 2030 purchase estimate is shown in Draft PEIR Table 3.3 (Vol. 1, Chapter 3, p. 3-18) as well as Table 7.2 (Vol. 4, Chapter 7, p. 7-18).

The Draft PEIR (Vol. 1, Chapter 3, pp. 3-17 to 3-20 and Vol. 5, Appendix E.2) summarizes the steps involved in establishing base-year water usage and projecting future demand to 2030 using end-use demand models for the wholesale and retail customer service areas. Demand Side Management Least-Cost Planning Decision Support System (DSS) end-use models[2] were used in the wholesale service area and a similar end-use model was used in the retail service area. As the PEIR indicates, the SFPUC selected the end-use models over other forecasting methods (such as forecasting water use by land use type or on a simple per-capita basis) because end-use models allow for a more accurate representation of changing conditions, such as the future impact of plumbing and appliance codes and the effects of additional specific-use planned conservation (URS, 2004a).

In addition, as described in the Draft PEIR (Vol. 4, Chapter 9, pp. 9-47 to 9-51), the SFPUC, in cooperation with its wholesale customers and BAWSCA, undertook a study to assess the potential for additional conservation and recycled water projects, including potential regional projects, that were not already considered to be implemented locally by 2030 as part of the WSIP purchase estimates. The results of this study provided the basis for the Aggressive Conservation/ Water Recycling and Local Groundwater Alternative evaluated in the Draft PEIR (Vol. 4, Chapter 9, pp. 9-47 to 9-59) as well as an element of the Modified WSIP Alternative (Vol. 4, Chapter 9, pp. 9-78 to 9-84).

1 Total 2030 demand (417 mgd) includes expected savings due to compliance with existing plumbing codes, which contain efficiency requirements. Total SFPUC service area 2030 demand without plumbing code savings is estimated at 453 mgd.
2 A DSS model was prepared to forecast demand for each wholesale customer (URS, 2004a).

Employment Projections – Use of ABAG's *Projections 2002*

Representative comments on this topic include:

- *Wholesale demand study may overestimate future employment, thereby inflating 2030 nonresidential demand. [SI_PacInst-08, SI_TRT-CWA-SierraC-01]*
- *Employment projections used in the demand model were based on ABAG employment projections released in 2002. In 2005, ABAG revised the employment projections for the nine-county San Francisco Bay Area:* Projections 2005 *forecasts over 46,000 fewer jobs than* Projections 2002. *[SI_PacInst-76]*
- *The wholesale demand study may overestimate future employment, thereby inflating 2030 nonresidential demand. Recent data indicate that the economic recovery in the San Francisco Bay Area has been slower than expected and consequently the job outlook for the region has been adjusted downward. A slower economy would reduce projected water demand for the nonresidential sector. The demand forecast should be adjusted according to the most current information available. [SI_TRT-CWA-SierraC-31]*
- *Demand modeling methodology used employment projections from ABAG that are inflated. The SFPUC used employment projections from 2002 that were updated in 2005. The later projections showed 48,000 fewer jobs[3] in the Bay Area. Using the projections published by ABAG in 2005 would result in another lower projected demand for water. In going from Draft to Final PEIR, the latest employment projections should be incorporated and the water demand projections altered accordingly. [SI_TRT6-02]*
- *Outdated ABAG employment projections from 2002 were used. 2005 data became available, which decreased the employment projections moving into the future, which means less growth in the commercial sector, which means less water use. [SI_TRT9-04]*
- *The projected employment growth is substantially greater than the projected population growth. While employment growth can exceed population growth, such a large discrepancy is highly unusual given the low unemployment rate in the region. This suggests the need for a reevaluation with another more realistic employment projection. [SI_PacInst-77]*
- *The projections rely on faulty urban growth statements that in turn rely on published studies that don't cover the time period up to 2030 and have not undergone environmental review. [SI_SierraC6-02, SI_SierraC7-03]*

Response

Comparison of Projections 2002 and Projections 2005

Projections 2002 was the current ABAG projections series at the time the water demand estimates were prepared. As such, it was the appropriate projections series to use at that time. Since then, *Projections 2003*, *2005*, and *2007* have been released. The Draft PEIR (Vol. 4, Chapter 7, pp. 7-22 to 7-26, and Vol. 5, Appendix E.3, pp. E.3-9 to E.3-35) reviews changes between ABAG *Projections 2002*, *2003*, and *2005* and compares the later projections to the

[3] Because *Projections 2005* reports a finding of 46,000 fewer new jobs compared to *Projections 2002* and does not indicate a difference of 48,000 jobs in its analysis, it is assumed that this reference to 48,000 jobs is a misstatement, and that the commenter refers to the comparison of the two projections series discussed in *Projections 2005* and this response.

assumptions used in projecting 2030 water demand. (*Projections 2007* was released after Draft PEIR preparation and could not be considered prior to publication of the environmental document.) The review indicates that, although the later projections series (2003 and 2005) have lower estimates of current (2005) employment and somewhat steeper growth curves between 2005 and 2030, the general trends for the three are similar; the net result of the two principal changes in the later projections series (lower current population and employment combined with more growth between now and 2030) is that the estimates for the WSIP horizon year of 2030 are similar (Vol. 4, Chapter 7, p. 7-22 to 7-25).

Table 14.2-1 presents the comparison shown in Draft PEIR Table E.3.31 (Vol. 5, Appendix E.3, p. E.3-33) with supplementary information on percentages. The table quantifies the variation in employment estimates for the nine-county Bay Area, the four-county area served in whole or part by SFPUC water, and the area generally served by SFPUC water customers.

TABLE 14.2-1
ABAG PROJECTIONS OF EMPLOYMENT IN 2025 AND 2030: SUMMARY COMPARISON

Area	Year	Projections 2002	Projections 2003	Projections 2005	Projections 2003 as % of Projections 2002	Projections 2005 as % of Projections 2002	Projections 2005 as % of Projections 2003
Nine-County Bay Area	2025	4,932,590	4,982,800	4,788,330	101%	97%	96%
	2030		5,226,400	5,120,600			98%
Four-County Area	2025	3,682,510	3,739,920	3,516,890	102%	96%	94%
	2030		3,911,320	3,765,020			96%
SFPUC Water Customers[a]	2025	2,169,600	2,184,360	2,032,650	101%	94%	93%
	2030		2,265,410	2,173,400			96%

[a] Estimates for the wholesale service area are based on the geographic area assignments used in the Draft PEIR (see Vol. 5, Appendix E.3, Tables E.3.A.1 and E.3.A.2, pp. E.3-48 and E.3-49), which are more generalized than those used for the actual demand projections.

SOURCE: Draft PEIR, Vol. 5, Appendix E.3, Table E.3.31, p. E.3-33.

Although *Projections 2002* does not provide forecasts for 2030, the text discussion in *Projections 2005* presents a comparison of the expectations of job growth from 2000 to 2030 for the two projections series. According to that discussion, *Projections 2005* forecasts 46,000 fewer new jobs for the nine-county Bay Area by 2030 than does *Projections 2002*, as noted in some comments.[4] *Projections 2005* provides this comparison of *Projections 2002* and *Projections 2005* employment (and population) growth for the period from 2000 to 2030 as a way to highlight the changes resulting from the smart-growth assumptions that were incorporated into the ABAG methodology beginning with *Projections 2003*. With respect to this comparison, ABAG states:

[4] The website cited by one commenter as the source for the *Projections 2002–Projections 2005* comparison (http://planning.abag.ca.gove/currentfcst/summary1.html) no longer provides the information cited in the comment. It is assumed that the information cited (“ABAG Projections 2005: Summary of Findings”) is similar to the text discussion introducing and summarizing *Projections 2005* discussed herein.

> The earlier forecast, with some caveats, can be viewed as a "base-case" forecast. In other words, *Projections 2002* is an estimate of future activity in the Bay Area without the implementation of Smart Growth policies (ABAG, 2004, p. 4).

The comparison of *Projections 2002* and *Projections 2005* presented in *Projections 2005* includes a table comparing the projected job growth of the two projections series by county, as well as for the nine-county region as a whole (ABAG, 2004, pp. 4 to 7). Information from this table for the four counties served in whole or part by SFPUC water is presented in **Table 14.2-2**. As shown, *Projections 2005* forecasts 22,930 fewer new jobs for the four-county area by 2030 than does *Projections 2002* (as compared to 46,000 fewer for the nine-county region).

TABLE 14.2-2
COMPARISON OF PROJECTED EMPLOYMENT GROWTH (NEW JOBS): PROJECTIONS 2005 AND PROJECTIONS 2002

	Change in Employment, 2000–2030 (Number of New Jobs)		
County	**Projections 2002**	**Projections 2005**	**Difference**
Alameda County	314,540	338,710	24,170
San Francisco County	161,810	186,590	24,780
San Mateo County	128,060	120,500	-7,560
Santa Clara County	360,160	295,840	-64,320
Total	**964,570**	**941,640**	**-22,930**

NOTE: Information shown is for the entire county.

SOURCE: ABAG, 2004, Table 2, p. 7.

The comparison of the two projections series for the four counties indicates that *Projections 2005* anticipates greater job gains for Alameda and San Francisco Counties than does *Projections 2002*, while San Mateo and Santa Clara Counties are expected to gain fewer jobs. These changes in expectations are consistent with the detailed comparisons of *Projections 2002*, *Projections 2003*, and *Projections 2005* presented in Draft PEIR Appendix E.3 (Vol. 5, pp. E.3-9 to E.3-35), and with the characterization of the job losses in the early part of this decade as the "dot-com bust": San Mateo and Santa Clara Counties, the heart of Silicon Valley, lost the greatest number of jobs.

Table 14.2-3 compares the difference in the projections of *total* employment in each of the four counties for all years that are reported in both *Projections 2002* and *Projections 2005* (2000 through 2025) as well as for 2030.[5] Similar to the comparison of new jobs above, this table shows that the job loss was most severe in Santa Clara County (employment estimate for 2005) and that Santa Clara and San Mateo Counties are not expected to recover the lost existing and projected jobs by 2030. In Alameda and San Francisco Counties, in contrast, the lost jobs are expected to be

5 *Projections 2002* does not provide projections for 2030; county-level data for 2030 presented here are based on the comparison of *Projections 2002* and *Projections 2005* forecasts of new jobs presented in *Projections 2005* (ABAG, 2004).

TABLE 14.2-3
DIFFERENCE IN EXISTING AND PROJECTED TOTAL EMPLOYMENT: PROJECTIONS 2005 MINUS PROJECTIONS 2002

	2000	2005	2010	2015	2020	2025	2030[a]
Alameda[b]	-1,520	-42,900	-38,610	-29,820	-11,430	7,770	22,650
San Francisco[b]	8,070	-80,680	-66,370	-45,940	-21,750	5,600	32,850
San Mateo[b]	-9,300	-75,170	-65,430	-58,050	-47,110	-32,250	-16,860
Santa Clara[b]	-48,200	-227,020	-223,780	-211,750	-179,500	-146,740	-112,520
Four-County Total	-50,950	-425,770	-394,190	-345,560	-259,790	-165,620	-73,880

[a] The comparison of *Projections 2002* and *Projections 2005* for 2030 is based on information presented in *Projections 2005*.
[b] Information shown is for the entire county.

SOURCES: ABAG, 2001; ABAG, 2004.

recovered by 2025; that is, in those two counties, *Projections 2005* forecasts greater employment by 2025 than does *Projections 2002*. In *Projections 2005*, ABAG estimates that the four-county area had 50,950 fewer jobs in 2000 than were estimated in *Projections 2002* and nearly 426,000 fewer jobs in 2005 than were expected when *Projections 2002* was published. The difference in total employment in 2030 (73,880) reflects the difference in expectations of job growth in the four counties from 2000 to 2030 (22,930 fewer new jobs forecasted, discussed above) plus the lower estimate of jobs in 2000 assumed in *Projections 2005* (50,950 fewer than were estimated for 2000 in *Projections 2002*).

As discussed in the Draft PEIR (Vol. 4, Chapter 7, p. 7-22), ABAG updates its projections series frequently (typically, every other year) to reflect new information about existing conditions as well as recent and emerging trends. Projections may be revised upward or downward depending on the understanding of a variety of factors and conditions that influence future growth. In terms of the PEIR analysis, even if the SFPUC overestimated demand based on employment projections that have been lowered in ABAG's subsequent projections, the likely effect would be a reduction in the use of water from the Tuolumne River and local watersheds, which could result in a reduction in impacts on those watersheds, not an underestimation of the WSIP's impacts. To the extent the SFPUC has overestimated demand based on employment growth projections, the WSIP PEIR may overestimate the impacts associated with induced growth and with increased diversions of imported water.

In addition, at the same time *Projections 2005* reduced the estimates of total employment in 2030, the estimates of total population in 2030 were increased. According to *Projections 2005*, the projected growth in population for the nine-county Bay Area will result in 330,000 more residents in 2030 than were projected in *Projections 2002.* The population increase is based on an expectation that Bay Area communities, recognizing the pressures on natural and fiscal resources created by the growth of urban areas, would adopt smart growth policies that would lead to more intensive development in the existing urbanized areas.

Table 14.2-4, which is based on Draft PEIR Tables E.3.31 and E.3.32 (Vol. 5, Appendix E.3, pp. E.3-33 and E.3-34), summarizes the changes in expected employment and population growth between *Projections 2002* and *Projections 200*5 for 2025.[6] This table shows that ABAG reduced its forecast of total employment in 2025 by about 6 percent (a reduction of about 137,000 jobs for the areas generally served by the SFPUC's water customers), but increased its forecast of total population by about 5 percent (an increase of about 130,600 residents).

TABLE 14.2-4
ABAG PROJECTIONS OF EMPLOYMENT AND POPULATION IN 2025: SUMMARY COMPARISON

Area	Year	Projections 2002	Projections 2005	Projections 2005 as % of Projections 2002
		Employment		
SFPUC Water Customers	2025	2,169,600	2,032,650	94%
		Population		
SFPUC Water Customers	2025	2,693,000	2,823,600	105%

SOURCE: Draft PEIR, Vol. 5, Appendix E.3, Tables E.3.31 and E.3.32.

The net effect of the *Projections 2005* expectations (more population and less employment) on 2030 water demand is that the reduction in demand due to fewer jobs would be offset to some extent by an increase in demand due to increased population.

In any case, fluctuations in each successive ABAG *Projections* series are to be expected. As noted above, if it turns out that the SFPUC has overestimated demand, the likely effect would be that less water would be used than was projected, which could result in fewer or less severe impacts on the Tuolumne River and local watersheds and potentially fewer or less severe impacts associated with growth.

Projections 2007

While the Draft PEIR compares ABAG's *Projections 2002* forecasts with those of *Projections 2003* and *Projections 2005*, *Projections 2007* was released after Draft PEIR preparation and could not be considered prior to publication of the environmental document, as noted above. *Projections 2007* and *Projections 2005* use the same estimate of jobs in 2000 (which, as discussed above, are somewhat lower than was assumed in *Projections 2002* and *Projections 2003*). *Projections 2007* shows a slightly greater loss of jobs by 2005 than did *Projections 2005*, and a slightly slower recovery or growth in new jobs between 2005 and 2030 than was forecasted in *Projections 2005*. As a consequence, *Projections 2007* forecasts fewer jobs in 2030 for all four counties served (partly or entirely) by SFPUC water than were forecasted in *Projections 2002*.

6 Projections for 2025 rather than 2030 are presented because 2025 is the *Projections 2002* horizon year.

Similar to *Projections 2003* and *Projections 2005*, *Projections 2007* forecasts somewhat greater population growth than does *Projections 2002* (with about 200,000 more people forecasted in the four-county area by 2025, the last year for which *Projections 2002* provides forecasts). **Figure 14.2-1** presents a comparison of the expectations of job and population growth for the four counties served (partly or entirely) by SFPUC water in the four ABAG projections series.

How Projections Were Used in the End-Use Demand Models

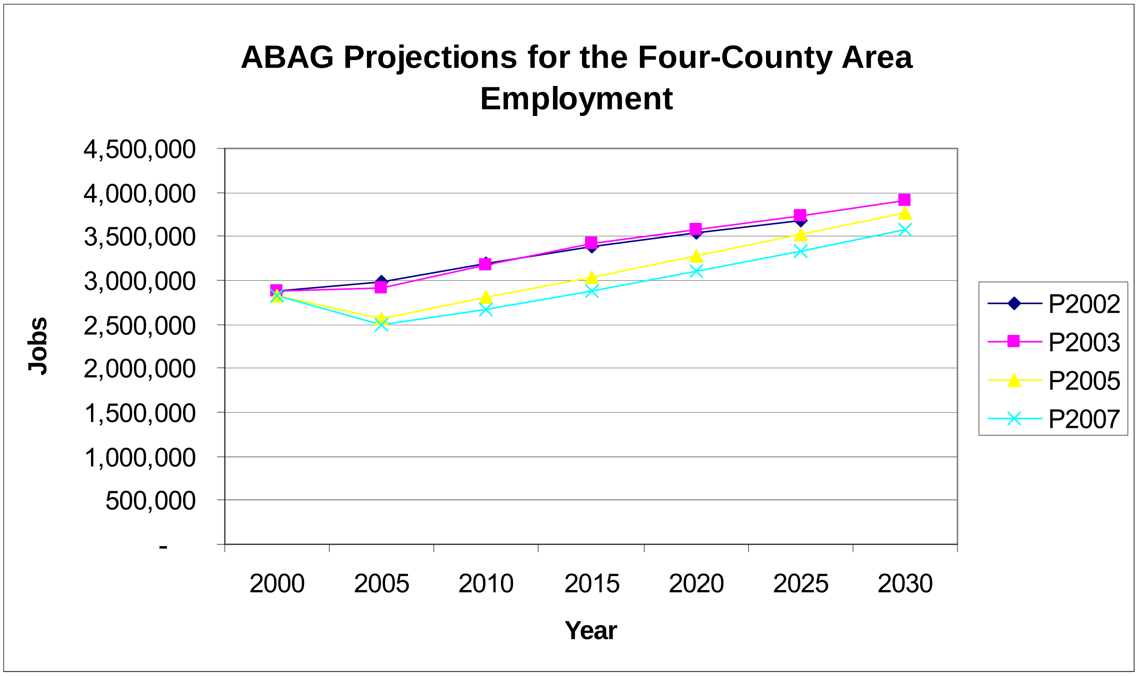
Although the demand modeling incorporated the retail service area and wholesale customer-selected projections of future employment and population levels to project future water demand, the models actually applied the *rate* of growth reflected in selected projections to existing water accounts in order to project growth in demand, as explained in Draft PEIR Chapter 7 (Vol. 4, p. 7-14). The demand models are not based on per-capita consumption, but rather are end-use models. Therefore, the estimates of future population and employment were not used to calculate future demand on a per-capita basis. *Projections 2002* forecasts a slower rate of growth from 2005 to 2030 than does *Projections 2003*, *Projections 2005*, or *Projections 2007*. As discussed above and in Draft PEIR Chapter 7 (Vol. 4, pp. 7-23 and 7-24), the estimates of employment in 2005 provided in *Projections 2005* are noticeably lower than those of *Projections 2002* or the customer-selected estimates of employment for that same year. This is due to the decline in jobs between 2000 and 2005 reflected in *Projections 2005* as compared to *Projections 2002*. Overall, *Projections 2002* and *Projections 2005* show a similar growth rate between 2000 and 2030.[7] The population and employment estimates incorporated in the demand modeling are used in the PEIR because they provide a reasonable expression of growth assumptions that allows for comparisons with other forecasts of future growth, such as those in general plans and ABAG projections. However, as noted, it was the growth rates reflected in the projections that were applied in the demand models.

ABAG as Projections Source

Some comments assert that the employment projections are unrealistic or that the difference in employment and population growth rates is unusual and that the demand projections should be reevaluated using “more realistic” employment projections. The demand modeling for the wholesale customers relied on ABAG projections, which are based on a consensus-driven process to validate ABAG’s work with local cities, as the best source of employment projections; the ABAG numbers were not altered. ABAG is the official regional planning agency of the San Francisco Bay region; it was selected as a credible source, as its projections are relied on by many agencies throughout the Bay Area. The comments asserting that the ABAG projections are unrealistic provide no evidence in support of this assertion, nor do they suggest an alternative source that would have more credibility than ABAG as a source of regional employment projections for the wholesale customer service area. The demand modeling for San Francisco also relied on ABAG data, in conjunction with County Business Patterns data.

---

7 As noted previously, assumptions about *Projections 2002* estimates for 2030 are based on ABAG’s comparison of *Projections 2002* and *Projections 2005* for the period 2000 to 2030.



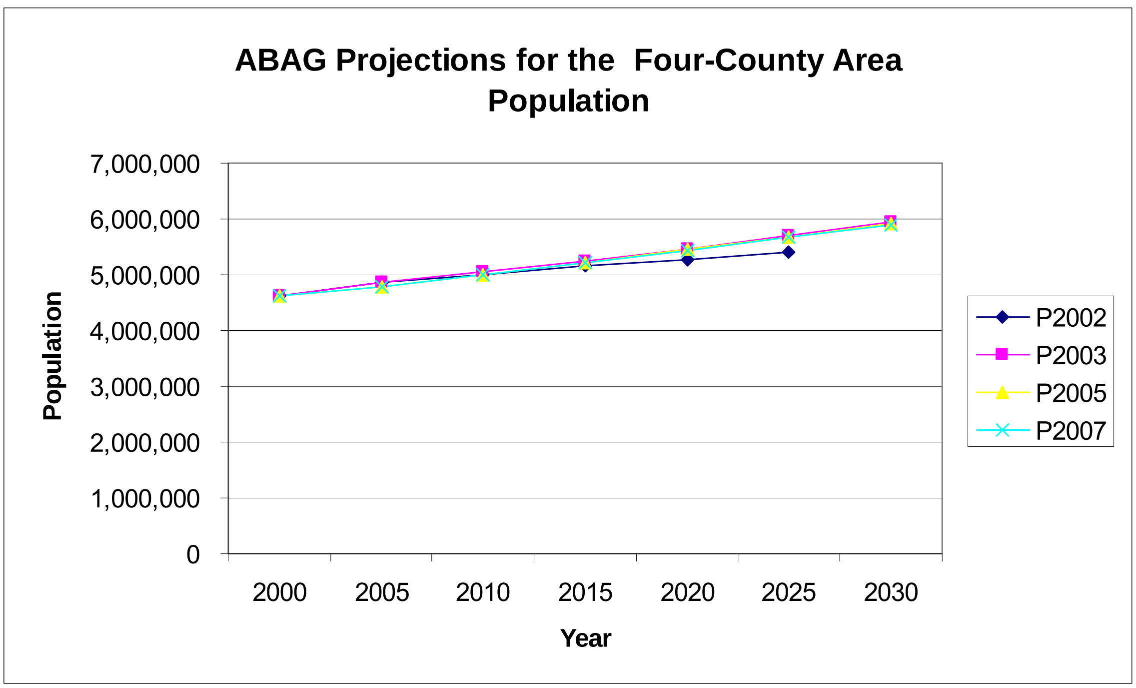


Figure 14.2-1
ABAG Employment and Population Projections
for the Four-County Area

Projections to 2030

The comments that "growth statements" rely on published studies that do not cover the time period up to 2030 and have not undergone environmental review apparently refer to the use of ABAG's *Projections 2002* in the water demand models. The statement that ABAG's *Projections 2002*—the source of many of the population and employment projections used in the water demand models—only provides forecasts to 2025 is correct. Similarly, most of the other projections sources selected by the water customers[8] did not extend to 2030, the WSIP planning horizon. As described in the Draft PEIR (Vol. 5, Appendix E.2, p. E.2-6), it was therefore necessary to extend the projections to 2030 for use in the demand models (refer to the referenced page in Appendix E.2 for a summary of the methodology used to extend the forecasts to 2030). Thus, contrary to the implication of several comments on this issue, the level of growth assumed in the WSIP demand projections extends to the WSIP horizon year of 2030. This is the level of growth that was considered in Draft PEIR Chapter 7, Analysis of Growth-Inducement Potential and Indirect Effects of Growth (Vol. 4, pp. 7-1 to 7-91). The Draft PEIR compares the population and employment projections assumed in the water demand modeling with ABAG's *Projections 2005* forecasts—which include projections for 2030—for the years 2005, 2025, and 2030; refer to Draft PEIR pp. 7-23 to 7-26 (Vol. 4, Chapter 7).

Environmental Review of ABAG Projections

Some comments correctly noted that ABAG projections are not subject to environmental review. This fact does not, by itself, make such projections unreliable, nor do such projections constitute a "project" that would normally be subject to environmental review. They constitute information, not policies, and have been treated as such in the PEIR and in the demand modeling. In any event, despite not being subject to CEQA, ABAG projections are frequently cited as the projections source in general plans and similar planning documents, which are subject to environmental review under CEQA. Here, the Draft PEIR growth-inducement analysis (Vol. 4, Chapter 7, pp. 7-19 to 7-59) compares projections assumed in the SPFUC demand study with those of jurisdictions' adopted general plans.

Use of Total Jobs Projections for the Wholesale Customer Service Area

Representative comments on this topic include:

- *The forecasting methodology has two important errors that can lead to potentially large inaccuracies in forecasted demand: it assumes that the current composition of commercial and industrial businesses within the nonresidential sector will not change over time, and it ignores the variability in water use in both quantity and purpose among users in the nonresidential sector. [SI_PacInst-07, SI_PacInst-79, SI_TRT-CWA-SierraC-31] The DSS model applies the economic growth rate to all nonresidential accounts equally, thereby assuming that all subsectors grow at the same rate. This is highly unlikely. [SI_PacInst 79]The SFPUC should reevaluate nonresidential demand projections for its*

8 As discussed in the Draft PEIR (Vol. 4, Chapter 7, p. 7-14), although *Projections 2002* was used for all but two water customers for employment forecasts and for most of the population forecasts used in the demand models, about one-third of the wholesale customers used other projections sources for their population forecasts.

wholesale customers using industry-specific economic growth projections, water use, and conservation potential. [SI_PacInst-12]

- *A more accurate, comprehensive analysis based on industry-specific growth and water-use rates, such as the analysis performed for the SFPUC retail customers, should be employed and applied to the wholesale customers. [SI_PacInst-79] The projected increase in water demand for the 2.4 million people who consume Hetch Hetchy water is inflated. The studies of projected water demand are looking at old technology. The shift from manufacturing to service and information, which use considerably less water, wasn't taken into consideration. [SI_TRT8-02]*

Response

Comments that the DSS modeling ignores differences in water use among users in the nonresidential sector are incorrect. The DSS models used the monthly billing data classifications provided by the individual water agencies. Typical classifications included the following:

- Commercial
- Industrial
- Public or Institutional
- Municipal

The modelers verified the classification of certain types of accounts, such as hospitals and schools, and collected data to quantify water used by certain types of users, such as restaurants and hotels.

One comment refers to Standard Industrial Classification (SIC) code water use coefficients to illustrate differences in water use by different types of businesses. The fact that different types of land uses entail different levels of water use is acknowledged and reflected in the demand modeling. However, unless more is known about given enterprises, such per-employee water use coefficients can be misleading. For example, hospitals have a low water use coefficient (refer to Table 8 of Comment SI_PacInst-79 [Vol. 6, Chapter 12, Section 12.4]); however, because hospitals have so many employees, water use by hospitals can be very high. As a type of business, hospitals would be ranked by the DSS modelers near the top of the list for nonresidential water users in the wholesale service area, contrary to their ranking by SIC code water use coefficients. Therefore, unless no baseline nonresidential water use data were available, and employment projections by SIC code were available, per-employee water use coefficients would be of little value in a demand projection. Baseline water usage provides a more reliable measure of actual nonresidential water use for different types of accounts. The DSS models used actual water use data for existing accounts to establish baseline water usage for each wholesale customer.

With respect to nonresidential growth rates, the DSS demand models did not use the overall job-growth rate for ABAG's entire nine-county area (or the job-growth rate for the four-county area served by the SFPUC) in modeling the growth in nonresidential demand in the wholesale customer service area, as some comments imply. The DSS modeling was conducted at the individual wholesale customer service area level.

Industry-specific growth projections were used to model demand for the retail service area[9] (the city of San Francisco). Some commenters stated that this methodology should have been used in the wholesale service area, and that failure to use industry-specific projections and water use rates resulted in inflated demand projections. However, while it was possible to take this approach for the retail service area demand projections, the SFPUC determined that using industry-specific projections in the wholesale service area would be impractical and would likely result in projections that are no more reliable (or even less reliable) than the methodology used. The industry-specific methodology cannot currently be used in the wholesale service area for the following reasons:

a) ABAG projections are tabulated by jurisdictional boundaries.[10] In contrast to San Francisco, whose jurisdictional boundaries coincide with the retail service area for which demand projections were developed, few of the wholesale customers' service area boundaries coincide with jurisdictional boundaries, and some of the service areas include large areas of unincorporated county lands (refer to Draft PEIR Table 7.1, Vol. 4, Chapter 7, p. 7-12). While it is possible to assign population and total employment to service areas based on the percentage of a service area within a jurisdiction, the assignment of jobs by specific classifications would be much more problematic because jobs (especially certain categories of jobs) tend to be concentrated within small subsections of the service areas.

b) The wholesale customers assign a billing category (such as commercial, industrial, public or institutional, and municipal) to individual meter accounts. However, the categories used by each of the 27 wholesale customers are not necessarily consistent with the categories used by the other wholesale customers. Nor are the categories used by the wholesale customers consistent with the industry-specific employment categories used by ABAG, which makes a direct correlation of accounts with ABAG industry categories impossible. Each meter account has an "identifier" that includes the address of the water meter and the name of the person and organization who receives the water bill. In some cases, it is possible to correlate a particular account to an ABAG category based on the account name; however, such instances are the exception rather that the rule.

   Because appropriate data are not currently available, a door-to-door survey of businesses would be required, in many cases, in order to use industry-specific projections. Such a survey could require the breakdown of a single water account into multiple categories to conform with ABAG's classification system (for example, if "professional and managerial" and "financial and leasing" businesses occur within a single building, the water account currently categorized as "commercial" would require multiple ABAG categories). Assuming such surveys were conducted and the billing systems would accommodate it, a code could then be added to the accounts to allow the sorting of data by the new classifications. While it may be possible and desirable to do this in the future, it would be a costly and time-consuming task that the SFPUC deemed infeasible to implement for all of the wholesale customers at this time. In addition, even with business categories that are comparable to ABAG's, the problem of appropriately apportioning a jurisdiction's job projections by category to the service area discussed in (a), above, would remain.

---

[9] The retail service area model used composite employee water use rates with ABAG industry-specific employment projections to project nonresidential water demand, as described in the Draft PEIR (Vol. 1, Chapter 3, Section 3.4.4, p. 3-20).

[10] This includes projections for each incorporated city and for the city plus any unincorporated area within the city's planning area.

Moreover, it is not apparent that this approach would contribute significantly to the accuracy of the demand projections. ABAG's employment projections use a shift-share methodology that incorporates assumptions about future shifts in employment among economic sectors. As noted above, the DSS modeling was conducted at the level of individual water agency service areas, which would capture projected employment dynamics at that level.

The wholesale service area currently has over 1.1 million jobs, and total service area water demand (for residential and nonresidential use) in 2030 is expected to increase by 52 mgd, or 19 percent. Current water use (i.e., 2001 base-year demand) accounts for 84 percent of the water demand projected for 2030. Given the percentage of overall demand represented by future demand, the issues discussed above, and the fact that the DSS modeling relied on reasonable assumptions based on ABAG employment projections for each wholesale customer service area, the San Francisco Planning Department believes that the modeling effort provided a reasonable, conservative forecast for use in the Draft PEIR, which reflects the CCSF's best effort at analysis and disclosure. Furthermore, in light of the impracticality of the suggested approach, there is no evidence that this approach would yield a more reliable result.

Effects of the Future Price of Water on Projected Demand

Representative comments on this topic include:

- *Flaws in modeling demand include ignoring the effect the expected price increase will have on future demand. [SI_TRT2-02]*
- *The analysis of future water demand does not include price-driven efficiency improvements, despite an estimated quadrupling of the price of water from the SFPUC by 2015. [SI_PacInst-04, SI_TRT-CWA-SierraC-01]*
- *As the price of water increases demand decreases, particularly for nonresidential and outdoor uses. Because the SFPUC expects to quadruple the price of water by 2015, the effects of water price increases should be integrated into the demand projections. Failing to do so may result in an overestimate of future demand and revenue shortfalls. [SI_PacInst-13]*
- *Given the projected increase in water price, price will likely be an important driver of conservation in the coming years, but neither the wholesale nor retail demand analyses consider price-driven efficiency due to concerns about double counting. [SI_PacInst-62]*

Response

Some comments criticized the end-use demand models for not incorporating the effects of the future price of water on projected demand. Such comments are based on the economic premise that water demand is price-elastic, meaning that as the price of water increases, demand will decrease. According to these comments, the demand models fail to incorporate the expected quadrupling of the price of water by 2015, resulting in demand projections that are higher than if the future price of water had been adequately considered.

It is acknowledged that water use is influenced to some extent by changes in price. Price elasticity studies indicate that while water users respond to price increases by decreasing use, declines in use are small compared to the changes in price; that is, these studies indicate that water demand is relatively price-inelastic (DWR, 1998). The price elasticity of water demand can vary by region, water use, customer type, and other factors, as one comment correctly states (refer to Comment SI_PacInst-62 [Vol. 6, Chapter 12, Section 12.4]). Since outdoor water use is commonly assumed to be discretionary, the low outdoor water use within San Francisco suggests that water demand in the retail service area is less price-elastic than in other parts of the state. Please refer to **Response SI_PacInst-62** (Vol. 7, Chapter 15, Section 15.4) for a more detailed discussion of the price elasticity of water demand.

Consideration of Water Price in WSIP Background Studies

Even if water demand is relatively inelastic, it is expected that price will be an important driver of conservation in coming years. However, in the background technical studies conducted for the WSIP, price is considered in the *conservation potential* studies rather than in the end-use water *demand* models used in the retail and wholesale service areas. As described in the Draft PEIR (Vol. 5, Appendix E.2, pp. E.2-12 to E.2-15), cost-benefit analyses were conducted in both the wholesale and retail service areas to determine whether given conservation measures would be cost-effective. In the analysis of whether given conservation measures would be cost-effective and therefore selected for implementation (assuming the measures were also determined to be effective and feasible for the individual agencies to implement), “the major benefit to wholesale customers was the avoided price of purchased SFPUC water. Because the cost of water is scheduled to increase… the estimated future (2015) price was used in [the] study” (URS, 2004b). The projected water savings from the conservation measures selected for implementation, along with supplies from other water sources, were deducted from projected demand to arrive at the customers’ 2030 purchase estimate, and the wholesale customers were aware of the estimated future price of water when they submitted the purchase estimates. Thus, “price-driven efficiency improvements”—that is, conservation measures to which customers have committed in order to avoid future water costs—have been incorporated in the *purchase estimates* submitted to the SFPUC. However, the mechanism through which these price-driven efficiency improvements were identified was the cost-benefit analyses conducted as part of the conservation potential studies, not as part of the water demand studies. This approach provides a reliable method of quantifying the effects of price-driven efficiency improvements.

Some comments suggest that price needs to be factored into the demand modeling as well as considered in the cost-benefit analyses of conservation measures. However, the SFPUC and its technical consultants are concerned that factoring price into both the demand models and the cost-benefit analyses would result in the double-counting of conservation savings. In modeling demand (as opposed to conservation potential), the challenge would include assessing the degree to which a water customer reduces water use in response to the price of water *apart from* participating in a conservation program—installing water saving fixtures or equipment under a rebate program, for example. To date there are no known studies that would allow the modelers to separate the effects of price and the rebate program (Maddaus, 2008).

According to the SFPUC's DSS technical consultant (Mr. Bill Maddaus of Maddaus Water Management), most literature on the responsiveness of demand to price assumes that all water savings are due to price policies. For example, a study of water use in Seattle, Phoenix, and Tucson concluded that "[a]n examination of the long-term water usage by these three water utilities demonstrates that significant reductions in water usage are possible with the support of conservation-oriented rates. This appears particularly true if these rates are implemented in conjunction with active water conservation programs" (Cuthbert, 1996). The three water utilities in this study have had long-standing water conservation programs, and although the author was able to detect a water reduction, he could not separate the reductions due to price or non-price conservation programs (Maddaus, 2008). Thus, the approach taken by the SFPUC and its technical consultants of considering the effects of the future cost of water in the evaluation of conservation potential provides a more reliable and quantifiable means to estimate the effects of future water costs than would consideration of the effects of cost on demand, for which a tested and reliable methodology has not yet been demonstrated.

Revised Estimate of the Future Price of Water

As discussed above and in the Draft PEIR (Vol. 5, Appendix E.2, p. E.2-12 and E.2-15), cost-benefit analyses were prepared for the conservation measures that were considered for implementation in the wholesale and retail service areas, and cost-benefit analyses were also conducted for each of the three programs of conservation measures (Programs A, B, and C) that were compiled for the retail service area and each wholesale customer, in order to determine program cost-effectiveness (URS, 2004c). As discussed above, because the price of water is expected to increase, the estimated future price of water was used in these evaluations. Although the cost-benefit analyses showed that many of the individual conservation measures and each of the compiled conservation programs was cost-effective, the incremental cost of adopting conservation measures in addition to those measures the agency had selected for implementation (or for moving from implementing Program A to B or from Program B to C) was a less important factor in an agency's decision not to adopt additional measures than were concerns about the feasibility of implementing additional measures. Practical constraints related to implementing additional measures, such as the need to add additional conservation program staff that might be triggered by the addition of one or more measures (to those already selected for implementation), was a more important consideration, especially for smaller water districts with limited staff. The measures and programs of compiled measures were found to be cost-effective based on the estimated future (2015) cost of water at the time the technical studies were prepared. Since then, the SFPUC's estimate of the future (2015) price of water has increased, from approximately three times the 2003 price assumed in the conservation potential study to approximately four times the 2003 price, according to the price quoted by SFPUC staff cited in Comment SI_PacInst-62 (Vol. 6, Chapter 12, Section 12.4).

Because many of the conservation measures were found to be cost-effective based on the earlier (lower) estimated future price, the effect of the revised future price on the number of measures and conservation programs implemented by the wholesale customers may be minor. Some of the individual measures previously found not to be cost-effective are now likely to be found cost-effective, and those already found to be cost-effective would be more cost-effective. However, since the wholesale customers identified feasibility constraints rather than costs as a limitation to implementing additional measures, the increase in future cost will not necessarily translate into more measures being implemented. Nevertheless, it is reasonable to expect that as the price of water increases and measures become more cost-effective as a result, some existing barriers to implementing additional conservation measures may be overcome, at least in some cases. It would be up to each wholesale customer, not the SFPUC, to determine whether additional conservation would be feasible as well as cost-effective in light of rising water prices.

Finally, in considering the effect of the future cost of water, it should also be noted that the rise in raw water cost will translate into smaller increases in retail prices, on a percentage basis, because other costs (such as fixed costs, chemical costs, and salaries) are not forecasted to rise as quickly.

The purchase estimate submitted by each wholesale customer represents the customer's best estimate of water purchases in 2030. Acknowledging the role that the cost of water plays in purchase decisions, each estimate states that the "estimate is subject to change based on changed conditions, such as the future cost of water." The conservation potential studies incorporated the best information available at the time they were conducted, including the estimated future cost of water. If, due to revised estimates of the future cost of water or other factors, the SFPUC underestimated conservation potential, the effect of implementing more conservation than is currently considered feasible would likely be a reduction in the use of water from the Tuolumne River and local watersheds. As noted in the introduction to this response, comments about the accuracy of conservation potential may be taken into account by decision-makers in evaluating the feasibility of alternatives, but do not indicate that the PEIR underestimated the impacts of the WSIP. Please refer to **Response SI_PacInst-62** for additional information on the use of water pricing as a water agency tool and **Response SI_PacInst-47** regarding tiered pricing rate structures (these responses are provided Vol. 7, Chapter 15, Section 15.4).

Per-Capita Demand

Representative comments include the following:

- *Per-capita demand for the wholesale customers is projected to increase over current (2001) per-capita demand, despite numerous studies showing that substantial cost-effective reductions in per-capita demand are possible with available technology and policies. [SI_PacInst-03]*
- *The increase in per-capita demand is simply out of step. It demonstrates inefficient use of water and of a resource that's held in public trust. [SI_TRT6-02]*
- *It's telling that projected per-capita consumption is expected to increase in this area. [SI_TRT8-02]*

Response

Some comments cited an alleged projected increase in per-capita demand in the SFPUC wholesale customer service area as evidence that the demand studies are faulty, based on the supposition that per-capita demand should not be expected to increase given improvements in technology, plumbing code effects, and other factors. Some comments also cite the Draft PEIR as the source of per-capita figures in making this claim. However, the statement that per-capita demand in the SFPUC service area is increasing is incorrect. The weighted average per-capita values in all sectors[11] are projected to decrease between 2001 and 2030, both *without* active conservation programs (due to implementation of plumbing codes) and *with* active conservation; in the latter case the decrease is greater. For example, the gross per-capita weighted average demand for the wholesale customer service area calculated for the 2001 base year is 168 gallons per-capita per day (gpcd) (SFPUC, 2006, p. 150); projected demand for 2030 is 167 gpcd without planned conservation (SFPUC, 2006, p. 156) and 160 gpcd with planned conservation (SFPUC, 2006, p. 162). While it is the case that per-capita demand is projected to increase for some individual wholesale customers, the trend within the service area as a whole shows a decrease in per-capita demand, as these figures demonstrate. In the retail service area, projected gross per-capita demand with plumbing codes, without additional conservation, is 103 gpcd in 2005[12] and 96 gpcd in 2030 (SFPUC, 2006, p. 129); with additional conservation, projected gross per-capita demand is 102 gpcd in 2005 and 91 gpcd in 2030 (SFPUC, 2006, p. 130). In addition, the Draft PEIR does not present per-capita information. The information cited in this response is based on SFPUC calculations using the demand models, but wholesale customer demand was not projected based on per-capita consumption but rather on the end-use of water and growth in water accounts (as discussed above in this master response). Per-capita demand information was prepared by the SFPUC in response to specific requests by participants at the September 2006 Sustainable Water Supply Briefing; for more information on this briefing, refer to the introduction to the **Responses to Pacific Institute Comments** (Vol. 7, Chapter 15, Section 15.4). Increases in demand for the individual wholesale customers and the retail service area are shown in Draft PEIR Table 7.3 (Vol. 4, Chapter 7, p. 7-18) and described in Section 7.3.6, Customer-Specific Summaries (pp. 7-34 to 7-59).

The following two more specific comments were submitted on this topic:

- *For the wholesale customers, per-capita demand reached a high of 187 gpcd in the mid-1980s, declined precipitously during the drought of the late 1980s and early 1990s, and has been relatively constant since 1996. Projected 2030 per-capita demand increases slightly over 2005 levels but is similar to the per-capita estimates in previous years. [SI_PacInst-57]*

Response

The per-capita demand projections for 2030 are based on average annual demand projections assuming "normal year" precipitation levels in the service area, similar to the 2001 base-year conditions assumed for the modeling. Lower-than-normal water use in 2005 and 2006 is attributable to above-normal precipitation in the wholesale customer service area, which would

[11] That is, total per-capita consumption and gross per-capita consumption for single-family residential, multifamily residential, and nonresidential sectors.

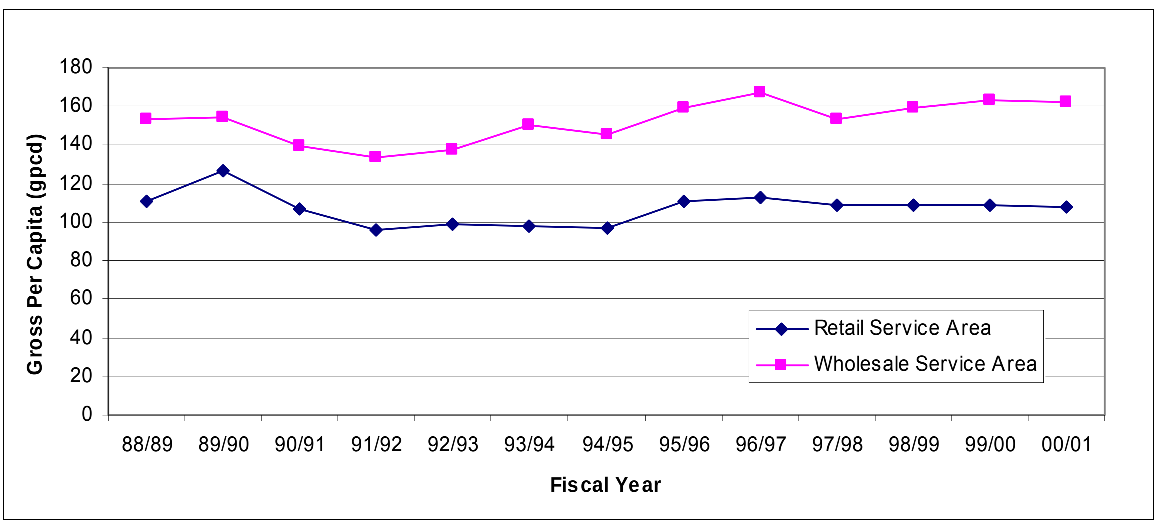
[12] The Sustainable Water Supply Briefing materials (SFPUC, 2006) do not include an estimate of gross per-capita demand for 2000 (the base year for the retail service area demand study), which is why the 2005 estimate is presented here. Total per-capita *consumption* (i.e., not including unaccounted-for water losses) in the retail service area in fiscal year 2000/2001 was 97 gpcd (SFPUC, 2006, p. 128).

account for the dip in per-capita demand for those years (Maddaus, 2008). Refer also to the figure in following response.

- *For retail customers, gross per-capita demand has declined over time. Per-capita demand reached a peak of 127 gpcd in 1989, declined during the drought, and has declined steadily since 1996. By 2030, per-capita demand in the retail service area is projected to decline to 91 gpcd, nearly half of the per-capita demand of the wholesale customers. Simple comparisons of gross per-capita water demand between the wholesale and retail customers can be misleading because water use is affected by a variety of economic and demographic factors, such as housing type and density and the type of businesses present in a given region. Local climate conditions and water-use efficiency also affect demand. [SI_PacInst-58]*

Response

For fiscal years 1988/1989 through 2000/2001 (the years that available data were provided to the Pacific Institute for retail and wholesale customers), gross per-capita demand values show similar patterns, as illustrated in **Figure 14.2-2**, below. These patterns indicate that use declined during the drought period of the late 1980s through the early 1990s and increased thereafter to a peak in the mid-1990s; between the mid-1990s peak and fiscal year 2000/2001, use patterns diverged slightly, with more variability in the wholesale customer service area, although usage in both the wholesale and retail areas remained lower than during the mid-1990s peak. The decline in use for fiscal year 1994/1995 per-capita was due to a wet year (Maddaus, 2008). As noted in the comment, a variety of economic and demographic factors, including housing type and density, the type of commercial and industrial activities in the region, climate, and existing levels of water use efficiency can affect per-capita demand. Some of these factors are likely responsible for the differences in the degree of change in per-capita demand over time in the retail and wholesale customer service areas.



SFPUC Water System Improvement Program ▪ 203287

Figure 14.2-2
Historical Gross Per-Capita Demand – SFPUC Customers

Substantiation of the Need for Sizable Water Supply Increases and Documentation of Water Conservation Efforts

Representative comments on this topic include:

- *Communities requesting sizable water supply increases should be questioned for some substantiation of need and for documentation of water conservation efforts. [SI_CNPS-SCV2-07]*

Response

Some comments suggested that communities requesting sizable water supply increases should be questioned and required to substantiate the need for the increased water and to document their water conservation efforts. As discussed above and described in the Draft PEIR (Vol. 5, Appendix E.2), the demand projections were developed following reasonable, accepted methodologies and based on the best demographic information available at the time. The SFPUC and its DSS modeling consultant worked in close consultation with the wholesale customers to develop the demand projections, and evaluated any requests for customer-specific model adjustments to ensure such adjustments were reasonable, could be substantiated, and were in agreement with land use planning documents. For example, for some wholesale customers, one or more new account categories with higher usage rates were included in the service area demand modeling. The rationale for the new account categories is discussed in the Draft PEIR (Vol. 5, Appendix E.2, p. E.2-7), and the specific reasons for each new category are summarized in Table E.2.2 (pp. E.2-8 and E.2-9). The adjustments made to customers' accounts are also discussed, if applicable, in the customer-specific summaries in Chapter 7 (Vol. 4, pp. 7-35 to 7-59). The Draft PEIR also discusses SFPUC Policy 00-0110, which encourages the wise use of water resources by the CCSF and the SFPUC's suburban customers, including conservation, water recycling, and groundwater development (Vol. 1, Chapter 2, p. 2-46). For information on the conservation efforts in the SFPUC service area, refer to Section 14.2.3, below.)

Outdoor Water Use

Representative comments on this topic include:

- *Increases in residential demand are largely due to outdoor water use. For wholesale and retail customers, per-capita outdoor use is projected to increase, indicating that the proposed conservation does not adequately address this use. [SI_PacInst-05]*
- *The nonresidential sector is responsible for over 80 percent of the projected 2030 demand increase. About 35 percent of that increase is due to outdoor use. [SI_PacInst-06]*
- *For wholesale customers, the total demand increase is 38 mgd between 2000 and 2030. The nonresidential sector accounts for about two-thirds of that increase, or 24.1 mgd. Over 40 percent of the increase in nonresidential demand is due to outdoor use. Residential demand growth, largely due to increases in outdoor water use, accounts for the remaining one-third of total demand growth in the wholesale service area. [SI_PacInst-63]*
- *Outdoor water use alone is driving 60 percent of the anticipated increase in water demand. [SI-TRT8-03, C_Raffa-03]*

Response

Because these figures could not have been derived from information presented in the Draft PEIR or the technical memoranda prepared for the wholesale and retail customer service areas, it is assumed that the comments and figures on outdoor demand are based on material provided by the SFPUC and BAWSCA (SFPUC, 2006) as background information for the September 2006 Sustainable Water Supply Briefing; for a description of this briefing, refer to the introduction to the **Responses to Pacific Institute Comments** (Vol. 7, Chapter 15, Section 15.4).

Residential

Regarding the references to increased residential demand, note that although residential demand among several customers is projected to increase, the increases are relatively small. The SFPUC calculates that overall, with plumbing codes and planned conservation programs, residential demand in the entire SFPUC service area would increase by only 3 mgd,[13] despite the estimated 17 percent increase in population in the service area over the planning horizon.

On a per-capita basis, residential demand would decrease. The SFPUC calculated the following estimates of outdoor residential per-capita demand based on the per-capita demand tables presented in the background information for the Sustainable Water Supply Briefing (SFPUC, 2006, Section 6, Attachments 1 and 3):

- For the retail service area, despite a projected increase in the outdoor residential per-capita demand of 0.2 gpcd,[14] the overall residential per-capita demand would decrease approximately 14 gpcd.

- For the wholesale service area, despite a projected increase in the outdoor residential per-capita demand of about 1 gpcd, the overall weighted average wholesale residential per-capita demand (with conservation and plumbing codes) would decrease by 21 gpcd.[15]

Proposed conservation measures would address residential outdoor use. As shown in Table 14.2-7 in Section 14.2.3 below, most of the wholesale customers have included conservation measures that address residential outdoor use in conjunction with their "high-range" purchase estimate.[16] Of the three that did not, Estero Municipal Improvement District and North Coast County Water District included conservation and outdoor measures in conjunction with their "low-range" purchase estimate, and Los Trancos County Water District has since merged with California

---

[13] This calculation is based on the tables showing projected demand by individual customer presented in the background information for the Sustainable Water Supply Briefing (SFPUC, 2006, Section 3, Attachment 4).

[14] Due to rounding, the figures presented in Section 6, Attachment 1 of SFPUC 2006 (pp. 128 and 130) suggest that outdoor residential demand is projected to increase by 1 gpcd; however, the actual projected increase is 0.2 gpcd (from 1.43 to 1.61 gpcd). (The projected 1.61 gpcd outdoor residential per-capita demand in 2030 is an estimate based on 3 percent outdoor use.)

[15] Note that this calculation is based on the overall weighted average wholesale *residential* per-capita demand excluding unaccounted-for water and, obviously, nonresidential per-capita demand. The data in Response SI_PacInst-30 includes residential and nonresidential as well as unaccounted-for water.

[16] As shown in Draft PEIR Table 3.3 (Vo1. 1, Chapter 3, p. 3-18) and Table 7.2 (Vol. 4, Chapter 7, p. 7-15), some customers submitted a purchase estimate range for 2030, depending on achievement of a range of potential savings from conservation and recycled water use. (That is, the high end of the purchase estimate range would correspond to achievement of the low end of the conservation/recycling estimate and vice versa.)

Water Service–Bear Gulch, which has included outdoor measures in its purchase estimate baseline conservation program.

The conservation savings associated with these outdoor measures is summarized as follows:

- For the retail service area, the per-capita retail residential outdoor use is projected to increase by 0.3 gpcd without additional conservation and by 0.2 gpcd with additional conservation.
- For the wholesale service area, the weighted average per-capita wholesale residential outdoor use is projected to increase by 3 gpcd without additional conservation and by 1 gpcd with additional conservation.

Therefore, implementation of the conservation measures to which the SFPUC and the wholesale customers have committed would save approximately 0.1 gpcd of retail customer residential outdoor use and 2 gpcd of wholesale customer residential outdoor use.

Nonresidential

The statement that the nonresidential sector in the SFPUC service area is responsible for over 80 percent of the projected 2030 demand increase and that about 35 percent of that increase is due to outdoor use is correct. These figures refer to the combined demand of the nonresidential sector in the retail and wholesale customer service areas, taking into account plumbing code and projected conservation savings. The statement that the increase in nonresidential demand in the wholesale customer service area accounts for about two-thirds of the increase in the wholesale customer service area is correct. However, using the DSS models, the SFPUC calculated the slightly different figures indicated below. Demand referenced here takes into account plumbing code savings and active conservation. (Refer to **Response SI_PacInst-63** [Vol. 7, Chapter 15, Section 15.4] for additional specific calculations.)

- The total demand increase in the wholesale customer service area is 36.8 mgd, not 38 mgd.
- The nonresidential sector in the accounts for 23.6, not 24.1 mgd, of the increase in demand in the wholesale customer service area.
- About 39 percent, not over 40 percent, of the increase in wholesale customer nonresidential demand is due to outdoor use.

Overall Outdoor Demand

The statement that 60 percent of 2030 water demand is for outdoor irrigation appears to be based on information provided by BAWSCA for the Sustainable Water Supply Briefing. The BAWSCA information was provided as part of a package of material (SFPUC, 2006) requested by briefing participants. According to BAWSCA, the increase in outdoor consumption from 2001 to 2030 (20.2 mgd) represents 58 percent of the total increase in consumption over that period (34.6 mgd) (SFPUC, 2006, p. 32). Note that the figures in the cited reference refer to consumption for 2001 and 2030, which is somewhat different from the figures of total demand (which includes consumption and unaccounted-for water) shown in the Draft PEIR. Some comments on increased outdoor water use imply that outdoor water use is equivalent to water use for irrigation and landscaping. In addition to these uses, nonresidential outdoor uses also include cooling, pools and fountains, wash-down of facilities, and external leakage; residential outdoor uses also include pools and fountains, wash-down of houses, car washing, and external leakage. Some comments recommend that recycled water be used to replace potable supplies for nonresidential outdoor uses. Please refer to Section 14.2.3 for a discussion of conservation measures and recycled water use addressing outdoor water demand. Tables 14.2-7 and 14.2-8, below, show the conservation measures, including outdoor measures, to which the SFPUC and the wholesale customers have committed.

Requests for Reevaluation of Demand Projections

Representative comments on this topic include:

- *The SFPUC should reevaluate its projections for future water demand and conservation potential in light of flaws and inaccuracies in its studies. [SI_CNPS-EB1-17, SI_CRS-05, C-Raffa-10]*

- *These flaws led to inflated demand projections and they need to be corrected in the Final PEIR. [SI_TRT2-02]*

- *In going from Draft to Final PEIR, the analysis should incorporate the latest employment projections and then alter the water demand projections accordingly. [SI_TRT6-02]*

Response

The SFPUC's demand projection effort was comprehensive, thorough, and appropriate for long-range planning purposes. The demand methodology utilized reasonable assumptions and the best information available at the time. The PEIR reflects the CCSF's best efforts to disclose information about the demand studies and their results as well as the environmental impacts of the WSIP as required under CEQA. As the responses to the specific comments above indicate, revision or reevaluation of the 2030 demand projections is not warranted.

Summary of Issues Raised by Commenters

Submittals on the Draft PEIR contained several hundred comments addressing conservation and recycling in some manner. Many (about 150) of these comments stated that any additional demand should be met through increased conservation, efficiency, and recycling.[17] While these comments stem from concerns about impacts on the Tuolumne River, Alameda Creek, and Peninsula watersheds (including Pilarcitos Creek), they essentially conveyed an opinion about the WSIP and the program alternatives; a number of the comments expressed support for the Aggressive Conservation/Water Recycling and Local Groundwater Alternative evaluated in Draft PEIR Chapter 9 (Vol. 4, pp. 9-47 to 9-59). These comments regarding how conservation and recycling will be incorporated into the WSIP or an alternative of the WSIP are acknowledged. As described in Chapter 1 (Vol. 1, p. 1-12), Chapter 3 (Vol. 1, pp. 3-86 to 3-88), and Chapter 11 (Vol. 6, pp. 11-1 and 11-2), the San Francisco Planning Commission will consider all comments received on the Draft PEIR as well as these responses in considering certification of the Final PEIR. If the SFPUC accepts the certified Final PEIR and associated CEQA findings, the SFPUC would adopt the CEQA findings and then approve and adopt the WSIP or an alternative of the WSIP analyzed in the PEIR. Other comments on conservation and recycling were more specific, raising issues that in part pertained to the content of the PEIR. Examples of these comments included requests for additional studies on feasible conservation and recycling, and criticisms of conservation levels in the Bay Area compared to conservation levels in other metropolitan areas.

Many of these comments suggested a lack of information regarding existing and planned conservation and recycling among the wholesale and retail customers, and the technical studies undertaken by the SFPUC. Accordingly, this section of the master response is organized as follows:

- *Background*. This section presents an overview of conservation and recycling associated with the WSIP and related studies conducted by the SFPUC.
- *Frequently Submitted Comments Addressing Conservation and Recycling*. This section presents the most frequently submitted comments expressing specific concerns about conservation and recycling.

Background

Existing and planned conservation in the SFPUC retail and wholesale customer services areas breaks down as follows:

1) *Plumbing Code Savings* – Water savings assumed to occur as a result of the natural replacement of fixtures under current plumbing codes (passive conservation).

2) *Existing and Planned Conservation Measures*

    a. *Projected Conservation Measures* – Water savings that will occur from the continued implementation of conservation programs already in place.

[17] Examples include C_Raffa-11, C_Breso-02, C_GreenD-02, C_Ross-09, C_Thaga-02, C_VermeJ-01, and C_Willi-02.

b. *Additional Conservation Measures* – Water savings that will result from implementation of additional conservation measures planned by the SFPUC and its wholesale customers.

Table 14.2-5 summarizes 2030 water savings associated with conservation. Table 14.2-5 contains references to Draft PEIR Table 3.3 (Vol. 1, Chapter 3, p. 3-18) to assist the reader in correlating the numbers with the information presented in the Draft PEIR.

TABLE 14.2-5
SUMMARY OF 2030 WATER SAVINGS DUE TO EXISTING AND PROPOSED CONSERVATION (in mgd)

	Wholesale	Retail	Total
Plumbing Code Savings (not explicitly shown in Draft PEIR Table 3.3)	25.4	10.3	35.7
Projected Conservation Savings (programs in place)[a] (included in Table 3.3)	7.7	0.64	8.34
Savings from Additional Conservation Measures (planned)[b] (included in Table 3.3)	5 – 7.3	0 – 3.36	5 – 10.7
Total Conservation Savings, excluding plumbing code savings (Column B, Table 3.3)	13 – 15	0 – 4	13 – 19
Total Conservation Savings, including plumbing code savings	38 – 40	10 – 14	49 – 55

[a] Existing savings based on savings identified for Program/Package A in URS, 2004b and Hannaford and Hydroconsult, 2004.
[b] Additional savings based on the difference between total 2030 conservation savings shown in Draft PEIR Table 3.3 and savings from measures currently being implemented.

SOURCES: URS, 2004b; Hannaford and Hydroconsult, 2004; SFPUC, 2004.

Plumbing Code Savings (Passive Conservation)

Water fixtures are replaced over time due to failure, aging, or remodeling and must be replaced by more efficient models, as required by plumbing codes. Future water savings from plumbing code implementation were estimated based on assumptions regarding the average annual rate of fixture replacement (as discussed in Draft PEIR Appendix E.2, Vol. 5, pp. E.2-7 to E.2-10). The water savings due to compliance with existing plumbing codes in the SFPUC service area was estimated to be approximately 36 mgd in 2030. However, because the end-use models used in the demand analyses incorporated the effects of plumbing codes on demand, the estimated 36 mgd savings from this "passive conservation" has already been subtracted from estimates of future water demand (Vol. 1, Chapter 3, p. 3-17, footnote). Because these savings are reflected in reduced demand,[18] they are not shown as "2030 Projected Conservation Savings" (column B) in Draft PEIR Table 3.3 (Vol. 1, Chapter 3, p. 3-18) and therefore are not apparent.

[18] 2030 demand unadjusted for plumbing code savings would be 453 mgd, as compared to 417 mgd shown in Draft PEIR Table 3.3 (Vol. 1, Chapter 3, p. 3-18).

Conservation Studies

As part of its water supply planning efforts for the WSIP, the SFPUC conducted comprehensive studies (listed in Section 14.2.2, above) to assess future water conservation potential in the wholesale and retail service areas. The studies assessed potential savings from continued implementation of existing conservation practices and from implementation of potential additional indoor and outdoor conservation measures for residential and nonresidential customers. The wholesale service area conservation potential was evaluated in close consultation with the wholesale customers.

The conservation potential studies for the wholesale and retail service areas are summarized in the Draft PEIR (Vol. 1, Chapter 3, p. 3-21) and described in more detail in Appendix E.2 (Vol. 5, pp. E.2-10 to E.2-16). Conservation measures were initially screened for various factors, such as the commercial availability of technology, customer acceptance/equity, the relative effectiveness of the measures, and the appropriateness of the measure or technology considering such factors as climate, building stock, and lifestyle. Following this initial qualitative screening, the remaining measures were combined together to avoid duplication and to take advantage of economies of scale, and some measures that had failed the initial screening were combined with similar measures that had passed the screening to create an equitable and workable program (URS, 2004b, p. 2-4). Eventually, 48 measures in the retail service area and 32 measures in the wholesale service area were retained for further consideration. The measures were evaluated for feasibility and cost-effectiveness. The cost-benefit analysis considered costs and benefits from both the standpoint of the water agency and the standpoint of the retail water customers (URS, 2004b). Measures included rebate and incentive programs for installing water-saving devices, city/county ordinances requiring the installation of water-saving devices, and educational outreach and award programs that promote water use reduction in businesses and landscaping. The conservation measures were compiled into three “programs” or “packages”[19] of measures generally considered to be feasible and cost-effective, as follows:

- *Program/Package A* – Conservation measures currently being implemented. Program/ Package A measures were estimated to result in savings of 7.7 mgd in the wholesale service area and 0.64 mgd in the retail service area; refer to Draft PEIR Table E.2.4 (Vol. 5, Appendix E.2, p. E.2-14) and Table 14.2-5, above.

- *Program/Package B* – Program A measures plus additional conservation measures considered to be the most readily implemented and achievable; considerations included social acceptance of the measures and the costs of implementation. Program/Package B measures (including measures in Program/Package A) were estimated to result in savings of 14.5 mgd in the wholesale service area and 3.9 mgd in the retail service area; refer to Draft PEIR Table E.2.4 (Vol. 5, Appendix E.2, p. E.2-14).

- *Program/Package C* – Program A and B measures plus conservation measures considered to be the upper bound of potentially feasible and cost-effective measures. Although all measures included in Programs/Packages A, B, and C were, by definition, assumed to be feasible and cost-effective (at least theoretically), some measures in Program/Package C are not presently

[19] The retail service area study used the term “package” while the wholesale service area study used “program” to describe the three suites of measures compiled for each customer.

technologically or financially feasible, but were included based on the assumption that the technology would improve (Hannaford and Hydroconsult, 2004). Program/Package C measures (including measures in Programs/Packages A and B) were estimated to result in additional savings of 19.6 mgd in the wholesale service area and 4.45 mgd in the retail service area; refer to Draft PEIR Table E.2.4 (Vol. 5, Appendix E.2, p. E.2-14).

The actual conservation measures that met the customers' screening criteria differed for each water customer; as a result, each Program/Package A, B, and C was unique to the water customer.

Existing and Planned Conservation Measures

Following the assessments of potential conservation savings (URS, 2004b; Hannaford and Hydroconsult, 2004), the SFPUC and each wholesale customer submitted their specific estimates of 2030 conservation savings with their estimates of 2030 water purchases from the SFPUC. These estimates of conservation savings are shown in Draft PEIR Table 3.3 (Vol. 1, Chapter 3, p. 3-18). In general, the wholesale customers' estimates of conservation savings are similar to Program B savings levels, whereas the SFPUC submitted an estimated savings range of 0.64 to 4.02 mgd for the retail service area.[20] Table 14.2-5, above, shows the total projected 2030 savings from implementation of conservation measures and includes a breakdown in the savings expected from the continuation of existing measures and from the additional measures to which the SFPUC and the wholesale customers have committed under the WSIP.

Table 14.2-6 describes the existing and planned conservation measures for the SFPUC service area. **Table 14.2-7** and **Table 14.2-8** show existing and planned conservation measures for the retail service area and the wholesale customers, respectively, and indicate those measures that are California Urban Water Conservation Council (CUWCC) best management practices (BMPs) and those measures identified as part of the *SFPUC Wholesale Customer Water Conservation Potential* (URS, 2004b) and *City and County of San Francisco Retail Water Demands and Conservation Potential* (Hannaford and Hydroconsult, 2004). The projected 2030 conservation savings from existing and proposed conservation programs (excluding passive conservation) totals 13–15 mgd for the wholesale area and 0–4 mgd for the retail area, as shown in Table 14.2-5, above, and Draft PEIR Table 3.3.

In addition, as discussed below under the heading Additional Conservation and Recycling Potential, subsequent to completion of the conservation potential studies and the customers' submittal of estimated 2030 conservation savings, the SFPUC, in conjunction with its wholesale customers and BAWSCA, undertook a study to assess the potential to develop a regional program to implement additional conservation and recycling programs in the SFPUC service area.

Existing Recycled Water Projects

In the wholesale service area, 14 recycled water projects currently produce approximately 12.6 mgd of recycled water. Recycled water is used for stream flow augmentation, wetlands

[20] This range reflects the original estimates of Programs A and C for the retail service area; errata published on August 28, 2005 (after the purchase estimates were submitted) adjusted Program C to 4.45 mgd. The SFPUC has subsequently committed to implementing the Program C measures in the retail service area.

restoration, and irrigation at commercial/industrial facilities, golf courses, cemeteries, and parks; the use of recycled water does not always replace a potable water supply (this is typically the case when recycled water is used for environmental purposes like stream flow augmentation and wetland restoration). According to the *SFPUC Wholesale Customer Recycled Water Potential Technical Memorandum* (RMC, 2004), of the 12.6 mgd produced by current (2004) recycled water projects, an estimated 4.3 mgd replaces potable supplies. There are no existing recycled water projects in the SFPUC retail service area.

Proposed Recycled Water Projects

As part of its water supply planning efforts, the SFPUC also conducted studies (listed in Section 14.2.2, above) to evaluate recycled water potential in the wholesale and retail service areas. The recycled water potential studies identified additional projects that were considered relatively certain to be implemented in the near future, as well as projects in the early planning stages that were considered possible but less certain. The studies indicated that potentially feasible recycled water projects could produce from 6.3 to 33.4 mgd in the wholesale customer service area and up to 6 mgd in the retail customer service area. Draft PEIR Table E.2.5 (Vol. 5, Appendix E.2, p. E.2-17) summarizes the recycled water potential for the SFPUC service area. Challenges associated with implementing the recycled water projects include costs and funding, gaining public support, establishing new partnerships to improve feasibility, and managing water quality (RMC, 2004). As shown in Draft PEIR Table 3.3 (Vol. 1, Chapter 3, p. 3-18), the wholesale customers estimate that about 10 mgd of recycled water will replace potable supplies in 2030. Additional recycled water projects that do not replace potable supplies (e.g., recycled water used for marsh or wetland restoration projects) are not shown in Table 3.3.

The *Recycled Water Master Plan* (RMC, 2006) assesses the feasibility of recycled water projects in the Westside area of San Francisco and identifies projects with the potential to provide approximately 6.2 mgd of recycled water. The first phase of these projects, which provides 4.1 mgd of recycled water, is included in the WSIP, as shown in the 2030 demand projections.

Summary of Projected 2030 Conservation and Recycling

Table 14.2-9 summarizes the estimated savings from conservation and recycled water projects to which the SFPUC and the wholesale customers have committed as part of WSIP planning. As shown, existing and planned conservation and recycled water use is expected to offset demand for potable water by a minimum of 22.3 mgd, excluding savings from plumbing codes (and by a minimum of 58 mgd with savings from plumbing codes included).

Additional Conservation and Water Recycling Potential

As part of the WSIP planning process, the SFPUC, in cooperation with its wholesale customers and BAWSCA, also undertook a study to assess the potential for additional conservation and recycled water projects, including potential regional projects that were not identified in the previous studies or already considered to be implemented locally by 2030. This study considered projects that could be feasible if implemented regionally, including ones that may have been found to be infeasible for individual customers. This study, *Investigation of Regional Water*

TABLE 14.2-6
DESCRIPTION OF EXISTING AND PROPOSED/PLANNED BEST MANAGEMENT PRACTICES AND CONSERVATION MEASURES WHOLESALE AND RETAIL CUSTOMERS

MEASURES FOR INDOOR WATER USE

Residential Measures

- Clothes Washer Rebate/Homeowners. Provide a rebate on new water-efficient clothes washers for homeowners.
- Clothes Washer Rebate/Apartment Complexes. Provide a rebate to new apartment complexes over a certain size with a common laundry room equipped with efficient washing machines.
- Dishwasher Rebate. Provide a rebate or voucher for high-efficiency dishwashers (4.5 gallons per load).
- Residential ULF Toilet Rebate. Provide a rebate to homeowners to replace an existing high-volume toilet with a new ultra-low-flow toilet.
- Require 1.6-gal/flush Toilets Replace on Sale. Work with the real-estate industry to require a certificate of compliance be submitted to the water utility verifying that a plumber has inspected single-family and multifamily properties and that efficient fixtures were either present or installed at the time of sale, before the close of escrow.
- Rebates for 6/3 Dual-Flush or 4-liter Toilets. Provide a rebate or voucher for the retrofit of a 6/3 dual-flush, 4-liter, or equivalent very low water use toilet. Rebate amounts would reflect the incremental purchase cost and would be in the range of $50 to $100 per toilet replaced.

Other Residential Measures

- Residential Plumbing Retrofits. Provide owners of pre-1992 homes with retrofit kits that contain easy-to-install low-flow showerheads, faucet aerators, and toilet tank retrofit devices.
- Home Leak Detection and Repair. Use leak detection equipment to determine whether and where leaks are occurring on the premises and provide a plumber to the customer to repair leaks for free.
- Incentives for Retrofitting Sub-metering. Rescind any regulations that prohibit sub-metering of multifamily buildings and encourage sub-metering (a method in which multi-tenant properties bill tenants for individual measured utility usage) through water audits and direct mail promotions and/or incentives to building owners.
- Require Sub-metering in New Multifamily Units. Require all new multifamily units to provide sub-meters on individual units.
- Metering with Commodity Rates. Require meters for all new service connections. Establish a program for retrofitting existing unmetered service connections, and read meters and bill customers by volume of use.

Nonresidential Audit Measures

- Hotel/Motel Water Audits. Provide free water audits to hotels and motels covering bathrooms, kitchens, ice machines, cooling towers, and irrigation system schedules.
- Water Audit. Provide conservation potential goals for nonresidential accounts and offer assistance in the form of audits and employee education.
- Audits – Hospitals. Provide water audits to hospitals.
- Audits – Laundry Self-Serve Rebates. Offer laundromat managers or washing machine leasing companies incentives to retrofit or use efficient clothes washers.
- Audits – Schools and Universities. Provide water audits to schools and universities.
- Audits – Schools and Universities, Toilets. Provide toilet rebates or vouchers to schools and universities.

Other Nonresidential Measures

- Low-Flow Spray Rinse Nozzles. Provide free installation of 1.6-gal/minute spray nozzles for the rinse/clean operations in restaurants and other commercial kitchens.
- Hotel Retrofits (w/ financial assistance). Following a free water audit, offer participating hotels a rebate for identified water savings. Provide a rebate schedule for certain efficient equipment such as air-cooled ice machines for hotels that do not participate in an audit.
- Replace Inefficient Water-Using Equipment. Provide a rebate for a standard list of water-efficient equipment, including icemakers, dishwashers, and cooling towers, to replace once-through cooling, irrigation controllers, and certain process equipment.
- Cooling Tower Regulations. Prohibit the discharge of cooling tower blowdown unless the total dissolved solids in the water are at least a certain level (ensures 5 to 10 cycles of concentration).
- New Hotel Water Audit (WAVE). This program encourages hotels to do their own water audit and then analyze their water use with the software provided. The software identifies water saving projects and computes paybacks. Hotels that agree to participate in the program also agree to install cost-effective water conserving equipment.
- Steamers – Restaurants. Provide rebates or vouchers to restaurants that purchase electric steam cookers.
- Coin-op Laundry Incentive. Offer incentives to apartment and coin-op laundry managers to retrofit or use efficient clothes washers. The rebate would either go to the manager or the washing machine leasing company.
- ULF Toilet and Urinal Rebates. Provide rebates to pre-1994 businesses with high-use fixtures for commercial ULF toilets (1.6-gal/flush) and commercial ULF urinals (1.0-gal/flush).
- Require 0.5-gal/flush Urinals in New Buildings. Require new buildings be fitted with 0.5-gal/flush urinals.

MEASURES FOR OUTDOOR WATER USE

Homeowner Landscaping Measures

- New Home Efficient Irrigation. Provide information for planting water-efficient landscaping, including avoiding strip turf sections that are difficult to water efficiently and using native plants that do not require supplemental watering. Information would be mailed or provided in brochures with the water bill. Informational displays at water utility offices and nurseries could also be provided.
- Landscape Requirements (turf limitations / regulations). Enforce existing requirements on the use of native or low-water-using plants for landscaping purposes. Proof of compliance would be necessary to obtain a water connection on all new multifamily residential and commercial projects. Non-compliers would face a surcharge on their water bill until they complied.
- Xeriscape Education. Sponsor training for the staff of stores where plants and irrigation equipment are sold to educate sales people about the benefits of native (low-water-use) plants and efficient irrigation.
- Homeowner Irrigation Classes. Sponsor classes at stores where irrigation equipment is sold or other suitable venues on the selection and installation of efficient equipment (drip irrigation, smart controllers, low-volume sprinklers, etc.) and low-water-use plants.

Measures for Large-Scale Irrigation

- Water Budgets. Provide a monthly irrigation water use budget as information on the water bill for all irrigators of landscapes larger than one acre with separate irrigation accounts.
- ET Controller Rebates. Provide a rebate for the latest state-of-the-art irrigation controllers with onsite temperature sensors or a signal from a central weather station that modifies irrigation times at least weekly (preferably daily) as the weather changes.
- Financial Incentives for Complying with Water Use Budget. Link a landscape water budget to a rate schedule that penalizes the account holder for exceeding its water budget and rewards them for using less than the budget.
- Irrigation Upgrade Incentives. Provide rebates for selected types of irrigation equipment upgrade.
- Require Dedicated Irrigation Meters. Require new accounts with a substantial amount of irrigated landscape to have dedicated landscape meters, and charge on a separate rate schedule that recognizes the high peak demand placed on the system by irrigators.
- Large Landscape Conservation Audits. Provide free landscape water audits to all public and private irrigators of landscapes larger than one acre with separate irrigation accounts upon request.

Nonresidential Measures

- Water Brooms. Provide water brooms to nonresidential customers. Savings are based on reduced flow rate and labor time. It is estimated that water brooms reduce the flow rate from 8.4 gal/minute to 3.6 gal/minute and labor time is reduced in half.
- Artificial Turf Program for Schools and Universities. Provide incentives for schools and universities to use artificial turf in playgrounds/athletic fields.
- City/SFPUC Landscaping. Provide free landscape water audits and financial incentives for irrigation upgrades to all city departments.

OTHER MEASURES

Residential Measure

- Residential Water Surveys. Offer indoor and outdoor water surveys to existing single-family and multifamily residential retail customers with high water use; provide customized report to homeowners.

Public Information / Education Measures

- Public Information Program. Provide public education to raise awareness of conservation measures available to retail customers. Programs could include poster contests, speakers to community groups, radio and television time, and printed educational material such as bill inserts, etc.
- School Education Programs. Implement a school education program to promote water conservation and water-conservation-related benefits. Programs include working with school districts and private schools in the water suppliers' service area to provide instructional assistance, educational materials, and classroom presentations that identify urban, agricultural, and environmental issues and conditions in the local watershed.

Water Utility / City Department Measures

- Water Utility / City Department Water Reduction Goals. Provide water use reduction goals for metered city and county accounts and offer audits and employee education.
- Retail Conservation Pricing. Promote water-conserving retail water rate structures. Recognize that each agency or water enterprise fund has a unique rate-setting system and history.
- Conservation Coordinator. Designate a water conservation coordinator and support staff whose duties include coordinating and overseeing conservation programs and best management practice (BMP) implementation, preparing and submitting the Council BMP Implementation Report, and communicating and promoting water conservation issues to agency senior management.
- Water Waste Prohibition. Enact and enforce measures prohibiting gutter flooding, single-pass cooling systems in new connections, non-recirculating systems in all new conveyer car wash and commercial laundry systems, and non-recycling decorative water fountains.
- System Audits, Leaks. Complete an annual prescreening system audit to determine the need for a full-scale system audit. Agencies shall advise customers whenever it appears possible that leaks exist on the customer's side of the meter, perform distribution system leak detection when warranted and cost-effective, and repair leaks when detected.

Nonresidential Measures

- Commercial Water Audits. Provide a free water audit to high-water-use commercial accounts that evaluates ways for the business to save water and money.
- Business Award Program. Sponsor an annual awards program for businesses that significantly reduce water use. Provide a plaque, presented at a lunch with the mayor.
- Large New Project Incentives. Provide incentives for conservation on new/proposed large nonresidential projects.

TABLE 14.2-9
TOTAL ESTIMATED 2030 WATER SAVINGS FROM CONSERVATION AND RECYCLING
(in mgd)

	Wholesale	Retail	Total
Plumbing Code Savings (passive conservation)	25.4	10.3	35.7
Projected Conservation Savings (programs in place)[a]	7.7	0.64	8.3
Savings from Additional Conservation Measures (planned)[b]	5 – 7.3	0 – 3.36	5 – 10.7
Savings from Existing Recycled Water Projects that Offset Potable Water Use	4.3	0	4.3
Savings from Additional Recycled Water Projects that will Offset Potable Water Use (planned)[c]	4.7 – 5.7	0 – 4	4.7 – 9.7
Total Savings from Conservation and Recycling, excluding Plumbing Code Savings	21.7 – 25	0.6 – 8.0	22.3 – 33.0
Total Savings from Conservation and Recycling, including Plumbing Code Savings	47.1 – 50.4	10.9 – 18.3	58 – 68.7

[a] Existing savings based on savings identified for Program/Package A in URS, 2004b and Hannaford and Hydroconsult, 2004.
[b] Additional savings based on the difference between total 2030 conservation savings shown in Draft PEIR Table 3.3 and savings from measures currently being implemented.
[c] Additional recycled water in the wholesale service area is based on the projected 2030 use of 9 to 10 mgd, which is an increase of 4.7 to 5.7 mgd from what was being done in 2004.

SOURCES: URS, 2004b; Hannaford and Hydroconsult, 2004; SFPUC, 2004, RMC 2004.

Supply Option No. 4 Technical Memorandum (SFPUC, 2007, Appendix D), provided the basis for the Aggressive Conservation/Water Recycling and Local Groundwater Alternative analyzed in the Draft PEIR (Vol. 4, Chapter 9, pp. 9-47 to 9-59).

The Regional Water Supply Option No. 4 study identified and evaluated 53 recycled water and groundwater projects for their potential to offset demand on the SFPUC regional water system, and evaluated regional conservation programs consisting of between 8 and 23 conservation measures to be implemented in addition to the conservation programs already planned locally by SFPUC customers. The SFPUC assessed these 53 potential projects to determine their eligibility for the Regional Water Supply Option No. 4 program. Eligibility was based on the ability of the project to offset SFPUC supplies. Projects that were determined to be ineligible were not considered further. Projects that were considered eligible or potentially eligible were evaluated for likelihood of implementation based on available information derived during the early planning stages, such as information on feasibility, cost, conceptual engineering, environmental review, community support, and specifications. These projects were categorized as follows: Category 1 (about 11 mgd) included projects likely to be implemented by 2030; Category 2 (15.2 mgd) included eligible projects in the early planning stages; and Category 3 (2.25 mgd) included potentially eligible future projects that might offset SFPUC regional water system supplies by 2030. The SFPUC subsequently incorporated the Category 1 San Francisco local projects into the WSIP.[21]

The remaining projects that could potentially provide up to 19 mgd of water supply have varying degrees of feasibility. As the analysis of the Aggressive Conservation/Water Recycling and Local Groundwater Alternative indicated, there are numerous uncertainties with regard to water quality, end-users, long-term sustainable yield, and public acceptance issues (related to the use of recycled water for nonpotable uses). In addition, issues related to institutional arrangements, funding sources, or permitting requirements could render any one of these projects infeasible. Further, the proposed levels of service under the WSIP assume that, during drought years, the SFPUC would be able to impose systemwide rationing of up to 20 percent; the feasibility of requiring 20 percent rationing during drought periods would be questionable under this alternative due to demand hardening.[22] Elements of this alternative were also incorporated into the Modified WSIP Alternative (see Vol. 4, Chapter 9, pp. 9-78 to 9-84), which the Draft PEIR identified as the environmentally superior alternative. Please also refer to **Section 14.10, Master Response on Modified WSIP Alternative** (Vol. 7, Chapter 14, Section 14.10.3).

Frequently Submitted Comments Addressing Conservation and Recycling[23]

As indicated in the introductory text to Section 14.2.3, many comments expressed the opinion that any additional demand should be met through increased conservation, efficiency, and recycling; a smaller number of comments specifically advocated that the SFPUC adopt the Aggressive Conservation/Water Recycling and Local Groundwater Alternative or the Modified WSIP Alternative (both of which include more conservation and recycling than would occur with the proposed program). Those opinions are acknowledged. The comments addressed below represent the most frequently submitted comments on this topic *beyond* those expressing that opinion. In this section, each comment (or summary of like comments) is presented in italics and followed by a response. In addition, numerous comments suggested specific conservation measures that the SFPUC and/or the wholesale customers should undertake; these suggested measures are grouped at the end of this subsection.

---

21 These include recycled water projects that provide about 4 mgd, local groundwater projects in San Francisco, and participation in a regional conjunctive-use project providing about 3 to 5 mgd (Draft PEIR, Vol. 1, Chapter 3, pp. 3-55 and 3-56).

22 Demand hardening refers to the increasing inelasticity of demand as additional conservation measures are implemented (refer to Draft PEIR Vol. 4, Chapter 9, p. 9-28).

23 Several related topics are not addressed in this master response. Comments specifically addressing the wholesale customers with the largest share of the projected increase in demand were submitted and addressed in the responses to individual letters. Refer to the following comments/responses for more information on this topic: **SI_CNPS-EB1-11** through **SI_CNPS-EB1-14** (Vol. 7, Chapter 15, Section 15.4). A number of comments addressed Raker Act requirements related to the development of water supplies in the SFPUC service area prior to additional diversions from the Tuolumne River. For information on this topic, refer to **Response L_TUD1-05** (Vol. 7, Chapter 15, Section 15.3). Lastly, BAWSCA submitted numerous comments describing its objections to the Aggressive Conservation/Water Recycling and Local Groundwater Alternative. For more information on this topic, refer to **Comments/Responses L_BAWSCA-27** through **L_BAWSCA-39** (Vol. 6, Chapter 12, Section 12.3 and Vol. 7, Chapter 15, Section 15.3).

- *The SFPUC's preferred alternative ignores conservation and efficiency recycling measures that their own studies found could eliminate the need to divert more water from the Tuolumne River by at least 74 percent. [Representative comments: C_Raffa-07, C_Breso-02, C_Ross-05, C_Stein-02, C_Hasso-03, C_Picku-01, C_Poult-01]*

The reference in these comments is to the report *Investigation of Regional Water Supply Option No. 4 Technical Memorandum* (SFPUC, 2007, Appendix D) described above. The preceding discussion describes the conservation and recycling associated with the proposed program; the Aggressive Conservation/Water Recycling and Local Groundwater Alternative (Draft PEIR Vol. 4, Chapter 9, pp. 9-47 to 9-59) includes additional conservation and recycling projects described in the Water Supply Option No. 4 report, but not included in the proposed program. As indicated in the Draft PEIR (p. 9-49), this alternative could meet up to 74 percent of the additional projected 2030 average annual water supply need; however, at least 6 mgd of this projected demand would be unmet, and this alternative would also provide less drought reliability compared to the WSIP, requiring an increased frequency of rationing.

- *The SFPUC should conduct a study to determine the maximum technical potential for conservation and efficiency savings within the SFPUC service territory. [Representative comments: SI_CRS-05, C_Berko-02, C_BoutiF-02, C_Dippe-02, C_Hsiun-02, C_Raffa-11, C_Ross-09, C_Thaga-02]*

The SFPUC did conduct such a study—the *Investigation of Regional Water Supply Option No. 4 Technical Memorandum* described above.

- *Water conservation measures are the cheapest, easiest, and least destructive ways to meet demand and extend supply. [Representative comments: SI_SierraC4-02, C_Hasso-03, C_Means1-01, C_Raffa-07, C_Ross-05, C_Walk-03, C_Willi-05]*

Comments acknowledged. The PEIR authors concur that conservation measures are less detrimental to the environment than the development of water supplies; this is one of the reasons the Draft PEIR included multiple alternatives involving higher levels of conservation and recycling and reduced diversions from the Tuolumne River, including the Aggressive Conservation/Water Recycling and Local Groundwater Alternative and the Modified WSIP Alternative. (The Draft PEIR does not address the costs of conservation measures.)

- *Per-capita water use is projected to increase for wholesale customers, indicating they lack effective conservation programs. [Representative comments: C_Raffa-07, C_Ross-05]*

The Draft PEIR does not present per-capita information, nor were future demands projected based on per-capita consumption, as discussed in Section 14.2.2, above. As that discussion indicates, per-capita demand for the wholesale customer service area is not projected to increase; the average weighted per-capita demand for residential and nonresidential sectors is projected to decrease, both with and without additional conservation programs. While it is the case that per-capita demand is projected to increase for some individual wholesale customers, the overall trend within the service area shows a decrease in per-capita demand.

Per-capita demand is influenced by a range of factors, including economic, demographic, and climatic conditions. Consequently, comparisons between different areas can be misleading unless the specific factors influencing the demand are understood. In addition, the methodology used to measure water use and calculate per-capita demand may vary. Numerous comments assert that per-capita demand in the wholesale service area is high compared to other areas, with some comments citing per-capita demand as evidence that conservation measures are ineffective. The DWR's California Water Plans provide useful information on how the Bay Area compares with the rest of the state. Per-capita demand in each hydrologic region in the state, based on information in the 1995 and 2005 California Water Plans (DWR, 1998; DWR, 2005), is shown in **Tables 14.2-10** and **14.2-11**, below. As the tables indicate, the San Francisco Bay region had the second lowest per-capita water usage in the state in 1995, and the lowest urban and residential per-capita usage in the state in 2000.[24] The information in each table is from the same source, and the per-capita estimates shown in each table were calculated using consistent factors and methodology; therefore, these tables provide a reasonable means to compare average usage rates in different parts of the state.

The San Francisco Bay hydrologic region includes more than the SFPUC service area, and low per-capita residential demand within the city of San Francisco (where there is comparatively less outdoor water use than in other areas) would serve to lower the average per-capita rate for the region as a whole. Therefore, the per-capita information for the San Francisco Bay hydrologic region does not definitively establish that per-capita demand in the wholesale customer service area is relatively low. Per-capita demand information provided by the SFPUC for the September 2006 Sustainable Water Supply Briefing does, however, suggest that per-capita demand in the wholesale service area compares favorably to that in other parts of the state.

Table 14.2-12 presents 2001 and 2030 estimates for single-family and multifamily residential per-capita use for the wholesale customers. As noted above, comparisons between different areas can be misleading unless the underlying dynamics of the given areas, as well as the factors and methodology used to calculate given statistics, are understood. In addition to these constraints, per-capita demand information provided for the Sustainable Water Supply Briefing (SFPUC, 2006) does not include estimates for total residential per-capita consumption, preventing a direct comparison of total residential demand. Nevertheless, based on the 2001 per-capita estimates of single-family residential use in the wholesale service area (which would be higher than total residential use) and the 2000 DWR information on residential usage (Table 14.2-11), it appears that the per-capita residential use for the wholesale customers is relatively low. The wholesale customers' weighted average gross per-capita demand for the 2001 base year—166 gpcd (SFPUC, 2006)—also compares favorably to urban per-capita usage in other parts of the state.

---

24 Although the information in Tables 14.2-10 and 14.2-11 is from two editions of the *California Water Plan*, it should be noted that the per-capita information for 1995 (Table 14.2-10) is provided as shown in the 1995 *California Water Plan* (DWR, 1998), whereas the per-capita information for 2000 (Table 14.2-11) was calculated from information on the hydrologic regions provided in the *California Water Plan Update 2005* (DWR, 2005). Therefore, while each table provides a means for comparing different regions for the given year, comparisons *between* the tables would be misleading, since somewhat different methodologies and factors were used to calculate the per-capita information. For example, weather-normalized data were used to compute the 1995 per-capita information and conveyance losses were excluded, whereas the 2000 per-capita information was calculated for this PEIR based on total urban water use (and the subset of residential water use) data and population data provided for each hydrologic region in the 2005 plan.

TABLE 14.2-10
PER-CAPITA WATER USE[a] BY HYDROLOGIC REGION – 1995
(in gpcd)

Hydrologic Region	Usage
Colorado River	564
North Lahontan	411
San Joaquin River	310
Tulare Lake	298
Sacramento River	286
South Lahontan	282
North Coast	249
South Coast	208
San Francisco Bay	**192**
Central Coast	179

[a] Includes residential, commercial, industrial, and landscape use supplied by public water systems and self-produced surface and groundwater. Does not include recreational use, energy production use, and losses from major conveyance facilities. Data are normalized.

**TABLE 14.2-12
WEIGHTED AVERAGE RESIDENTIAL PER-CAPITA DEMAND
WHOLESALE CUSTOMER SERVICE AREA, 2001 AND 2030
(in gpcd)**

Wholesale Customers	2001 Single-Family Residential	2001 Multifamily Residential	2030 Single-Family Residential (without additional conservation)	2030 Multifamily Residential (without additional conservation)	2030 Single-Family Residential (with conservation)	2030 Multifamily Residential (with conservation)
Weighted Average	108	75	103	67	98	64

SOURCE: SFPUC, 2006.

The above evidence suggests that per-capita water use in the wholesale service area is, in fact, relatively low. Lower per-capita use, however, may suggest that the potential for additional conservation would also be relatively low. The information on projected 2030 per-capita residential demand shown in Table 14.2-12 indicates that the continued implementation of plumbing codes and planned conservation measures will continue to reduce per-capita demand within the service area. Regarding changes in per-capita outdoor demand in the wholesale and retail service areas, refer to the discussion in Section 14.2.2, above, under the heading Outdoor Water Use. For additional response on this topic, refer to Section 14.2.3 under the heading Per-Capita Demand.

Many comments compared the Bay Area's water consumption and conservation to that of other areas or water utilities.

- *In contrast to other metropolitan areas that have managed to reduce water demand in the face of growth, the anticipated 14 percent increase in demand projected by the SFPUC is large and out of step for the Bay Area. [Representative comments: C_Elbizri-02, C_Garba-01, C_Hasso-03, C_Raffa-04, C_Ross-02, C_Schri-01, C_Thoma-01]*

- *The conservation savings identified in the analysis are low in comparison to savings achieved in recent water conservation assessments and in other water districts. [SI_PacInst-62]*

- *When it comes to conservation, the Bay Area lags far behind other metropolitan areas such as Seattle and Los Angeles that are reducing water consumption even in the face of growth. As a region known for a strong environmental ethic, the Bay Area should be a leader in water efficiency and conservation. [Representative comments: C_Breso-02, C_Bucki-02, C_Cant-01, C_Dippe-01, C_Garba-01, C_Hanke-02, C_Hasso-02, C_Hsuin-02, C_Picku-01, C_Raffa-07, C_Reich-01, C_Ross-05, C_Sugar-02, C_Shea-01, C_Thoma-01, C_Willi-02, C_Unreadable1-01]*

These comparisons with other areas apparently refer to studies of water conservation and other demand management programs cited in comments submitted by the Pacific Institute and possibly studies identified in Comment SI_TRT-CWA-SierraC-196,[25] although this latter comment presents a list of studies with no discussion or analysis. As discussed above, statewide studies conducted by the DWR indicate that per-capita consumption in the Bay Area is lower, not higher, than in Los Angeles. Where comments addressed specific studies from other areas, the SFPUC's DSS technical consultant reviewed the examples in-depth and found, for various reasons (summarized in the responses below), that the studies do not support the assertion that the Bay Area is conserving less than other areas (Maddaus, 2008).

The water savings achieved in one area may not be directly transferable to another area. Water use can vary widely between regions, and even within a region, due to differences in the factors that influence water use (e.g., climate, land use—including the type, density, and size of residential housing, and the types of commercial, industrial, and other nonresidential land uses—and economic factors), specific characteristics of water use patterns (e.g., average gallons per flush for existing fixtures), and differences in the methodology used to report demand (e.g., whether/how factors such as existing conservation and unaccounted-for water are reflected in demand). Consequently, absent an understanding of such factors, the assumption that a percent reduction through conservation achieved in one area can be achieved in another is overly simplistic. As noted above, the lower existing usage in the Bay Area suggests that water savings or reductions achieved in areas that use water more intensively are not comparable to the Bay Area.

Note also that these comments and the ones citing more specific examples from other areas (discussed below) do not address the rationing that would be imposed during drought periods under the WSIP and the attendant demand hardening that could occur. Refer to **Response SI_PacInst-27** (Vol. 7, Chapter 15, Section 15.4) for more information on demand hardening.

- *Projections to 2030 indicate that water use efficiency improvements are still not being implemented effectively for the wholesale customers despite the development of numerous technologies and policies to cost-effectively reduce water waste. For example, Seattle Public Utilities successfully reduced per-capita demand from 150 gpcd in 1985 to 105 gpcd in 2004 through higher water rates, plumbing codes, conservation, and improved system operation. Likewise, EBMUD reduced per-capita demand from 210 gpcd in 1970 to 155 gpcd in 2005 through a variety of conservation measures. [SI_PacInst-59]*

Comparisons of long-term per-capita demand between areas with substantially different economic, demographic, and climatic conditions can be misleading, unless the comparisons can be substantiated by a scientific analysis that accounts for the different conditions. The reasons for changes in per-capita demand are unique to the dynamics of an individual water service area and its customers. Regarding the decrease in per-capita demand experienced by EBMUD, one relevant factor is that during the time period cited (1970–2005) one of EBMUD's largest industrial users, a refinery, began to recycle water. The use of recycled water dramatically cut the refinery's water use and reduced overall usage in EBMUD's service area. Regarding the experience of Seattle Public Utilities, again, as noted, comparisons between utilities that have different economic, demographic, and climatic conditions can be misleading, and may be

[25] These comment letters are provided in Vol. 6, Chapter 12, Section 12.4.

especially problematic when the methodology used to measure water use and calculate per-capita demand (which can vary) is not known. Table 14.2-10, above, summarizes DWR's comparison of per-capita water use among the state's hydrologic regions; as noted in the table, the DWR used normalized water use data for its calculations and a consistent methodology to calculate the per-capita estimates.

- *Recent conservation assessments indicate that there are a substantial number of cost-effective technologies that can drastically reduce indoor and outdoor residential water demand to levels far below those projected for the wholesale and retail customers. A 1997 study by the American Water Works Association (AWWA) found that conservation could reduce indoor water use from 65 gpcd to 45 gpcd for single-family homes, a savings of over 30 percent. The largest reductions were realized by replacing inefficient toilets and clothes washers with more efficient models. A Seattle study found that installing new, water-efficient fixtures and appliances reduced single-family indoor water use from 64 gpcd to 40 gpcd, a savings of nearly 40 percent and far below the 2030 levels projected in the SFPUC studies. The savings achieved in these studies are supported by a recent Pacific Institute study that quantified the potential for water conservation and efficiency improvements in California's urban water use and concluded that existing cost-effective technologies could substantially reduce California's current residential indoor and outdoor water use. [SI_PacInst-71]*

As discussed above, the water savings achieved in one area may not be directly transferable to another area, and an understanding of the factors that influence water use is necessary to avoid overly simplistic comparisons. The specific water conservation measures mentioned in the comment (replacement of fixtures and appliances with less water-intensive models and water-efficient landscaping) have already been considered by the SFPUC and its wholesale customers and are included in existing and proposed conservation programs (refer to Tables 14.2-6 through 14.2-8). (As shown in the tables, the SFPUC and all of the wholesale customers participate in clothes washer rebate programs, and nearly all participate in low-flow toilet rebate programs.) The SFPUC's DSS technical consultant prepared the following information on the studies cited (Maddaus, 2008).

American Water Works Association Study. The 1997 AWWA study cited in this comment is actually a WaterWiser website posting that was based on preliminary data. The final report on the study, entitled *Residential End Uses of Water*, was published by the AWWA Research Foundation and AWWA in 1999. The results presented in the final report indicated that, for the 12 cities where measurements were made, the average usage for single-family residences was 69 gcpd, and the range was 57 to 84 gcpd (AwwaRF and AWWA, 1999). The report did not conclude that water use could be reduced by 30 percent (to 45 gcpd) through conservation measures such as replacing toilets and clothes washers; this conclusion is an extrapolation based on certain assumptions and on preliminary data, rather than on the final reported data.

Seattle Study. Although the "Seattle study" is cited as documentation for a general indoor water use reduction potential of 40 percent, it was a small pilot study that involved retrofitting 37 homes (DeOreo et al., 2001). The study documented a water savings of 37.7 percent in clothes washer use and computed a water savings of about 5.6 gpcd, which is the value used in the SFPUC conservation potential technical assessment. Other significant water savings were achieved by replacing toilets (10.9 gpcd) and fixing leaks (4.3 gpcd), although showerheads and faucet aerators were also replaced. The Seattle study reported an average pre-retrofit flush volume of 3.6 gallons per flush and a post-retrofit flush volume of 1.4 gallons per flush. SFPUC studies determined the 2001 average flush volume in the wholesale customer service area to be 3 gallons per flush, and therefore the level of savings reported in the Seattle study would not apply; if this retrofit project had been conducted in the wholesale customer area, less water would have been saved. The toilets used in the Seattle study, called high-efficiency toilets, were considered in the SFPUC conservation potential analysis (URS, 2004b) as conservation measure 12 (rebates), and as New Measure NM1 (direct installations) in the Regional Water Supply Option No. 4 study (SFPUC, 2007, Appendix D) (which provided the basis for the additional savings considered in the Aggressive Conservation/Water Recycling and Local Groundwater Alternative). The post-retrofit period measurements for the Seattle study were made within one year of the original retrofit, and no follow-up measurements have been conducted. However, the experience of the SFPUC and the DSS technical consultant has shown that the reported savings due to leak reduction in toilets are not permanent, but disappear over time as the new toilets begin to leak. Some of the savings reported in the Seattle study apparently resulted from behavioral changes, such as a 1.7 gpcd savings due to a reduction in the number of baths. Studies of other conservation measures involving behavioral changes have documented that such savings are not permanent.[26]

Pacific Institute Report. The commenter states that the AWWA and Seattle studies are supported by the water savings potential for California reported in Pacific Institute's 2003 report *Waste Not, Want Not: The Potential for Urban Water Conservation in California*. The shortcomings of the cited AWWA and Seattle studies with respect to their applicability and relevance to the Bay Area are discussed above. This Pacific Institute report is not applicable because it estimates savings for the state of California as a whole and includes individual measures that are not applicable to the wholesale customers, such as installation of water meters in Central Valley communities. Estimates of water savings potential based on a peer-reviewed summary of all published literature is available in the CUWCC *BMP Cost and Savings Study* (A&N Technical Services, 2005); the October 2004 version of this study was used in the SFPUC conservation potential technical analysis (URS, 2004b, Table 3-2).

- *Studies in Austin, Texas and Las Vegas, Nevada, and in the Irvine Ranch Water District, City of Santa Monica, and Municipal Water District of Orange County in California, show that a number of outdoor conservation measures are cost-effective and yield substantial water savings, providing evidence that more can be done in the wholesale customer service area to reduce outdoor water use. Examples of measures include rebates or direct payments for removing water-intensive grass and maintaining water use budgets below levels established by the city (Austin and Las Vegas); use of evapotransporation (ET) controllers (Irvine Ranch Water District); funding for new and remodeled garden design that uses native plants, water-efficient plants, water-efficient irrigation systems, landscape*

[26] For example, the decline in residential water audit savings, which rely on behavioral changes, is well documented in the literature (refer to the *BMP Costs and Savings Study*, A&N Technical Services, 2005). Consequently, the reported savings of 23.7 gpcd will likely decline substantially over time. The wholesale customer conservation potential study accounted for the decline in savings that is expected to occur over time, as documented in relevant studies (Maddaus, 2008).

> *audits, stormwater catchment systems, or graywater systems as well as other innovative water-saving features (City of Santa Monica); and programs to train landscape professionals (Municipal Water District of Orange County). [SI_PacInst-72]*

As discussed above, because of differences in the factors that influence water use (e.g., climate and land use), comparisons between water savings in different areas can be misleading. Water savings achieved in arid places like Austin and Las Vegas are not transferable to the Bay Area, where the climate is substantially different. The DSS technical consultant prepared the following information on the other studies cited in this comment (Maddaus, 2008).

Irvine Ranch Study. The Irvine Ranch study of ET controllers mentioned in the comment found a range of savings that were reported over a number of years in different reports. The later reports in the series were more scientific in that they addressed some anomalies in the data and had more post-retrofit data. The correct, final figure for the reduction in outdoor use is 16 percent, as reported in the CUWCC's *BMP Costs and Savings Study* (A&N Technical Services, 2005). This savings is compatible with the values used in the wholesale customer conservation potential study (URS, 2004b, Table 3-2).

Please also refer to Comment L_BAWSCA1-110 (Vol. 6, Chapter 12, Section 12.3), in which BAWSCA indicates that the results of a three-year study on the effectiveness of ET controllers in the Bay Area are expected in about a year. As stated in this comment, BAWSCA is awaiting these results to inform its decisions regarding any ET controller rebate program. Table 14.2-8, above, shows the wholesale customers currently committed to implementing ET controllers.

Municipal Water District of Orange County's Landscape Program. According to the comment, Orange County's Landscape Performance Certification Program targets large landscape customers that have dedicated irrigation meters. The program provides technical training sessions for landscape contractors and property managers, prepares water budgets, and follows up with site assessments for compliance with the water budgets. Based on compliance with the water budgets, bronze, silver, or gold certificates are awarded, and companies that achieve certification are promoted. The program is estimated to save each customer an average of 765 gallons per day, a 20 percent reduction in outdoor use.

For the SFPUC conservation potential study conducted for the wholesale customers, the amount of turf (grass lawn, field, etc.) within each customer area was estimated. Various conservation measures—including CUWCC BMP 5 (Large Landscape Conservation), water budgets (with a unit savings of 15 percent), and ET controllers (with a unit savings of 15 percent)—similar to those in the Orange County program—were applied to sites with large areas of turf. The latter two measures combined were estimated to produce more savings per unit than the 20 percent savings cited for the Orange County program. Because the wholesale customers, for the most part, have far fewer large turf areas and a cooler climate than Orange County, the overall effect for all wholesale customers is likely to be less than for all of Orange County (refer to Table 14.2-8, above, which shows the wholesale customers currently committed to implementing these measures).

- *The conservation potential identified for the SFPUC wholesale and retail customers is weak and misses important efficiency opportunities. Other conservation assessments [citing a 2003 statewide study by the Pacific Institute and a survey conducted by the Santa Clara Valley Water District (SCVWD)] have concluded that the actual conservation potential of the nonresidential sector is substantially higher. [SI_PacInst-80]*

For reasons noted above, the estimated savings identified in the Pacific Institute study cited in this comment are not directly applicable to the wholesale service area. The Pacific Institute study's estimated savings are for the state of California as a whole, and the study includes individual measures that are not applicable to the wholesale customers, such as the installation of water meters in Central Valley communities. Regarding the three examples of promising technologies cited in this comment (pre-rinse spray valves, cooling towers, and x-ray machines), the SFPUC and BAWSCA are implementing a pre-rinse spray valve program in the SFPUC service area (as noted in Comment SI_PacInst-38 [Vol. 6, Chapter 12, Section 12.4]), and the SFPUC participates in a regional program that offers rebates for a range of water saving devices, including cooling towers and x-ray machines (SFPUC, 2006, p. 7).[27]

The SCVWD survey cited in this comment (of 26 commercial, industrial, and institutional facilities) is not representative of all nonresidential customers in that water district or of the SFPUC wholesale customers. Twenty-six customers is a small sample, and the sample was self-selected (participants volunteered for a water survey). The comment states that the Santa Clara survey identified a "conservation potential of 38 percent." It has been the experience of the DSS technical consultant and other water supply professionals that only a fraction of identified conservation potential is actually implemented. For example, in the mid-1990s the Metropolitan Water District of Southern California conducted the most comprehensive Commercial, Industrial, and Institutional (CII) study ever undertaken. Sweeten and Chaput (1997) analyzed the results of 179 CII surveys taken at a broad range of sites, from large industrial facilities to smaller commercial and institutional sites. Overall, the surveys identified a potential savings of 29 percent; however follow-up telephone surveys found that only 30 percent of this estimated savings (i.e., less than one-third of the estimated 29 percent) was reported to have been implemented (Sweeten and Chaput, 1997). Thus, the overall savings from this intensive effort was estimated to be 8.7 percent of pre-survey water use. Actual water use reductions or persistence were not measured, and long-term savings may be less (Maddaus, 2008).

Over the past nine years, the DSS technical consultant (Maddaus Water Management) who conducted the wholesale customer demand and wholesale customer conservation potential studies (URS, 2004a, 2004b) has prepared water conservation assessments for over 115 communities in the United States, including 67 in California. In the past five years, this firm has completed studies in multiple Bay Area communities, including studies for Sonoma County and the Marin Municipal Water District (MMWD). The savings in these other areas are comparable to the savings identified in the wholesale customer service area, particularly considering that per-capita water use in the wholesale area is low compared to California averages. For example, in 2006 and

[27] In addition, BAWSCA has indicated interest in joining the SFPUC to launch a cooling tower feasibility study to assess the water savings that could be achieved from a cooling tower retrofit program; refer to Comment L_BAWSCA-114 (Vol. 6, Chapter 12, Section 12.3).

2007, Maddaus worked with MMWD to develop four conservation program alternatives (Programs A through D). For programs with comparable conservation measures, the projected 2030 water savings (including the conservation programs and the effects of plumbing codes) ranged from 13 percent (Program A) to 17 percent (Program D). This is 3 percent higher than the total savings identified for the SFPUC service area of 10 to 14 percent (Maddaus, 2008).

Regarding the relationship between the implementation of long-term conservation measures and the imposition of short-term cutbacks in water use during drought periods, refer to **Response SI_PacInst-27** (Vol. 7, Chapter 15, Section 15.4).

- *Additional mandatory conservation will not be required for the wholesale customers, but will be required for retail customers. The wholesale model does not penalize additional water usage. [Representative comment: C_Clark1-09]*

This and similar comments warrant clarification regarding (1) the actions proposed by the SFPUC as part of the WSIP versus the actions proposed by the wholesale customers, and (2) the CCSF's authority to require wholesale customers to do more conservation. The future conservation programs described above for the wholesale customer service area are proposed by, and would be carried out by, the wholesale customers; those in the retail service area would be carried out by the SFPUC as part of the WSIP. The two alternatives that require greater levels of conservation and recycling than the proposed program—the Aggressive Conservation/Water Recycling and Local Groundwater Alternative and the Modified WSIP Alternative—assume that the wholesale customers would actively and willingly participate, in coordination with the SFPUC, in developing additional conservation and recycling programs. However, although BAWSCA supports the Modified WSIP Alternative (with changes outlined in Comments L_BAWSCA-51 through L_BAWSCA-53), it opposes the Aggressive Conservation/Water Recycling and Local Groundwater Alternative based on the wholesale customers' current low water use and the conservation and local supply projects they already have in place (see Comment L_BAWSCA1-27 [Vol. 6, Chapter 12, Section 12.3]). Regarding the SFPUC's authority to require more conservation, the SFPUC does have the regulatory authority to impose conservation programs in the retail customer service area; however the SFPUC's ability to influence the wholesale customers is limited to its contractual agreements with them.

- *Over half of the demand is outdoor water use and is a major cause for the increased demand. Water conservation and efficiency measures, along with recycling, should eliminate the need for additional future water supplies. [Representative comments: C_MartiM-02, C_Chiap-03, C_Hanke-02, C_Helld-01, C_Parke-02, C_Raffa-03]*

As indicated in Section 14.2.2, outdoor water use does account for 58 percent of the increase in projected demand in the wholesale customer service area, according to BAWSCA data; outdoor water use includes irrigation as well as uses such as cooling. Table 14.2-8 of this master response shows the conservation measures to which the wholesale customers have committed during normal and wet years; the measures in green apply to outdoor water uses. These measures reduce but do not eliminate the projected increase in demand associated with outdoor use. For example, in the retail service area, the per-capita residential outdoor use is projected to increase by 0.3 gpcd without additional conservation and by 0.2 gpcd with additional conservation; in the wholesale service area, the weighted average per-capita wholesale residential outdoor use is projected to increase by 3 gpcd without additional conservation and by 1 gpcd with additional conservation. The potential to use recycled water in nonresidential outdoor applications (such as for cooling and landscape irrigation) is recognized; however, some constraints limit the potential to use recycled water in specific areas or applications. As discussed above, challenges associated with implementing recycled water projects include costs and funding, public acceptance, development of partnerships to improve the feasibility of recycled water projects, and managing water quality.

As discussed in the Draft PEIR, during prolonged dry years, SFPUC customers would be subject to 20 percent systemwide rationing under the WSIP. Although drought management strategies would likely differ somewhat among customers, urban rationing programs typically shift the worst impacts to outdoor water uses, particularly residential exterior and commercial landscaping uses. Consequently, short-term, dry-year conservation measures implemented by SFPUC customers in response to rationing are very likely to target outdoor use.

Conservation Measures Suggested by Commenters

A number of commenters suggested the following specific conservation measures that could help reduce diversions from the Tuolumne River:

- *Prevent individuals from hosing down sidewalks. [C_BrookL-01]*
- *Offer rebates to residents that replace lawns with native plants. [C_Lubin-01]*
- *Provide incentives to conserve water. [C_Byron-09, C_Joye-01]*
- *Provide public education about the need for and methods of water conservation. [C_Britt-01, C_BrookL-01, C_Ellis-01]*
- *Raise water rates in a tiered manner. [C_Byron-01, C_Eddy2-02]*

As shown in Tables 14.2-6, 14.2-7, and 14.2-8, the SFPUC and the wholesale customers are currently implementing or committed to implementing conservation measures similar to those suggested above. The SFPUC and most of the wholesale customers have landscaping requirements and offer programs to encourage residents to switch to low-water-use plants and implement efficient irrigation, such as homeowner irrigation classes, xeriscape education, and irrigation upgrade incentives. Almost all of the wholesale customers (along with the SFPUC) implement conservation education programs. For its nonresidential customers, the SFPUC has planned programs for landscape audits and water-broom measures. The SFPUC and all of the wholesale customers currently implement conservation pricing (the CUWCC's BMP 11). These water conservation programs are also described in Comment L_BAWSCA1-114 (Vol. 6, Chapter 12, Section 12.3). The programs vary by agency, as each agency has evaluated the programs it believes would be most cost-effective based the characteristics of the service area.

Comments from special interest groups also suggested several programmatic water conservation measures. These comments include the following:

- *Each agency should assess what is driving demand growth and measures to reduce that demand. Agencies must take a more proactive role in identifying ways to reduce demand growth, particularly in new developments. [SI_PacInst-19]*

The factors that contribute to future demand were assessed in the end-use demand models used to develop the demand projections in the wholesale and retail service areas. These factors typically included the specific water use characteristics of single-family and multifamily residential, commercial, and industrial uses within each service area, other factors that applied to the given service area, and the extent of future population and job growth expected in each service area. The SFPUC conducted studies to identify the potential for conservation measures and the use of recycled water to offset demand, working closely with each customer to identify all feasible conservation potential. The projected conservation savings, use of recycled water, and use of other potable sources were factored into the purchase estimates submitted by San Francisco and each wholesale customer to the SFPUC. The Draft PEIR thoroughly describes, evaluates, and discloses the assumptions, methodologies, and results of these studies consistent with CEQA requirements (CEQA Guidelines Section 15144).

- *All agencies should sign the CUWCC's Memorandum of Understanding Regarding Urban Water Conservation in California (MOU) and work to implement all BMPs. [SI_PacInst-21]*

The SFPUC and 14 wholesale customers are signatories to the MOU, and three other wholesale customers (not signatories themselves) participate via the SCVWD, which is a CUWCC signatory. Tables 4.2-7 and 14.2-8, above, indicate the CUWCC BMPs currently being implemented in the wholesale and retail service areas.

- *Purchases from the SFPUC should be capped at current levels and financial incentives/disincentives should be instituted to encourage conservation/discourage growth in demand. [SI_PacInst-24]*

A No Purchase Request Increase Alternative was evaluated in the Draft PEIR (Vol. 4, Chapter 9, pp. 9-40 to 9-47), as were two variations of the Aggressive Conservation/Water Recycling and Local Groundwater Alternative, one with and one without supplemental water from the Tuolumne River (pp. 9-47 to 9-59). None of these was identified as the environmentally superior program alternative (pp. 9-95 and 9-96). Refer to **Responses SI_PacInst-47** and **SI_PacInst-62** (Vol. 7, Chapter 15, Section 15.4) regarding conservation pricing and tiered rate structures, and to Tables 14.2.7 and 14.2.8, above, regarding conservation measures the SFPUC and its wholesale customers are implementing or have committed to implement under the WSIP.

- *Local governments should be provided incentives to change their construction permitting to allow greywater systems for individual homes and to limit large irrigation systems. [SI_CI-01]*

The current state standards provide for the use of graywater for subsurface irrigation only (California Code of Regulations, Title 24, Part 5, Appendix G). The SFPUC has no legislative or permit authority over individual wholesale customer service areas. Refer to "Measures for Large-Scale Irrigation" in Table 14.2-6 regarding large irrigation systems.

- *The SFPUC and its wholesale customers should implement water and wastewater rate structures that encourage water conservation among their customers and fund conservation programs. [SI_PacInst-20]*

The SFPUC and each of the wholesale customers have adopted the CUWCC's BMP 11, Conservation Pricing (refer to Tables 14.2-7 and 14.2-8). Please also refer to **Response SI_PacInst-62** and **Response SI_PacInst-47** (Vol. 7, Chapter 15, Section 15.4) regarding the use of water pricing as a water agency tool and tiered pricing rate structures, respectively. The SFPUC and the wholesale customers currently fund and implement conservation programs, and the 2030 purchase estimates reflect savings from the implementation of additional measures to which the customers have committed.

- *The SFPUC and BAWSCA should work together to establish more effective regional conservation and recycling programs; institutional mechanisms should be developed to encourage wholesale customers to move more effectively toward efficiency improvements. [SI_PacInst-22]*

The SFPUC is currently evaluating methods of encouraging additional conservation among its wholesale water customers; refer to the description of the Modified WSIP Alternative (Vol. 4, Chapter 9, pp. 9-78 to 9-84).

14.3 Master Response on Proposed Dry-Year Water Transfer

14.3.1 Introduction

Overview

This master response addresses questions about the proposed dry-year water transfer included as part of the WSIP's water supply option. Commenters raised questions regarding the feasibility of the proposed transfer; whether the Turlock Irrigation District (TID) and/or the Modesto Irrigation District (MID) have agreed to such a transfer; and the validity of evaluating the proposed transfer when no official agreement among the agencies has been made. This master response is organized by the following subtopics:

14.3.2 Description of Dry-Year Water Transfer Assumptions Analyzed in the PEIR
14.3.3 CEQA Review of the Proposed Dry-Year Transfer

Commenters also raised questions about proposed Mitigation Measure 5.3.6-4a, Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water, which would lessen the environmental impacts of the dry-weather transfer on the lower Tuolumne River, downstream of La Grange Dam. Comments on Mitigation Measure 5.3.6-4a are addressed in **Section 14.7, Master Response on Lower Tuolumne River Issues**, and comments on the water transfer of conserved water included as part of the Modified WSIP Alternative are addressed in **Section 14.10, Master Response on Modified WSIP Alternative** (Vol. 7, Chapter 14).

PEIR Section Reference

The Draft PEIR describes the dry-year water transfer in Vol. 1, Chapter 3, Section 3.6.2, pp. 3-36 to 3-39. Because the dry-year transfer is an integral part of the proposed WSIP water supply and system operations, it was included in the modeling for the future with-WSIP condition. The impacts of the WSIP water supply and system operations on water resources in the Tuolumne River watershed are described in Vol. 3, Chapter 5, Section 5.3.1, pp. 5.3.1-1 to 5.3.1-39, and the impact analysis includes the effects of the dry-year water transfer. Modeling data for the future with-WSIP condition used in the Draft PEIR are presented in Vol. 5, Appendices H1 and H2, and results of the updated modeling conducted after publication of the Draft PEIR and used in the refined analyses provided in the Comments and Responses document are presented in Vol. 8, Appendix O. All model results include the effects of the dry-year transfer as part of the proposed program.

14.3.2 Description of Dry-Year Water Transfer Assumptions Analyzed in the PEIR

Summary of Issues Raised by Commenters

- There is no formal agreement on a dry-year transfer with TID and/or MID.

- The dry-year transfer may not be feasible because no agreement for such a transfer has been executed.
- The details of the proposed dry-year transfer should be fully described.

Response

The City and County of San Francisco (CCSF), TID, and MID hold rights to Tuolumne River water. TID and MID are senior to the CCSF for some of their direct and storage water rights. The Raker Act granted rights-of-way to the CCSF to construct the Hetch Hetchy Project on federal lands provided certain conditions were met, including recognition of TID's and MID's senior water rights (Vol. 1, Chapter 2, pp. 2-33 and 2-34). To meet these conditions, the CCSF is required at certain times to release certain flows from its reservoirs in the upper Tuolumne River watershed for use by TID and MID.

The CCSF's reservoirs in the upper Tuolumne River watersheds are not sized to capture the CCSF's full entitlement of Tuolumne River water. When the Don Pedro Project was built in the early 1970s, the CCSF contributed to the project's cost to receive the right to "prepay" TID and MID for water the CCSF would otherwise have to release from its upstream reservoirs to meet its Raker Act obligations. The water bank acts as "virtual storage" that allows the CCSF to use a greater portion of the Tuolumne River water to which it is entitled. All water stored in Don Pedro Reservoir belongs to TID and MID, and the CCSF cannot divert water directly from the reservoir. The Don Pedro Reservoir water bank is described further in the Draft PEIR (Vol. 1, Chapter 2, pp. 2-37 to 2-39).

When inflow to Don Pedro Reservoir exceeds the TID's and MID's Raker Act entitlements and there is space available in the water bank, the excess water is credited to the CCSF's water bank account. When the CCSF would otherwise have to release water from its reservoirs in the upper Tuolumne River watershed to fulfill its Raker Act obligations to TID and MID, the CCSF's water bank account in Don Pedro Reservoir is debited so that TID and MID receive their full entitlement of Tuolumne River water. This water banking arrangement enables the CCSF to divert and store more water in Hetch Hetchy Reservoir than it otherwise would, preserving the water for use in the Bay Area.

As described in the Draft PEIR (Vol. 1, Chapter 3, pp. 3-33 to 3-39), the SFPUC's existing water supply sources are insufficient to satisfy the WSIP water supply goal of no greater than 20 percent systemwide rationing during droughts under current (2005) demand (purchase requests). This shortage will become more severe by 2030 with the projected increase in purchase requests. Under the WSIP, the SFPUC would establish supplemental dry-year water sources, one of which would be a transfer of water from TID and MID. Although the SFPUC would only need the dry-year transfer fairly infrequently, the transfer would need to occur administratively every year because at the beginning of a year it would not be possible to know when hydrologic circumstances would make a transfer necessary. The proposed dry-year water transfer under the WSIP would occur as follows. Each year TID and MID would transfer ownership of a block of water in Don Pedro Reservoir to the SFPUC. In many years, the SFPUC would be able to meet its customers' needs without using the transferred water, and ownership of the water would likely revert to TID and MID. Occasionally, the SFPUC would need the transferred water, which it would secure by decreasing releases from its reservoirs in the upper Tuolumne River watershed and using the block of water in Don Pedro Reservoir to meet its Raker Act obligations to TID and MID. This would enable the SFPUC to increase its diversions from Hetch Hetchy Reservoir during droughts, and, in combination with the Westside Basin conjunctive-use program, to meet customer purchase requests while limiting rationing to 20 percent systemwide, thereby achieving the WSIP level of service objective for deliveries during droughts.

The Hetch Hetchy/Local Simulation Model was used to estimate the size of the transfer needed to limit rationing to 20 percent systemwide during droughts. In the Draft PEIR, the size of the necessary transfer was estimated to be 25,765 acre-feet per year (23 million gallons per day) averaged over the 8.5-year design drought (Vol. 1, Chapter 3, p. 3-36). As described in Section 13.3 (Vol. 7, Chapter 13), the input assumptions for the model were improved and updated after publication of the Draft PEIR. Using the improved and updated input assumptions, the size of the necessary transfer was estimated to be 29,350 acre-feet per year (26 million gallons per day) averaged over the 8.5-year design drought. Due to the combination of updated input assumptions to the model, the overall level of diversions from the Tuolumne River remained unchanged, even with the revised size of the dry-year transfer. As discussed in Section 13.3, review of the updated model results confirmed that the change in the size of the transfer would not have any direct effect in terms of the environmental consequences of the WSIP. The original modeling for the Draft PEIR and the updated modeling produced similar results, and the PEIR conclusions with respect to the significance of the WSIP's environmental impacts remain valid.

Although the dry-year transfer described above is proposed as part of the WSIP, no agreement to make such a transfer has been executed among the CCSF, TID, and MID. In fact, as explained below in Section 14.3.3, it would be improper to enter into such an agreement in the absence of completed CEQA review.

The CCSF has cooperatively worked with TID and MID for many years in analyzing water supply availability from the Tuolumne River watershed, and the SFPUC's studies indicate that there could be water available for a dry-year transfer without a loss of water to these agencies. The CCSF understands that neither TID nor MID have confirmed the availability of water for this transfer or made any commitments to the CCSF for such a transfer. If the San Francisco Planning Commission certifies the Final PEIR and the SFPUC adopts the WSIP, CCSF staff will pursue a formal agreement with TID and MID for the proposed dry-year transfer. Nonetheless, agreements or approvals from TID or MID regarding the proposed water transfer are not required, nor could final agreements be executed, prior to certification of the PEIR and adoption of the WSIP (or any alternative or variation of it). The absence of such agreements does not affect the validity of the environmental analysis presented in the Draft PEIR. Reasonable assumptions were made in the Draft PEIR with respect to the SFPUC's ability to secure a dry-year water transfer from TID and MID, and they provided sufficient information to perform the environmental analysis.

14.3.3 CEQA Review of the Proposed Dry-Year Transfer

Comment Summary

This section of this master response responds to all or part of the following comments:

L_MID-02	L_MIDTID1-28	C_Clark1-05
L_MIDTID1-05	L_TUD1-09	
L_MIDTID1-23	SI_TRT-CWA-SierraC-58	

Summary of Issues Raised by Commenters

- The dry-year transfer is insufficiently defined for CEQA purposes.
- The PEIR develops and supports alternatives and mitigation measures that are based on the assumed success of these transfer agreements.
- The proposed dry-year transfer would result in an additional drawdown of water from the Tuolumne River.

Response

As described in the Draft PEIR (Vol. 1, Chapter 3, p. 3-36), the dry-year transfer as proposed would be made from TID and MID to the SFPUC. In the Draft PEIR analysis, it was assumed that water owned by TID and MID and stored in Don Pedro Reservoir would be the source of the dry-year transfer. This assumption resulted in the greatest reduction in storage in Don Pedro Reservoir and the greatest impacts on the Tuolumne River, thereby depicting a worst-case scenario for CEQA purposes. As such, the impact analysis of the dry-year transfer presented in the Draft PEIR is conservative and adequate for CEQA review of the WSIP.

It is possible that TID and MID would provide some or all of the water for the dry-year transfer by conserving water or otherwise changing water management practices within their service areas. If this were the case, the environmental impacts on the Tuolumne River would be less than those described in the Draft PEIR. (The conserved water transfer is included in Mitigation Measure 5.3.6-4a and the Modified WSIP Alternative; for more information, refer to **Section 14.7, Master Response on Lower Tuolumne River Issues**, and **Section 14.10, Master Response on Modified WSIP Alternative**, respectively.)

The CCSF acknowledges that no agreement is in place for a dry-year transfer of water from TID and MID. For further information, please refer to Section 14.3.2, above.

It is appropriate to analyze the environmental effects of the proposed dry-year transfer before a formal agreement is made because neither TID and MID nor the CCSF can enter into or approve such an agreement before CEQA review is completed. Because the details of the dry-year water transfer were not known, the Draft PEIR evaluated a worst-case scenario of water supply and system operations impacts on the lower Tuolumne River, as noted above.

If an agreement for a dry-year water transfer was to be made among TID and MID and the SFPUC, as described in the Draft PEIR, additional project-level CEQA review would not be required. The transferring agencies, TID and MID, would serve as responsible agencies for CEQA compliance and could use the PEIR to make their own findings as required by CEQA Guidelines Section 15096. If the characteristics of the dry-year transfer were not as described and analyzed in the Draft PEIR, then additional CEQA review would likely be required. TID and/or MID would be the lead agency for the subsequent, project-specific CEQA review. However, the environmental impacts on the Tuolumne River and associated resources of any dry-year transfer considered as an alternative to the transfer described in the Draft PEIR would likely be less than those of the transfer included in the WSIP and analyzed in the Draft PEIR.

14.4 Master Response on PEIR Appropriate Level of Analysis

14.4.1 Introduction

Overview

This master response addresses the issues commenters raised about the impact analysis and implementation of mitigation measures related to individual facility improvement projects versus the overall program under the WSIP. In particular, numerous comments questioned the level and basis of analysis used for potential impacts on biological resources. Commenters also specifically requested changes to the project descriptions of facility improvement projects and coordination with the SFPUC during project planning and development of mitigation measures. This master response is organized by the following subtopics:

14.4.2 Intent of Programmatic Impact Analysis
14.4.3 SFPUC Coordination with Other Agencies
14.4.4 Biological Resources Level of Analysis

Summary of Issues Raised by Commenters

- More detailed design information needed on specific WSIP projects along with more detailed project locations in order to better determine jurisdiction, encroachments, etc.
- More detailed impact assessment needed under certain environmental resource areas for specific projects.
- The adequacy of program mitigation measures for specific projects and specific situations as well as for the WSIP as a whole is questionable.

Response

Section 15168 of the CEQA Guidelines allows a Program EIR to be prepared on a series of actions that can be characterized as one project for the purpose of analysis under CEQA. A Program EIR enables a lead agency to examine the overall effects of a proposed course of action and take steps to avoid unnecessary adverse environmental effects by considering the series of actions, or project, as a whole. Chapter 4 (Vol. 2) of the Draft PEIR considers the WSIP facility improvement projects as series of related actions and identifies general, program-level types of impacts that could occur under the individual projects; in addition, Section 4.16 in Chapter 4 considers all of the WSIP projects as a whole and evaluates the overall impacts that could result from construction of all projects combined. Several discussions presented in the Draft PEIR explain the role of this PEIR as it relates to the individual WSIP facility projects; these discussions are summarized below:

- Section 1.2 (Vol. 1, Chapter 1, pp. 1-1 to 1-3) states that the PEIR provides a foundation for any necessary future environmental review documents that focus on the individual WSIP projects. As this section indicates, Chapter 4 of the Draft PEIR evaluates the major environmental effects of implementing the proposed facility improvement projects from a broad, *program-level* perspective, framing the nature and magnitude of the expected environmental impacts and identifying *program-level* mitigation measures to address these impacts. While the PEIR provides *project-level* CEQA analysis of certain combined program impacts that apply to all projects proposed under the WSIP (e.g., facility-related collective/cumulative impacts, water supply effects, regional influences, secondary effects of growth, and other factors that apply to the program as a whole), Section 1.2 indicates that *project-level* CEQA review will be conducted separately for the individual WSIP facility improvement projects when more detailed design, construction, and operation details become available for each project. In general, project-specific EIRs or negative declarations for site-specific activities will be completed after the Final PEIR is certified, as the act of certification carries with it the lead agency decision-making body's conclusion that the document fully satisfies the requirements of CEQA.

- Section 3.8 (Vol. 1, Chapter 3, pp. 3-48 to 3-73, including Tables 3.10, 3.11, and 3.12) and Appendix C (Vol. 5, pp. C-1 to C-26) present the facility descriptions, locations, and schedules that served as the basis for the program-level impact evaluation contained in Chapter 4 of the Draft PEIR (Vol. 2). Section 3.8 states that the purpose of the Chapter 4 analysis is to provide a comprehensive environmental review of the overall range of effects resulting from the WSIP facility improvement projects as a whole as well as to identify programmatic mitigation measures. As Section 3.8 indicates, once additional project details and site-specific information have been developed, it is possible that the individual project effects identified in the PEIR might not occur or that additional project effects not identified in the PEIR could in fact occur. Such changes in project details would be addressed during the project-specific environmental reviews.

- Section 4.1 (Vol. 2, Chapter 4, p. 4.1-1) notes that the Chapter 4 impact analysis is based on preliminary information about the individual projects that would be implemented following approval of the WSIP, and that the level of detail of the information presented is appropriate for the programmatic analysis of these projects. The Draft PEIR (p. 4.1-2) notes that many of the WSIP projects have been developed at the conceptual level only, and that only some projects have more detailed siting and design information. Accordingly, the Chapter 4 program-level evaluation addresses all projects from a broad, overview perspective. Section 4.1 states that all of the WSIP projects will be examined in more detail at the project level, and that if individual WSIP projects have additional significant impacts that were not addressed in the PEIR, the San Francisco Planning Department will prepare EIRs or negative declarations to examine the site-specific and project-specific effects of the individual projects. More detailed information about the individual projects (i.e., construction plans as well as siting and operational details) will be considered in the project-level environmental documents.

- Section 4.1 (p. 4.1-2) also states that Chapter 6 (Vol. 4) of the Draft PEIR identifies the appropriate program-level mitigation measures in general terms, and that these measures will be refined to specifically apply to each project as the projects are further refined.

Commenters requested more detailed information about specific WSIP project locations, boundaries, and design in order to define agency jurisdiction, determine ordinance compliance and general plan conformity, identify encroachments on other agencies' properties or facilities, or determine effects on existing infrastructure that crosses project facilities. Commenters also requested clarification regarding the disposition of certain existing facilities to be decommissioned after project completion, as well as more detailed impact assessment of specific projects on topics such as: effects on downstream water users in the Alameda Creek watershed due to construction-related dewatering and discharges in the Sunol Valley; site-specific flooding where construction could induce settlement of levees along the San Francisco Bay shoreline; specific historical resources that could be affected by the WSIP; construction-related traffic, access, and parking impacts on specific uses (including those with easements on SFPUC land); construction work hours, haul truck restrictions, and vibration monitoring; potential disruption of service during relocation of utilities that cross project facilities; and compliance with local noise ordinances.

However, as indicated in the above-listed sections of the Draft PEIR, such detailed project information was not available for all WSIP projects during preparation of the Draft PEIR, nor was this detailed information necessary to define the overall programmatic effects of the individual facility improvement projects. Therefore, a detailed impact analysis is more appropriately presented in the project-level CEQA documentation for each WSIP facility project when such information becomes available. The primary purpose of the PEIR is to evaluate the combined or collective impacts resulting from all of the WSIP projects—that is, the impacts of the WSIP as a whole (Vol. 2, Chapter 4, p. 4.16-1)—which will allow decision-makers to make an informed decision on the proposed program based its overall environmental effects. The PEIR also helps to define the scope of project-level impact evaluations by providing an overview of the broad impact categories that could be associated with implementation of the WSIP, by identifying the impact categories that could apply to each WSIP facility project, and by formulating program-level mitigation measures that could be translated into more specific measures as individual projects are proposed and analyzed. As part of the project-level CEQA review for each project, the impact significance determinations identified in the PEIR will be reevaluated. The programmatic mitigation measures will also be reevaluated and, if applicable, will be confirmed, refined, or replaced with an equivalent measure.

It should be noted that the PEIR significance determinations err on the conservative side, since the impact analyses at the program level must generalize the types and classes of impacts as well as the feasibility of mitigation measures to reduce impacts to a less-than-significant level. Some commenters recommended additional mitigation measures or clarification of program measures to: reduce impacts identified by the commenter; include a specific jurisdiction’s standard conditions for construction; provide more protection from construction noise and vibration; minimize public inconvenience and ensure public safety; and ensure traffic and emergency access and parking are maintained for businesses affected by project facility construction. However, it would be premature to provide more detailed mitigation measures for project-specific impacts without more detailed impact analyses to justify the added requirements. These commenters’ concerns will be addressed when project-level environmental documents are prepared for individual projects, at which time the project-level reviews may find that the commenters’ recommended measures are appropriate mitigation.

As suggested above, program-level mitigation measures included in the PEIR are intended to be general in nature, commensurate with the program-level impact analysis. The SFPUC standard construction measures that will be applied to all proposed WSIP facility projects are listed in Section 6.2 of the Draft PEIR (Vol. 4, Chapter 6, pp. 6-4 to 6-6), and these measures will reduce some identified program-level impacts. Program-level mitigation measures are listed in Section 6.3 (Vol. 4, Chapter 6, pp. 6-7 to 6-47), and these measures will reduce many of the program-level impacts identified in Chapter 4 to a less-than-significant level. Additional program-level mitigation measures that address the WSIP's combined or collective impacts are also included in Section 6.3 (i.e., the measures numbered 4.16-x). The summary tables in Section 6.6 (Vol. 4, Chapter 6, Tables 6.3 to 6.9, pp. 6-64 to 6-170) list all of the program-level impacts and mitigation measures that would apply to each WSIP facility project.

14.4.3 SFPUC Coordination with Other Agencies

Comment Summary

This section of this master response responds to all or part of the following comments:

Summary of Issues Raised by Commenters

- Numerous agencies requested that the SFPUC coordinate with them during project planning and development of mitigation measures.

Response

As noted in Draft PEIR Section 3.13 (Vol. 1, Chapter 3, p. 3-86), each of the individual WSIP facility improvement projects will undergo project-level CEQA review, and each project's environmental documentation will provide more detailed and up-to-date information on needed approvals by local, state, and federal agencies. Section 3.13 also references Table C.6 (Vol. 5, Appendix C, p. C-26), which lists specific permits and approvals that could be required for individual projects. As shown below, this table is revised and expanded to include the commenting agencies that have requested consultation during the planning and design phases of certain WSIP projects. These agencies are listed below, along with a summary of the requested consultation or other information that these agencies indicate should be considered as part of project-level review.

- *U.S. Department of the Interior, National Park Service, Golden Gate National Recreation Area*. This agency requests consultation during project development and advance notification of meetings and would like to assist in creating mitigations for potential impacts for the following projects: Crystal Springs/San Andreas Transmission Upgrade (PN-2), HTWTP Long-Term Improvements (PN-3), Lower Crystal Springs Dam Improvements (PN-4), and Pulgas Balancing Reservoir Rehabilitation (PN-5).

- *U.S. Department of the Interior, Fish and Wildlife Service (USFWS) and Coastal Conservancy*. The USFWS and the Coastal Conservancy are interested in acquiring clean dredge material generated by the Bay Division Pipeline Reliability Upgrade project (BD-1) for use in wetland

NOTES: ACOE = U.S. Army Corps of Engineers; BAAQMD = Bay Area Air Quality Management District; BCDC = San Francisco Bay Conservation and Development Commission; Caltrans = California Department of Fish and Game Transportation; CDFG = California Department of Fish and Game; CUPA = Certified Unified Program Agency; DHS = California Department of Health Services; DWR = California Department of Water Resources; EC = Early Coordination Requested; (FWCA = Fish and Wildlife Coordination Act); GGNRA = Golden Gate National Recreation Area; MOA = Memorandum of Agreement; NMFS = U.S. National Marine Fisheries Service; (NWP = National Permit for Stream and Wetland Restoration Activities); RWQCB = Regional Water Quality Control Board; SHPO = State Historic Preservation Office; SWPPP = stormwater pollution prevention plan; SWRCB = State Water Resources Control Board; TBD = To Be Determined; TS = Thomas Shaft; USFWS = U.S. Fish and Wildlife Service.

a Additional approvals may be identified for WSIP facility projects when separate, project-level CEQA analysis is completed.

b The GGNRA requests consultation during project development and advance notification of meetings and would like to assist in creating mitigations for potential impacts from these projects.

c Section 6327 of the Public Resources Code provides that if a facility is for the "procurement of fresh-water from and construction of drainage facilities into navigable rivers, streams, lakes and bays," and if the applicant obtains a permit from the local reclamation district, State Reclamation Board, the U.S. Army Corps of Engineers, or the Department of Water Resources, then an application shall not be required by the State Lands Commission. Since the proposed program appears to fall within this section, a lease from the Commission would not be required, provided one of the above-listed permits is obtained.

d As part of project-level CEQA review, Caltrans requests that each facility improvement project be reviewed to determine if it encroaches on any state facilities. Any encroachment on Caltrans right-of-way would require an encroachment permit, and CEQA-related environmental studies may be necessary (including studies related to biological resources, cultural resources, and hazardous materials). A qualified professional must conduct these studies to satisfy Caltrans's environmental review policies. Ground-disturbing activities on the site prior to completing and/or approving the required environmental documents could affect Caltrans' ability to issue a permit for the project.

e The USFWS and the Coastal Conservancy are interested in acquiring clean dredge material generated by this project for use in wetland restoration associated with the South Bay Salt Pond Restoration Project, particularly within the Don Edwards San Francisco Bay National Wildlife Refuge (contact Clyde Morris, Manager, 510-792-0222, ext. 25). The USFWS recommends that the SFPUC coordinate with the USFWS's Division of Endangered Species at the Sacramento Fish and Wildlife Office (916-414-6600).

NOTE: EC = Early Coordination Requested

[f] As part of project-level CEQA review, the Alameda County Flood Control and Water Conservation District requests that each facility improvement project that includes pipelines be reviewed to determine if an encroachment permit is required where the pipelines cross the District's channels and creek inverts.

[g] The ACWD requests that the BD-1 project be coordinated with the ACWD earlier (during project planning and design phases, rather than during the construction phase) to minimize impacts associated with conflicting water facilities and potential impacts on the ACWD's ability to meet customer demands and fire flow requirements. In addition, all Sunol Valley projects (SV-1 through SV-6) will need to take into account potential effects of facility construction on downstream water intakes at ACWD's facilities in the flood control channel. The project-level CEQA review for the SV-2 project will need to consider coordination and notification related to Calaveras Reservoir release protocols that could affect downstream groundwater recharge and the potential for flooding.

[h] As part of project-level CEQA review, each facility improvement project in the Sunol Valley region should be reviewed to determine if it encroaches on EBRPD property. The EBRPD requests coordination of construction mitigation measures for certain WSIP projects in the Sunol Valley to minimize construction impacts on recreational uses and allow coordination of fire suppression planning and response (including review of traffic control plans). As part of the project-level EIR for SV-2, the EBRPD states that the SFPUC needs to coordinate the timing of water releases from Calaveras Dam to maximize benefits to amphibians and anadromous fish species.

[i] The City of Fremont requests consultation (regarding the applicability of encroachment permits, and development and review of traffic control plans) during the planning and design phases of the SV-2, BD-1, and BD-3 projects as well as any other WSIP project that could affect the Fremont transportation network.

[j] As part of the project-level CEQA review, mitigation measures should be developed to establish coordination and notification protocols between the SFPUC and the ACFCWCD regarding Calaveras Reservoir releases that could affect the potential for downstream flooding.

[k] The USFWS requests that the BD-1 project be coordinated with the Transit District's Dumbarton Rail Project to minimize habitat impacts for both projects.

[l] The Coastal Conservancy requests that the SFPUC coordinate with the Coastal Conservancy and Association of Bay Area Government's Bay Trail project (regarding completion of the Bay Trail gap through SFPUC lands).

[m] The City of Menlo Park requests coordination of construction mitigation measures for the BD-1 project to minimize construction impacts (e.g., access and parking) on local residents and businesses, including the Menlo Business Park.

[n] The City of Palo Alto requests early consultation on the BD-2 project.

[o] The Coastside CWD requests consultation during development of the adaptive management program for Crystal Springs Reservoir as part of the operations phase of the PN-4 project.

restoration associated with the South Bay Salt Pond Restoration Project, particularly within the Don Edwards San Francisco Bay National Wildlife Refuge.

The USFWS also recommends that the SFPUC coordinate with the USFWS's Division of Endangered Species at the Sacramento Fish and Wildlife Office.

- *San Mateo County Transit District*. The USFWS requests that the Bay Division Pipeline Reliability Upgrade project (BD-1) be coordinated with the Transit District's Dumbarton Rail Project to minimize habitat impacts for both projects.

- *Coastal Conservancy and Association of Bay Area Governments (ABAG)*. The Coastal Conservancy requests that the SFPUC coordinate with the Conservancy and ABAG's Bay Trail project (regarding completion of the Bay Trail gap through SFPUC lands).

- *California Department of Water Resources (DWR)*. The DWR requests that the San Joaquin Pipeline System project (SJ-3) be reviewed as part of the project-level CEQA review to determine if it encroaches on the State Plan of Flood Control for the Central Valley (Designated Floodway maps at http://recbd.ca.gov).

- *California Department of Transportation (Caltrans)*. Caltrans requests that each facility improvement project be reviewed as part of the project-level CEQA review to determine if it encroaches on any state facilities. It also states that any encroachment on Caltrans right-of-way would require an encroachment permit, and that CEQA-related environmental studies may be necessary (such as studies related to biological resources, cultural resources, and hazardous materials). The agency indicates that a qualified professional must conduct these studies to satisfy Caltrans' environmental review policies, and that ground-disturbing activities on the site prior to completion and/or approval of the required environmental documents could affect Caltrans' ability to issue a permit for the project.

- *Alameda County Flood Control and Water Conservation District (ACFCWCD)*. The ACFCWCD requests that each facility improvement project that includes pipelines be reviewed as part of the project-level CEQA review to determine if an encroachment permit is required where the pipelines cross the District's channels and creek inverts. The ACFCWCD also states that the project-level CEQA review for the Calaveras Dam Replacement project (SV-2) should include mitigation measures establishing coordination and notification protocols between the SFPUC and the ACFCWCD regarding Calaveras Reservoir releases that could affect the potential for downstream flooding.

- *Alameda County Water District (ACWD)*. The ACWD requests that the Bay Division Pipeline Reliability Upgrade project (BD-1) be coordinated with the ACWD earlier (during the project planning and design phases, rather than during the construction phase) to minimize impacts associated with conflicting water facilities and potential impacts on the ACWD's ability to meet customer demand and fire flow requirements. In addition, the ACWD indicates that all Sunol Valley projects (Alameda Creek Fishery Enhancement, SV-1; Calaveras Dam Replacement, SV-2; Additional 40-mgd Treated Water Supply, SV-3; New Irvington Tunnel, SV-4; SVWTP – Treated Water Reservoirs, SV-5; San Antonio Backup Pipeline, SV-6) need to take into account the potential effects of facility construction on downstream water intakes at ACWD facilities in the flood control channel. The ACWD also states that the project-level CEQA review for the Calaveras Dam Replacement project needs to consider coordination and notification protocols related to Calaveras Reservoir releases that could affect downstream groundwater recharge and the potential for flooding.

- *East Bay Regional Park District (EBRPD)*. The EBRPD requests that each facility improvement project in the Sunol Valley Region be reviewed as part of the project-level CEQA review to determine if it encroaches on EBRPD property. The EBRPD also requests coordination of construction mitigation measures for certain WSIP projects in the Sunol Valley to minimize construction impacts on recreational uses and allow coordination of fire suppression planning and response (including review of traffic control plans). The EBRPD states that the SFPUC needs to coordinate the timing of water releases from Calaveras Dam to maximize benefits to amphibians and anadromous fish species. This issue will be addressed further in the project-level EIR for the Calaveras Dam Replacement project (SV-2).

- *City of Fremont*. The City requests consultation (regarding the applicability of encroachment permits, and development and review of traffic control plans) during the planning and design phases of the Bay Division Pipeline Reliability Upgrade (BD-1), New Irvington Tunnel (SV-4), Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault (BD-3), and any other WSIP projects that could affect the Fremont transportation network.

- *City of Menlo Park*. The City requests coordination of construction mitigation measures for the Bay Division Pipeline Reliability Upgrade project (BD-1) to minimize construction impacts (e.g., access and parking) on local residents and businesses, including the Menlo Business Park.

- *City of Palo Alto*. The City requests early consultation on the BDPL Nos. 3 and 4 Crossovers project (BD-2).

- *Coastside County Water District (CWD)*. Coastside CWD requests consultation during development of the adaptive management program for Crystal Springs Reservoir as part of the operations phase of the Lower Crystal Springs Dam Improvements project (PN-4).

The PEIR serves as a guidance document for all subsequent, project-level CEQA review. The Draft PEIR (Vol. 1, Chapter 3, p. 3-86) indicates that each of the individual WSIP facility improvement projects will undergo project-level CEQA review, and that the environmental documents developed through those reviews will identify needed approvals by local, state, and federal agencies for the individual projects. The SFPUC and the San Francisco Planning Department, Major Environmental Analysis Division will review the agencies identified in updated Table C.6 for applicability and will update the list of agencies as necessary at the time of each project-level review.

In response to comments by numerous agencies requesting early consultation, early coordination, or other information, the Draft PEIR (Vol. 1, Chapter 3, p. 3-86, fourth full paragraph) is revised as follows:

> Each of the individual WSIP facility improvement projects will undergo project-level CEQA review, and CEQA documents developed through those reviews will identify needed approvals by local, state, and federal agencies for individual projects. Table C.6 of Appendix C presents the specific permits and approvals that could be required for individual projects as well as the interested agencies that have requested early consultation and coordination with the SFPUC. Several projects are expected to require U.S. Department of the Army permits to comply with the Clean Water Act, which, in turn, will require compliance with the Federal Endangered Species Act, the Clean Water Act Section 401, and the National Historic Preservation Act. Several projects are expected to require Streambed Alteration Agreements from the California Department of Fish and Game and compliance with the California Endangered Species Act. When individual projects undergo CEQA review, the project's environmental documentation will provide more detailed and up-to-date information on the

required approvals <u>and need for consultation with interested agencies</u>. The approval and adoption of the overall WSIP as a program and policy are distinct actions from the approvals for individual facility improvement projects.

14.4.4 Biological Resources Level of Analysis

Summary of Issues Raised by Commenters

- The level of detail of biological information presented in the Draft PEIR was not sufficient to support the analysis of impacts, both for the program-level and project-level analyses.

- The baseline (or existing) condition did not take into account the already altered conditions in the Tuolumne River as a result of decades of Hetch Hetchy system operations.

- Using the brief time period when Calaveras Reservoir has been at less than full capacity minimizes the finding of impact.

- Mitigation for the WSIP projects cannot be determined at the current level of program description, so it is not clear how any mitigation (such as the Habitat Reserve Program) can be considered sufficient.

Response

Level of Detail of Data and Analysis for the PEIR

Commenters challenged the adequacy of the PEIR analysis as data-deficient in several ways. Comment SI_CNPS-EB1-18 states that biological surveys must be performed at all sites as part of impact evaluation; Comment SI_CNPS-SCV1-05 specifies the need for a comprehensive study of the Tuolumne River watershed, and Comment SI_CNPS-SCV1-07 specifies the need for quantitative impact assessments before suitable mitigation can be proposed. However, CEQA Guidelines Section 15151 imposes a standard of adequacy that is "reasonably feasible" and sufficient to allow decision-makers to make a decision that takes account of environmental consequences. Data gathering need not be "exhaustive." In cases where the Draft PEIR is a precursor to project-level CEQA analysis (see Section 14.4.2, above), only reasonably expected project impacts and widely applicable mitigations are discussed. It would be unwieldy and inappropriate to evaluate all of the special-status species for the entire program region, and many aspects of the proposed facility improvement projects are so undefined that impacts would be difficult to assess for most individual species. Therefore, where a project-level analysis will be performed in the future, the PEIR preparers concentrated on listed species and sensitive natural communities as representative of the habitat needs of other special-status species, many of which occur in the identified sensitive natural communities. The Draft PEIR's program-level evaluation of the regional WSIP facility projects presented in Chapter 4 defers to the subsequent, project-specific CEQA review of each facility improvement project, at which time impacts and impact receptors will be better defined based on more detailed and site-specific project information. To present more specific findings at the PEIR stage would be speculative, which is discouraged by CEQA Guidelines Section 15145.

Chapter 5 (Vol. 3) of the Draft PEIR addresses the impacts of WSIP water supply and system operations at the project level. Some reviewers commented that the level of detail for these components was insufficient; however, the PEIR impact analysis meets the "reasonably feasible" standard. The analysis of terrestrial biological resources presented in Chapter 5 focused on the current composition and condition of the riparian and wetland systems of the Tuolumne River, Alameda Creek, and Peninsula watersheds, then considered the interactive responses of plant and animal species to hydrologic changes resulting from the WSIP. In the face of this complexity, the PEIR preparers relied on ecological principles, scientific literature, existing data, and site visits to assess potential impacts and develop appropriate mitigation measures. The Draft PEIR analysis was conservative in finding that an impact could be potentially significant if there was any possibility of impacts resulting from predicted hydrologic changes under the proposed WSIP water supply and system operations.

CEQA Baseline

Some commenters (e.g., SI_CNPS-EB1-08) found that baseline conditions for biological resources were not clearly explained. CEQA Guidelines Section 15125 acknowledges the importance of identifying a baseline that best ensures meaningful environmental review. As described above, Chapter 4 of the Draft PEIR provides a programmatic analysis of the facility improvement projects and includes a program-level description of existing conditions for biological resources. More detailed, site-specific baseline conditions will be included in the subsequent, project-specific CEQA review for the individual projects as appropriate.

For the analysis of WSIP water supply and system operations impacts, the Draft PEIR (Vol. 3, Chapter 5) provides a description of baseline conditions tailored appropriately for the type and nature of each impact. Historical and ongoing operation of the Hetch Hetchy system is part of the baseline for the proposed program; however, the ecological impacts of ongoing operations are not relevant to the impact analysis of the WSIP, although they are considered in the cumulative analysis. Nonetheless, in making significance determinations, the PEIR authors did consider the possibility that existing conditions have increased the sensitivity or vulnerability of biological receptors to additional impacts. Riparian ecosystems on the Tuolumne River that are already stressed by water withdrawals could be more vulnerable or sensitive to even small, incremental changes. For example, in the Poopenaut Valley, located in the upper Tuolumne River immediately below O'Shaughnessy Dam, past and ongoing operations have reduced seasonal groundwater recharge below natural levels, with the result that shallow-rooted native meadow vegetation is already stressed and thus vulnerable to any future reduction in seasonal meadow groundwater recharge. Over the long term, water stress and prevailing dry conditions would allow upland species to invade the meadow, reducing the extent and quality of meadow vegetation. This in turn would reduce the meadow's ability to retain water in the root zone of wetland plants, accelerating the meadow degradation. As wetland and riparian habitats in the Poopenaut Valley are considered to be sensitive and are already degraded by ongoing operations, the Draft PEIR determined that any changes in the quantity and timing of releases from O'Shaughnessy Dam under the WSIP would be potentially significant. The analysis also determined that this impact could be mitigated to a less-than-significant level with implementation of Measure 5.3.7-2 (Vol. 4, Chapter 6, pp. 6-49 and 6-50).

In the lower Tuolumne River, the chief habitat effect of WSIP water supply and system operations would be on extant riparian vegetation, which is already greatly reduced and likely stressed. Its maintenance is dependent on the very modest discharges that fill the streams at least occasionally from bank to bank. Thus, the Draft PEIR determined that even an incremental reduction in "bankfull" events due to delayed or absent spring flows under the WSIP would put this vegetation at increased risk. This impact was determined to be potentially significant, but could be mitigated to a less-than-significant level with implementation of Measure 5.3.6-4a (Vol. 4, Chapter 6, p. 6-48) or Measure 5.3.7-6 (pp. 6-50 and 6-51).

With regard to the comment that use of the existing "Calaveras Down" baseline conditions could camouflage the effects of the WSIP on Alameda watershed riparian systems, the Draft PEIR discloses that the current riparian habitat reflects longer-term conditions, and analyzes the potential impacts of the WSIP with this fact in mind(Vol. 3, Chapter 5, p. 5.4.6-18). The Draft PEIR discussion of impacts on riparian vegetation along Alameda Creek, which compares existing "Calaveras Down" conditions to pre-2002 "Calaveras Up" conditions, addresses only willow and mixed riparian habitat along the creek channel (not sycamore alluvial woodland, which is formed and sustained only under very high periodic flows such as those found in unimpeded streams). The distribution of willow and mixed riparian habitats is primarily the result of prevailing flows over several decades: in other words, the operational conditions described as Calaveras Up, which maximized the diversions at the Alameda Creek Diversion Dam prior to the 2001 Division of Safety of Dams (DSOD) restrictions on Calaveras Reservoir and represents the operating conditions for over 70 years prior to the DSOD restriction. The CEQA baseline for the WSIP hydrologic modeling (i.e., Calaveras Down) reflects reduced diversions and therefore increased flows in Alameda Creek below the diversion dam. Although substantially lower than existing flows under the Calaveras Down scenario, the proposed WSIP flows would resemble prior Calaveras Up conditions (i.e., historical operating conditions). As a result, the PEIR concluded that the impact on these riparian habitats would be less than significant.

Consistent with CEQA guidelines, the Draft PEIR uses the conditions present in 2005 as the baseline condition for the analysis of impacts of WSIP water supply and system operations on Alameda Creek (Vol. 3, Chapter 5, p. 5.1-13). This baseline condition (referred to as Calaveras Down due to the DSOD restrictions on Calaveras Dam) provides for a worst-case environmental analysis for hydrological effects since it represents the greatest change in stream flow conditions from those proposed under the WSIP. As described in the Draft PEIR (Vol. 3, Chapter 5, Section 5.1), the impacts of WSIP water supply and system operations were analyzed using the Hetch Hetchy/Local Simulation Model, which uses the existing conditions (i.e., the SFPUC operating conditions and facilities restrictions in 2005) and predicts the reservoir spills and releases (i.e., stream flow conditions downstream from SFPUC reservoirs) over an 82-year period of historical hydrology, and not the actual "brief" period of time during which Calaveras Reservoir has been operated under restricted conditions (i.e., 2002 to the present).

Mitigation for Biological Impacts

Several points were raised (in Comments SI_CNPS-SCV1-04, SI_CNPS-SCV1-07, and others) regarding the adequacy of mitigation for WSIP impacts on biological resources. As described above, the site-specific type and extent of biological resource impacts resulting from the WSIP facility improvement projects can be analyzed only at the project level once the project descriptions have been fully developed. As a result, the type and extent of mitigation for those impacts must also be determined on a project-specific basis at the project EIR stage. As described above, the Draft PEIR provides programmatic mitigation measures for impacts associated with the facility improvement projects, and these measures will be reevaluated and, if applicable, will be confirmed, refined, or replaced with an equivalent measure as part of the subsequent, project-level CEQA review for the individual WSIP projects.

As part of the project-level review, consultation with resource agencies will ultimately determine the type and extent of appropriate mitigation measures. The SFPUC's proposed Habitat Reserve Program (HRP) does not purport to provide compensation for all WSIP impacts, regardless of type or quantity. Rather, the HRP proposes steps to restore, create, or enhance a variety of habitats in several geographic areas in advance of specific project impacts, and the resulting habitat values may be applied to the WSIP projects if deemed appropriate during project-specific agency consultation (see Draft PEIR, Vol. 1, Chapter 3, pp. 3-84 to 3-86). The policies of the California Department of Fish and Game and the USFWS place a priority on implementing mitigation *before* project impacts have occurred in order to reduce the temporal extent and quantity of lost habitat. To accomplish this goal, the HRP proposes to begin habitat improvements before WSIP project implementation.

The WSIP and the HRP are separate but parallel projects, each with its own objectives and environmental analysis. The HRP will receive CEQA analysis through an EIR as a project that is distinct from the WSIP. All HRP actions will be designed to be consistent with the Alameda and Peninsula Watershed Management Plans, Habitat Conservation Plans, and the Watershed and Environmental Improvement Program, but would not overlap with other habitat improvements. Thus, any habitat improvement or enhancement would not be credited twice. In addition, if mitigation opportunities provided by the HRP are not of the type or quantity required for mitigation of the biological resources impacts of a specific WSIP project or any portion of a WSIP project, then other means will be developed and employed to mitigate those impacts.

14.5 Master Response on Water Resources Modeling

14.5.1 Introduction

Overview

This master response addresses questions about the water resources model used for the impact analysis of proposed WSIP water supply and system operations. Commenters raised questions about the model itself, the appropriateness of its use for the Draft PEIR, the assumptions used in the modeling analysis, and the model output. This master response is organized by the following subtopics:

14.5.2 Model Availability
14.5.3 Model Time Interval
14.5.4 Use of Year Type Averages
14.5.5 Model Validation
14.5.6 Modeling Assumptions
14.5.7 Model Limitations for Pilarcitos Creek Watershed
14.5.8 Units of Measure
14.5.9 Model Results for Tuolumne River Diversions

The PEIR addresses this topic area in Vol. 3, Chapter 5, Section 5.1.4, pp. 5.1-7 to 5.1-18. Additional information on the model and the detailed modeling results are contained in Vol. 5, Appendices H1 and H2, with further updated model information in Vol. 8, Appendix O.

14.5.2 Model Availability

Comment Summary

This section of this master response responds to all or part of the following comments:

L_MIDTID-01

Summary of Issues Raised by Commenters

- TID and MID requested that the model used in the analysis be made available to them so they could check the assumptions, and requested a 60-day comment period after receipt of the model.

Response

In response to the request by TID and MID, on October 4, 2007 the San Francisco Planning Department sent both agencies a CD containing hydrologic model output as well as related files to help them understand the data. In addition, a meeting was held on November 28, 2007 to discuss the Hetch Hetchy/Local Simulation Model (HH/LSM) and its use for the Draft PEIR;

representatives from TID, MID, the SFPUC, and the PEIR consultant team (representing the San Francisco Planning Department) attended the meeting. The SFPUC representative described how the HH/LSM was used to analyze the WSIP water supply and system operations and to estimate its effects on Tuolumne River flows, and identified the assumptions used in the analysis. A slide presentation was made and hard copy of the presentation provided to meeting attendees (included as an attachment to **Response L_MID-TID1**). The meeting was conducted informally, and the TID and MID attendees asked questions throughout the presentation.

The SFPUC representative noted that the assumptions and modeling approach used in the HH/LSM for TID and MID are consistent with the assumptions and approach used by the California Department of Water Resources (DWR) and the U.S. Bureau of Reclamation (USBR) in their modeling of the San Joaquin River using CalSim II, the statewide model developed by these agencies for planning purposes. The assumptions and approach used in the HH/LSM are also consistent with those used in modeling for MID's municipal water treatment plant.

At the end of the meeting, the TID and MID representatives indicated that the SFPUC representative had satisfactorily answered all of their questions with respect to the HH/LSM. The SFPUC transmitted an executable copy of the model to the Districts on December 21, 2007.

The San Francisco Planning Department declined to extend the comment period on the Draft PEIR as requested by the Districts.

14.5.3 Model Time Interval

Summary of Issues Raised by Commenters

- The HH/LSM predicts monthly average values of river flow, which are inappropriate for analyzing environmental elements that may be affected by hourly, weekly, or daily flows (biological resources) or peak flows (geomorphology) that occur rarely.

Response

The impact analysis in the Draft PEIR used a combination of approaches as deemed appropriate for the specific impact and resource being analyzed. The analysis of WSIP water supply and system operations (Vol. 3, Chapter 5) was based on modeled monthly flow data using the

HH/LSM and supplemented with data derived from operational records and stream flow gages as needed. As described in the Draft PEIR (Vol. 3, Chapter 5, pp. 5.1-7 to 5.1-18), the HH/LSM is a state-of-the-art model of the regional water system developed by the SFPUC for water supply planning and is the best available tool for predicting reservoir releases/spills under various operating scenarios. It was used in the Draft PEIR to estimate the effects of the WSIP water supply and system operations on river and creek flows downstream of SFPUC reservoirs compared to the existing condition. The SFPUC has been improving and refining the model during more than 10 years of use (see Section 14.5.5, Model Validation, below), but like all models that simulate complex systems, it involves various simplifying assumptions, including the use of a monthly time-step.

As described below, monthly flow estimates derived from the HH/LSM output provide an accurate depiction of conditions in most cases and are appropriate for use in assessing impacts. During many months of the year, large portions of the regional system operations often do not vary on a daily or weekly basis. For those time periods, the HH/LSM results were useful and appropriate in assessing impacts on fish, wildlife, and riparian vegetation. However, for other times of the year, reservoir operations require adjustments more frequently than once per month due to circumstances such as changing hydrological and meteorological conditions. For the impact analysis during those periods, the HH/LSM data were supplemented with operational and daily flow records to estimate flow changes and to assess impacts. A more detailed description of how HH/LSM data were used in combination with other data in the impact analysis is presented below.

For the impact analysis of resources in the Tuolumne River between Hetch Hetchy and Don Pedro Reservoirs, monthly flow estimates derived from the HH/LSM provide an accurate depiction of actual conditions for most months of the year. Flow in this reach of the river consists entirely of releases from Hetch Hetchy Reservoir. During the late summer, fall, winter, and early spring, dam operators typically release only the required minimum instream flow. Currently, this condition exists about 84 percent of the time; with the WSIP, it would occur about 85 percent of the time. During periods when only minimum releases are being made, the release rate does not vary on a day-to-day or week-to-week basis. The SFPUC operators adjust the release rate monthly as necessary to comply with the minimum release schedule, which is specified in terms of monthly releases. Consequently, the monthly flows estimated using the HH/LSM and presented in the Draft PEIR provide an accurate characterization of flow in the Tuolumne River below O'Shaughnessy Dam more than 80 percent of the time. During such times, flow in the river below the dam varies very little, and the daily, weekly, and monthly average flow rates are essentially the same; as a result, the flow estimates from the HH/LSM are useful in assessing impacts on fish and riparian vegetation and wildlife.

The HH/LSM results for monthly reservoir releases during the snowmelt period do not provide a complete characterization of river flow because dam operators may adjust releases to the river more frequently than once per month. At the beginning of the snowmelt period, when storage in Hetch Hetchy Reservoir is at its seasonal minimum, operators typically use most of the inflowing snowmelt to fill the reservoir, releasing only the minimum required to the river below O'Shaughnessy Dam. Once the reservoir has filled, or it becomes apparent that the reservoir will fill based on projections of inflow, operators begin to release more than the minimum required to the river below the dam. The release rate may be adjusted every few days based on the volume of water flowing into the reservoir and the volume of water exiting the reservoir via the Canyon Tunnel. Consequently, monthly averages alone do not provide a good characterization of river flow during the snowmelt period. Therefore, the HH/LSM analysis for the snowmelt period was supplemented by performing a second analysis based on operational records of representative years, which enabled daily flows to be estimated. The estimates of daily flows in the Tuolumne River below O'Shaughnessy Dam in 1999 are shown in Draft PEIR Figure 5.3.1-10 (Vol. 3, Chapter 5, p. 5.3.1-28). For the snowmelt period, daily flow information was used in assessing impacts on fish and riparian vegetation and wildlife.

Circumstances in the Tuolumne River below La Grange Dam are similar to those in the river below O'Shaughnessy Dam. Flow in this reach of the river consists entirely of releases from La Grange Dam. During the late summer, fall, winter, and early spring, dam operators typically release only the required minimum instream flow. Currently, this condition occurs about 73 percent of the time; with the WSIP, it is estimated to occur about 74 percent of the time. Releases in excess of the minimum required occur primarily during the late spring snowmelt period, but may also occur in the late fall and winter as operators adjust storage in Don Pedro Reservoir in response to rainfall and to maintain compliance with flood storage requirements. When releases in excess of the minimum required are necessary, operators may adjust releases daily, and so the average monthly flow estimates from the HH/LSM do not by themselves provide a good characterization of flow in the river. Consequently, the analysis using the HH/LSM was supplemented by performing a second analysis based on TID's operational records, which enabled daily flows to be estimated (TID operates Don Pedro Reservoir and La Grange Dam). The estimates of daily flows in the Tuolumne River below La Grange Dam in 2000 are shown in Draft PEIR Figure 5.3.1-13 (Vol. 3, Chapter 5, p. 5.3.1-37). Again, for the snowmelt period, daily flow information was used in assessing impacts on fish and riparian vegetation and wildlife.

The HH/LSM was also used in the Draft PEIR to analyze the effects of the WSIP on local watersheds in the Bay Area, including watersheds of Alameda, San Mateo, and Pilarcitos Creeks. In each case, the average monthly flow estimates derived using the monthly time-step model were supplemented by performing additional analysis based on U.S. Geological Survey (USGS) gage data and/or operational records that provide insight into daily flows. Section 5.4.1 (Vol. 3, Chapter 5, pp. 5.4.1-10 to 5.4.1-33) relies on HH/LSM results in combination with daily flow gage data from the USGS, including instantaneous data (15-minute readings) from 1997 to 2007, to fully and appropriately analyze the effects of the WSIP on flows in Alameda Creek; this overall data, in turn, is used to analyze effects on downstream fish and riparian resources.

Estimates of monthly river flows derived from the HH/LSM output are only marginally useful for the assessment of impacts on geomorphology. Channel form and sediment transport are most influenced by peak flows, which the HH/LSM does not estimate. When estimates of peak flows were needed, they were derived through a statistical analysis of long-term flow gaging records.

It should be noted that the SFPUC's use of a monthly time-step model such as the HH/LSM is typical of many water systems. Water managers conventionally use monthly time-step models to simulate water system operations for planning purposes. For example, the CalSim II model used by the DWR and USBR for statewide water planning is a monthly time-step model. If monthly time-step model output does not reflect a water manager's experience or expectations, the manager may use professional judgment in refining and extrapolating from model results to provide insight into weekly or daily operations. Models with a shorter time interval than monthly typically tier off the results of a monthly time-step model. Models with a shorter time-step are not widely developed or used because monthly time-step models are sufficient for most planning purposes.

Monthly time-step models are also often used in CEQA documents. Two examples of CEQA documents that used CalSim II are the Draft EIR on the Monterey Amendment to the State Water Project Contracts (DWR, 2007) and the Environmental Water Account EIS/EIR (DWR and USBR, 2003).

14.5.4 Use of Year Type Averages

Comment Summary

This section of this master response responds to all or part of the following comments:

SI_SierraC6-03	SI_TRT-CWA-SierraC-102	C_Hughe2-02
SI_TRT-CWA-SierraC-47	SI_TRT-CWA-SierraC-110	
SI_TRT-CWA-SierraC-82	SI_TRT-CWA-SierraC-141	

Summary of Issues Raised by Commenters

- River flow data from the model are sorted into year types and presented as averages within year types; the use of averages within year types is inappropriate for the purpose of for environmental analysis because it conceals extreme values and understates impacts.

Response

The HH/LSM estimates reservoir releases in every month of the 82-year hydrologic record, which enables estimates to be made of river flow in 984 individual months. There is no single perfect way to examine and present data of this type. The data are voluminous and difficult to interpret without simplification, and describe highly variable phenomena—that is, river flow, reservoir storage, and other hydrologic information. Data from each month can be averaged, and the result provides a piece of information that helps to roughly characterize the phenomena. At the other end of the scale, each individual monthly flow estimate can be examined to provide a more refined characterization, but one that is limited to a single month in an 82-year period. According to the technical specialists who run the model, the most practical approach is to use some combination of averaging data and examining data from individual months. This was the approach used for the Draft PEIR, as described below. It was also used for the Monterey Amendment EIR and the Environmental Water Account EIS/EIR referred to above in Section 14.5.3.

Averaging data within year types often provides insight into how a water system operates under different hydrologic conditions. For example, Draft PEIR Table 5.3.1-5 shows estimated monthly flows in the Tuolumne River below O'Shaughnessy Dam (Vol. 3, Chapter 5, p. 5.3.1-26). The table indicates that flow in the river in October, November, and December of all hydrologic year types is about the same, but that average monthly flow in June of wet years may be as high as 4,500 cubic feet per second (cfs)—about 20 times greater than in dry years. Although this information helps to characterize the pattern of river flows, it is recognized that conditions in any one wet or dry year may deviate considerably from the average. Draft PEIR Figure 5.3.1-9 shows reservoir releases in each month in the 984-month hydrologic record (Vol. 3, Chapter 5, p. 5.3.1-23). As the figure shows, although the average monthly flow in June of wet years averages 4,500 cfs, it can be as great as 7,500 cfs on rare occasions.

The monthly data used to create Table 5.3.1-5 and Figure 5.3.1-9 (Vol. 3, Chapter 5, pp. 5.3.1-5 and 5.3.1-23) are provided in the Draft PEIR (Vol. 5, Appendix H2-1). Monthly flow data derived from the HH/LSM were supplemented by information on daily flows shown in Figures 5.3.1-10 and 5.3.1-13 of the Draft PEIR (Vol. 3, Chapter 5, pp. 5.3.1-28 and 5.3.1-37). The monthly and daily flow data were used in combination to determine environmental impacts.

14.5.5 Model Validation

Comment Summary

This section of this master response responds to all or part of the following comments:

SI_TRT-CWA-SierraC-52	SI_TRT-CWA-SierraC-101	SI_TRT-CWA-SierraC-158

Summary of Issues Raised by Commenters

- The model's error and accuracy should be specified.

Response

The evaluation of physics-based hydrologic models such as the HH/LSM (i.e., models relying on the physics of water movement) is generally based on three different measures: calibration, verification, and validation. Calibration of a model is needed when the hydrologic parameters required to simulate the water movement are not available, and the model must use those parameters during simulations; however, because historical stream flow and water demand data are explicitly incorporated in and formulated as part of the HH/LSM, separate calibration (as is typically required for a numerical model) was not required for the HH/LSM.

Verification refers to the accuracy of computations in a model; however, because the HH/LSM is not a numerical model based on complex equations, verification related to numerical stability is not an issue. The HH/LSM is a simple mass-balance model designed with checks and balances to ensure that the basic principle of "conservation of mass" is maintained (i.e., that all water is accounted for in the system at all times, and that inflow balances with outflow and storage). The

HH/LSM is a linked-node model wherein an input of water to one part of the system—such as inflow to a reservoir—must balance with the output/storage from that same part of the system—such as the combination of releases from the reservoir, evaporation or losses from the reservoir, and a change in storage in that same reservoir. Similarly, water diverted into a pipeline must be accounted for through releases from that same pipeline. This system of checks and balances provides a built-in verification of the underlying mass-balance principle that forms the basis for the HH/LSM.

Validation refers to how well the output of the model matches the experimental or observed data. The HH/LSM is a long-term planning model that provides a simulation of water system operations over a range of hydrologic conditions. It is based on a consistent set of physical and institutional constraints (e.g., reservoir and pipeline capacities, flow requirements below reservoirs, and unimpaired runoff) and a systematic set of operational protocols that direct the operation of the water system. The model was designed to inform and direct the *long-term planning* of the system and not its *short-term operations*. Consequently, comparing absolute values of simulated operations with actual reservoir storage at the end or beginning of every hydrologic year has not been the objective of the HH/LSM.

Therefore, validation of the accuracy of the HH/LSM relates to how well the model portrays SFPUC water system operations within the context of the model's purpose. The complex operational rules incorporated into the model are based on historical data and the experience of operators, and thus achieve the best possible representation of the system for reliable and efficient system planning. In other words, the operational rules incorporated into the model are not hypothetical. The HH/LSM has been continuously refined for more than 10 years based on the modelers' expert knowledge as well as SFPUC system operators' periodical review of the model output. The model has produced reasonable and consistent results that have been confirmed by system operators and validate not only the results of the model but also the representation of the system. This continuous refinement of the HH/LSM, based on periodic review of the accuracy of the model by system modelers and operators, encompasses the generally expected validation requirements for this type of mass-balance model. For example, as described in Section 13.3 (Vol. 7, Chapter 13), the SFPUC conducted updated model runs in 2008 following publication of the Draft PEIR using more recent input assumptions for several model parameters as part of its ongoing system planning and management. And, as discussed in that section, the resulting output data were generally consistent with the 2007 data used in the Draft PEIR. The refined HH/LSM results were incorporated as appropriate into the Comments and Responses document.

In addition, the HH/LSM has been externally verified and validated on a number of occasions. The model was used in support of an application to amend the license for the Don Pedro Project, which was submitted to the Federal Energy Regulatory Commission (FERC) in 1993 and 1994. FERC approved the use and results of the model. The model was reviewed again in 2005, as part of the *Water Supply Improvement Program Assessment* (Parsons-CH2MHILL, 2005). The model review focused on each element of the HH/LSM to determine if the model input data, assumptions, operational criteria, and results were within the expected range of practice for this type of model application. The review included verification and validation of input hydrology, system demands, reservoir target, storage levels and capacities, transmission system flow capacities, general operations criteria, and simulation procedure logic. The reviews concluded that the comparison of HH/LSM results with historical operations provides a reasonable simulation of system deliveries and reservoir storage values for the existing SFPUC regional water system. Similarly, as applied to the long-term planning purposes for which the model was designed, the reviews also concluded that the representation of the existing SFPUC system is reasonably incorporated by procedural simulation logic. Such external reviews have additionally and independently validated the HH/LSM.

In conclusion, use of a model to simulate actions in a water system is a valid and widely used practice employed by many water agencies in the United States, including the DWR, and model results can provide adequate and acceptable data for both system planning purposes as well as for environmental analysis. The SFPUC considers the HH/LSM results to reasonably portray the current and anticipated operation of the regional water system under the scenarios developed in the PEIR, and the San Francisco Planning Department has determined that the HH/LSM is a reasonable and appropriate tool to use in assessing environmental impacts of the proposed WSIP water supply and system operations on resources in the Tuolumne River, Alameda Creek, and Peninsula watersheds.

14.5.6 Model Assumptions

Comment Summary

This section of this master response responds to all or part of the following comments:

SI-TRT-CWA-SierraC-68	SI-TRT-CWA-SierraC-79	

Summary of Issues Raised by Commenters

Questions regarding the model assumptions for:

- Future water demand and water conservation/recycling
- Future hydrology
- Future TID/MID diversions from the Tuolumne River
- Future instream flow releases at La Grange Dam

Response

Future Water Demand and Water Conservation/Recycling

For discussion of assumptions related to water demand and future water conservation and recycling, please refer to **Section 14.2, Master Response on Demand Projections, Conservation, and Recycling** (Vol. 7, Chapter 14). Those assumptions were incorporated into the HH/LSM input as part of the system customer purchase request/demand.

Future Hydrology

In the modeling performed for the Draft PEIR, future hydrology was assumed to be a recurrence of the historical hydrology. Although there is inherent uncertainty regarding whether historical hydrology will be repeated in the future—especially given the evolving information on the potential effects of global climate change—the use of historical data over 82 years provides a wide enough range of interannual variation to address the future hydrology with climate change effects expected by 2030 for the purposes of the PEIR. Use of historical hydrologic data is still the conventional practice in water supply system modeling, although many water agencies are examining potential climate change effects on future hydrology as well as on future water supply planning and management. Please refer to **Section 14.11, Master Response on Climate Change** (Vol. 7, Chapter 14) for more information on the effects of global climate change as it relates to the Draft PEIR impact analysis.

Although the modeling for the WSIP relied on historical hydrologic data, the SFPUC's water supply planning does assume that future droughts could be more severe than historical droughts. The SFPUC chose a design drought more severe than any drought in the hydrologic record because of San Francisco's unusual vulnerability in droughts and its experiences during earlier droughts. Most agricultural water agencies and many municipal water agencies have both surface and groundwater supply sources. During droughts, these agencies can increase pumping from their groundwater sources to make up for any shortfall in surface water supplies. When planning for the future, these agencies typically establish their design drought based on the historical record. If the historical record proves to be unreliable, and droughts more severe than those in the historical record occur, these agencies can turn to their groundwater supplies or, in the case of the agricultural water agencies, fallow some land. In this way, these agencies can avoid severe economic losses.

Unlike these agencies, however, the SFPUC depends almost exclusively on surface water supplies, and its water rights are restricted in a manner that means little or no water is available to the SFPUC from its primary source, the Tuolumne River, in very dry years. As a result, the risk of a severe water shortage, with the attendant economic losses, is much greater for the SFPUC's retail and wholesale customers who rely solely on the regional system for their water than for most other urban or agricultural communities. Because of these circumstances, the SFPUC must take a more conservative posture than many water agencies when it chooses a design drought. Although the SFPUC's design drought was not selected with climate change in mind, it does provide the SFPUC with a margin of safety in water supply planning if the climate becomes drier.

Future TID/MID Diversions from the Tuolumne River

The assumptions regarding water diversions by the SFPUC, TID, and MID used in the Draft PEIR analysis of the WSIP are consistent with the assumptions used by the DWR in developing the *California Water Plan*; these data were used as input to the HH/LSM studies used in the Draft PEIR analysis. TID and MID's water use rates were based on a DWR model which, for a given crop pattern, estimates the amount of water farmers will need to grow crops in a given month, taking account of precipitation and evapotranspiration. Part of the farmers' water needs in the TID and MID service areas is met with groundwater and the remainder is supplied from the

Tuolumne River. Depending on conditions in Don Pedro Reservoir, TID and MID may not be able to supply all of the surface water that farmers need every year. Under existing conditions, the model estimates that TID and MID need to divert an average of 867,000 acre-feet per year at La Grange Dam for crop irrigation and delivery system operation.

With respect to future diversions of Tuolumne River water by TID and MID at La Grange, the analysis in the Draft PEIR assumed that the future (2030) need for water for agricultural irrigation would be the same as the present need. This assumption was based on the projection that agricultural lands in the TID and MID service areas are already fully developed, and so agricultural water use would not be expected to increase. Municipal use of Tuolumne River water in the TID and MID service areas is expected to increase considerably by 2030, but the increase would be offset by a reduction in agricultural use of Tuolumne River water.

Until recently, TID and MID provided surface water exclusively to agricultural users, and the municipalities in the TID and MID service areas obtained their water from groundwater wells. Farmers in the service areas obtained surface water from TID and MID and groundwater from wells. Because some of the wells in the TID and MID service areas are contaminated with small amounts of agricultural chemicals, they are more suitable for agricultural use than municipal use. The municipalities, together with TID and MID, have developed plans for regional surface water systems that would supply high-quality Tuolumne River water to municipal water users and reduce the municipal use of wells. Tuolumne River water flowing in the Turlock and Modesto Canals would be diverted to water treatment plants and, after treatment, delivered to municipal water users.

As described in the Draft PEIR (Vol. 3, Chapter 5, pp. 5.7-10 and 5.7-11), MID's municipal water treatment plant, which has a capacity of 30 million gallons per day (mgd) and serves the city of Modesto, was put in service in 1994. Its capacity is currently being expanded to 60 mgd, and the expanded plant will be in service in 2009. TID's water treatment plant is under construction and will have a capacity of 42.5 mgd. The plant will serve the city of Turlock and several other communities and will be operational in 2010. As municipalities increase their use of surface water and decrease their use of groundwater, more groundwater would become available for agricultural use. Agricultural users would increase their use of groundwater and decrease their use of Tuolumne River water.

Some reduction in agricultural water use and an increase in municipal water use is also expected as agricultural lands are converted to residential and commercial areas. But agricultural land and housing subdivisions use roughly equivalent amounts of water, so the land use change would not have much effect on overall water use.

A commenter notes that MID's urban water management plan indicates the District's demand for municipal water will increase by 70 percent by 2030, and that this figure seems inconsistent with the assumption of no increase in diversions by MID and TID at La Grange Dam. However, any projected increased use of Tuolumne River water to serve projected urban growth in the MID service area or to serve customers switching from groundwater to Tuolumne River water would be offset by a corresponding reduction in agricultural use of Tuolumne River water, as described above.

Although global climate change could cause an increase in future agricultural water use in the TID and MID service areas, other factors such as land use conversion and agricultural market forces make it too speculative at this time to quantify potential changes in agricultural water demand. Please refer to **Section 14.11, Master Response on Climate Change** (Vol. 7, Chapter 14) for further discussion.

Future Instream Flow Releases at La Grange Dam

The SFPUC assumed that the required instream releases at La Grange Dam in support of fisheries would remain the same as the current releases. Continuation of the current releases is a reasonable future scenario, and any other assumption would be speculative. For further discussion of instream releases, please refer to **Section 14.7, Master Response on Lower Tuolumne River Issues** (Vol. 7, Chapter 14, Section 14.7.4).

14.5.7 Model Limitations for Pilarcitos Creek Watershed

Comment Summary

This section of this master response responds to all or part of the following comments:

SI_TRT-CWA-SierraC-79

Summary of Issues Raised by Commenters

- The model limitations for the Pilarcitos Creek watershed should be explained.

Response

Model limitations for the Pilarcitos Creek watershed are described briefly in the Draft PEIR (Vol. 3, Chapter 5, p. 5.1-14). The analysis in the Draft PEIR used the best available information from the 2007 HH/LSM model runs, even though it did not fully represent operations at Pilarcitos Reservoir. This element of the HH/LSM has been modified, and updated model runs have been conducted that provide an improved representation of that system, as described in Chapter 13, Section 13.3 of this document. The updated model runs did not identify any environmental impacts that were not reported in the Draft PEIR, but they did enable the impacts to be better described. Some text changes have been made in the sections of the Draft PEIR that describe the impacts of the WSIP in the Pilarcitos Creek watershed (see the staff-initiated text changes for Section 5.5 in Vol. 7, Chapter 16).

Although the modifications to the model improved the HH/LSM's ability to simulate storage in Pilarcitos Reservoir and flows in Pilarcitos Creek, the changes to the model assumptions in the Pilarcitos system have a negligible effect on other elements of the SFPUC water system. This is because storage in Pilarcitos Reservoir represents only about 0.5 percent of the SFPUC's total water storage capacity, and water production from its watershed represents only about 1.2 percent of the deliveries under the WSIP.

14.5.8 Units of Measure

Comment Summary

This section of this master response responds to all or part of the following comments:

L_MID-TID1-04
SI_TRT-CWA-SierraC-81

Summary of Issues Raised by Commenters

- Requests for the use of consistent units of measure in the Draft PEIR.

Response

No single unit of flow is the best descriptor of a hydrologic element in all cases. In describing their overall operations, agricultural water agencies typically use acre-feet per year as their primary unit, whereas municipal water agencies use million gallons per day (expressed as an average of all days in the year). Flow in rivers, on the other hand, is usually expressed in cubic feet per second. The Draft PEIR uses the units that were appropriate for the particular circumstances. However, it is recognized that readers may want to convert one unit to another for comparison purposes. Conversion factors are included in the Draft PEIR at the end of the glossary and acronyms (Vol. 1, p. xxxviii) and are as follows:

1 million gallons per day = 1,120 acre-feet per year = 1.55 cubic feet per second

Summary of Issues Raised by Commenters

- Confusion regarding the magnitude of increased diversions from the Tuolumne River compared to the increase in purchase requests in 2030.

Response

Many comments indicated confusion about the estimates provided in the Draft PEIR for the increase in customer purchase requests by 2030 compared to the increase in Tuolumne River diversions under the WSIP. The confusion derives from PEIR statements regarding a *25 mgd increase in purchase requests* and a *27 mgd increase in diversions from the Tuolumne River*. As explained below, these two estimates are different, since they represent distinct, though related, system parameters. For clarification, these system parameters are defined as follows:

- *Purchase requests* represent the customer demand for water from the SFPUC regional system; this term is used interchangeably with *demand on the regional system*. This concept differs from simple “demand,” since demand for some customers is served by sources other than the SFPUC regional system.
- *Diversions* represent water from the supply sources (such as the Tuolumne River or Alameda Creek) that is transferred either to customers or to storage.
- *Deliveries* represent the portion of diversions that is transmitted to customers.

Purchase Requests

On an average annual basis, customer purchase requests from the regional water system are currently 265 mgd and, by 2030, are projected to be 300 mgd—an increase of 35 mgd over the existing condition (Vol. 1, Chapter 3, p. 3-33). Under the WSIP, 10 mgd of this increase in purchase requests would be met by recycled water, groundwater, and conservation in San Francisco, and the adjusted purchase requests under the WSIP would be 290 mgd. The SFPUC proposes to serve the remaining 25 mgd of increased purchase requests from a combination of increased diversions from the Tuolumne River and improvements to the local watershed system (primarily attributable to the restoration of full capacity at Calaveras and Crystal Springs Reservoirs). In summary, the estimates for determining the average annual increase in customer purchase requests are shown in **Table 14.5-1**, below.

Deliveries

Under the existing condition, the regional system does not have sufficient water supply, stored water, or supplemental water sources to fully meet customer purchase requests during extended dry periods, at which time the SFPUC must impose rationing. Therefore, during these periods, deliveries from the regional system are less than the customer purchase requests. The HH/LSM results indicate that over the 82-year historical hydrology, the SFPUC’s average annual system deliveries to customers are approximately 258 mgd of the 265 mgd in purchase requests (approximately 97 percent) due to the shortfall in deliveries when rationing is imposed during droughts. The analysis in the Draft PEIR indicated that the source of the 258 mgd in system

TABLE 14.5-1
AVERAGE ANNUAL CUSTOMER PURCHASE REQUESTS FROM THE REGIONAL SYSTEM
(average annual, mgd)

Scenario	Customer Purchase Requests
WSIP, 2030	300
Amount of purchase requests to be met with recycled water/groundwater/conservation in San Francisco	10
Adjusted purchase requests, 2030	290
Existing condition, 2005	265
Total increase in purchase requests under the WSIP to be met by Tuolumne River and local watershed supplies	25

NOTE: Data shown from Draft PEIR, Vol. 1, Chapter 3.

deliveries consists of an average annual amount of 218 mgd from the Tuolumne River and 40 mgd from the local watersheds.

Under the WSIP by 2030, the SFPUC would substantially improve overall delivery reliability and would be able to meet customer purchase requests more consistently than it currently does. However, during extended droughts, the system would still be unable to fully meet customer purchase requests, even though it would implement supplemental dry-year water sources, including water transfers from TID and MID and a conjunctive-use program in the Westside Groundwater Basin. The SFPUC would still need to impose rationing, but it would be limited to 20 percent systemwide. The HH/LSM results indicate that over the 82-year historical hydrology, the average annual system deliveries to customers under the WSIP would be approximately 287 mgd of the 290 mgd in purchase requests (approximately 99 percent), indicating improved delivery reliability over existing conditions. The Draft PEIR analysis showed that on an average annual basis, the 287 mgd would consist of 245 mgd in deliveries from the Tuolumne River and 42 mgd in deliveries from the local watersheds. The estimates for determining the average annual system deliveries from the SFPUC's water sources under existing and proposed conditions are shown in **Table 14.5-2**.

TABLE 14.5-2
SOURCE OF CUSTOMER DELIVERIES FROM THE REGIONAL SYSTEM
(average annual, mgd)

Scenario	Total System Customer Deliveries	Tuolumne River Diversions for Customer Deliveries	Local Watershed Diversions for Customer Deliveries[a]
WSIP, 2030	287	245	42
Existing Condition, 2005	258	218	40
Increase under the WSIP	29	27	2

[a] The increase in local watershed diversions under the WSIP is due to the restored capacity in Calaveras and Crystal Springs Reservoirs.

NOTE: Data shown based on 2007 HH/LSM studies; refer to Appendix H (Vol. 5).

Diversions

As indicated in Table 14.5-2, the SFPUC currently diverts an estimated annual average of 218 mgd from the Tuolumne River, and, under the WSIP, this amount would increase to 245 mgd. Thus, as stated in the Draft PEIR (Vol. 4, Chapter 9, p. 9-13), the estimated increase in diversions from the Tuolumne River for customer deliveries would be 27 mgd.

14.6 Master Response on Upper Tuolumne River Issues

14.6.1 Introduction

Overview

This master response addresses questions and comments about the impact analysis for the upper Tuolumne River; that is, the river between O'Shaughnessy Dam and Don Pedro Reservoir. This master response is organized by the following subtopics:

14.6.2 Minimum Required Instream Flows
14.6.3 Adequacy of Data on Streamside Meadows
14.6.4 Mitigation Measure 5.3.7-2
14.6.5 Impacts on Flow/Hydrology
14.6.6 Impacts on Geomorphology
14.6.7 Impacts on Water Quality

Summary of Issues Raised by Commenters

- The Draft PEIR lacks sufficient data to determine whether current flows support public trust values.
- The Draft PEIR lacks sufficient data to reach conclusions on the WSIP's impacts.

Response

The purpose of the Draft PEIR is to describe the consequences of the proposed WSIP relative to the existing condition. CEQA requires that an EIR contain a description of the existing "without project" condition, but does not require that an EIR determine whether the existing condition complies with current regulations or supports public trust values. The U.S. Geological Survey operates a stream gage below O'Shaughnessy Dam, which provided ample data to characterize the existing condition with respect to river flow.

The current minimum required releases from O'Shaughnessy Dam to support fisheries are shown in Table 5.3.1-2 of the Draft PEIR (Vol. 3, Chapter 5, p. 5.3.1-12). The releases are made in accordance with an agreement between the City and County of San Francisco (CCSF) and the U.S. Department of the Interior (DOI), which determined the minimum flow schedules for resident trout. Anglers continue to catch trout in the reach of the river below the dam, but no detailed information on fish populations has been gathered since the U.S. Fish and Wildlife Service (USFWS) studies in the early 1990s. Obtaining new information on fish populations was determined to be unnecessary for the purpose of the PEIR based on the projected nature, frequency, and magnitude of flow changes attributable to the WSIP.

The SFPUC will adhere to the minimum release schedule whether or not the WSIP is implemented. As indicated in the Draft PEIR (Vol. 3, Chapter 5, p. 5.3.1-25), implementation of the WSIP would not reduce river flow during those times when minimum releases are being made under the existing condition. It would increase the number of months during which only minimum releases are made, from 837 months in the 984-month hydrologic record to 843 months. The fisheries impact analysis in the Draft PEIR, which was performed by an expert fisheries biologist, was based on the hydrological changes that would occur under the WSIP and an understanding of species habitat requirements. The expert concluded that the small increase in the number of months when minimum releases are being made would not have a significant adverse effect on resident fisheries.

A draft report prepared by the USFWS in 1992 recommended an increase in minimum releases from O'Shaughnessy Dam, based on an Instream Flow Incremental Methodology (IFIM) study. The draft report concluded that resident trout populations could be increased if releases from O'Shaughnessy Dam were increased. As described in the Draft PEIR (Vol. 3, Chapter 5, p. 5.7-7), the CCSF provided comments on the draft study questioning the basis for some of the recommendations, but the matter was left unresolved. Beginning in 2005, the SFPUC began working with the USFWS to resolve issues regarding the recommended releases. Cooperative field studies are in progress, and the CCSF and USFWS expect to reach agreement on the releases in 2009. The new studies will include the use of IFIM or an alternative flow and habitat assessment methodology.

The 1987 CCSF and DOI agreement provided for supplemental releases of 4,400 to 15,000 acre-feet per year from O'Shaughnessy Dam, depending on hydrologic year type. The supplemental releases are shown in Draft PEIR Table 5.7-4 (Vol. 3, Chapter 5, p. 5.7-30). The supplemental releases have not been made since 1992 because the USFWS has yet to make a determination about the schedule needed for supplemental releases. Supplemental releases were made between 1989 and 1992 in support of the studies that resulted in the USFWS's 1992 draft report. Because these releases (or some other schedule of releases derived from the ongoing studies) will occur in the future, they were included in the cumulative impact analysis contained in the Draft PEIR (Vol. 3, Chapter 5, Section 5.7).

The analysis indicated that any increase in minimum releases for the benefit of resident trout during the minimum release period (more than 80 percent of the time) could have adverse biological effects. The release of more water from Hetch Hetchy Reservoir during the minimum release period would cause the reservoir to be drawn down farther just prior to the snowmelt than it would with the current schedule of minimum releases. Because more water would be needed to refill the reservoir, the total volume of water released in the spring snowmelt period would be reduced and the release would be delayed by a few days. The reduction and delay in the spring release could have an adverse effect on riparian and meadow vegetation in the Poopenaut Valley, as described in the Draft PEIR (Vol. 3, Chapter 5, pp. 5.3.7-21 and 5.3.7-22). Before recommending changes to the current release schedule, the SFPUC and USFWS will consider both the benefits and adverse effects of additional releases on fisheries and other biological resources during the spring, summer, fall, and winter.

14.6.3 Adequacy of Data on Streamside Meadows

Comment Summary

This section of this master response responds to all or part of the following comments:

SI_SPUR-07	SI_TRT-CWA-SierraC-15	C_Dulma-01
SI_TRT-CWA-SierraC-04	SI_TRT-CWA-SierraC-16	
SI_TRT-CWA-SierraC-14	SI_TRT-CWA-SierraC-18	

Summary of Issues Raised by Commenters

- The Draft PEIR lacks sufficient data to characterize impacts on streamside meadows.

Response

The San Francisco Planning Department (as the CEQA lead agency) and the SFPUC (as the project sponsor) both acknowledge that little published information is currently available on the flora and fauna of streamside meadows in the Poopenaut Valley, and that acquisition of comprehensive data would take several years. However, in the course of preparing the PEIR, the consulting biologists conducted a reconnaissance survey of the meadow and discussed conditions in the meadow with National Park Service biologists, who are beginning surveys of the Poopenaut Valley in coordination with the SFPUC. As described in **Section 14.4, Master**

Response on PEIR Appropriate Level of Analysis (Vol. 7, Chapter 14, Section 14.4.4), CEQA Guidelines Section 15151 imposes a standard of adequacy that is "reasonably feasible" and sufficient to allow decision-makers to make a decision that takes account of environmental consequences. Data gathering need not be "exhaustive." The Draft PEIR analysis of the WSIP water supply and system operations on biological resources in the Poopenaut Valley was based on current knowledge regarding the composition and condition of the riparian system, and a consideration of the interactive responses of plant and animal species to hydrologic changes resulting from the WSIP. The analysis relied on ecological principles, scientific literature, existing data, and site visits. The Draft PEIR analysis was conservative in finding that an impact could be potentially significant if there was a possibility of impacts from the WSIP water supply and system operations.

In general, it is known that the ecological health of mountain meadows depends on periodic recharge of the underlying groundwater, which supports vegetation through the dry summer months. In the Poopenaut Valley, groundwater recharge occurs as a result of runoff from the canyon sides into the valley, and when high flows in the Tuolumne River flood the meadow or otherwise raise groundwater levels. Little is known about the condition of the Poopenaut Valley before the construction of Hetch Hetchy Reservoir in the 1920s. The meadow itself, and its flora and fauna, have adapted to changes in the magnitude and seasonal pattern of river flow since the reservoir was built. From the 1920s to the late 1960s, Hetch Hetchy Reservoir affected the seasonal pattern but not the magnitude of flow in the river within the Poopenaut Valley. Water was diverted for municipal supply at Early Intake, several miles downstream of the Poopenaut Valley. In 1967, the completion of Canyon Tunnel enabled the diversion of water at Hetch Hetchy Reservoir for municipal water supply and hydropower generation several miles upstream of the Poopenaut Valley. Beginning in 1967, average annual flow in the Tuolumne River through the Poopenaut Valley was reduced by about 50 to 60 percent compared to pre-1967 flows.

Compared to the existing condition, the WSIP would reduce the total volume of flow in the Tuolumne River through the snowmelt period and delay releases from Hetch Hetchy Reservoir by a few days. With the WSIP, the average annual diversion from the river at Hetch Hetchy Reservoir would increase from the current 469,000 acre-feet to 478,500 acre-feet, an increase of about 2 percent. The increased average annual diversion would produce a corresponding reduction in average annual releases to and flow in the river. Because the change in flow and the delay in the initial release of snowmelt have the potential to reduce groundwater recharge and thus affect the flora and fauna of the meadow, the effect of the WSIP on biological resources in the Poopenaut Valley was determined to be potentially significant. Detailed knowledge of the meadow's flora and fauna was not necessary to reach this conclusion.

Mitigation Measure 5.3.7-2 (Vol. 4, Chapter 6, pp. 6-49 and 6-50) identified an approach to reduce the potential impacts of WSIP-induced flow changes in the Poopenaut Valley to a less-than-significant level. Currently, the operators of Hetch Hetchy Reservoir do not actively shape the late spring/early summer release from the reservoir to achieve any particular environmental goal. With Mitigation Measure 5.3.7-2 in place, operators would shape the release to recharge groundwater in the valley in a manner that approximates conditions characteristic of typical Sierra Nevada meadows. The performance standard to be achieved by this measure is no net loss of the extent, diversity, and condition of the existing meadow and wetland vegetation types in the Poopenaut Valley. The mitigation measure includes a monitoring and baseline data collection component.

The National Park Service, in coordination with the SFPUC, is currently conducting studies in the Poopenaut Valley that include vegetation surveys, rare species surveys, and groundwater level monitoring. The results of the studies will be available during the course of WSIP implementation and will enable monitoring of the WSIP's effects as well as refinement of how the proposed mitigation measure (Measure 5.3.7-2) would be implemented. Once the WSIP is adopted, the monitoring component of Measure 5.3.7-2 would provide the information necessary to determine if the performance goal is being met and if the release pattern needs to be modified.

14.6.4 Mitigation Measure 5.3.7-2

Comment Summary

This section of this master response responds to all or part of the following comments:

SI_SPUR-07	SI_TRT-CWA-SierraC-17	C_Dulma-01
SI_TRT5-03	SI_TRT-CWA-SierraC-18	

Summary of Issues Raised by Commenters

- The Draft PEIR does not specify the timing or magnitude of releases.

Response

Mitigation Measure 5.3.7-2 (Vol. 4, Chapter 6, pp. 6-49 and 6-50) would impose a specific release strategy on the reservoir operators and require releases sufficient to maintain the existing meadow communities.

It is not possible to specify exactly the timing and magnitude of controlled releases because they would vary from year to year. Under the existing condition, the SFPUC releases only the required minimum flows from Hetch Hetchy Reservoir for most of the time (837 months in the 984-month hydrologic record). During the spring snowmelt period, the SFPUC attempts to refill Hetch Hetchy Reservoir, and in most years (74 years in the 82-year hydrologic record) the reservoir fills completely. Once the reservoir is full, or it is apparent to the reservoir operators that it will fill, releases in excess of the minimum required release begin. The magnitude of the total release above the minimum required depends on the volume of runoff entering the reservoir from its watershed and the rate of diversion to Canyon Tunnel. The release pattern is not currently designed or deliberately shaped, but is simply a consequence of the operators' response to upstream hydrology and choices with respect to reservoir management and the consequent opening and closing of gates and valves.

With implementation of Measure 5.3.7-2, the water available for release would be released in a pattern that increases the chance of inundating the meadow in the Poopenaut Valley. Examination of the soil types in the valley indicate that the underlying groundwater in the meadow can probably be recharged in a matter of a few hours or a day, and that extended inundation would not increase recharge substantially. As an example, operators may currently choose to release water from Hetch Hetchy Reservoir during the snowmelt period at a rate of 1,000 cubic feet per second (cfs) for 10 days. With Mitigation Measure 5.3.7-2 in place, the reservoir operators could choose to release the same amount of water in the following pattern: 1,000 cfs for the first day, 2,000 cfs for the second day, 3,000 cfs for the third day, 2,000 cfs for the fourth day, and 1,000 cfs for the fifth and sixth days. The modified release pattern would increase the chance that the meadow would be inundated.

The most effective release pattern would be determined by monitoring the effect of releases and refined as information becomes available from the ongoing National Park Service/SFPUC studies in the Poopenaut Valley and baseline studies associated with Measure 5.3.7-2. An experimental release of 3,000 cfs made by the SFPUC in 2007 raised the river level in the Poopenaut Valley by 11 feet, sufficient to flood the meadow. The SFPUC operators made additional experimental releases in the spring of 2008 that showed similar results.

The third full paragraph of Mitigation Measure 5.3.7-2, Controlled Releases to Recharge Groundwater in Streamside Meadows and Other Alluvial Deposits (Vol. 4, Chapter 6, p. 6-50, first full paragraph) is revised as follows for clarification. There are no revisions to the footnote in this paragraph, so it is not included here but should be retained as part of the text.

> As part of this measure the SFPUC will gather baseline data regarding the extent, species composition and condition of the existing meadow vegetation within the Poopenaut Valley. Some of these environmental baseline data may be available as a result of current study efforts in the Poopenaut Valley. As needed, the SFPUC will augment this information by carrying out vegetation composition surveys in the meadow before implementing the WSIP and at 5 year intervals after WSIP implementation to assess the efficacy of mitigation releases in maintaining or improving the percentage cover of meadow species as described by Ratliff (1985). The basic methodology for baseline vegetation survey and subsequent mitigation monitoring will be generally accepted quantitative vegetation sampling methods to permit statistical comparison of vegetation composition over time, as well as mapping the meadow vegetation in the Poopenaut Valley. The SFPUC will consult with a qualified biologist to assist in shaping the releases from Hetch Hetchy Reservoir in consideration of baseline and future meadow vegetation data. If a significant decline in the extent or diversity of native meadow vegetation occurs, releases will be modified as needed to achieve the mitigating effect of sustaining the existing meadow communities.

14.6.5 Impacts on Flow/Hydrology

Summary of Issues Raised by Commenters

- Numerous comments expressed confusion about the existing and proposed levels of diversions by the SFPUC from the Tuolumne River.
- The Draft PEIR's conclusions regarding the flow impacts and significance of hydrology impacts are questionable.

Response

Level of Diversions

The average annual unimpaired flow in the Tuolumne River at Hetch Hetchy Reservoir is estimated to be 749,600 acre-feet. Currently, the SFPUC diverts about 63 percent of the average annual unimpaired flow into Canyon Tunnel at Hetch Hetchy Reservoir. Thus, flow in the Tuolumne River immediately below O'Shaughnessy Dam is about 37 percent of its average annual unimpaired value. Water flows through Canyon Tunnel to the Kirkwood Powerhouse. After passing through the turbines at the powerhouse, about two-thirds of the flow enters Mountain Tunnel for conveyance to the Bay Area; the other third is returned to the river at Early Intake. Flow in the Tuolumne River below Early Intake is at least 50 percent of its average annual unimpaired value.

With the WSIP in place, the SFPUC would divert about 64 percent of the average annual unimpaired flow in the Tuolumne River into Canyon Tunnel at Hetch Hetchy Reservoir. Thus, flow in the Tuolumne River immediately below O'Shaughnessy Dam would be about 36 percent of its average annual unimpaired value. Flow in the Tuolumne River below Early Intake would be at least 49 percent of its average annual unimpaired value.

Note that the values presented in the two paragraphs above are slightly different from those provided in the Draft PEIR. After completion of the Draft PEIR, some improvements were made to the Hetch Hetchy/Local Simulation Model, and the values in the preceding paragraphs were obtained using the update model, as described in Section 13.3 (Vol. 7, Chapter 13) of the Comments and Responses document.

Flow Impacts and Significance of Hydrology Impacts

Under the existing condition, flow in the Tuolumne River between O'Shaughnessy Dam and Early Intake consists almost entirely of releases from the dam. Minimum releases from the dam and minimum flows in the river are specified in an agreement between the CCSF and DOI, as shown in Draft PEIR Table 5.3.1-1 (Vol. 3, Chapter 5, p. 5.3.1-12). The minimum releases represent the low end of the range of flows in this reach of the river. The minimum flow is 35 cfs under the schedule for critically dry years (8 percent of all years). The minimum flow occurs in most months of years when precipitation at Hetch Hetchy Reservoir is less than certain values specified in the CCSF/DOI agreement. If the WSIP is implemented, the SFPUC would still have to adhere to the minimum release schedules specified in the agreement; therefore, the WSIP would not affect the low end of the range of flows in this reach of the river.

Typically, flows in the Tuolumne River below O'Shaughnessy Dam are at their seasonal maximum in the late spring and early summer when the snowpack melts. One of the dam operators' goals is to fill Hetch Hetchy Reservoir by the end of the snowmelt period. Another goal is keep flow in the river below the dam to no more than 8,000 cfs to prevent flooding at the Kirkwood Powerhouse. The dam operators monitor the depth of the snowpack, measure inflow to the reservoir, and adjust releases from the dam as necessary to meet these goals. Water can be diverted from the reservoir to the Canyon Tunnel at a maximum rate of about 1,400 cfs, and released to the river via eight valves at a maximum rate of about 9,000 cfs. Above these values, water passes over the spillway to the river in an uncontrolled manner. This is a rare occurrence, and dam operators are usually able to manage the reservoir without uncontrolled releases.

Maximum flows in the river below O'Shaughnessy Dam typically occur in the spring of years when the snowpack in the Sierra Nevada is heavy and melts rapidly. Modeled average monthly flows in the river below O'Shaughnessy Dam under the existing condition and with the WSIP are shown in Figure 5.3.1-9 (Vol. 3, Chapter 5, p. 5.3.1-23). The figure shows that average monthly flows under the existing condition and with the WSIP would exceed 5,000 cfs eight times in the 82-year hydrologic record.

A red line on Figure 5.3.1-9 shows the average monthly release from Hetch Hetchy Reservoir to the river with the WSIP. A blue line shows the average monthly release from Hetch Hetchy Reservoir to the river under the existing condition. Where the red and blue lines occupy the same space, the red line overwrites the blue line. Examination of the figure for the years in which average monthly flow exceeded 5,000 cfs (1922, 1938, 1956, 1969, 1978, 1983, 1995, and 1998) indicates that the red line overwrites the blue line in all eight years. This shows that in very high flow years, the WSIP would have no effect on the peak average monthly flow.

The reason the WSIP would have no effect on the highest average monthly peak flows is that the capacity of Hetch Hetchy Reservoir is small relative the amount of runoff produced in its watershed in very high runoff years. In years when the snowpack is deep, the reservoir fills rapidly at the beginning of the snowmelt period, after which operators must release any additional runoff to the river below the dam. The peak release to the river usually occurs after the reservoir is full or is close to full.

Average daily flows in the river below O'Shaughnessy Dam typically exceed average monthly flows because, in the snowmelt period, reservoir operators may adjust releases to the river every few days. U.S. Geological Survey gaging records show that average daily flows in the river below the dam equaled or exceeded 10,000 cfs on at least one day in 1929, 1933, 1935, 1938, 1943, 1950, 1951, 1983, 1995, and 1997, usually in May or June. A maximum average daily flow of 16,400 cfs occurred in 1997 in an unusual storm that caused rain to fall on the snowpack in January. Operators of the dam estimate that the instantaneous peak release on January 3, 2007 was probably about 20,000 cfs. It is unlikely that the WSIP would have any effect on the highest average daily peak or instantaneous peak flows for the same reason that it would not have any effect on average monthly peak flows.

In summary, the WSIP would have no effect on either the low or high ends of the range of current flows in the Tuolumne River below O'Shaughnessy Dam. The WSIP would not "substantially alter stream flows such that they are outside the range of pre-project conditions," and its impact on flows was therefore judged to be less than significant.

Although the WSIP would not affect the magnitude of relatively rare, very large peak flows, it would affect the magnitude of the smaller average monthly peak flows that occur more frequently than once every 10 years. The modeled flows shown in Figure 5.3.1-9 of the Draft PEIR indicate that the WSIP would not have any effect on average monthly peak flows during the large runoff events that occur about once every 10 years (eight times in the 82-year hydrologic record); this would be the case under conditions that occurred in 1922, 1938, 1956, 1969, 1978, 1983, 1995, and 1998. Average monthly peak flows during runoff events with a frequency of more than once in 10 years may be affected at times. For example, as shown in Figure 5.3.1-9, average monthly peak flows with the WSIP under conditions that occurred in 1989, 1991, 2001, and 2002 would be lower than under the existing condition.

Except on rare occasions, daily and instantaneous peak flows are a result of management decisions by dam operators. If there were no change in current reservoir management practices with the WSIP, average daily and instantaneous peak flows during runoff events with a higher frequency than once in 10 years would be reduced. However, Mitigation Measure 5.3.7-2 calls for a change in reservoir management practices; that is, the shaping of releases from O'Shaughnessy Dam to increase the chance of recharging groundwater in the Poopenaut Valley. Implementation of this measure would also reduce or eliminate the effects of the WSIP on daily or instantaneous peak flows during runoff events with a higher frequency than once in 10 years.

14.6.6 Impacts on Geomorphology

Summary of Issues Raised by Commenters

- The PEIR should not reference average flow data.
- The Draft PEIR's conclusions regarding sediment transport are speculative.

Response

The average monthly flow data provided in Table 5.3.1-5 of the Draft PEIR (Vol. 3, Chapter 5, p. 5.3.1-26) played only a minor role in the assessment of the WSIP's effects on the geomorphology of the Tuolumne River below O'Shaughnessy Dam. Changes in peak flows attributable to the WSIP provided the primary informational basis for reaching conclusions regarding impacts on geomorphology. The WSIP would have little effect on the range of flows experienced in the Tuolumne River below O'Shaughnessy Dam. It would have no effect on the magnitude of infrequent, very large flows because Hetch Hetchy Reservoir is small relative to the volume of runoff produced in its watershed. However, the WSIP could have an effect on the frequency of smaller peak flows. Please see Section 14.6.5, above, for more information.

A commenter opines that the analysis of sediment transport and gravel bed conditions in the Draft PEIR is qualitative and largely speculative. The San Francisco Planning Department acknowledges that the analysis is qualitative but disagrees that it is speculative. Although little data are available on substrate conditions in the upper Tuolumne River between Hetch Hetchy and Don Pedro Reservoirs, it is the San Francisco Planning Department's view that the data are sufficient to make a reasonable analysis, without excessive speculation, of the WSIP's impacts on sediment movement.

The information on existing sediment conditions in the Tuolumne River between Hetch Hetchy and Don Pedro Reservoirs provided in the Draft PEIR (Vol. 3, Chapter 5, pp. 5.3.2-1 to 5.3.2-3) was obtained from reports prepared for the SFPUC by McBain and Trush and RMC. The most recent in a series of reports summarized available data on the ecosystem in the upper Tuolumne River and provided recommendations for monitoring (McBain and Trush and RMC, 2007). The report confirmed the general description contained in the Draft PEIR of channel and sediment characteristics in this reach of the river.

Much of the upper Tuolumne River flows in a bedrock channel in a deep canyon. Alluvial deposits and riparian vegetation are limited along most of this river reach, but generally increase somewhat in a downstream direction. The only location where the floodplain broadens is in the Poopenaut Valley where an extensive streamside meadow has developed. For about 80 years, O'Shaughnessy, Cherry, and Eleanor Dams have prevented the downstream movement of bedload from the watersheds upstream of Hetch Hetchy Reservoir, Lake Lloyd, and Lake Eleanor. The reservoirs have also reduced peak daily flows in the river in all but the very largest floods.

Little information is available on the relationship between peak flows and the movement of sediment, gravel, and boulders in this reach of the Tuolumne River. As noted in the Draft PEIR, limited studies of the Clavey River, a Tuolumne River tributary, provide some information on the relationship between peak flows and bedload transport in the Clavey River. Because the Clavey River and the Tuolumne River share some characteristics (they both have a relatively steep bedrock channel confined within a canyon), the Clavey River data provide some insight into the geomorphology of the Tuolumne River.

As indicated in the Draft PEIR (Vol. 3, Chapter 5, p. 5.3.2-3), the Clavey River data suggest that:

- Common small floods that occur every one to three years scour and deposit sand in pools and bars.
- Moderate-sized floods that occur every 12 to 17 years move gravel and cobbles, reshape side channels, and move large woody debris.
- Very large floods that occur every 70 to 100 years erode large bars, remove and create side channels, and move large boulders over short distances.

As described in Section 14.6.5, above, the WSIP would have no effect on infrequent, large peak flows in the Tuolumne River below O'Shaughnessy Dam, but it would have some effect on smaller and more frequent peak flows. The WSIP would have no effect on moderate-sized or very large floods and would therefore have no impact on the transport of gravel, cobbles, and boulders. It could reduce the transport of sand somewhat relative to existing conditions. However, despite this minor effect on sediment movement, the Draft PEIR concludes that the WSIP would not result in substantial changes in erosion or siltation rates, and this impact was determined to be less than significant.

14.6.7 Impacts on Water Quality

Comment Summary

This section of this master response responds to all or part of the following comments:

SI_SPUR-07	SI_TRT-CWA-SierraC-160	C_Goite-01
SI_TRT-CWA-SierraC-131	C_BramlD1-01	C_Goodm-02

SI_TRT-CWA-SierraC-159	C_Elbiz-01	C_Sprin-01

Summary of Issues Raised by Commenters

- The Draft PEIR's conclusions regarding water temperature are questionable.
- The WSIP would violate water quality objectives.

Response

As described in the Draft PEIR, Hetch Hetchy Reservoir is typically filled in the late spring and early summer and is drawn down during the rest of the year. Under ordinary conditions, the required releases to support coldwater fish in the Tuolumne River below the reservoir during the warm summer and early fall months are drawn from the pool of cool water, deep within the reservoir. During droughts, the reservoir is drawn down farther than in more typical conditions. Under existing conditions and with the WSIP, the pool of cool water in the reservoir is great enough to enable releases of cool water throughout the summer and early fall in all but one drought, the 1976–1977 drought. In a drought like the 1976–1977 drought, the reservoir would probably destratify in September, and warmer water would be released to the river from the reservoir. Both under the existing condition and with the WSIP, water temperature in the river below O'Shaughnessy Dam would increase by more than the water quality objective of 5 degrees Fahrenheit. With the WSIP, elevated water temperatures could persist for several days or weeks longer than under the existing condition.

The conclusion in the Draft PEIR that the WSIP would have a less-than-significant impact on water quality was based on an assessment of whether the beneficial use that the objective is intended to protect—coldwater fish—would be significantly harmed. Both the severity and the frequency of exceedances entered into the assessment. Under typical conditions, water released from the bottom of Hetch Hetchy Reservoir in the summer is quite cool, about 8 degrees Celsius (ºC). This is probably considerably cooler than the summer water temperature in the river under natural (i.e., pre-O'Shaughnessy Dam) conditions. While this water temperature is suitable for resident trout, it is below the optimum for rearing juvenile trout, which is 13 to 21 ºC. In a severe drought, the temperature of water released from O'Shaughnessy Dam would be 10 to 12 ºC warmer and would raise water temperature in the river to 18 to 20 ºC, toward the upper end of the acceptable range for resident trout. It is not expected that the temperature increase, which would occur over a week or two, would harm resident trout, because water temperatures would remain within the acceptable range. Even if the temperature rise increased stress on resident trout, the rise would occur very infrequently, about one fall in every 82 years. Because the risk to resident trout when water temperatures rise is small, and because WSIP-caused temperature increases would be very infrequent, it was concluded that the WSIP's impact on water quality in the Tuolumne River between Hetch Hetchy and Don Pedro Reservoirs would be less than significant.

14.7 Master Response on Lower Tuolumne River Issues

14.7.1 Introduction

Overview

This master response addresses questions and comments about the impact analysis for the lower Tuolumne River; that is, the river between La Grange Dam and the San Joaquin River. This master response is organized by the following subtopics:

14.7.2 Chinook Salmon in the Lower Tuolumne River
14.7.3 Steelhead in the Lower Tuolumne River
14.7.4 FERC-Required Minimum Flows
14.7.5 Impacts on Water Quality
14.7.6 Impacts on Flow/Hydrology
14.7.7 Impacts on Geomorphology
14.7.8 Mitigation Measure 5.3.6-4a
14.7.9 Mitigation Measure 5.3.6-4b

Summary of Issues Raised by Commenters

- More up-to-date information on salmon needs to be presented.
- More complete data on the historical occurrence of salmon need to be presented.
- The WSIP has the potential to harm already declining anadromous fish populations.

Response

The Draft PEIR provides information on Chinook salmon populations in the Tuolumne River (Vol. 3, Chapter 5, pp. 5.3.6-13 to 5.3.6-17). Table 5.3.6-2 shows the results of spawning surveys for the period 1971 to 2004, which show a declining trend in Chinook salmon production. A commenter provided similar information that also shows a declining trend; the receipt of this information is acknowledged (see **Response SI_TRT-CWA-SierraC-194**).

The information on Chinook salmon provided in the Draft PEIR was sufficient to reach the conclusion that the WSIP could have a potentially significant adverse impact on salmonids in the Tuolumne River below La Grange Dam. As stated in the Draft PEIR (Vol. 3, Chapter 5, pp. 5.3.6-28 to 5.3.6-32), overall flow reductions coupled with the projected infrequent water temperature increases that could result from the WSIP would have an adverse impact on habitat conditions for juvenile salmonids. The *Habitat Restoration Plan for the Lower Tuolumne River Corridor* (McBain and Trush, 2000) establishes goals for fishery habitat restoration, and the National Marine Fisheries Service (NMFS) and others have identified goals for fishery enhancement in this reach of the river. The WSIP's small but incremental contribution to adverse effects on the lower river would make planned restoration of habitat and fishery resources more difficult. Thus, the Draft PEIR reflects the view of a commenter that the WSIP has the potential to cause a significant adverse effect on anadromous fish in the Tuolumne River below La Grange Dam.

Although the information in the Draft PEIR was sufficient to reach the conclusion referred to above, the following supplementary information is provided to augment and clarify the discussion in the Draft PEIR in response to the comments.

The San Joaquin River and its major tributaries historically supported large populations of both spring-run and fall-run Chinook salmon. During the late 1800s and early 1900s, construction of a number of dams and impoundments within the watershed to provide hydroelectric power generation as well as water supplies for agricultural and municipal usage substantially altered the hydrologic regime of the rivers in terms of the seasonal timing and magnitude of instream flows. The dams also created complete impassable barriers to the upstream migration of adult salmonids, thereby precluding access to otherwise suitable spawning and juvenile rearing habitat located farther upstream within the watershed. The construction of various dams and impoundments coupled with land use changes within the watershed cumulatively contributed to the declining abundance of Chinook salmon, ultimately leading to the extirpation of both spring-run and fall-run Chinook salmon on the mainstem San Joaquin River downstream of Friant Dam. Fall-run Chinook salmon continued to persist within the three major tributaries to the San Joaquin River, including the Stanislaus, Merced, and Tuolumne Rivers, within habitat reaches located downstream of major dams on each of these three tributaries. In addition to naturally spawning, self-sustaining populations of Chinook salmon within the three tributaries, a mitigation hatchery was constructed on the Merced River for the production of Chinook salmon, which has also contributed to the population abundance and dynamics of Chinook salmon within the lower watershed.

Since completion of the major dams in the San Joaquin River watershed during the late 1940s, the Chinook salmon population inhabiting the Tuolumne, Merced, and Stanislaus Rivers has been characterized by highly variable and fluctuating numbers of adult salmon returning to the tributaries each year to spawn. Adult Chinook salmon population abundance within the three tributaries over the past six decades has fluctuated from a low of several hundred fish to a high of over 40,000 adult salmon. Recent fall-run Chinook salmon escapement averages from 1992 through 2006 were 3,700 adults for the Stanislaus River, 4,600 for the Tuolumne River, and 3,800 for the Merced River. Maximum fall-run escapement over the period from 1967 to 2006 was between 10,000 and 14,000 adults for the Stanislaus River, between 10,000 and 20,000 for the Tuolumne River, and between 10,000 and 15,000 for the Merced River. The fluctuations in adult abundance appear to follow a long-term cyclical pattern, which has been hypothesized to be related to a variety of environmental factors. During the two most recent years, 2006 and 2007, adult Chinook salmon returns to the three tributaries have declined substantially to near-record lows.

There is a high degree of uncertainty and disagreement on the causal mechanisms that have contributed to the high fluctuations in adult returns to the Tuolumne River and other San Joaquin River tributaries. Research on the Tuolumne River suggests that numerous in-river mortality factors may be affecting the abundance and survival of Chinook salmon within the Tuolumne River and other tributaries, including the following: predation by piscivorous fish such as largemouth and smallmouth bass, striped bass, and Sacramento pikeminnow, both within the river and associated with gravel pits; exposure to seasonally elevated water temperatures, particularly during drier water years; low water velocities; habitat degradation within the tributaries; reduced instream flows supporting spawning, egg incubation, juvenile rearing, and adult and juvenile migration; redd superimposition; lack of turbidity during smolt outmigration; and limitations on available juvenile rearing habitat.

It appears that much of the fry and smolt mortality takes place after the juvenile Chinook salmon emigrate from the tributary rivers to the mainstem San Joaquin River, the Delta, or the ocean where there are a number of adverse conditions. Potential sources of mortality within the mainstem San Joaquin River and Delta include exposure to seasonally elevated water temperatures; exposure to potential entrainment risk at unscreened water diversions; entrainment and salvage risk as a result of operation of the State Water Project (SWP) and Central Valley Project (CVP) water export facilities; exposure to contaminants and toxics; vulnerability to predation mortality by striped bass, largemouth bass, Sacramento pikeminnow, and other predatory fish and birds; and delays in adult and juvenile migration as a result of changes in Delta hydrologic conditions associated with water export operations. In addition, the availability of suitable food supplies may be reduced for emigrating juvenile salmon within the lower San Joaquin River and the Delta. Furthermore, the results of correlation analyses between hydrologic conditions within the San Joaquin River basin during the spring period of juvenile emigration and the subsequent number of adult Chinook salmon returning to the tributaries two and one-half years later suggest the importance of river flow as a factor affecting the survival of juvenile Chinook salmon as they migrate downstream from the San Joaquin River tributaries through the lower mainstem and Delta.

There is growing scientific evidence that coastal oceanographic conditions, such as changes in water currents, changes in ocean water temperatures, and changes in ocean upwelling, are important influences on coastal productivity. They affect the species composition and abundance of zooplankton, macroinvertebrates, and fish inhabiting coastal marine waters. Changes in oceanographic conditions and coastal productivity have been related to salmon survival and ultimately the population abundance of adults. Within Pacific coastal waters, changes in oceanographic conditions associated with the Pacific decadal oscillation have been used to predict the abundance of returning adult Chinook salmon to inland tributaries to spawn. Ocean commercial and recreational harvesting of adult Chinook salmon has also been identified as a factor affecting the population dynamics and abundance of Central Valley Chinook salmon stocks.

Concern has been expressed that the hatchery production of Chinook salmon in the Merced River and other Central Valley hatcheries could affect the genetic integrity and population dynamics of Chinook salmon stocks within the San Joaquin River watershed and throughout the Central Valley. The NMFS and California Department of Fish and Game (CDFG) are working cooperatively to identify hatchery management practices that will reduce the potential effects of hatchery production on the genetic integrity of Central Valley Chinook salmon populations, as well as the effects of hatchery planting practices and the ocean harvesting of hatchery-produced salmon on the health and abundance of wild in-river Chinook salmon produced within the Central Valley tributaries.

A variety of scientific investigations and management programs have been implemented recently in an effort to better understand the factors affecting the survival and population dynamics of Chinook salmon within San Joaquin River tributaries, including the Tuolumne River, as well as programs designed to protect and enhance habitat conditions for Chinook salmon spawning, egg incubation, juvenile rearing, and adult and juvenile migration. For example, the Vernalis Adaptive Management Program (VAMP, described in Vol. 3, Chapter 5, pp. 5.2-17 and 5.2-18) was specifically designed to: (1) provide improved protection and survival of juvenile Chinook salmon emigrating from the San Joaquin River tributaries through the Delta during the spring months, and (2) provide a scientific framework for testing and evaluating the potential relationship between changes in stream flows within the San Joaquin River at Vernalis, installation of the Head of Old River barrier, and reductions in SWP and CVP export rates during the spring months on juvenile Chinook salmon survival. The VAMP investigations are ongoing.

Investigations have also been conducted to monitor the seasonal loading and concentrations of various toxics and potential pollutants within the mainstem San Joaquin River and its tributaries. Land use within the San Joaquin River watershed includes both urban populations as well as extensive agricultural production. Runoff within the watershed may include a variety of water quality contaminants, including pesticides and herbicides, petroleum products, selenium, and salts. Scientific investigations in combination with various regulatory programs have been designed to characterize the potential effects of these water quality constituents on the health and survival of aquatic resources, including San Joaquin River basin Chinook salmon, as well as to identify management actions to reduce or avoid the potential risk of exposure to these water quality constituents.

Large-scale management and habitat restoration programs, such as the CALFED Bay-Delta Program, have invested substantial staff and financial resources in conducting scientific investigations and in supporting habitat enhancement and improvement projects designed to benefit Chinook salmon and other aquatic resources in the lower Tuolumne River and other Central Valley rivers. In addition, the Anadromous Fish Restoration Program under the Central Valley Project Improvement Act has invested substantial time and financial resources to improve the scientific understanding of various factors affecting Chinook salmon in the San Joaquin River tributaries as well as to implement various management actions and habitat restoration and enhancement programs designed to improve the quality and availability of suitable habitat for Chinook salmon and other fish species.

One of the significant environmental factors that affects habitat quality and availability within the Tuolumne River and other San Joaquin River tributaries for Chinook salmon spawning, egg incubation, juvenile rearing, and adult and juvenile migration is exposure to seasonally elevated water temperatures. A variety of scientific programs designed to develop simulation and predictive models have been implemented in recent years; these models can be used to assess the effects of various reservoir operating strategies, stream flow schedules, coldwater pool management strategies, and other factors influencing the seasonal and longitudinal gradients of water temperatures within the tributaries that potentially affect the health and survival of Chinook salmon in the watershed.

As part of previous State Water Resources Control Board Bay-Delta water quality and water-right proceedings as well as the Federal Energy Regulatory Commission (FERC) hydroelectric project relicensing, considerable emphasis has been placed on evaluating and potentially modifying instream flow schedules for the Tuolumne River and other San Joaquin River tributaries. These management changes to instream flows were intended to improve the physical habitat for various life-history stages of Chinook salmon and other fishery resources as well as to provide more suitable seasonal water temperature conditions in an effort to improve the overall health and survival of Chinook salmon. Investigations into the relationship between instream flows and the hatching success, abundance of fry, abundance of smolts, juvenile emigration survival, and ultimately the abundance of adult Chinook salmon returning to the tributaries to spawn are continuing.

Ongoing investigations are also being performed by the CDFG, NMFS, and the Pacific Fishery Management Council to better identify the effects of recreational and commercial harvesting of Chinook salmon from various river systems, including the Tuolumne River, on population dynamics and adult escapement. Since the Central Valley Chinook salmon populations are comprised of both naturally spawning, in-river-produced salmon as well as fish produced within the Central Valley hatcheries, including the Merced River Fish Hatchery, regulation of commercial and recreational harvesting is an important factor in protecting weaker stocks, such as the wild, in-river Chinook salmon produced in the Tuolumne River. Since 2007, a large-scale constant fractional marking program has been implemented at Central Valley hatcheries to provide additional information on the contribution of various hatcheries to adult salmon populations in the ocean, the effects of harvest on various salmon stocks, adult straying among Central Valley rivers, and the relationship between various environmental factors within the rivers, the Delta, and ocean environments that ultimately affect the health and survival of Central Valley populations.

In recent years, a settlement was reached in federal court that is intended to restore instream flows and self-sustaining populations of spring-run and fall-run Chinook salmon to the mainstem San Joaquin River downstream of Friant Dam. The San Joaquin River Restoration Program is in its early stages, but has identified a number of physical features within the mainstem San Joaquin River that need to be modified or altered in order to reestablish Chinook salmon populations. The restoration program is seeking funding to implement the various restoration elements of the program, which are ultimately expected to support long-term fishery restoration within the river. There are, however, a number of uncertainties regarding the performance and effectiveness of the proposed restoration actions as well as the relationship between Chinook salmon populations and physical habitat within the mainstem and the survival of fall-run Chinook salmon inhabiting the lower tributaries. Full implementation of the San Joaquin River Restoration Program is expected to take a decade or longer.

Currently, the California Department of Water Resources and U.S. Bureau of Reclamation are engaged in a formal Section 7 consultation with the U.S. Fish and Wildlife Service regarding the potential effects of SWP and CVP export operations on the health and survival of delta smelt. The NMFS is responsible for issuing biological opinions under the Federal Endangered Species Act regarding the coordinated operations of the SWP and CVP for the protection of listed stocks of Chinook salmon, steelhead, and green sturgeon. The current Section 7 re-consultation process is expected to result in modifications to SWP and CVP export operations and other facilities within the Delta estuary, such as installation of the Head of Old River barrier and the south Delta barrier project, which may also have direct and indirect effects on the survival of juvenile Chinook salmon emigrating from the San Joaquin River tributaries downstream through the Delta.

The environmental and biological factors affecting the abundance of adult Chinook salmon returning to spawn in the Tuolumne River and other San Joaquin tributaries are dynamic and vary within and among years. An understanding of these various factors and their associated level of uncertainty provides, in part, the framework used in the Draft PEIR to assess potential impacts of the WSIP operations on habitat quality and availability for various life-history stages of Chinook salmon inhabiting the lower Tuolumne River.

14.7.3 Steelhead in the Lower Tuolumne River

Comment Summary

This section of this master response responds to all or part of the following comments:

SI_TRT-CWA-SierraC-11	SI_TRT-CWA-SierraC-152	

Summary of Issues Raised by Commenters

- No data on steelhead trout are included in the Draft PEIR.
- Recent studies indicate that some steelhead are present in the Tuolumne River.

Response

A comment on the Draft PEIR refers to the lack of data on steelhead trout and cites McEwan (2001) as a source of information on current steelhead presence and population in the Tuolumne River. The comment notes that the McEwan study provides more recent information on steelhead presence in the Tuolumne River than the data included in the Draft PEIR from the FERC study (1996).

Section 5.3.6.1 of the Draft PEIR (Vol. 3, Chapter 5, pp. 5.3.6-1 to 5.3.6-24) provides setting information and discussion on the presence of steelhead trout in the Tuolumne River. The data presented in the Draft PEIR on habitat conditions in the lower Tuolumne River indicate that this reach of the river is unsuitable for significant populations of steelhead trout due to high temperatures over summer months. The studies by FERC (1996) concluded that no significant populations of steelhead or rainbow trout are present within the lower Tuolumne River system.

The McEwan study includes a discussion on the historical distribution of steelhead and documents historical evidence of steelhead in the lower Tuolumne River. The study also estimates the present range of likely steelhead occurrence, including in the Tuolumne River. Consistent with the Draft PEIR, the McEwan study states that high water temperatures are a primary stressor for juvenile steelhead through the summer months. Dam construction over the last century has made coldwater spawning and rearing habitat at mid-range and high elevations in the Tuolumne River watershed inaccessible to steelhead. Steelhead are now confined to the lower elevation reaches, where high summer water temperatures are a major stressor (McEwan, 2001).

Additionally, consistent with the Draft PEIR, McEwan found that no significant populations of steelhead/rainbow trout are present in the lower Tuolumne River system. Section 5.3.6.1 of the Draft PEIR presents the findings of rainbow trout surveys conducted between 1982 and 2004. These findings concluded that, while rainbow trout are present and their range has been moderately extended downstream as a result of FERC Settlement Agreement flows, large anadromous steelhead occur in the system very infrequently. Also consistent with the Draft PEIR, McEwan presents data from surveys on the Tuolumne River that established the presence of rainbow trout. However, the surveys (conducted by a CDFG biologist in 2001) documented only a single rainbow trout of 28 inches and a single steelhead smolt of 11 inches, captured in the same location within a few days of each other. These findings by McEwan (2001) on steelhead presence in the lower Tuolumne River are consistent with those provided in the Draft PEIR in showing that no significant populations of steelhead are present within the lower Tuolumne River system.

14.7.4 FERC-Required Minimum Flows

Comment Summary

This section of this master response responds to all or part of the following comments:

S_CDFG2-05	SI_TRT-CWA-SierraC-172	SI_TRT6-04
L_MIDTID-08	SI_TRT-SWA-SierraC-64	C_Sprin-01

Summary of Issues Raised by Commenters

- The FERC-imposed minimum instream flows will probably increase when Don Pedro Reservoir is relicensed.
- The analysis in the Draft PEIR should assume greater FERC-imposed minimum flows.

Response

Table 5.3.1-3 in the Draft PEIR shows current minimum stream flow requirements for the Tuolumne River below La Grange Dam (Vol. 3, Chapter 5, p. 5.3.1-12). The minimum flows are a condition of the license issued by the FERC in 1996 for the Don Pedro Project. Various other conditions are contained in the settlement agreement that led to issuance of the license, including a requirement that water quality and fish populations be monitored and certain fish habitat restoration projects completed. The Don Pedro Project is scheduled for relicensing in 2016, at which time the FERC will review the results of the monitoring program and the minimum instream flow requirements.

Several commenters indicated that because fall-run Chinook salmon populations in the Tuolumne River below La Grange Dam have declined in the last 10 years, it is likely that the FERC will increase the minimum instream flow requirements. Therefore, the commenters stated that the analysis of the WSIP in the Draft PEIR should have allowed for an increase in minimum flows.

The Draft PEIR did not incorporate a possible increase in the future minimum flow requirement in its primary analysis of the WSIP (Vol. 3, Chapter 5, Section 5.3.6), although it did consider the possibility of an increase in the future minimum flow requirement in the cumulative impact analysis (Vol. 3, Chapter 5, Section 5.7). The PEIR did not include an increase in the future minimum instream flow in its primary analysis of the WSIP for two reasons. First, it is impossible to predict what the future minimum instream flow requirements might be, and to assume flow requirements other than the current minimum flows would be speculative. Secondly, an increase in the minimum instream flows would likely have both beneficial and adverse effects on salmonids. Increased stream flow would likely benefit salmonids at times, such as providing increased quality and quantity of spawning and rearing habitat, but would also cause Don Pedro Reservoir to be drawn down farther than it is under the current minimum flow regime. This would reduce the magnitude of pulse flows in excess of the minimum required during the winter months and delay the typical large spring release during the snowmelt period. The changes in pulse flows and the delay in spring release could harm salmonids. The delay in spring release due to an increase in the minimum flow requirement would be additive to the delay in spring release caused by the WSIP, producing a longer delay than the WSIP alone. The combined delay would have a more severe adverse effect on salmonids in the river below La Grange Dam than the WSIP alone. Therefore, while the Draft PEIR acknowledges that the FERC relicensing process will likely result in minimum flow requirements remaining the same or increasing, the San Francisco Planning Department determined that, in the absence of any information, the most reliable (and least speculative) assumption to use in the impact analysis was the existing, known minimum instream flow requirements.

A commenter notes that the SFPUC currently pays the Turlock Irrigation District (TID) and Modesto Irrigation District (MID) to make minimum instream release below La Grange Dam; this is consistent with information presented in the Draft PEIR (Vol. 1, Chapter 2, p. 2-42). The commenter further notes that this arrangement may not be acceptable to the Districts in the future if minimum instream flow requirements are increased. As the terms of any future agreements with the Districts are unknown, it would be speculative for the Draft PEIR to assume anything other than a continuation of the existing arrangements. Currently, the need to make releases for minimum instream flows causes Don Pedro Reservoir to be drawn down farther than it would without the releases. However, if TID and MID declined to make releases from Don Pedro Reservoir on the SFPUC's behalf in the future, then the SFPUC's water bank account could be reduced to provide a portion of the releases, if the Districts demonstrated that their water entitlements would be adversely affected by making the releases without an adjustment in the SFPUC's water bank account. This would likely require the SFPUC to draw down Hetch Hetchy Reservoir farther than it does currently. The result would be to transfer some of the environmental consequences of delayed spring releases from the lower to the upper Tuolumne River. The SFPUC's obligation with respect to FERC minimum required flows is described in the Draft PEIR (Vol. 1, Chapter 2, p. 2-42).

14.7.5 Impacts on Water Quality

SI_TRT-CWA-SierraC-167	C_Goite-01	

Summary of Issues Raised by Commenters

- The analysis of the WSIP on water temperature is inadequate.
- The occasional increases in water temperature could still have significant effects.

Response

A comment states that the information contained in Table 5.3.3-2 (Vol. 3, Chapter 5, p. 5.3.3-3) is not comprehensive or well explained. The table shows maximum summer and fall water temperatures in the Tuolumne River at five locations between La Grange Dam and Modesto for the period 1996 through 2004. The data summarized in Table 5.3.3-2 were obtained in the course of studies conducted by TID and MID pursuant to the 1995 FERC Settlement Agreement with respect to licensing for the Don Pedro Project. The water temperature data were obtained from thermographs installed in the river. Thermographs are typically set to record water temperature every few minutes. The table shows the maximum temperatures recorded at five stations from 1996 to 2004. The values are not instantaneous maxima but are close to them. For graphs showing daily maximum, minimum, and average water temperatures, please see *2005 Ten Year Summary Report*, FERC Project No. 2299-024, TID/MID, 2005.

The temperatures shown in Table 5.3.3-2 are not cut off at 20 degrees Celsius (ºC). The footnote on the table simply indicates that maximum temperatures equal to or greater than 20 ºC are shown in bold print.

A comment notes that Table 5.3.3-2 contains information on summer maximum water temperatures, and that water temperatures in the winter and spring are also important for the development and out-migration of juvenile salmon. Under the existing condition, the operators of Don Pedro Reservoir sometimes release pulses of water to the lower Tuolumne River in the winter months as they seek to preserve the flood control reservation in the face of winter storms. The pulse releases are in addition to the minimum required releases. Because Don Pedro Reservoir would be drawn down somewhat farther with the WSIP than under the existing condition, the winter pulse releases with the WSIP would be smaller than under the existing condition. Water released from the reservoir in the winter is cool, typically between 9 and 11 ºC. It is not expected that the WSIP would have any effect on the temperature of these winter releases.

As noted above, Don Pedro Reservoir would be drawn down farther with the WSIP than under the existing condition, resulting in a delay in the release of water in excess of the minimum required in the spring as snowmelt runoff reaches the reservoir. The delay could cause water temperatures below the reservoir in the spring to rise above the values that occur under the current condition. Water temperatures in the river with and without the WSIP were modeled and are shown in Figures 5.3.3-3 and 5.3.3-4 (Vol. 3, Chapter 5, pp. 5.3.3-18 and 5.3.3-19). In most years, the WSIP would have little effect on water temperature below La Grange Dam. Sometimes (in 12 months in the 82-year hydrologic record) the WSIP could cause average daily water temperatures to rise by 1 or 2 ºC. Very rarely (in one month in the 82-year hydrologic record), the WSIP could cause average daily water temperatures to rise by 10 ºC. In terms of a water quality impact (Vol. 3, Chapter 5, pp. 5.3.3-17 to 5.3.3-19), the Draft PEIR concluded that the rare exceedances of the water temperature objective would not impair the river's ability to support the designated beneficial uses that the objective is designed to protect, including coldwater fisheries. However, the occasional increases in water temperature in the Tuolumne River below La Grange Dam, together with other factors, contributed to the conclusion that the WSIP could have a significant adverse effect on salmonids in this reach of the river (Vol. 3, Chapter 5, pp. 5.3.6-28 to 5.3.6-32).

Summary of Issues Raised by Commenters

- Numerous comments were raised about the existing and proposed levels of diversions by the SFPUC from the Tuolumne River.
- Objection to the rationale for the Draft PEIR's significance determination for hydrology impacts (the "within current range" argument).

Response

Level of Diversions

The average annual unimpaired flow in the Tuolumne River at La Grange Dam is estimated to be 1,850,000 acre-feet. Currently, TID and MID divert about 47 percent of the average annual unimpaired flow into the Turlock and Modesto Canals at La Grange Dam. The SFPUC's current diversion of water from its reservoirs in the upper Tuolumne River watershed represents about 13 percent of the average annual unimpaired flow at La Grange Dam. Together, current diversions by the SFPUC, TID, and MID represent about 60 percent of the average annual unimpaired flow. Thus, flow in the Tuolumne River immediately below La Grange Dam is about 40 percent of its average annual unimpaired value.

With the WSIP in place, it is assumed that diversions by TID and MID at La Grange Dam would be unchanged, while diversions by the SFPUC in the upper Tuolumne River watershed would increase. With the WSIP, the SFPUC's diversion of water from its reservoirs in the upper Tuolumne River watershed would represent about 15 percent of the average annual unimpaired flow at La Grange Dam. Together, diversions by the SFPUC, TID, and MID would represent about 62 percent of the average annual unimpaired flow. Thus, flow in the Tuolumne River immediately below La Grange Dam would be about 38 percent of its average annual unimpaired value.

Note that the values presented in the two paragraphs above are slightly different from those provided in the Draft PEIR. After completion of the Draft PEIR, some improvements were made to the Hetch Hetchy/Local Simulation Model, and the values in the preceding paragraphs were obtained using the updated model as described in Section 13.3 (Vol. 7, Chapter 13) of the Comments and Responses document.

Range of Flows

Several comments challenged the conclusion in the Draft PEIR that river flows with the WSIP would remain within the range experienced under the existing condition, and therefore that the impacts on hydrology would be less than significant.

Flow in the Tuolumne River below La Grange Dam consists entirely of releases from the dam. Minimum releases from the dam and minimum flows in the river are specified in an agreement among TID, MID, and FERC, and are shown in Draft PEIR Table 5.3.1-2 (Vol. 3, Chapter 5, p. 5.3.1-13). The minimum releases represent the low end of the range of flows in this reach of the river. The minimum flow is 50 cubic feet per second (cfs), which occurs between June 1 and September 30 in the driest years. TID, the operator of La Grange Dam, would continue to adhere to the minimum releases specified in the agreement whether or not the WSIP is implemented. Therefore, the WSIP would not affect the low end of the range of flows in this reach of the river.

Typically, flows in the Tuolumne River below La Grange Dam are at their seasonal maximum in the winter and spring. One of the goals of dam operators is to fill Don Pedro Reservoir by the end of the snowmelt period if possible. The operators' ability to meet this goal is constrained by the requirement that space be retained in Don Pedro Reservoir to reduce possible flooding downstream of La Grange Dam. The flood control reservation requirement increases from zero on September 8 to 340,000 acre-feet on October 7, and is again reduced to zero between April 27 and June 3. Another goal is to keep flow in the river below La Grange Dam to no more than 9,000 cfs to prevent flooding in the Modesto area. The dam operators monitor the depth of the snowpack in the upper watershed, measure inflow to Don Pedro Reservoir, and adjust releases from Don Pedro Reservoir as necessary to meet the operating goals. At times when inflow to the reservoir is high, the capacity of the gates and valves at Don Pedro Dam can be exceeded, causing water to flow over the dam spillway. Water released from Don Pedro Reservoir flows two miles to La Grange Dam. Water can be diverted at La Grange Dam into the Turlock and Modesto Canals and released to the river through a number of valves. If very large releases from Don Pedro Reservoir are made, water can pass over La Grange Dam to the river in an uncontrolled manner. Uncontrolled releases over the spillways at Don Pedro and La Grange Dams are rare and are usually avoided by the dam operators.

Maximum flows in the river below La Grange Dam typically occur in the winter or spring of years when the snowpack in the Sierra Nevada is heavy and it melts rapidly or is subject to rainfall. Modeled average monthly flows in the river below La Grange Dam under the existing condition and with the WSIP are shown in Draft PEIR Figure 5.3.1-12 (Vol. 3, Chapter 5, p. 5.3.1-33). The figure shows that average monthly flows under both the existing condition and with the WSIP would exceed 6,000 cfs in 14 years in the 82-year hydrologic record.

A red line on Figure 5.3.1-12 shows the average monthly release from La Grange Dam to the river under the WSIP. A blue line shows the average monthly release from La Grange Dam under the existing condition. Where the red and blue lines occupy the same space, the red line overwrites the blue line. Examination of the figure for the years in which average monthly flow exceeded 6,000 cfs (1922, 1938, 1956, 1967, 1969, 1970, 1980, 1982, 1983, 1984, 1986, 1995, 1997, and 1998) indicates that the red line overwrites or almost overwrites the blue line in all 14 years. This shows that in very high flow years, the WSIP would have little or no effect on the peak average monthly flow.

The reason the WSIP would have little or no effect on the highest average monthly peak flows is that the operators of Don Pedro Reservoir must limit the capture of runoff during the winter and spring in order to maintain the required flood control reservation. In years when rainfall is abundant, the reservoir fills rapidly and reaches the maximum storage permitted consistent with the flood control requirements. Operators must release any additional inflow to the reservoir to the river below La Grange Dam. The peak release to the river usually occurs after the reservoir is at the maximum storage permitted consistent with flood control requirements.

Average daily flows in the river below La Grange Dam typically exceed average monthly flows because, in the winter and spring, reservoir operators may adjust releases to the river every few days to maintain the flood storage reservation. U.S. Geological Survey gaging records show that average daily flows in the river below the dam equaled or exceeded 10,000 cfs on at least one day in 1983 and 1997. A maximum average daily flow of 58,900 cfs occurred in 1997 in an unusual storm that caused rain to fall on the snowpack in January. It is unlikely that the WSIP would have any effect on the highest average daily peak or instantaneous peak flows for the same reason that it would not have any effect on average monthly peak flows.

In summary, the WSIP would have little or no effect on either the low or high ends of the range of current flows in the Tuolumne River below La Grange Dam. The WSIP would not "substantially alter stream flows such that they are outside the range of pre-project conditions," and its impact on flows was therefore judged to be less than significant.

Although the WSIP would not affect the magnitude of relatively rare, very large peak flows, it would affect the magnitude of the smaller average monthly peak flows that occur more frequently than once every 10 years. The modeled flows shown in Figure 5.3.1-12 of the Draft PEIR (Vol. 3, Chapter 5, p. 5.3.1-33) indicate that the WSIP would not have any effect on average monthly peak flows in large runoff events that occur about once every six years (14 times in the 82-year hydrologic record). This would be the case during conditions that occurred in 1922, 1938, 1956, 1967, 1969, 1970, 1980, 1982, 1983, 1984, 1986, 1995, 1997, and 1998. Average monthly peak flows in runoff events with a higher frequency than once in six years may be affected at times. For example, as shown in Figure 5.3.1-12, average monthly peak flows with the WSIP under conditions that occurred in 1936, 1950, 1965, 1978, and 1993 would be lower than under the existing condition.

14.7.7 Impacts on Geomorphology

Comment Summary

This section of this master response responds to all or part of the following comments:

Summary of Issues Raised by Commenters

- Objection to the rationale for the Draft PEIR's significance determination for geomorphology impacts (the "within current range" argument).
- The sediment transport analysis is not quantitative and is speculative.

Response

The average monthly flow data provided in Table 5.3.1-6 of the Draft PEIR (Vol. 3, Chapter 5, p. 5.3.1-35) played only a minor role in the assessment of the WSIP's effects on the geomorphology of the Tuolumne River below La Grange Dam. Changes in peak flow attributable to the WSIP provided the primary informational basis for reaching conclusions regarding impacts on geomorphology. The WSIP would have little effect on the range of flows experienced in the Tuolumne River below La Grange Dam. It would have no effect on the magnitude of infrequent, very large flows for the reasons described in Section 14.7.6, above.

A commenter opines that the analysis of sediment transport and gravel bed conditions in the Draft PEIR is qualitative and largely speculative. The San Francisco Planning Department acknowledges that the analysis is qualitative but disagrees that it is speculative. Although limited data are available on substrate conditions in the lower Tuolumne River below La Grange Dam, it is the San Francisco Planning Department's view that the data are sufficient to make a reasonable analysis, without excessive speculation, of the WSIP's impact on sediment movement.

The information on existing sediment conditions in the lower Tuolumne River provided in the Draft PEIR (Vol. 3, Chapter 5, pp. 5.3.2-3 and 5.3.2-4) was obtained from reports prepared by McBain and Trush (McBain and Trush, 2000; McBain and Trush and J. Vick, 2004). The lower Tuolumne River extends from La Grange Dam to the confluence with the San Joaquin River. The uppermost half of the reach, between La Grange Dam and the community of Hughson, has a gravel bed and banks. From Hughson to the confluence with the San Joaquin River, the river has a sand bed and banks. The broad riparian forest that once existed has been largely removed, and levees and agricultural encroachment confine much of the river corridor. The channel itself has been reshaped by gold mining in the 19th century and by gravel mining in the 20th century. For more than 130 years, the La Grange, Don Pedro, and New Don Pedro Dams have prevented the downstream movement of bedload from the upper Tuolumne River watershed. Abandoned gold and gravel mining pits within the river corridor below La Grange Dam also impede the movement of bedload. The pits trap gravel and prevent its downstream migration. Don Pedro Reservoir has also reduced peak flows in the river below La Grange Dam, which reduces the rate of downstream movement of bedload in this reach of the river.

As noted in the Draft PEIR, the WSIP would have very little effect on large infrequent floods, such as the flood that occurred in 1997. It would reduce the magnitude of the smaller bankfull peak flows that occur every one to three years and are the primary channel-forming events. This reduction would slow the rate of downstream fine sediment movement and affect channel formation, but the scale of the changes would be small relative to the changes wrought by past water management and mining activities and the clearing of the riparian forest. Therefore, the San Francisco Planning Department concluded that the impacts of the WSIP on the geomorphology of the lower Tuolumne River would be less than significant.

The quality of salmonid spawning gravels in the Tuolumne River below La Grange Dam has been greatly degraded by the past practices referred to above. Conditions suitable for salmonid spawning occur in a 25-mile-long gravel-bedded river reach between La Grange Dam and the community of Hughson, but most salmon spawn in the five-mile reach immediately below La Grange Dam. Salmonid spawning is most successful in gravel-bedded rivers with relatively small amounts of fine silt and sand. The quality of salmon-spawning habitat in the gravel-bedded reach of the river is impaired by a lack of coarse sediment from the watershed above and by an excess of fine sediment. More than 130 years ago, the construction of the first dam on the Tuolumne River, near the site of La Grange Dam, halted the downstream transport of coarse sediment from the upper watershed. Fine sediment enters the Tuolumne River below La Grange Dam from Gasburg Creek and Peaslee Creek, both of which drain agricultural areas. The WSIP-induced reduction in the magnitude of the bankfull peak flows that occur every one to three years may reduce the rate at which fine sediments are washed out of the gravel-bedded reach of the river.

In terms of a geomorphology impact (Vol. 3, Chapter 5, p. 5.3.2-7), the Draft PEIR concluded that the WSIP would not result in substantial changes in erosion or siltation rates or channel form, and this impact was determined to be less than significant. However, the WSIP-caused reduction in the rate of fine sediment movement in the Tuolumne River below La Grange Dam, together with other factors, contributed to the conclusion that the WSIP could have a significant adverse effect on salmonids in this reach of the river (Vol. 3, Chapter 5, pp. 5.3.6-28 to 5.3.6-32).

14.7.8 Mitigation Measure 5.3.6-4a

Comment Summary

This section of this master response responds to all or part of the following comments:

S_CDFG2-07	SI_TRT2-03	SI_TRT-CWA-SierraC-170
SI_CRS-07	SI_TRT5-03	SI_TRT-CWA-SierraC-155
SI_EnvDef-04	SI_TRT-CWA-SierraC-58	SI_TRT-CWA-SierraC-188

Summary of Issues Raised by Commenters

- Expression of uncertainty related to the feasibility of Mitigation Measure 5.3.6-4a.

Response

As stated in the Draft PEIR, the WSIP-caused reductions in flow and increases in water temperature in the reach of the Tuolumne River below La Grange Dam would have a potentially significant adverse effect on salmonids (Vol. 3, Chapter 5, p. 5.3.6-28 to 5.3.6-32). The Draft PEIR identified Mitigation Measure 5.3.6-4a as the preferred approach to reduce the impacts on salmonids to a less-than-significant level (Vol. 4, Chapter 6, p. 6-48). Several comments noted that, as acknowledged in the Draft PEIR, there is uncertainty regarding the feasibility of Mitigation Measure 5.3.6-4a. Because of this uncertainty, the Draft PEIR also identified an alternative mitigation measure, Measure 5.3.6-4b (see Section 14.7.9, below).

In order for Measure 5.3.6-4a to be effective, water levels in Don Pedro Reservoir with the WSIP would have to be essentially the same as they are under the existing condition. This could only be accomplished by reducing TID's and MID's use of water from Don Pedro Reservoir by an amount equal to the SFPUC's increased diversion from the Tuolumne River under the WSIP. Surface water use in the TID and MID service areas could be reduced through conservation efforts, such as installing more efficient irrigation systems, lining irrigation canals, recycling irrigation tailwater, improving conjunctive use of surface and groundwaters, planting crops that need less water, permanently or temporarily fallowing land, and by water savings in urban areas. The SFPUC could pay for these measures, and TID and MID could transfer the water saved to the SFPUC. Projects of this type are difficult but not impossible to implement; an example of such a project is an agreement between the Imperial Irrigation District and San Diego County Water Authority, whereby the Authority financed agricultural water conservation measures within the Imperial Irrigation District in order to secure the conserved water for its customers.

Another possible approach would be for the SFPUC to obtain water from a water agency other than TID and MID. The water acquired by the SFPUC would be conveyed to TID and MID so that the Districts would be able to reduce their use of Don Pedro Reservoir water. As indicated in the Draft PEIR, additional CEQA compliance might be required on a specific proposal to develop and transfer conserved water; it is expected that the transferring agency would serve as the CEQA lead agency for project-level review if required.

Mitigation Measure 5.3.6-4a is the San Francisco Planning Department's preferred measure to lessen the impacts of the WSIP on salmonids and riparian resources. Accordingly, the City and County of San Francisco has begun discussions with TID, MID, and other water agencies' staff in an initial effort to obtain commitments and reduce uncertainty with respect to Measure 5.3.6-4a. **Section 14.10, Master Response on Modified WSIP Alternative** (Vol. 7, Chapter 14) provides more information on the conserved water transfer under Measure 5.3.6-4a.

14.7.9 Mitigation Measure 5.3.6-4b

Comment Summary

This section of this master response responds to all or part of the following comments:

S_CDFG2-08	SI_TRT5-04	SI_TRT-CWA-SierraC-171
S_CDFG2-10	SI_TRT-CWA-SierraC-59	SI_TRT-CWA-SierraC-189
SI_EnvDef-04	SI_TRT-CWA-SierraC-60	SI_TRT-CWA-SierraC-190
SI_NCFFSC-01	SI_TRT-CWA-SierraC-62	
SI_TRT2-03	SI_TRT-CWA-SierraC-170	

Summary of Issues Raised by Commenters

- Mitigation Measure 5.3.6-4b does not reflect the latest knowledge on fish predation.
- Mitigation Measure 5.3.6-4b is inadequate because it is not similar in kind to the impact.

Response

As stated in the Draft PEIR, the WSIP-caused reductions in flow and increases in water temperature in the reach of the Tuolumne River below La Grange Dam would have a potentially significant adverse effect on salmonids (Vol. 3, Chapter 5, p. 5.3.6-28 to 5.3.6-32). The Draft PEIR identified Mitigation Measure 5.3.6-4a as the preferred approach to reduce the impacts on salmonids to a less-than-significant level (Vol. 4, Chapter 6, p. 6-48). However, there is some uncertainty associated with this measure because it cannot be implemented by the SFPUC alone, but requires the cooperation of another water agency (see Section 14.7.8, above). Although Measure 5.3.6-4a is the preferred measure, the Draft PEIR also identified an alternative measure (Mitigation Measure 5.3.6-4b) in the event that Measure 5.3.6-4a cannot be implemented. Measure 5.3.6-4b would reduce the impacts of the WSIP on salmonids by making habitat improvements in the reach of the river below La Grange Dam that would offset the potential habitat degradation attributable to the WSIP-induced flow reductions (Vol. 4, Chapter 6, pp. 6-48 and 6-49).

Mitigation Measure 5.3.6-4b, as described in the Draft PEIR, would either implement a spawning gravel augmentation project or eliminate one of the former gravel pits harboring fish that prey on juvenile salmonids. Several comments received on the Draft PEIR were critical of Measure 5.3.6-4b. These comments stated that the mitigation measure poorly matches the impact it is designed to mitigate and questioned the effectiveness of quarry pit removal from the river in benefiting salmonids. As indicated in the Draft PEIR and this response, Measure 5.3.6-4a is the preferred mitigation and would most directly addresses the nature of the WSIP impact on the lower river fisheries (i.e., an incremental flow reduction that would infrequently result in elevated water temperatures that could adversely affect salmonids). However, as discussed in the Draft PEIR analysis, since the flow reductions coupled with the projected infrequent water temperature increases that could occur under the WSIP would have an adverse impact on habitat conditions for juvenile salmonids, mitigation that improves habitat for juvenile salmonids is appropriate under CEQA.

Measure 5.3.6-4b would provide for implementation of an action that would improve habitat for juvenile salmonids. The measure calls for the SFPUC to implement one of two specific actions: gravel augmentation or gravel pit removal from the river. These actions, which were designed to either increase habitat quality and availability or reduce the vulnerability of juvenile salmonids to potential predation mortality, were selected in part based on (1) a review of the *Habitat Restoration Plan for the Lower Tuolumne River*, (2) information provided by Mesick et al. (2007), (3) discussions with the Anadromous Fish Restoration Program and resource agencies, and (4) a review of existing physical habitat conditions in the lower river and the ability of mitigation measures to reduce the effects of various potentially limiting factors related to the successful production of juvenile salmonids in the lower river. The two alternative actions described in Measure 5.3.6-4b would offer important long-term benefits to salmonid production that would enhance habitat conditions in the lower river in every year. Implementation of this measure would provide an incremental benefit in every year as a tradeoff for a potentially adverse periodic impact with a low frequency of occurrence.

A commenter observed that restoring spawning gravel would not mitigate impacts on later salmonid life stages and could harm later life stages by causing overcrowding of rearing habitat. The WSIP would reduce flow and increase water temperatures in May and June of some years, which could have adverse effects on juvenile Chinook salmon that are rearing in the stream and have yet to migrate downstream. There is no reason to believe that a gravel augmentation project that resulted in the production of larger numbers of juvenile salmon would have an adverse effect on later life stages; on the contrary, increased production of juvenile salmon could increase the chance of more salmon surviving to return to spawn.

The intent of the gravel augmentation action is to directly contribute to an increase in the availability and quality of habitat for various life-history stages of salmonids, which would result in increased reproductive success, better health and survival of rearing juveniles, and increased overall productivity in the lower river. The benefits of a multifaceted habitat enhancement action involving gravel augmentation are as follows: it would contribute to the improved quality and availability of spawning gravels for adult Chinook salmon and steelhead, increase suitable substrate available for macroinvertebrate production as a food resource for juvenile rearing salmonids, improve habitat quality and availability for juvenile salmonid rearing, increase instream cover and velocity refuges for rearing juveniles, and provide an overall increase in the habitat carrying capacity of the lower river for juvenile salmonid rearing. Observations of similar multifaceted habitat enhancement projects in the lower Mokelumne River have demonstrated benefits to both spawning and juvenile rearing for salmonids as well as increased macroinvertebrate production (Merz, 2004).

It has been hypothesized that the availability and quality of juvenile rearing habitat may be a factor limiting the production of salmonids in the lower Tuolumne River. Gravel augmentation and associated habitat enhancement would help directly address the carrying capacity for juvenile rearing by providing increased habitat quality and availability, increased habitat complexity and diversity, and increased instream cover for juvenile rearing, and would be expected to contribute to an increase in the health, growth rates, and survival of juvenile salmonids produced in the lower river. The benefits of such a physical habitat enhancement project would be present within the lower river year-round under all hydrologic-year type conditions and would provide long-term habitat benefits to salmonids spawning and rearing in the lower river.

Implementation of the gravel pit removal action would directly contribute to a reduction in predation mortality for those juvenile salmonids rearing in the lower Tuolumne River or emigrating downstream and could result in cooler water and greater food production as a result of improved riparian habitat. Comments on this measure raised questions about the effectiveness of this measure in benefiting salmonids. Although pilot studies conducted by TID on a similar action have shown disappointing results, the concept remains promising, and further study may prove to be more successful. Results of screw trap monitoring and other investigations in the lower Tuolumne River have identified predation mortality by a variety of piscivorous fish, including largemouth and smallmouth bass, striped bass, and Sacramento pikeminnow, in addition to avian predation as a factor contributing to the high mortality rates for juvenile salmonids rearing and emigrating from the lower river. Juvenile salmonids experience an increased vulnerability to predation associated with certain physical habitat structures, including captured gravel pits and incised pool habitat, where turbulent flow can cause disorientation of juvenile salmonids and increase their vulnerability to predation mortality. Physical structures such as gravel pits provide suitable habitat for many of the predatory fish as well as areas where prey can accumulate and concentrate, thereby increasing their vulnerability to predation mortality.

As part of the quarry pit removal action identified in this mitigation measure, physical modifications would be made to one or more existing structures within the lower Tuolumne River. These modifications, which could include gravel pit isolation, removal of physical structures that provide habitat for predatory fish, modifications to existing scour pools that provide holding habitat and ambush points for predators, or other physical and structural modifications to existing habitat conditions within the lower river, would be aimed specifically at reducing predation mortality for juvenile salmonids, thereby increasing their survival and potential contribution to the adult population. Modifications to decrease predation vulnerability within the lower river would benefit juvenile salmonids year-round in all hydrologic-year types, thus resulting in a long-term benefit by increasing the survival of salmonid fry and smolts produced in the lower river.

In response to comments on Mitigation Measure 5.3.6-4b (Vol. 4, Chapter 4, pp. 6-48 and 6-49), the following text revisions are made to clarify the method of implementation:

Fishery Habitat Enhancement

Measure 5.3.6-4b: If Measure 5.3.6-4a is not implemented, then the SFPUC will mitigate potential fishery effects on the lower Tuolumne River by implementing (or funding) one of the following two habitat enhancement actions ~~directed at fish habitat improvements~~ that are designed to sustain fishery resources under the river's flow regime, which are consistent with the Habitat Restoration Plan for the Lower Tuolumne River Corridor: gravel augmentation<u>/habitat enhancement</u> <u>to provide salmonid spawning and rearing habitat</u>, or isolating or filling a captured former gravel quarry pit along the river <u>that provides habitat for salmonid predators</u>.

The gravel augmentation/habitat enhancement project ~~Spawning gravel enhancement~~ will be implemented to increase salmonid spawning success and to improve the survival of rearing salmonids in the reach of the river downstream of La Grange Dam. Spawning success will be improved by the addition of suitable gravel to the stream channel. Other habitat features will be created to provide cover for juvenile salmonids and to increase the availability of substrate for macroinvertebrates ~~production~~ that would be used as ~~an enhanced~~ food ~~supply~~ by rearing juvenile salmon and steelhead~~and other species~~. The ~~spawning~~ gravel augmentation/habitat enhancement project will involve the planning, design, permitting, purchase, placement, and monitoring of suitable gravel and associated habitat enhancements ~~to be placed~~ at three riffle locations within the spawning reach between Basso Bridge and La Grange Dam. The three locations will meet ~~that meets~~ the criteria for suitable habitat as described in the Habitat Restoration Plan for the Lower Tuolumne River Corridor ~~at each location~~. The gravel will preferentially be rounded river rock of native origin that would be sized and pre-washed before placement into the river. The gravel augmentation/habitat enhancement project will also involve the addition of large woody debris and boulders to create increased habitat complexity and diversity at each of the three enhancement sites. After construction of the gravel augmentation/habitat enhancement project, it will be surveyed to establish its baseline condition. A survey of the three sites will be made at a minimum of five-year intervals by a qualified fisheries biologist. The fisheries biologist will determine whether the three sites continue to meet established criteria for salmonid spawning and rearing habitat. If the sites do not meet the criteria, as part of its long-term operations, the SFPUC will make the improvements necessary to return it to baseline conditions. ~~The depth and quality (e.g., percentage fines and cementation) of gravel will be monitored at five-year intervals and if the gravel deposits do not meet the criteria for suitable habitat SFPUC will be obligated to further augment or enhance the gravel deposits. The SFPUC will continue this gravel augmentation project and periodic monitoring as part of long-term system operations.~~

~~Alternately~~As an alternative to the gravel augmentation project, the SFPUC will remove from the lower river channel one of the former gravel quarry pits that has been "captured" by the river and acts as predator zones for fish such as largemouth and striped bass to prey on rearing and emigrating juvenile salmonids. ~~This~~Removal could be accomplished by filling the pit or installing a levee berm around the pit to isolate it permanently from the river channel. The SFPUC could implement this action directly or fund implementation by another entity involved in river restoration.

The performance standard for gravel pit removal would be an established permanent reduction in area of salmonid predator habitat. The SFPUC will monitor the pit removal project at five-year intervals. If floods have eroded the fil1 or damaged the levees in a manner that restores salmonid predator habitat, the SFPUC will make the necessary repairs. The SFPUC will continue periodic monitoring and repair as part of long-term system operations.

14.8 Master Response on Delta and San Joaquin River Issues

14.8.1 Introduction

Overview

This master response addresses issues raised by commenters regarding the WSIP's effects on the San Joaquin River and Sacramento–San Joaquin River Delta, and, as a consequence, on the State Water Project (SWP) operated by the California Department of Water Resources (DWR) and Central Valley Project (CVP) operated by the U.S. Bureau of Reclamation (USBR), both of which convey water through the Delta to customers south of the Delta. This master response is organized by the following subtopics:

14.8.2 Review of WSIP Effects on the San Joaquin River and Delta
14.8.3 Potential Effects on CVP and SWP Operations and Related Indirect Effects

Summary of Issues Raised by Commenters

- The Draft PEIR analysis of impacts on the San Joaquin River and Delta is inadequate; it does not provide enough information.
- The Draft PEIR does not identify significant impacts on flow or water quality in the San Joaquin River and/or Delta because it assumes that the CVP and/or SWP operations will be modified to maintain compliance with regulatory flow and quality standards.
- The Draft PEIR baseline of 2005 is inadequate because of changes that have occurred since that time.
- The PEIR has significance criteria for impacts on water supplies but does not apply these criteria to impacts on the San Joaquin River or Delta.

Response

Draft PEIR Impact Assessment for the San Joaquin River and Delta

The effects of the WSIP on the San Joaquin River and Delta are addressed in several sections of the Draft PEIR, as listed above under the heading PEIR Section Reference. The analysis of effects on flows in the San Joaquin River and Delta is based on the detailed modeling and assessment of the WSIP's effects on Tuolumne River flows presented in the Draft PEIR (Vol. 3, Chapter 5, Section 5.3, with additional detail provided in Vol. 5, Appendix H).[1]

As described in Impact 5.3.1-4 (Vol. 3, Chapter 5, p. 5.3.1-30), the WSIP would indirectly result in flow changes in the lower Tuolumne River. Increased diversions under the WSIP would not directly result in reduced flow downstream in the lower Tuolumne River; rather, under the WSIP the increased water diversion at Hetch Hetchy Reservoir upstream of Don Pedro Reservoir to meet 2030 SFPUC customer purchase requests would cause a reduction in inflow to Don Pedro Reservoir thus leading to a reduction in reservoir storage at Don Pedro Reservoir. The way in which the WSIP would result in indirect effects on flow in the lower Tuolumne River is described below.

Don Pedro Reservoir, which is owned and operated by the Modesto Irrigation District (MID) and Turlock Irrigation District (TID) (together, "the Districts"), stores water from the upper Tuolumne River. In most below-normal or drier years, all of the runoff from the watershed upstream of Don Pedro Reservoir is captured and stored in the reservoir. The Districts make releases from the reservoir to the Modesto and Turlock Canals to make deliveries to their agricultural customers and also to the lower Tuolumne River in accordance with FERC requirements. In some years, usually wet or above normal years, the runoff volume is too great to either be used by the Districts or stored in the reservoir. In these years, water in excess of the FERC requirements is released to the lower Tuolumne River below La Grange Dam. As a result, in the future with the WSIP, the Districts would draw Don Pedro Reservoir down farther in many years than it would have been drawn down under the existing condition. Consequently, the Districts would have to capture a greater proportion of spring runoff to refill the reservoir, and the volume of excess water released to the lower Tuolumne River would be reduced compared to the existing condition. The SFPUC does not have any authority over the operation of Don Pedro Reservoir. The PEIR impact analysis assumes that, in the future, the Districts would continue to divert water from the reservoir into the canals that serve their agricultural customers as they do now, without adjustment; thus, the reduction in reservoir storage resulting from the WSIP would in turn cause a reduction, in some months and years, in the amount of excess water released by TID from the reservoir to the lower Tuolumne River. In this way, the WSIP would indirectly result in flow reductions in the lower Tuolumne River. The following discussion uses the term "WSIP-induced" flow reductions to refer to fact that the WSIP would not directly reduce flow in

[1] The Draft PEIR analysis was performed using the Hetch Hetchy/Local Simulation Model (HH/LSM), a state-of-the-art model of the regional water system developed by the SFPUC for water supply planning. The model provides information on reservoir releases, and this information was used in the Draft PEIR to estimate the effects of the WSIP on stream flows downstream of SFPUC reservoirs. The SFPUC has been improving and refining the model during more than 10 years of use.

the lower Tuolumne River or farther downstream in the San Joaquin River and into the Delta, but would do so indirectly.

As discussed in Impact 5.3.1-5 (Vol. 3, Chapter 5, p. 5.3.1-38), the WSIP-induced flow reductions described in detail for the lower Tuolumne River would also occur downstream in the San Joaquin River in the reach between the confluence with the Tuolumne River and the confluence with the Stanislaus River. Downstream of the confluence with the Stanislaus River, flow conditions in the San Joaquin River would reflect a combination of effects resulting from both the WSIP and the USBR's water releases from New Melones Reservoir. In the Delta, hydrologic conditions would reflect the combined effects of the WSIP and the actions taken by the USBR and/or DWR in accordance with their regulatory obligations for the CVP and SWP, respectively (along with actions by many others that affect the Delta).[2]

As described in the Draft PEIR (Vol. 3, Chapter 5, pp. 5.3.4-1 and 5.3.4-2), the USBR and DWR hold post-1914 appropriative water rights, subject to the continuing jurisdiction of the State Water Resources Control Board (SWRCB), under which these agencies divert water into CVP and SWP reservoirs and canals upstream of the Delta and from the Delta itself. Because of the size of the diversions made by the CVP and SWP, the nature of their authorizing legislation, and the priority level of their water rights, the SWRCB has assigned unique responsibilities to the USBR and DWR for compliance with Delta water quality and flow objectives. Under preceding SWRCB water-rights decisions and current Water Right Decision 1641, the CVP and SWP must be operated in a manner that maintains compliance with Delta water quality and flow objectives. The USBR's and DWR's water rights are conditioned such that they can not be exercised in a manner that would cause a violation of the Delta objectives. These regulatory requirements are not mitigation measures, as suggested by some commenters, but rather regulatory obligations established in existing decisions and orders.[3] The water rights for the CVP and SWP are junior to the City and County of San Francisco's (CCSF's) Tuolumne River water rights. For this reason, too, the USBR and DWR must accommodate their operations to the lawful exercise by CCSF of its more senior water rights.

Draft PEIR Table 5.3.1-6 (Vol. 3, Chapter 5, p. 5.3.1-35) and Figure 5.3.1-12 (p. 5.3.1-33) present detailed information on the projected timing, frequency, and magnitude of the WSIP-induced flow reductions that could affect the San Joaquin River and Delta. As discussed in the Draft PEIR (p. 5.3.1-38), the WSIP-induced flow reductions affecting the San Joaquin River and Delta would primarily occur from January through June in wet or above-normal years, and during the season when flow in the San Joaquin River is at its annual maximum. As stated in the

[2] Regulatory flow and water quality objectives established by the SWRCB for the San Joaquin River and Delta are described in the Draft PEIR (Vol. 3, Chapter 5, pp. 5.3.1-18 to 5.3.1-19, pp. 5.3.4-3 to 5.3.4-4, and pp. 5.3.3-9 to 5.3.3-12)

[3] In the early and late 1990s, the SWRCB considered alternatives to requiring the CVP and SWP to maintain water quality objectives in the Bay-Delta, including allocation of responsibility on a watershed-by-watershed basis, a strict water-rights priority basis, and equitable apportionment based on diversions. Any SWRCB initiative to implement Bay-Delta water quality objectives by assigning responsibilities to senior water-rights holders would require lengthy regulatory proceedings and even longer litigation. As a practical matter, the CVP and SWP are the only projects large enough to control water quality conditions in the Delta; therefore, it would be speculative to assume regulatory conditions for the WSIP other than the current regulatory regime.

Draft PEIR (p. 5.3.1-38), in most cases (except in three months over the 82-year [984-month] historical record), the WSIP-induced flow reductions would not result in conditions in the San Joaquin River upstream of the Delta that would affect the achievement of regulatory objectives established to maintain flow levels and water quality parameters protective of beneficial uses. In these few such instances, the USBR would act to ensure compliance with the regulatory objectives. The WSIP-induced flow reductions during these periods would have a less-than-significant effect on hydrology and the related areas of water quality, water supply, and fisheries.

Concerning the Delta, WSIP-induced flow changes within the San Joaquin River could affect the operation of the CVP and SWP if operational adjustments are needed to comply with regulatory obligations. The effect on operations could be a change in releases from upstream reservoirs, a change in the level of CVP or SWP Delta diversions, or a combination of both. As discussed in the Draft PEIR (Vol. 3, Chapter 5, pp. 5.3.1-38 and 5.3.1-39), the USBR and DWR, as operators of the CVP and SWP, would be required to take action to maintain compliance with flow and water quality objectives in accordance with their regulatory obligations by either increasing releases from upstream reservoirs or reducing the level of Delta diversions. The PEIR assumes that these agencies would continue to meet the applicable regulatory requirements for the San Joaquin River and Delta following WSIP implementation, and concludes that the WSIP-induced flow reductions would result in a less-than-significant impact on these downstream water bodies and the environmental resources they support. Further discussion of the potential WSIP effects on CVP and SWP operations and related indirect effects is presented below in Section 14.8.3.

Some commenters questioned whether "frequency of occurrence" should be considered in determining impact significance and suggested that only "severity" or magnitude should be considered. Evaluating environmental impacts and determining their significance involves consideration of several factors, including the nature of the impact, the sensitivity of the affected resources, the local and regional environmental context, as well as impact magnitude, frequency, and duration. Other factors may be important in determining impact significance, depending on the environmental resource or issue under review. In general, the impact significance criteria used in the Draft PEIR provide guidance on what could constitute a significant impact and, where appropriate, identify the specific metrics for evaluation. For each project, the impact analysis provides a project-specific discussion of relevant information to substantiate whether or not a potential effect would be significant. The frequency of impact, along with other factors, was relevant to the analysis of WSIP effects on flows to the San Joaquin River and Delta and on the related issues of water quality, fisheries and aquatic resources, and water supply. Section 14.8.3, below, provides further discussion of potential WSIP effects on CVP and SWP operations and on water contractors that receive supply deliveries for agricultural, municipal, and industrial uses.

An example of how frequency of effect can be relevant to determining impact significance arises in the analysis of a project's effect on water supply to other users. A substantial reduction in supply delivery to a customer that occurs infrequently and lasts for a short period (such as a single year) has different consequences than a substantial frequent or chronic reduction in supply that reduces the overall long-term supply reliability. The customer can often make short-term arrangements to address an infrequent, short-term supply reduction (e.g., using conservation and/or other supply reserves such as groundwater) without experiencing lasting land use or environmental changes or damage, while a chronic reduction in previously available supply could result in more permanent effects. In the first scenario, an infrequent, short-term supply reduction would not constitute a significant impact on water deliveries, while the second scenario—a recurring supply reduction of sufficient frequency to appreciably reduce the long-term supply reliability—could represent a significant impact. In this and many other examples, frequency of impact is an important and relevant factor for determining impact significance. The following review of the potential WSIP effects clarifies when and why frequency of effect is relevant in determining impact significance.

Baseline for Impact Assessment

In accordance with CEQA guidance regarding the selection of an appropriate baseline for analysis, the year 2005 is used in the assessment of potential WSIP effects. The CEQA Guidelines indicate that, in most cases, the potential environmental impacts of a project should be determined relative to the existing conditions that exist at the time the environmental process is initiated. This baseline year was selected because the Notice of Preparation for the PEIR was published in 2005, and because it represented the most current, complete year for which information about water resource conditions was available for use in the Draft PEIR impact analysis (which was conducted primarily in 2006 and early 2007 prior to release of the Draft PEIR in June 2007).

In addition, model information for CalSim II, which was relevant to portions of the PEIR analysis, was updated in 2005. CalSim II, a model developed jointly by the USBR and DWR to assess CVP and SWP operations and resulting conditions in the Delta, is the central tool and source of comprehensive information used for water resources planning and impact assessment related to the Sacramento and San Joaquin Rivers and the Delta. While the PEIR analysis did not employ the CalSim II model—which does not address the Tuolumne River system or overall SFPUC water system operations in detail the way the Hetch Hetchy/Local Simulation Model [HH/LSM][4] does—the analysis makes use of information compiled for the 2005 update of the CalSim II model.

Comment SI_SLDWWKC-06 suggests that the 2005 baseline is inadequate because of changes that have occurred since then, but does not identify any specific changes of concern for consideration. Numerous ongoing activities and proposed actions are affecting the San Joaquin River and Delta, as summarized in the Draft PEIR cumulative impact analysis (Vol. 3, Chapter 5, pp. 5.7-5 to 5.7-52). Key events or activities that have occurred or are now in progress since Draft PEIR publication in mid-2007 include: (1) the Judge Wanger decision in late 2007 regarding delta smelt, which imposed interim export pumping restrictions tied to flow conditions on Old and Middle Rivers in the Delta; (2) the Endangered Species Act reconsultation now in progress for

[4] The Draft PEIR analysis was performed using the HH/LSM, a state-of-the-art model of the regional water system developed by the SFPUC for water supply planning. The model provides information on reservoir releases, which was used in the Draft PEIR to estimate the effects of the WSIP on stream flows downstream of SFPUC reservoirs.

the coordinated operations of the CVP and SWP (known as the "OCAP" [Operations Criteria & Plan] reconsultation), which will establish revised, long-term operating requirements for the CVP and SWP operations to protect endangered species (replacing Judge Wanger's interim measures for delta smelt and establishing other operational constraints for the protection of additional endangered species, including salmon); (3) the Judge Wanger decision to invalidate the OCAP Biological Opinion for anadromous salmonids, including steelhead, and winter-run and spring-run salmon[5]; and (4) the proposed Bay Delta Conservation Plan (BDCP), for which the state and federal environmental review processes have recently been initiated (spring 2008) with release of a Notice of Preparation for an Environmental Impact Report and a Notice of Intent for an Environmental Impact Statement, respectively.

Among these four recent developments, only the Judge Wanger decision provides adequate information for use in reevaluating potential WSIP effects. The SFPUC has prepared a supplemental modeling assessment of potential WSIP effects on the San Joaquin River and Delta for this master response that addresses the interim export pumping restrictions imposed by the 2007 Judge Wanger decision (see Section 14.8.3, below, for a discussion of the supplemental analysis). As described in detail below, the supplemental analysis using this updated information corroborates the Draft PEIR findings regarding the WSIP's effects on the San Joaquin River and Delta. Based on this supplemental modeling assessment, the baseline information used in the Draft PEIR analysis of the WSIP effectively addresses current 2008 baseline conditions; the PEIR baseline is adequate and supports a meaningful assessment of the potential effects of WSIP implementation on the San Joaquin River and Delta.

There is insufficient information regarding either the description or the consequences of the other three activities listed above for use in evaluating potential WSIP effects. It would be speculative to describe how these other potential actions might affect the Delta and/or tributary rivers or to assess potential effects related to these activities. For the OCAP reconsultation process now in progress, there are no specific results or decisions regarding modified CVP and SWP operations that could be effectively incorporated into the WSIP impact analysis. The interim export pumping restrictions represent the best available information regarding potential changes in CVP and SWP Delta operations as they relate to the WSIP. For the BDCP, this program proposes substantial modification of the existing water supply conveyance through the Delta, including consideration of both through-Delta conveyance as well as isolated-conveyance and dual-conveyance system alternatives. However, at this time, there is insufficient information about the proposed BDCP alternatives to incorporate into a meaningful impact analysis of the WSIP. As noted, the environmental review process for the BDCP alternatives was initiated this spring (2008), and a draft environmental analysis is not expected until 2009. In the review presented below of potential WSIP effects on the Delta, CVP and SWP operations, and water contractors, there are references made, where appropriate, to how the OCAP reconsultation, the Wanger decision on salmonids, and the BDCP might influence WSIP effects or the response to WSIP effects;

5 Judge Wanger has yet to issue a remedy in the salmonid case, and any interim remedy will be superceded by the Endangered Species Act reconsultation now in progress for the OCAP, which will establish revised, long-term operating requirements for the CVP and SWP operations to protect endangered species. It would be speculative to posit Judge Wanger's remedy in the salmonid case or what conditions may be imposed under the OCAP Biological Opinion.

however, technical analysis of such effects is not possible given the lack of current information on these activities.

Similarly, while the PEIR addresses the issue of climate change and potential effects on water resources and water supply (see Vol. 3, Chapter 5, pp. 5.7-92 to 5.7-96, and Vol. 7, Chapter 14, Section 14.11, Master Response on Climate Change), it does not include a detailed technical analysis of the potential effects of climate change on the San Joaquin River or the Delta because there is insufficient information to do so. The USBR and DWR are currently updating the modeling tools used to evaluate water resources and impacts on the Delta in order to incorporate potential climate change scenarios (as required in part by the Judge Wanger decisions on OCAP Biological Opinions addressing delta smelt and salmonid species). This process involves development and peer review of appropriate assumptions about climate change with respect to the Delta and tributary river system and of the modeling approach, which will begin to provide the analytical tools necessary to evaluate potential climate change scenarios. In the absence of these analytical tools and information, the PEIR provides a qualitative assessment of WSIP impacts with consideration of climate change effects and determines that near-term climate change effects (through 2030) would not change the conclusions of the impact analysis presented in the Draft PEIR on the lower Tuolumne River as well as on downstream effects on the San Joaquin River and Delta (see Vol. 7, Section 14.11.4).

Effects on Delta Water Users

Comments related to the WSIP's effects on Delta surface water supplies delivered to water users for agricultural and municipal/industrial use purposes were received from water agencies that are "in-Delta" diverters, such as the Contra Costa Water District (CCWD); from the USBR, which operates the CVP; and from agencies that receive water from the CVP and/or SWP water systems that export water from the Delta, including the San Luis & Delta-Mendota Water Authority, Westlands Water District, Kern County Water Agency, Santa Clara Valley Water District, Zone 7, and the State Water Contractors (representing all SWP contractors). The following discussion responds to comments from the CCWD, which diverts water directly from the Delta into its system. Section 14.8.3, below, addresses comments about the WSIP's effects on the CVP and SWP and associated water contractors.

Comments L_CCWD-01 and L_CCWD-02 stated that the PEIR does not adequately analyze changes in Delta water quality, and that changes in Delta water quality could affect its water supply operations and, in turn, its supply reliability. The Draft PEIR discusses WSIP effects on Delta water quality in Section 5.3.3, Surface Water Quality (Vol. 3, Chapter 5, pp. 5.3.3-19 and 5.3.3-20) as well as in Section 5.3.4, Surface Water Supplies (Vol. 3, Chapter 5, pp. 5.3.4-9 to 5.3.4-11). Based on the detailed analysis of WSIP-induced flow effects, the PEIR concludes that the potential effects on Delta water quality would be less than significant for several reasons.

First, WSIP-induced flow reductions affecting the Delta would occur primarily in wet and above-normal year types, and in the winter and spring periods, in the season when flows are at their annual maximum. Given the magnitude of flow through the Delta during these periods, WSIP-related flow reductions would not appreciably affect Delta water quality. The impact analysis presented in the Draft PEIR (p. 5.3.4-11) indicates that WSIP-induced flow reductions affecting the Delta would be minimal, typically on the order of 500 cubic feet per second (cfs) as compared to a Delta outflow that is greater that 10,000 cfs. On rare occasions, the WSIP-induced flow reductions could range from 1,000 cfs to 4,000 cfs. Detailed modeling of the WSIP indicated that this type of flow reduction could occur in seven months out of the 984-month hydrologic record. Additional modeling (including use of the DSM2 model) was not considered necessary because information available from the HH/LSM modeling effort provided evidence that impacts on Delta water quality would be less than significant.

The CCWD operates its Delta intakes to meet both water supply and water quality criteria. In addition to the SWRCB's water quality objectives for the Delta, the CCWD has established a delivered water quality goal for its customers and manages its water supply diversions to help achieve this goal. The CCWD uses the Los Vaqueros Reservoir project to help manage the quality of its delivered water. The CCWD diverts high-quality Delta water to storage in the first months of each year and uses this stored water to blend with lower quality supply being diverted from the Delta later in the year; in this way, CCWD compensates for periods of lower Delta water quality and maintains delivered water quality to meets its standards. CCWD adjusts Delta diversions, storage, and the timing and extent of supply blending each year to manage for variations in Delta water quality and maintain a consistent delivered water quality to its customers. Under the WSIP, it is assumed the CCWD would continue this same type of water supply diversion, storage, blending, and delivery operation. In most years, the WSIP would not affect CCWD water diversion operations; very infrequently (less than 1 percent of the time), WSIP effects on the Delta might affect water quality such that the CCWD would make some adjustment in Delta pumping and/or blending, as it does now to address the constant variations in Delta water quality. Based on the impact significance presented in the Draft PEIR (Vol. 3, Chapter 5, p. 5.3.4-4), this very infrequent potential effect on Delta water quality would not represent a substantial change in water quality that would result in a substantial adverse change in CCWD water diversion operations or decreases in water deliveries for its customers.

14.8.3 Potential Effects on CVP and SWP Operations and Related Indirect Environmental Effects

Comment Summary

Summary of Issues Raised by Commenters

- The Draft PEIR does not address WSIP effects on CVP and SWP operations, which might have environmental effects.
- The Draft PEIR does not address WSIP effects on CVP and SWP operations, which might affect water supply deliveries. The Draft PEIR does not properly apply impact significance criteria related to surface water supplies to the San Joaquin River or Delta (i.e., to the CVP and SWP).

Response

Introduction

The Draft PEIR analyzes effects on the San Joaquin River and the Delta and, as discussed above in Section 14.8.2, indicates that WSIP-induced flow reductions to these water bodies could in some cases require the USBR and/or DWR to adjust CVP and/or SWP operations in order to meet their obligations to maintain compliance with regulatory flow and water quality objectives. Adjustments to CVP or SWP operations could include increasing water releases from system reservoirs and/or reducing export pumping of supply from the Delta. The Draft PEIR analysis indicates that WSIP-induced flow reductions could require adjustment of CVP or SWP operations. In response to comments received on this topic, the SFPUC conducted a supplemental modeling assessment to help the San Francisco Planning Department further examine the potential WSIP-induced effects on the San Joaquin River and the Delta and, in turn, on CVP and SWP operations (Vol. 8, Appendix O4). This supplemental modeling assessment is presented in Appendix O (Vol. 8) of the PEIR. This supplemental assessment uses information on the WSIP derived from the HH/LSM in combination with information from the 2005 CalSim II model.

Focused primarily on operations of the CVP and SWP, CalSim II incorporates the simulated operations of non-CVP/SWP water projects that exist on tributaries to the San Joaquin and Sacramento Rivers. Development of the CalSim II model during 2005 included a refinement of the depiction of San Joaquin River basin operations and hydrology. On the Tuolumne River, CalSim II models operation of the Don Pedro Project (including releases below Don Pedro Reservoir at La Grange Dam that affect Tuolumne River flow contributions to the San Joaquin River and Delta). Although the HH/LSM and CalSim II are different models, the underlying logic of operations for the Don Pedro Project in each of the models was developed coincidentally and the models produce similar results. For this supplemental analysis, the CalSim II model was used to further evaluate the effect that WSIP-induced flow reductions in the lower Tuolumne River would have on the San Joaquin River and Delta. The findings of this supplemental modeling assessment, described here, corroborate the impact findings of the Draft PEIR.

Effects on the San Joaquin River and on CVP Operations at New Melones Reservoir

The supplemental modeling analysis corroborates the findings that WSIP-induced flow reductions affecting the San Joaquin River would typically occur during wetter years, and that the more sizeable changes in flow would occur during years when the flows in the river are relatively large.

To further assess potential WSIP effects on the USBR's CVP operations at New Melones Reservoir due to flow reductions in the San Joaquin River, modeling results indicating when and to what extent the WSIP would result in flow reductions in the San Joaquin River were compared to modeling results for the "base case" (without WSIP implementation) that estimates periods over the 82-year (984-month) historical hydrologic record when the USBR would have to make releases from New Melones Reservoir on the Stanislaus River to maintain either flow or water quality objectives for the San Joaquin River. This comparison identified those instances when WSIP effects would "trigger" a response from the CVP system and require the USBR to make a release from New Melones Reservoir that it otherwise would not have been required to make.

This analysis identifies three monthly instances (over the 984-month record) when the WSIP would trigger the need for a release from New Melones Reservoir; in two instances, the WSIP-induced flow reductions occurred during a period when flow objectives were a controlling condition of the USBR's operations, and in one instance the reductions occurred when water quality objectives were the controlling condition. This finding corroborates the analysis presented in the PEIR that only very infrequently would reductions in San Joaquin River flow attributable to the WSIP be sufficient to cause flow in the San Joaquin River to fall below the established objectives and trigger a compensatory reaction from the USBR's CVP New Melones Reservoir. In most months modeled over the 82-year period of hydrologic record, the WSIP's effect on flow in the San Joaquin River would not require any changes in CVP operations at New Melones Reservoir. The supplemental modeling reaffirms the result that the WSIP could affect CVP operations on the San Joaquin River upstream of the Delta only rarely—less than 1 percent of the time.

Based on the PEIR impact significance criteria regarding potential effects on surface water supplies and water users (Vol. 3, Chapter 5, p. 5.3.4-4), the WSIP's effects on USBR CVP operations at New Melones Reservoir would not result in substantial adverse changes in operations or substantial decreases in water supply deliveries for water users. The WSIP's effects would be very infrequent and of a limited magnitude and duration. The WSIP would not result in the need for a frequent or sustained schedule of release from New Melones Reservoir that would chronically reduce the available supply for CVP contractors. Rather, the WSIP would very rarely require a release of water from New Melones Reservoir, and the resulting reduction in stored water might or might not affect supply deliveries to CVP contractors the following year. Depending on the timing of the required reservoir release and the climate and hydrology of that year and the following year, the reservoir could refill and restore storage levels without any reduction in deliveries to CVP contractors. If the reservoir did not refill and restore the amount of water released, then some CVP contractors could experience a reduction in supply delivery in the following year due to the WSIP-induced flow changes downstream in the San Joaquin River.

The eastside CVP contractors that receive water from New Melones Reservoir include Stockton East Water District and Central San Joaquin Water District. At present, the supply delivered to these contractors from the CVP system varies from year to year. Very infrequently, the WSIP could contribute to a short-term reduction in deliveries to these contractors. As they do now to address year-to-year variations in supply from the CVP New Melones system, these contractors would implement various actions, including the use of other supplies (groundwater and other surface water supplies); short-term reductions in crop acreage, the number of crop rotations, or crop type; and increased conservation (irrigation improvements). These contractors are already actively pursuing the development and acquisition of supplemental water supply sources and are engaged in ongoing conservation efforts to address several factors, including the following: the need to remedy existing groundwater overdraft in the San Joaquin Valley region and develop an effective regional conjunctive-use program; the growing long-term CVP system water delivery reliability issues due to regulatory requirements for addressing special-status fishery resources in the Delta (delta smelt) and its tributary rivers (salmonid species); and overall surface water reliability issues such as the potential future effects of climate change on water supply availability. These contractors have identified the need to pursue multiple conservation and supplemental water supply strategies regardless of WSIP implementation. While the potential effects of the WSIP would contribute to possible supply delivery reductions to CVP contractors, the WSIP contribution is not considered to be cumulatively considerable, given how infrequently the reductions would occur coupled with their limited magnitude and duration.

Effects on the Delta and on the CVP and SWP Systems

With respect to WSIP-induced effects on the Delta, a supplemental analysis was conducted using CalSim II modeling information to identify periods when the Delta is in “excess condition” versus “balanced condition” (see Vol. 8, Appendix O). The term “excess condition” is used to describe those periods when there is more water flowing through the Delta than is needed to meet Delta environmental standards (for flow and water quality) and the needs of water diverters. The term “balanced condition” is used to describe periods when there is not enough water flow through the Delta, and the USBR and DWR have to actively operate the CVP and SWP to balance reservoir releases with export operations in order to provide specific Delta outflow to meet either the flow or water quality objectives. A WSIP-induced flow reduction that affected Delta inflow during excess conditions would possibly require the USBR or DWR to alter its CVP or SWP export operations but would not necessarily require a change in upstream reservoir releases. During these excess conditions, a WSIP-induced flow reduction could affect Delta outflow. A WSIP-induced flow reduction that affected Delta inflow during balanced conditions could require the USBR and DWR to make either upstream reservoir releases or adjustments to CVP and SWP export operations.

Modeling analysis indicates that WSIP-caused flow reductions would affect Delta inflow about 15 percent of the time, or in 145 months in the 984-month hydrologic record (see Vol. 8, Appendix O for more information). Most of the WSIP-caused reductions in Delta inflow would occur during excess conditions (118 months in the 984-month hydrologic record, or about 12 percent of the time) and thus would result in reductions in Delta outflow and could but would not necessarily affect CVP or SWP export operations. These reductions in Delta outflow would occur during periods of relatively high flow through the Delta and would not result in significant adverse effects on Delta environmental resources, as illustrated by the location of the freshwater/brackish water interface (referred to as “X2,” an important indicator of the health of aquatic life in the Delta). When Delta outflow is large, X2 moves downstream deep into Suisun

Bay; when outflow is small, X2 moves into the western Delta. The Delta environmental standards include a provision specifying that X2 should not be located upstream of certain locations between February and June to protect aquatic life. In effect, the standard requires that the SWP and CVP operate their facilities in a manner that causes Delta outflow to be great enough to maintain X2 in a downstream location between February and June.

When the Delta is in an excess condition, more water is flowing through the Delta than is needed to meet Delta standards and, consequently, X2 is located downstream of the specified locations. In 127 months out of the 145 months in the 984-month hydrological record, when modeling indicates that the WSIP would affect Delta inflow, the WSIP-caused reductions in monthly Delta outflow would be less than 20,000 acre-feet, insufficient to have much effect on Delta outflow or the position of X2. Occasionally (occurring in 4 months out of the 984 months modeled), relatively large WSIP-caused reductions in monthly Delta outflow of more than 100,000 acre-feet would occur. However, since monthly Delta outflow during excess conditions typically exceeds 1,000,000 acre-feet, the outflow reductions would likely cause X2 to move upstream, but it would still remain downstream of the locations specified in the Delta standards. Because of this, the impacts of WSIP-caused reductions in Delta outflow on biological resources would be less than significant.

Although during excess conditions a change in Delta inflow due to WSIP-induced flow changes in the San Joaquin River may not affect CVP and SWP upstream release operations, CVP and SWP export operations may be affected. This effect is described later below.

Concerning WSIP-induced effects on the Delta that could affect CVP and SWP operations during balanced conditions, the supplemental analysis used CalSim II modeling information to identify periods when the Delta is in a balanced condition, which could require the USBR and DWR to make adjustments in CVP and SWP operations to address the flow or water quality effects of the WSIP. The supplemental modeling analysis identified 26 months out of the 984-month (82-year) record in which WSIP-induced flow reductions would occur during Delta balanced conditions (less than 3 percent of the time). The average annual reduction in inflow during these balanced conditions would be 7,000 acre-feet. When these flow reductions occur, the USBR and DWR might elect to increase reservoir releases, decrease Delta exports, or a combination of both to maintain the required Delta outflow and achieve required flow and water quality objectives.

The CVP and SWP systems include multiple reservoirs upstream of the Delta and two major export pumping facilities in the Delta (Jones Pumping Plant and Banks Pumping Plant, respectively), which the USBR and DWR use in a coordinated manner to meet their environmental obligations as well as contract delivery responsibilities. The CVP and SWP together deliver an annual average of about 5 million acre-feet of water to users south of the Delta, about 3 million acre-feet to farmers, and the rest to urban areas. The two projects pump water from the south Delta and convey it directly to users or (when water availability exceeds users' needs) into storage at their jointly owned south-of-the-Delta reservoir, San Luis Reservoir, near Los Banos. Because of the size and complexity of these two federal and state water systems, it is not possible to determine exactly how the USBR and DWR would adjust system operations to respond to a WSIP-induced flow change in the Delta. The analysis of potential WSIP effects on the San Joaquin River, summarized above, is able to consider specific effects on the New Melones Reservoir, since it is the only CVP facility that would respond to flow changes in the San Joaquin River. By contrast, this discussion of possible effects on the CVP and SWP systems, the Delta, and south-of-Delta contractors in response to a WSIP-induced flow change in the Delta must address various possible impact scenarios rather than a specific impact on a particular facility or user(s). Under existing conditions, it is expected that the USBR and DWR would primarily increase reservoir releases rather than reduce exports to achieve Delta standards; however, in the future, it is possible that the CVP and SWP operational changes necessary to address the pending requirements of the Judge Wanger decision on salmonid species protection could limit the ability of the USBR and DWR to use reservoir releases to meet Delta standards, thus leading to a greater reliance on export reductions.

Whether the USBR and DWR choose to increase reservoir releases or reduce export pumping, the WSIP-induced Delta inflow reductions that occur during balanced conditions in the Delta would not necessarily reduce the amount of water available in the short term for delivery to CVP and SWP contractors. Whether actual deliveries to contractors would be reduced would depend on hydrological and year-to-year system operation objectives. For example, a release of water from a CVP and/or SWP reservoir upstream of the Delta would reduce the amount of water in storage that year. However, that reduction in storage might not immediately lead to a reduction in contractor deliveries and the reservoir might refill the following year, in which case storage levels would be restored with no resulting shortage in actual water deliveries to contractors. Releases from upstream reservoirs to address WSIP-induced effects would increase the risk of a supply delivery reduction by reducing the amount of water in storage, but would not necessarily result in an actual delivery reduction.

While the USBR and DWR could decide to restrict Delta export pumping to address flow and water quality objectives in those occasional instances when WSIP-induced flow reductions occur during Delta balanced conditions, there are also other constraints on the CVP and SWP systems that limit water exports from the Delta based on hydraulic conditions in the south Delta whether the Delta is in an excess or balanced condition. In particular, the emergency remedy measures to protect delta smelt imposed by Judge Wanger establish allowable reverse flows in Old and Middle Rivers between January and June. These flows are dependent on the hydraulics of the south Delta, including the amount of water that enters the Delta from the San Joaquin River. A general rule-of-thumb is that approximately 50 percent of the flow at Vernalis in the San Joaquin River (downstream of the confluence with the Tuolumne River) affects the flow in Old and Middle Rivers, and exports have an almost direct (1:1) effect on flow in Old and Middle Rivers. As a result, about one-half of the change in flow in the San Joaquin River will affect the amount of allowed water export.

A conservative assessment was undertaken of the average effect per year of WSIP-induced flow reductions in the San Joaquin River. The assessment is conservative in that it includes WSIP-induced flow reductions in years with extremely high flow when the WSIP reductions might not constrain Delta exports, and no adjustment is made for the fact that in some wet years a reduction in allowable Delta water export might not affect south of Delta deliveries. Using this conservative assessment, the average annual effect of the WSIP on CVP and SWP exports amounts to approximately 10,000 acre-feet per year. This is the amount of water that, on an average annual basis, the CVP and SWP would not have available to export to contractors south of the Delta with the implementation of the WSIP. The amount of water exported from the Delta by the CVP and SWP varies annually. Between 1995 and 2004, the SWP diverted an average of 2.4 million acre-feet per year from the Delta; the CVP diverts an average of 1.7 million acre-feet per year. Based on the impact significance criteria presented in the Draft PEIR (Vol. 3, Chapter 5, p. 5.3.4-4), this potential indirect WSIP effect on the CVP and SWP water supply deliveries does not represent a substantial change in CVP and SWP operations or a substantial decrease in water deliveries for water users.

On the occasions when WSIP-caused reductions in Delta inflow could affect deliveries to SWP and CVP water users, adverse environmental impacts could occur if the users were forced by this loss of water supply to substantially alter their water management practices. For example, if the WSIP effects resulted in a sustained, long-term reduction in supply availability, then agricultural users might take land permanently out of production, which could then cause dust emissions, at least in the few years before native vegetation became established. Agricultural and municipal water users might replace the lost SWP or CVP water with water from other sources, and the use of the other sources could itself have environmental impacts. However, for the reasons described below, SWP and CVP water users would not be likely to substantially alter their water management practices as a result of the WSIP.

WSIP-induced reductions in CVP and SWP deliveries would be small in magnitude compared to the differences in year-to-year deliveries that result due to hydrological factors. SWP and CVP deliveries often vary widely from year to year. For example, in 1991, a very dry year, the SWP delivered about 550,000 acre-feet of water to users; in 2000, a wet year, it delivered about 3,500,000 acre-feet of water to users. Because water users are subject to such variability in SWP and CVP deliveries, they have developed their long-term water management strategies accordingly. Most users of SWP and CVP water do not rely solely on the projects, but have other water sources that can be used when SWP and CVP water is in short supply. Many users of SWP and CVP water have the ability to store water available in wet years in surface reservoirs or groundwater banks for later use in dry years.

SWP and CVP water users are also able to adapt to short-tem changes in water availability. Each fall, the operators of the SWP and CVP make an initial estimate of the amount of water they expect to be available to users in the coming spring and summer, and then periodically update the estimate as hydrological information accumulates. The estimates are based on weather forecasts and the amounts of water in storage in reservoirs in the Central Valley, including Don Pedro Reservoir, and in storage as mountain snow. SWP and CVP water users are able to respond to rapidly developing shortages or surpluses. Agricultural users may increase or decrease their planting of annual crops. Municipal users may impose water rationing or place surplus water in storage. The infrequent changes in SWP and CVP water availability attributable to the WSIP would be accommodated within the water users' existing short-term water management strategies. The minor changes in availability of SWP and CVP water attributable to the WSIP are unlikely to cause SWP and CVP water users to substantially alter either their long-term or short-term water management strategies. Therefore, the environmental impacts of WSIP-caused delivery reductions (should such impacts occur) would be less than significant.

This supplemental analysis supports the Draft PEIR conclusions that WSIP effects on flow, water quality, as well as beneficial uses (i.e., fish/aquatic resources and water supply) would be less than significant. It should also be noted that while the PEIR determines the WSIP effects on the San Joaquin River and Delta to be less than significant and requiring no mitigation, the PEIR does identify a mitigation measure to address the WSIP-induced flow effects in the lower Tuolumne River on fisheries and riparian habitat that would also essentially avoid WSIP-induced effects downstream in the San Joaquin River and the Delta. Mitigation Measure 5.3.6-4a, Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water, calls for the SFPUC to secure a water transfer from MID/TID and/or other water agency such that the water acquired is developed through actions that result in a reduction of demand on Don Pedro Reservoir as a result of conservation, improved delivery efficiency, interagency water transfer of conserved water, or use of an alternative supply such as groundwater. Consequently, MID/TID would deliver less water from Don Pedro Reservoir, and the resulting increase in water storage in the reservoir would offset the reduction in reservoir inflow attributable to the WSIP. Thus, the WSIP would not trigger a change in downstream reservoir releases to the lower Tuolumne River. While this measure is not fully in the SFPUC's control to implement and requires agreements and actions by other entities, the SFPUC intends to adopt and pursue this measure as part of WSIP implementation. This measure would further reduce, if not fully eliminate, the downstream effects of the WSIP on the San Joaquin River and the Delta as well as on the CVP and SWP and their water contractors.

14.9 Master Response on Alameda Creek Fishery Issues

14.9.1 Introduction

This master response addresses comments on the adequacy of the impact analysis and mitigations with respect to the WSIP's effects on the steelhead fishery in Alameda Creek, as well as other comments on Alameda Creek fishery resources, including fish-related stream flows and water quality. Comments concerning fisheries in the context of climate change are addressed in part in this master response, but refer to **Section 14.11, Master Response on Climate Change** (Vol. 7, Chapter 14) for detailed discussion of climate change effects. Comments concerning riparian corridors and related aspects of terrestrial biology are addressed in part in this master response and also in the responses to individual comments (see Vol. 7, Chapter 15) pertaining to terrestrial biology.

Updated Assumptions Used in this Master Response

Since publication of the Draft PEIR, a number of changes have occurred with respect to the Draft PEIR's discussion of the potential for steelhead reestablishment in the upper Alameda Creek watershed. These changes include updated status of fish passage improvement projects, modifications to the descriptions of the Alameda Creek Fishery Enhancement (SV-1) and Calaveras Dam Replacement (SV-2) projects, and updated Alameda Creek flow modeling. This master response incorporates these changes and updated assumptions as part of the comprehensive response to the numerous comments on the Draft PEIR related to steelhead fisheries in Alameda Creek.

Changes in Steelhead Conditions

Although the presence of steelhead in Alameda Creek above the Bay Area Rapid Transit District (BART) weir is not an "existing condition" as defined by CEQA and as described in the Draft PEIR (Vol. 3, Chapter 5, pp. 5.4.5-4 to 5.4.5-11), it is a possible future condition that could occur as the result of the cumulative implementation of many planned and proposed projects and actions designed to restore steelhead in Alameda Creek. As a result of information provided by commenters regarding future projects influencing the future habitat conditions for steelhead in the Alameda Creek watershed, the Draft PEIR analysis of cumulative effects (Vol. 3, Chapter 5, pp. 5.7-52 to 5.7-67) has been updated to incorporate a discussion of cumulative impacts of the WSIP on future-occurring steelhead. This master response provides an expanded discussion of the "future cumulative scenario" in which it is assumed that the steelhead fishery has been restored above the BART weir, and then discusses the potential effects of the WSIP on potential future-occurring steelhead. Following this expanded discussion, specific text revisions to the Draft PEIR are identified.

Changes to the Calaveras Dam Replacement and Alameda Creek Fishery Enhancement Projects

Sections 13.2 and 16.2 (Vol. 7, Chapters 13 and 16, respectively) present the revised project descriptions for WSIP components affecting system operations, including changes to the Alameda Creek Fishery Enhancement (SV-1) and Calaveras Dam Replacement (SV-2) projects. Since publication of the Draft PEIR, the SFPUC has incorporated both project revisions and protective measures into these two projects to reduce the WSIP's potential to affect habitat conditions for potential future-occurring steelhead in the upper watershed (SFPUC, 2008). The project revisions would occur regardless of steelhead presence or absence upstream of the BART weir and are as follows:

- The Calaveras Dam Replacement project would include facility modifications at the Alameda Creek Diversion Dam (ACDD) to construct a new bypass structure needed to implement bypass stream flows.
- If a structural alternative involving construction of a recapture facility is selected under the Alameda Creek Fishery Enhancement project, the recapture facility would be located at the downstream end of the reach of Alameda Creek between the lower Sunol Valley and the confluence with Arroyo de la Laguna. As an alternative to the recapture facility, the SFPUC may coordinate with other water agencies to develop and implement other means of recapturing fishery enhancement flows consistent with the 1997 California Department of Fish and Game Memorandum of Understanding (CDFG MOU).

The project description modifications also include protective measures that were designed in the event that man-made barriers in Alameda Creek are removed and steelhead gain access to Alameda Creek above the BART weir. These protective measures would provide both a long-term strategy of working with federal and state agencies, as well as interim protection in the event that: (1) the National Marine Fisheries Service (NMFS) and/or the CDFG have determined steelhead to be present in Alameda Creek above the BART weir; (2) construction of the Calaveras Dam Replacement project is complete; and (3) the Alameda Watershed Habitat Conservation Plan (HCP) has yet to be finalized. The project components designed to provide protective measures for future-occurring steelhead would include the following:

- An operational plan to provide minimum stream flows to support steelhead spawning below the ACDD to the confluence with Calaveras Creek when precipitation naturally generates runoff and flow in the creek, including the site-specific studies needed to determine the specific minimum stream flow requirements to support steelhead spawning in this reach of the creek.
- A detailed monitoring plan to survey and document steelhead spawning, subject to review and comment by the appropriate resource agencies. Monitoring would occur for a minimum of five years and a maximum of 10 years following implementation of the bypass flows for steelhead. At the completion of the monitoring period, the SFPUC would provide a report describing the methods, data collected, and results used to assess the performance of the minimum stream flow in providing suitable habitat for steelhead spawning.
- Interim minimum flows would be implemented if the NMFS and/or CDFG have determined that steelhead are present in Alameda Creek above the BART weir, construction of the Calaveras Dam project is complete, and the Alameda Watershed HCP

has yet to be finalized. The interim bypass flow releases would be consistent with the 1997 CDFG MOU, with the additional requirement that these flows would be achieved through bypass flows at the ACDD at all times when flows are available in upper Alameda Creek, rather than through releases at Calaveras Dam. Any changes in bypass flows provided for in this measure would be limited by the SFPUC's ability to achieve the bypass flow schedule, taking into consideration such factors as natural annual and interannual (i.e., seasonal) variations in flow in Alameda Creek immediately above the ACDD, and the SFPUC's ability to maintain all appropriated water rights in Alameda Creek. If supplemental releases need to be made for 1997 CDFG MOU compliance due to naturally low stream flows in upper Alameda Creek, releases would be made from Calaveras Dam. Based on flow studies conducted by Hagar and Payne (ETJV, 2008), it has been determined that the performance criteria, monitoring requirements, and other specifications included in the 1997 CDFG MOU could be readily adapted to benefit steelhead as well as sensitive amphibians. The MOU flow schedule provides the following instream flows:

  - 5 cubic feet per second (cfs) between November 1 and January 14
  - 20 cfs between January 15 and March 15
  - 7 cfs between March 16 and October 31 (reduced on ramping schedule to avoid settling of fines)

- Until the studies needed to resolve the physical and institutional requirements for future steelhead migration in Alameda Creek have been completed, the following interim measure would be implemented, but only after the following conditions are met: construction of the Calaveras Dam Replacement project (SV-2) is completed; existing barriers to passage are remedied; and the NMFS and/or CDFG have determined that steelhead can migrate above the BART weir of their own volition:

  - The SFPUC would provide seasonal flow bypasses at the ACDD and/or flow releases from Calaveras Dam, either (1) without recapture or (2) with recapture at a point approximately at the downstream end of the reach of Alameda Creek between the lower Sunol Valley and the confluence with Arroyo de la Laguna, below critical riffle locations or lower in the creek, between December 1 and June 30 (combined adult and juvenile migration period) in an amount equivalent to the flow release schedule provided in the 1997 CDFG MOU.

  - As an alternative to the recapture facility, the SFPUC would coordinate with other water agencies to develop and implement other means of recapturing enhancement flows consistent with the 1997 CDFG MOU at a location downstream of the reach of Alameda Creek between the lower Sunol Valley and the confluence with Arroyo de la Laguna.

Draft PEIR Mitigation Measure 5.4.5-3a

In order to reflect the incorporation of the project revisions and additional protective measures into the Calaveras Dam Replacement project (SV-2) component of the WSIP, Draft PEIR Mitigation Measure 5.4.5-3a, Minimum Flows for Resident Trout on Alameda Creek (Vol. 4, Chapter 6, pp. 6-52 and 6-53), has been modified to be implemented in conjunction with the bypass flows at the diversion dam proposed as part of the Calaveras Dam Replacement project (and described above) to meet the 1997 CDFG MOU flow requirements (see Vol. 7, Chapter 16 for specific text changes).

Updated Flow Modeling

Subsequent to publication of the Draft PEIR, the SFPUC conducted updated model runs with the Hetch Hetchy/Local Simulation Model (HH/LSM)[1] to reflect more recent input assumptions for several model parameters as part of its ongoing system planning and management. Revised model assumptions and data are discussed in Section 13.3 (Vol. 7, Chapter 13), and new model output is shown in Appendix O (Vol. 8) of this PEIR. With respect to Alameda Creek, the updated model runs resulted in generally minor changes in flows and reservoir operations compared to the data presented in the Draft PEIR. The results of the updated model runs are integrated into the responses to comments, updated analyses, and protective measures.

Master Response Organization

This master response is organized by the following subtopics:

- 14.9.2 Steelhead Fishery – Existing Conditions in Alameda Creek
- 14.9.3 Impacts on Steelhead in Lower Alameda Creek below the BART Weir
- 14.9.4 Steelhead – Future Fishery Scenario and Potential Cumulative Effects
- 14.9.5 Other Fish Species and Aquatic Habitat in Alameda Creek
- 14.9.6 Climate Change and Cumulative Effects on Future Fish Passage and Fish Habitat

Comments on Alameda Creek fishery issues were received from the following entities:

Federal Agencies

- None

State Agencies

- California Department of Fish and Game – S_CDFG2

Local and Regional Agencies

- Alameda County Flood Control and Water Conservation District – L_ACFCWCD
- Alameda County Water District – L_ACWD
- East Bay Regional Park District – L_EBRPD
- Zone 7 Water Agency – L_Zone7

Groups

- Alameda Creek Alliance – SI_ACA1, SI_ACA2
- California Native Plant Society, East Bay Chapter – SI_CNPS-EB2
- Environmental Defense – SI_EnvDef
- Golden West Women Flyfishers – SI_GWWF2
- Northern California/Nevada Council of the Federation of Fly Fishers Steelhead Committee – SI_NCFFSC

[1] The Draft PEIR (Vol. 3, Chapter 5, pp. 5.1-9 to 5.1-17) analyzed the WSIP's impacts on river and steam flow using a computerized mathematical simulation model developed by the SFPUC. This model, the HH/LSM, simulates the operations of the regional water system using a monthly time-step.

Citizens

- None

PEIR Section Reference

The Draft PEIR evaluates impacts on fisheries and habitat in Alameda Creek, presents mitigation measures to reduce or eliminate impacts, and discusses future fishery habitat enhancement projects in the following locations: Vol. 1, Summary, Table S.6, p. S-53; and Vol. 3, Chapter 5, Section 5.4.1 (stream flow), Section 5.4.3 (water quality), Section 5.4.5 (fisheries), and Section 5.7.3 (cumulative impacts).

The Draft PEIR addresses issues concerning Alameda Creek fisheries-related legal issues and water rights in the following locations: Vol. 1, Chapter 2, Section 2.4.2 (regulatory requirements); Section 2.5.1 (institutional considerations); Table 2.3 (SFPUC water resources policies); Vol. 2, Chapter 4, Section 4.6 (biological resources); Vol. 3, Chapter 5, Section 5.2 (plans and policies) and Section 5.4.5 (fisheries).

14.9.2 Steelhead Fishery – Existing Conditions in Alameda Creek

Introduction

This section of the master response addresses comments concerning the existing conditions in Alameda Creek for steelhead and rainbow trout, including their regulatory status and the SFPUC's current and ongoing stewardship and management efforts towards steelhead restoration. It also discusses flow requirements for steelhead with consideration of other native stream-dependent species. This section is organized by the following subtopics:

- Biological Distinctions and Regulatory Status for Steelhead and Rainbow Trout
- Anadromous Steelhead in Lower Alameda Creek
- Consideration of Fish Passage at the Niles Gaging Station
- SFPUC Environmental Stewardship and Alameda Creek Fishery Restoration Projects
- Consideration of Steelhead at the Alameda Creek Diversion Dam
- Other Native Stream-Dependent Species
- SFPUC's Ongoing Management and Stewardship of the Alameda Watershed

Comment Summary

This section of this master response responds to all or part of the following comments:

L_ACFCWCD-02	L_ACFCWCD-13	SI_ACA1-11
L_ACFCWCD-03	L_ACFCWCD-15	

Summary of Issues Raised by Commenters

- An arbitrary distinction is drawn between steelhead and rainbow trout.

- Clarification is needed regarding the regulatory status of steelhead and rainbow trout in Alameda Creek above the BART weir.
- Issues regarding fish passage above the BART weir, including:
  - The consideration of steelhead currently passing upstream over the BART weir is inadequate.
  - The distinction between naturally migrating fish past the BART weir and fish transported past the weir is arbitrary.
  - The effects of reduced peak winter flows on fish passage over the BART weir and middle inflatable dam are not adequately addressed.
  - Mitigation for effects of reduced peak winter flows on fish passage over the BART weir and middle inflatable dam needs to be included.
- The discussion of Niles gaging station with respect to fish passage is inadequate.
- SFPUC involvement in fishery enhancement projects is inconsistent with the position that steelhead are not present upstream of the BART weir.

Biological Distinctions and Regulatory Status for Steelhead and Rainbow Trout

Comments received on the Draft PEIR requested further validation of the biological distinctions made between anadromous steelhead and resident rainbow trout within the Alameda Creek watershed in determining WSIP-related impacts on steelhead populations. The Draft PEIR addresses the regulatory status, life history, and distinctions between resident and migratory populations, as well as flows needed to support populations, in Section 5.4.5 (Vol. 3, Chapter 5, pp. 5.4.5-4 to 5.4.5-11).

The life-history discussion presented in Section 5.4.5 is summarized here to facilitate an understanding of how the biological distinction was drawn between steelhead and rainbow trout in the Draft PEIR. Steelhead and rainbow trout are both genetically identified as the species *Oncorhynchus mykiss* (*O. mykiss*), but are distinguished by their different regulatory status and life-history strategies, as summarized here. Both steelhead and rainbow trout have a flexible life history and adopt varying life-cycle strategies. All *O. mykiss* hatch in the gravel substrate of coldwater streams (Gunther et al., 2000). During spawning, the female steelhead and rainbow trout clears and cleans a depression in the gravel (redd) where eggs are deposited, fertilized, and incubate until hatching. After the eggs hatch, fry emerge from the gravel and disperse through the stream, typically occupying low-velocity areas along stream margins (Reiser and Bjornn, 1979). Juvenile steelhead and rainbow trout often move to deeper pools and higher velocity areas as they grow, and remain in freshwater for at least one year.

Following this rearing period of at least one year, juveniles (parr) may follow a variety of life-history patterns, which include residents (non-migratory) at one extreme and individuals that migrate to the open ocean (anadromous) at the other extreme. Intermediate life-history patterns include fish that migrate within the stream (potamodromous), fish that migrate only as far as estuarine habitat, and fish that migrate to near-shore ocean areas.

Juveniles that become migratory typically do so after one or two years of rearing, but sometimes longer. Physiological changes (smoltification) in these fish (smolts) ultimately allow them to make a transition from freshwater to seawater. Smolts migrate to the ocean, spend a variable amount of time there (typically one to two years), grow rapidly and return to spawn, generally in the stream where they hatched. This is an anadromous life history, typical of many salmon and trout as well as other fish species, and anadromous *O. mykiss* are commonly known as steelhead. Within a given stream, some *O. mykiss* do not migrate to the sea, and the proportion may vary considerably depending on local circumstances. These resident fish are often known as resident or stream rainbow trout. While resident rainbow trout share many of the same life-history characteristics and environmental requirements as anadromous steelhead, unlike steelhead—which migrate to the ocean for a portion of their life cycle—resident rainbow trout complete their entire life cycle within the freshwater environments of streams and lakes.

In the past, the Alameda Creek watershed supported anadromous steelhead (Gunther et al., 2000). Scientists have determined that resident rainbow trout and anadromous steelhead are genetically the same species that exhibits two different life-history strategies. Specifically, these different life-history strategies do not appear to be genetically distinct, and steelhead and rainbow trout have been observed interbreeding. Tissue samples have been collected from steelhead and rainbow trout in the Alameda Creek watershed and from other streams in the area for genetic analyses (Gunther et al., 2000). These analyses concluded with a high level of confidence that the Alameda Creek samples are not of hatchery origin and are genetically part of the Central California Coast (CCC) Distinct Population Segment (DPS) (formerly Evolutionarily Significant Unit, ESU) (Nielsen, 2003). Trout populations isolated above dams in the Alameda Creek watershed have been observed adopting an adfluvial life history, spending most of their lives in the reservoirs and migrating to tributary streams to spawn.

As described in the Draft PEIR (Vol. 3, Chapter 5, p. 5.4.5-4), while steelhead and resident rainbow trout are genetically identical, a distinction is made for steelhead based on the successful life-history strategy displayed. Although rainbow trout and steelhead are identified in the Draft PEIR as the same species, the two life-history strategies are not used interchangeably when discussing impacts on the listed special-status species of CCC steelhead. Steelhead are distinguished biologically as the anadromous life-history strategy. Anadromous steelhead have the ability to migrate to the sea and return to freshwater spawning areas in natal streams. Resident rainbow trout in upper Alameda Creek can migrate to coastal marine waters, but cannot return to spawning or rearing habitat upstream of the BART weir.

In January 2006, pursuant to the Federal Endangered Species Act (FESA), the NMFS listed as threatened the CCC steelhead DPS, including all naturally spawned anadromous steelhead populations below natural and manmade impassable barriers (71 Federal Register 834). The listing of the Alameda Creek CCC steelhead DPS as threatened applies only to the anadromous form of *O. mykiss* and is therefore limited to populations downstream of the BART weir. Specifically, the final listing determination stated, “Under our final approach of delineating steelhead-only DPSs of *O. mykiss*, the resident populations, including those in upper Alameda Creek and the Livermore-Amador Valley, are not considered part of the listed DPSs” (71 Federal

Register 841). Further discussion of the regulatory status of steelhead in Alameda Creek is presented in the Draft PEIR (Vol. 3, Chapter 5, p. 5.4.5-4).

As discussed in the Draft PEIR, a National Marine Fisheries Service (NMFS) ruling determined that steelhead and rainbow trout inhabiting a river or stream that allows the possibility of successful migration to and from coastal marine waters will, by definition, be classified as steelhead. Thus, the resident rainbow trout that occur in Alameda Creek upstream of the BART weir (a complete barrier to adult migration) are not designated as a listed species due to their inability to complete an entire life cycle involving adult upstream migration to the upper watershed with subsequent spawning. Therefore, a regulatory distinction currently exists that defines *O. mykiss* upstream of the BART weir as resident rainbow trout.

The NMFS has not designated the Alameda Creek watershed as critical habitat for steelhead, and has listed as threatened only those steelhead that currently exist below the lowest impassible barriers in the Alameda Creek watershed (i.e., the BART weir). Thus, the resident rainbow trout that occur in the creek above the BART weir are not designated as a listed species and are not proposed for listing. However, the NMFS has advised that the designation of critical habitat would be open to further evaluation if anadromous steelhead do obtain passage to upper Alameda Creek.

Anadromous Steelhead in Lower Alameda Creek

Many comments were received regarding fish passage in the lower portion of Alameda Creek and past the BART weir. Comments on this issue sought clarification on the extent to which the BART weir currently blocks upstream passage by anadromous CCC steelhead. Section 5.4.5 of the Draft PEIR (Vol. 3, Chapter 5, pp. 5.4.5-4 to 5.4.5-11) discusses steelhead populations in Alameda Creek, current barriers to fish passage, the regulatory status of steelhead in Alameda Creek, and the activities of the SFPUC, other agencies, and workgroups in passage improvement programs. Further discussion of this issue is provided in Section 14.9.3, below.

Alameda Creek historically hosted a steelhead run that spawned in the upper reaches of the watershed. That steelhead run was eliminated by the placement of several obstructions to migration within the Alameda Creek channel over the past century. These obstructions include the Alameda County Flood Control and Water Conservation District's (ACFCWCD) BART weir, located about 9.5 miles upstream from the creek's confluence with San Francisco Bay.

In February 2000, the Center for Ecosystem Management and Restoration published a report entitled *An Assessment of the Potential for Restoring a Viable Steelhead Trout Population in the Alameda Creek Watershed* (Gunther et al., 2000). The assessment found that suitable habitat exists in the watershed to support steelhead spawning and rearing, but that upstream adult migration was completely prevented by the presence of several barriers in the lower portion of the watershed. The assessment concluded that the BART weir presents a complete barrier to all migrating anadromous fish species under all flow conditions, with the possible exception of Pacific lamprey. Therefore, steelhead can currently migrate upstream within Alameda Creek only as far as the BART weir. The comment's assertion that the BART weir barrier is temporal (i.e., flow-dependent) is unsupported by either current literature (Gunther et al., 2000) or regulatory distinction.

Comments received on the Draft PEIR noted that individual steelhead fish have been transported upstream of the BART weir through citizen-group catch-and-release programs coordinated by the Alameda Creek Alliance. Concern was raised regarding impacts on these individual fish due to WSIP implementation. A discussion of steelhead in the Alameda Creek watershed is presented in Draft PEIR Section 5.4.5 (Vol. 3, Chapter 5), and a discussion of cumulative impacts on steelhead is presented in Section 14.9.4, below.

Steelhead that are artificially transported upstream of total passage barriers do not represent a naturally occurring, self-sustaining population, and, as such, impacts on these few individual fish are not evaluated in the Draft PEIR. These individuals are not considered part of the CCC steelhead DPS under FESA because these fish and their offspring, if successful in spawning, cannot return to the watershed upstream of the BART weir to complete a full life cycle. The Alameda Creek Alliance has been involved in transporting adult migrant fish past barriers in lower Alameda Creek. The Alameda Creek Alliance describes this transport operation on its website, which discusses the fact that the transport of a few individuals does not effectively move a sufficient number of fish upstream to create a viable spawning population (Alameda Creek Alliance, 2002).

Consideration of Fish Passage at the Niles Gaging Station

Comments raised concern that the Draft PEIR discussion of the U.S. Geological Survey (USGS) Niles gaging station (located upstream of the BART weir) was inadequate with respect to fish passage. Section 5.4.5 of the Draft PEIR (Vol. 3, Chapter 5, p. 5.4.5-9) discusses the Niles gaging station with respect to fish passage, as well as future habitat and passage improvement projects currently under study and planning. The Niles gaging station has been described as a potential impediment to fish passage (Gunther et al., 2000), although it remains passable during higher flow events. The downstream pool temperatures are characterized by stressful to highly unsuitable conditions in summer months, and improvements are required for both upstream and downstream passage (Hanson, 2008). The Northern California Council Federation of Fly Fishers has developed a preliminary study of fish passage by the Niles gage, and fish passage criteria and studies at the gaging station are ongoing. Because steelhead are unable to migrate upstream of the BART weir under existing conditions, impacts on steelhead passage at the Niles gaging station were not evaluated in the Draft PEIR. However, these impacts are considered in the cumulative impact analysis presented below in Section 14.9.4, which discusses future passage improvements and instream flow strategies as part of the SFPUC’s involvement in steelhead population recovery within the Alameda Creek watershed.

SFPUC Environmental Stewardship and Alameda Creek Fishery Restoration Projects

As part of the continuing effort to address steelhead restoration in Alameda Creek, the SFPUC has entered into an agreement with 17 public agencies and organizations as part of the Alameda Creek Fisheries Restoration Workgroup (ACFRW) to provide funding and collaborate on flow studies focused on steelhead restoration. To date, these studies have not developed instream flow recommendations, but an initial workplan—the *Alameda Creek Population Recovery Strategies and Instream Flow Assessment for Steelhead Trout*—has been developed to achieve this goal (McBain and Trush, 2007). Collaborative data collection is scheduled for the near future, and a joint process among the agencies has begun to recommend a range of flows to support steelhead restoration objectives. The referenced report details this effort to establish instream flow targets and outlines specific studies intended to result in a flow strategy for restoring and maintaining native fishes (McBain and Trush, 2007). Due to the many variables involved, these studies need to be completed before it is possible to develop a specific, scientifically based flow schedule for steelhead. Further detailed discussion on specific flow release volumes and schedules is provided in Section 14.9.4, below.

Comments raised concern that the Draft PEIR failed to mitigate or analyze impacts on fish passage within the context of proposed future projects designed to increase habitat quality and connectivity within Alameda Creek for steelhead. A detailed discussion of future cumulative scenario conditions and cumulative impacts associated with WSIP implementation is presented in Section 14.9.4. As previously described, various watershed and habitat studies have established that steelhead do not migrate above the BART weir (Gunther et al., 2000).

Regardless of the timing of the BART weir fish passage project and other planned habitat enhancement/restoration actions, the SFPUC will continue to participate in steelhead restoration efforts. Ongoing studies will recommend flows to support steelhead restoration (as detailed in Section 14.9.4), and the SFPUC will continue to work with the NMFS, CDFG, and other stakeholders on these studies. Section 14.9.4 provides a detailed discussion of the WSIP's potential contribution to cumulative impacts on future-occurring steelhead in Alameda Creek with the consideration of the revisions to the Calaveras Dam Replacement project (SV-2) and Draft PEIR mitigation measures summarized above in Section 14.9.1. The SFPUC plans to incorporate steelhead recovery strategies developed through the ACFRW process into its Alameda Watershed HCP or other regulatory mechanism, which will provide coverage under FESA for regional water system operations at the time steelhead return to the upper Alameda Creek watershed. The SFPUC will comply with FESA requirements for steelhead protection through the Alameda Watershed HCP, or other agreement/authorization acceptable to the permitting agencies, as described in Section 14.9.4.

Consideration of Steelhead at the Alameda Creek Diversion Dam

Comments on the Draft PEIR identified the desire to remove the ACDD as a barrier to fish passage in order to support restoration of the historical range of steelhead within Alameda Creek. The SFPUC has no plans to remove the ACDD, and its removal is not required to mitigate significant impacts of the WSIP. However, to address the potential for steelhead reestablishment in the upper Alameda Creek watershed, the SFPUC proposes to develop and implement an operational plan to provide minimum stream flows below the ACDD that will support steelhead spawning as part of the Calaveras Dam Replacement project (SFPUC, 2008). This operations plan will be developed in coordination with the ACFRW, CDFG, and NMFS. Other SFPUC actions proposed to address potential future-occurring steelhead in the upper watershed are discussed in Section 14.9.1, above. Additionally, as stated in Mitigation Measure 5.4.5-3a, Minimum Flows for Resident Trout on Alameda Creek, and Mitigation Measure 5.4.5-3b, Alameda Diversion Dam Diversion Restrictions or Fish Screens (Vol. 4, Chapter 6, pp. 6-52 to 6-54), the SFPUC would complete site-specific studies to determine appropriate bypass flows to address impacts on the resident trout fishery in Alameda Creek below the diversion dam. As stated in Measure 5.4.5-3a, providing minimum flows below the dam would support resident trout spawning and egg incubation; it is also expected that this measure would be sufficient to sustain the resident trout population in this reach of the creek, which is limited due to natural drying of the stream channel in alluvial sections during the summer months (Sak, 2007). As stated above and further discussed in Section 14.9.4, the SFPUC is committed to the ongoing management and stewardship of the Alameda Creek watershed, including fishery enhancement projects and measures to provide flows for native stream-dependent species, as detailed in Section 14.9.1, above.

Other Native Stream-Dependent Species

Comments received from the CDFG noted that Mitigation Measure 5.4.5-3a, Minimum Flows for Resident Trout on Alameda Creek, may not provide adequate protective flows for steelhead and native stream-dependent species. In response to the comment recommending further study to determine whether sufficient water will be available for different life stages of fish and native stream-dependent species, the Draft PEIR mitigation measure incorporates site-specific studies and coordination with the ACFRW to determine the appropriate minimum stream flow. Section 14.9.4 presents a detailed analysis of current habitat conditions for different life stages of steelhead and rainbow trout, the potential impacts of WSIP implementation on these various life stages, and the status of studies on instream flow requirements to protect fishery resources. Please refer to Section 14.9.4, below, as well as **Response S_CDFG2-15** and **Response L_ACWD-22** (Vol. 6, Chapter 15, Sections 15.2 and 15.3, respectively) for more discussion of bypass flows in Alameda Creek.

In response to comments regarding the ACDD bypass flows and reevaluation of Mitigation Measure 5.4.5-3a, the measure has been expanded to address other species and life stages. The following three excerpts from the Draft PEIR are revised as follows:

Vol. 3, Chapter 5, p. 5.4.6-19, third full paragraph:

> Overall, implementation of the proposed WSIP water supply and system operations would result in *potentially significant* impacts on terrestrial biological resources due to a potential reduction in aquatic breeding habitat for key special-status species. Measure 5.4.1-2, Diversion Tunnel Operation, calls for operation of the diversion tunnel in a manner that ensures that flows not required to maintain storage in Calaveras Reservoir are passed down Alameda Creek at the diversion dam. Measure 5.4.5-3a, Minimum Flows for Resident Trout on Alameda Creek, calls for <u>developing and implementing an operational plan to provide</u> minimum <u>bypass</u> flows below the diversion dam <u>to support habitat for rainbow trout and other native stream-dependent species</u> from December through April. Implementation of these measures would ensure that minimum flows in Alameda Creek are allowed to pass by the diversion dam. Taken together, these measures would reduce adverse impacts on key special-status species to a less-than-significant level.

Vol. 4, Chapter 6, p. 6-52, first paragraph under Fisheries, first sentence:

> **Measure 5.4.5-3a:** The SFPUC shall develop and carry out as part of the implementation of the Calaveras Dam Replacement (SV-2) project, an operational plan to implement minimum ~~stream~~ bypass flows when precipitation generates runoff into the creek below the diversion dam to the Calaveras Creek confluence from December 1 through April 30 to support ~~resident trout~~ spawning and egg incubation for resident trout as well as breeding habitat for other native stream-dependent amphibians.

Vol. 4, Chapter 6, p. 6-53, first paragraph, last sentence:

> The operational plan will allow for adapting minimum flow amounts to support resident trout spawning and egg incubation and other native stream-dependent species based on the monitoring results and best available scientific information.

Section 14.9.4, below, provides a detailed discussion of planned steelhead restoration within the Alameda Creek watershed and assesses potential cumulative effects on steelhead that could result from WSIP implementation. As described in Section 14.9.4, successful implementation of planned and proposed fishery enhancement projects would result in the removal of many barriers to passage for anadromous steelhead within Alameda Creek. As described in Section 14.9.1 above, when steelhead passage is restored to the upper watershed, the SFPUC will work with the CDFG and NMFS to comply with the applicable FESA requirements for steelhead through the Alameda Watershed HCP or other regulatory mechanism. Currently, the SFPUC is developing the Alameda Watershed HCP in compliance with FESA, which will addresses operation (but not construction) of the Calaveras Dam Replacement project (SV-2), and steelhead is a covered species in the HCP. The HCP is a long-term mechanism in which the SFPUC and regulatory agencies are assessing the requirements for steelhead restoration and other native fish and aquatic species in the watershed affected by SFPUC water system operations.

SFPUC's Ongoing Management and Stewardship of the Alameda Watershed

Comments also requested clarification of the SFPUC's position regarding the presence of steelhead in the upper watershed, and the reasons for SFPUC involvement in fishery enhancement projects upstream of the BART weir if the current understanding is that steelhead are not present in the upper watershed. Sections 5.4.5 and 5.7.3 of the Draft PEIR (Vol. 3, Chapter 5) discuss the SFPUC's involvement in habitat improvement programs planned for the Alameda Creek watershed.

The SFPUC manages its Alameda watershed lands to benefit a wide range of species, habitat, and natural resources in addition to specific efforts to restore steelhead to Alameda Creek. The SFPUC's watershed management and stewardship policies are detailed in the *Alameda Watershed Management Plan* (SFPUC, 2001) and the Water Enterprise Environmental Stewardship Policy (SFPUC, 2006). The SFPUC has dedicated much time and funding toward numerous long-term efforts to improve steelhead habitat and passage within the watershed, such as the recent removal of the Sunol and Niles Dams; it is also a major participant in the ACFRW, which is focusing on the restoration of steelhead to Alameda Creek. The SFPUC's work with the ACFRW includes developing a long-term strategy that encompasses a range of watershed management goals.

Additionally, independent of involvement in the ACFRW's fishery enhancement projects, the SFPUC has funded studies to better understand the biological characteristics required for successful steelhead restoration. It is the policy of the SFPUC to operate the SFPUC water system in a manner that protects and restores native fish and wildlife downstream of SFPUC dams and water diversions, within SFPUC reservoirs, and on SFPUC watershed lands.

14.9.3 Impacts on Steelhead in Lower Alameda Creek below the BART Weir

Introduction

This section of the master response addresses comments concerning the analysis of the WSIP's potential effects on steelhead and flows in lower Alameda Creek downstream of the BART weir. This section is organized by the following subtopics:

- Lower Alameda Creek as a Migration Corridor and a Transition Zone for Steelhead Smolts
- Impacts on Stream Flow and Fisheries Downstream of the BART Weir

Comment Summary

This section of this master response responds to all or part of the following comments:

L_ACFCWCD-04	L_ACWD-09	L_ACWD-19
L_ACFCWCD-14	L_ACWD-12	L_Zone7-01
L_ACWD-07	L_ACWD-17	SI_ACA1-02

Summary of Issues Raised by Commenters

- The discussion of lower Alameda Creek as a transition zone for steelhead is inadequate.
- Inadequate discussion of project impacts on steelhead below the middle inflatable dam.
- Lower Alameda Creek flow diversions would affect fisheries and habitat in the flood control channel.
- The WSIP would reduce winter and spring flows by 50 percent in normal years and could adversely affect steelhead passage below the BART weir.
- Flows below the recapture facility should be addressed; flows should be allowed to pass downstream.

Response

Lower Alameda Creek as a Migration Corridor and a Transition Zone for Steelhead Smolts

Comments on the Draft PEIR raised concern that reduced flows below the BART weir resulting from the WSIP would affect the estuarine zone of Alameda Creek and reduce the potential for steelhead smolt development within this possible zone of transition to marine waters.

The flood control channel represents the 12-mile reach of Alameda Creek from the confluence with San Francisco Bay to the mouth of Niles Canyon. It is an artificially managed and modified environment with a heavily sedimented, sandy bottom and riprap sides. The low riparian cover and high summer water temperatures in this creek section (Hanson, 2002a, 2002b) are not suitable for summer rearing by coldwater fish species. Gunther et al. (2000) classify the geographic range of the flood control channel as non-viable habitat for steelhead spawning or rearing.

Tidal influence in the flood control reach of lower Alameda Creek falls short of Alameda County Water District's (ACWD) lowermost inflatable dam (Gunther et al., 2000); unless flows overtop or bypass the inflatable dam, the channel below the inflatable dams can become dry, further reducing the potential under current conditions for the flood control channel to provide viable smolt transition habitat. Under typical operating conditions, ACWD's inflatable dams are raised to facilitate the diversion of flows into off-channel recharge areas, except during peak storm events.

Currently, no summer rearing habitat exists in this reach of lower Alameda Creek that could be considered suitable for either steelhead or rainbow trout. The 12-mile reach of the flood control channel, extending upstream to Niles Canyon, is a simplified system without natural features (such as pool/riffle sequences) and, even after the implementation of future restoration projects, it would primarily offer only migratory habitat (see Section 14.9.4, below). Implementation of the WSIP, as outlined in the Draft PEIR, would not affect smolt development in this section of the creek, as no suitable habitat exists within this reach for smolt development due to the physical characteristics of the engineered flood control channel. Additionally, implementation of the WSIP would not significantly affect the potential for steelhead to continue using this stretch as a migratory corridor. The response presented below addresses the potential impacts on migrating salmonids due to changes in seasonal flow under the WSIP, including the continued use of this creek reach as a migratory corridor.

Impacts on Stream Flow and Fisheries Downstream of the BART Weir

Comments raised concern that increased diversions under the WSIP would adversely affect steelhead passage in the 9.5 miles of channel from San Francisco Bay to the BART weir, and that the Draft PEIR did not contain sufficient analysis of impacts on stream flow and fisheries in the lower section of Alameda Creek.

The Draft PEIR (Vol. 3, Chapter 5, pp. 5.4.1-16 to 5.4.1-43) describes the changes in stream flow and reservoir water levels that would result from the WSIP. Impact 5.4.1-4 (pp. 5.4.1-39 to 5.4.1-43) discusses the analyses conducted on stream flow changes that would occur under the WSIP, and the potential impact of WSIP implementation on flow along Alameda Creek below the confluence with San Antonio Creek. The Draft PEIR analysis concluded that average monthly flows in Alameda Creek below the confluence with San Antonio Creek would be lowered due to the WSIP in winter months of normal or wetter years. It was also determined that changes in flow would be substantially dampened by inflows from other tributaries in the Sunol Valley; therefore, no adverse hydrological effects would result, and no mitigation measures would be required. Additionally, in considering the WSIP-related effects on flow in Alameda Creek, along with fishery flow releases (under the Calaveras Dam Replacement project, SV-2) being recaptured (under the Alameda Creek Fishery Enhancement project, SV-1), the Draft PEIR analysis found there would be no change in average monthly flows in most months of normal and wetter years, and no change in those flows in all months of drier years.

Section 5.4.5 of the Draft PEIR (Vol. 3, Chapter 5) describes fishery resources in Alameda Creek and the potential impacts that would result from the WSIP. Impact 5.4.5-6 (Vol. 3, Chapter 5, pp. 5.4.5-21 and 5.4.5-22) describes the WSIP's effects on fishery resources along Alameda Creek below the confluence with San Antonio Creek. The analysis concluded that potential impacts on fishery resources and habitat along Alameda Creek downstream of the confluence with San Antonio Creek would be less then significant, and no mitigation measures would be required.

In order to address comments regarding the WSIP's impacts on steelhead passage and fishery habitat in lower Alameda Creek downstream of the BART weir (to the confluence with San Francisco Bay), additional stream flow analysis was conducted (see Vol. 8, **Appendix N**); this analytical effort is summarized in the paragraphs that follow.

Downstream of the confluence of Alameda and San Antonio Creeks, Alameda Creek joins with the other major tributary in the Alameda Creek watershed, Arroyo de la Laguna. Below this confluence Alameda Creek enters Niles Canyon and flows for approximately 3.5 miles before exiting the canyon. Lower Alameda Creek, which begins downstream of the Niles Canyon reach, is a low-gradient creek characterized by flood control channels and several instream structures, including the BART weir and ACWD inflatable dams used for water diversion. The ACWD utilizes the lower creek for water supply via diversions and groundwater recharge. Lower Alameda Creek ultimately discharges to San Francisco Bay approximately 12 miles downstream of Niles Canyon.

Recent USGS flow records from three gaging stations on Alameda Creek (upstream of the San Antonio Creek confluence, near the downstream end of Niles Canyon, and from Arroyo de la Laguna) were reviewed to estimate the proportion of flow that upper Alameda Creek and Arroyo de la Laguna contribute to the lower reaches of Alameda Creek. The flow proportions were used to estimate the changes in flow that would occur in lower Alameda Creek as a result of the WSIP for hydrologic years 2000 to 2007.[2] **Figure 14.9-1** presents the locations of the three USGS gaging stations (labeled AC Welch, ADLL, and AC Niles) from which data were analyzed, and the contributing watersheds for each of the gages.

---

2 This analysis takes into account both the "Calaveras Up" and "Calaveras Down" base-case HH/LSM results because historical gage data were used in the analysis, and the Division of Safety of Dams (DSOD) restriction on Calaveras Dam operations was implemented during the period of analysis (in 2002). Therefore, the analysis uses model data from the Calaveras Up condition (prior to the DSOD restriction) for hydrologic years 2000 to 2001, and model data from the Calaveras Down condition (after the DSOD restriction and the base-case used for the Draft PEIR impact analysis) for the remainder of the years.

Figure 14.9-1
Location of 3 USGS Gages and
Contributing Watersheds for Lower Alameda Creek

Data from the three USGS gages were reviewed on an average monthly flow basis for overlapping periods of record (hydrologic years 2000 to 2007). Diversions from upper Alameda Creek to Calaveras Reservoir were substantially curtailed starting in 2002 due to the operating restrictions imposed on Calaveras Reservoir by the California Department of Water Resources, Division of Safety of Dams (DSOD). **Figure 14.9-2** presents average monthly flows over the eight-year period for the three gages. Review of the flow data reveals that flow measured at the Arroyo de la Laguna gage (shown as a blue shaded area) generally contributes a higher percentage of the flow measured at the Niles gage (shown as a black line) compared to that measured at the Welch gage (shown as a green shaded area). The discrepancy between the summation of the Arroyo de la Laguna and Welch gage flows and flow at the Niles gage (the white space below the black line) is assumed to be inflow from the watershed between the two upper gages and the Niles gage (labeled “Niles–SA watershed” on Figure 14.9-1).

Included in the Niles–San Antonio Creek watershed are releases made from the State Water Project, flow from San Antonio Creek, and contributions/losses from the watershed that occur downstream of the two upper gages.

Releases or spills from San Antonio Reservoir rarely occur. Most flows in San Antonio Creek result from groundwater seepage or runoff from the watershed downstream of Turner Dam. The Niles–San Antonio Creek watershed contribution noted in summer months (as a gap between the green and blue areas and the black line) is assumed primarily to be releases from the State Water Project and contribution from groundwater in Niles Canyon. Also notable in the chart are the spikes in flow from upper Alameda Creek in the winter and spring of the hydrologic years 2005 and 2006. These spikes are a result of above-normal runoff in the watershed combined with the restricted Calaveras Reservoir storage and required releases from the reservoir to maintain the DSOD-restricted level.

The data presented in Figure 14.9-2 were analyzed to determine the percentage of flow contributed by each of the watersheds tributary to the Niles gage (identified in Figure 14.9-1). **Tables 14.9-1** and **14.9-2** present the relative contribution of the upstream watersheds to flow at the Niles gage over the past eight hydrologic years, from 2000 to 2007.

SUMMARY OF FLOW CONTRIBUTIONS AT THE NILES GAGE
HYDROLOGIC YEARS 2000–2007

Watershed	Eight-Year Average Contribution	Eight-Year Range of Contribution
Arroyo de la Laguna	55%	43% – 71%
Upper Alameda Creek	33%	5% – 46%
Niles–San Antonio Creek	13%	8% – 27%

SOURCE: Hydroconsult Engineers Inc., 2008 (see Appendix N)

This analysis reveals that on average, approximately one-third of the flow at the Niles gage results from the upper Alameda Creek watershed. Since all SFPUC operations occur within the upper Alameda Creek watershed, implementation of the WSIP would only affect approximately one-third of the upstream flow that contributes to flow at the Niles gage. As such, flow changes in upper Alameda Creek as a result of the WSIP would be dampened in lower Alameda Creek by inflow from the other sub-watersheds. For instance, a flow of 100 cfs for Alameda Creek could hypothetically be reduced by 25 percent in a given month under the WSIP, resulting in a flow of 75 cfs for Alameda Creek. The same hypothetical flow at the Niles gage would be 300 cfs without the WSIP and 275 cfs with the WSIP, corresponding to an 8 percent reduction.

The results from the HH/LSM showing the percentage reductions in monthly flow for Alameda Creek below the San Antonio Creek confluence (see the Draft PEIR, Vol. 3, Chapter 5, Table 5.4.1-11, p. 5.4.1-42) were applied to monthly gage flow data from the Welch gage. Although the Welch gage and the HH/LSM analysis location of Alameda Creek below the San Antonio Creek confluence are not the same, this difference is not considered significant for this analysis. The San Antonio Creek confluence is approximately 2.7 miles downstream of the Welch gage, and the analysis presented in this section applies the percentage change in flow from the HH/LSM analysis, not actual flow data, to the Welch gage. Therefore, any difference in flows at the two locations would not affect this analysis, since the percentage reduction in flow was considered applicable to flow in Alameda Creek in the vicinity of the Welch gage.

Table 14.9-3 presents the flow changes estimated using the HH/LSM. The resulting changes in flow at the Welch and Niles gages are shown in **Tables 14.9-4** and **14.9-5** and **Figure 14.9-3**. Table 14.9-4 presents the results of applying the HH/LSM flow reductions to records from the Welch gage for the hydrologic years 2000–2007. Figure 14.9-3 and Table 14.9-5 detail the predicted changes in flow in Alameda Creek at the Niles gage over the eight-year period (2000–2007) with implementation of the WSIP. The solid blue area in Figure 14.9-3 represents average monthly flow at Niles, and the black line indicates calculated flow with implementation of the WSIP. The discrepancy between the two lines represents a change between gage records and calculated flow under the WSIP.

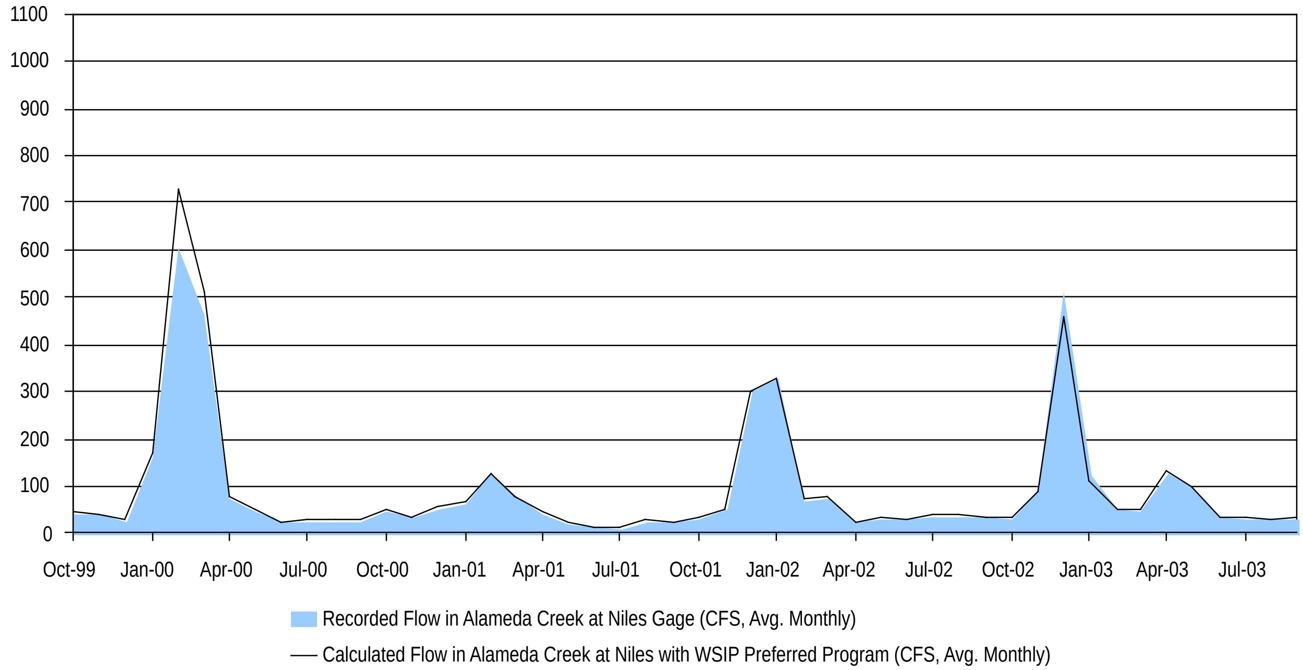
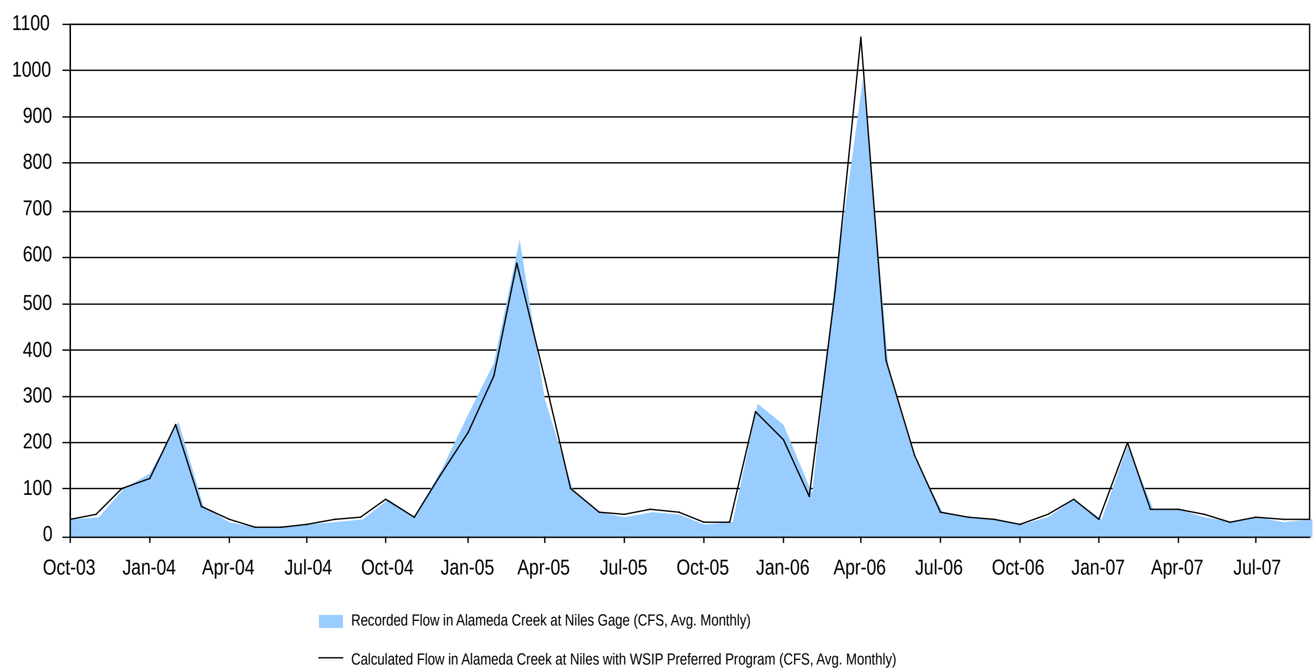
NOTE: The portion of the table titled “Calculated Flow at Niles for Revised WSIP” represents the future condition with implementation of the WSIP. “Revised” WSIP refers to the 2008 updated modeling results, as discussed in Section 13.3 (Vol. 7).

SOURCE: Hydroconsult Engineers Inc., 2008 (see Appendix N)

The analysis shows that based on the historical hydrology from 2000 to 2007, reductions in flow in Alameda Creek at Niles Canyon would occasionally occur under the WSIP. Reductions of up to 18 percent in average monthly flow could occur in years similar to the past eight years of record. The maximum flow reduction would occur during January of an above-normal year, but a flow increase of 13 percent would occur in April of that same hydrologic year type. No changes in flow would occur in dry years, and minimal changes (up to 3 percent reductions) would occur in February of below-normal years. It should be noted that in 2000—an above-normal year—there would be an increase in flow of up to 20 percent under the WSIP; this year represents historical operating conditions prior to the DSOD operating restrictions placed on Calaveras Dam. The past eight years include four of the five hydrologic year types (only a wet year is absent). However, as shown in Table 14.9-5, the greatest flow changes under the WSIP would occur during normal and above-normal years, which are represented in the 2000–2007 data and are therefore included in this analysis.





Notes:
- WSIP conditions includes recapture of MOU flows released from Calaveras Dam.
- Years 2000 and 2001analysis includes a comparison of Base with Calaveras Up vs WSIP Proposed Program. DSOD restriction was implemented in
- Analysis for WSIP only, no other cumulative projects analyzed.

SOURCE: SFPUC Water System Improvement Program

Figure 14.9-3
Comparison of Average Monthly Flow at the Niles Gage, Recorded Flow versus WSIP Proposed Program

The impact conclusion for Impact 5.4.1-4 (Vol. 3, Chapter 5, p. 5.4.1-43) states: "Flow in Alameda Creek below the confluence of San Antonio Creek would be altered as a result of the WSIP in winter months of normal or wetter years; however, the change in flows would be substantially dampened by inflows from other tributaries in the Sunol Valley and would not result in adverse hydrologic effects." The analysis presented in this section corroborates and provides further supporting detail for this impact conclusion, and also estimates the dampening effect. The largest calculated decrease in flow in lower Alameda Creek would occur during January 2005, with a reduction in average monthly flow of 46 cfs, or 18 percent, of the average monthly flow recorded in January 2005. This corresponds to a reduction in upper Alameda Creek flow of 39 percent. Further review of the data reveals that flow reductions are predicted to occur in December through March of normal to wet years and in April of wet years, and to a small degree in February of below-normal years. In all other months, including winter months of below-normal years (with the exception of a slight decrease in February) and dry years, flow in upper Alameda Creek and at the Niles gage would either remain the same or would increase with implementation of the WSIP.

The calculated flows for lower Alameda Creek under the WSIP are within the range of current flows in this segment of the creek. Further, the flood control infrastructure and water supply facilities in lower Alameda Creek were constructed and operational well before the current DSOD restriction on Calaveras Reservoir required the SFPUC to reduce its diversions at the ACDD. The HH/LSM results indicate that, compared to the flow conditions in existence prior to the DSOD restriction on Calaveras Reservoir, flows in lower Alameda Creek under the WSIP would increase in winter months of normal to wet years (with the exception of slight decreases in March and April of wet years) and would remain the same in all other months of other year types. Therefore, implementation of the WSIP would not affect the operation of flood control infrastructure and water supply facilities in lower Alameda Creek.

The stream flow analysis for the lower 12-mile reach of Alameda Creek from downstream of Niles Canyon to the confluence with San Francisco Bay demonstrates that the WSIP would not affect steelhead passage, fisheries, or fish habitat during any month of a below-normal or drier year (see Table 14.9-5). The analysis also demonstrates that no WSIP-related impacts on steelhead passage, fisheries, or fish habitat would occur between April and November for normal or wetter years (Table 14.9-5). As the table shows, the maximum calculated reduction in flow would occur during the winter months of normal and wetter years (from 262 to 216 cfs), and these flows are within the range of recorded flows typical for this segment of Alameda Creek (from 28 to 638 cfs). The WSIP is therefore unlikely to affect steelhead passage, fisheries, or fish habitat in this reach. Draft PEIR Section 5.4.5.1 (Vol. 5, Chapter 5, pp. 5.4.5-9) discusses steelhead passage improvement projects for the flood control channel of Alameda Creek at the BART weir. Studies conducted on these potential improvement projects estimate that the minimum level of flow needed to ensure adult steelhead passage could range from 10 to 50 cfs for projects that involve total removal of the structure and restoration of a "roughened channel" as well as for projects that involve three ladder and screen options.

Therefore, the impact conclusion for Impact 5.4.5-6 (Draft PEIR, Vol. 3, Chapter 5, pp. 5.4.5-21 and 5.4.5-22) that "impacts on Alameda Creek below the confluence of San Antonio Creek would be less than significant, and no mitigation measures would be required" is supported by the additional analysis performed.

14.9.4 Steelhead – Future Fishery Scenario and Potential Cumulative Effects

Introduction

Several comments expressed concern that the Draft PEIR did not identify potential WSIP impacts under a future scenario in which steelhead have been restored to the reaches of Alameda Creek above the BART weir, as is expected to occur following the implementation of several proposed projects to remove current fish passage barriers. As discussed in the Draft PEIR (Vol. 3, Chapter 5, pp. 5.4.5-1 to 5.4.5-15) and in Section 14.9.2 of this master response, steelhead are precluded from naturally migrating to spawning habitat upstream of the BART weir under existing baseline conditions. In accordance with CEQA Guidelines Section 15125, the Draft PEIR assessed the WSIP's effects with respect to existing conditions in the program area, and therefore did not address potential effects on steelhead (or steelhead habitat) above the BART weir.

The Draft PEIR provides a full discussion of proposed plans to restore anadromous steelhead to Alameda Creek above the BART weir, including the many steps required, parties involved, and agreements in place to accomplish this goal (Vol. 3, Chapter 5, Section 5.4.5.1). The Draft PEIR discusses the planned restoration of steelhead above the BART weir and describes the SFPUC's active participation with other agencies to achieve steelhead restoration; as the PEIR states, once such restoration occurs, the SFPUC will comply with all applicable environmental regulations (FESA foremost among them) to ensure that its water system operations and watershed management practices incorporate conservation measures to protect steelhead. The SFPUC is engaged in consultation with the USFWS, NMFS, and CDFG to prepare a plan for FESA and California Endangered Species Act (CESA) compliance. This plan, called the Alameda Watershed HCP, will address the potential effects of SFPUC water system operations and watershed management activities on several listed species within the SFPUC's Alameda watershed lands, including steelhead. Thus, the SFPUC is actively engaged with the resource agencies in developing appropriate measures to protect this species once steelhead have been restored to this reach of the creek.

Although the presence of steelhead in Alameda Creek above the BART weir is not an "existing condition" as defined by CEQA, it is a possible future condition that could occur through the cumulative implementation of the many proposed projects and actions designed to restore steelhead in Alameda Creek. In response to the comments received on this issue, the Draft PEIR analysis of cumulative effects (Vol. 3, Chapter 5, pp. 5.7-52 to 5.7-67) has been revised to incorporate a discussion of potential WSIP impacts on future-occurring steelhead. This section of this master response provides an expanded discussion of the "future cumulative scenario" (which assumes that the steelhead fishery has been restored above the BART weir) and then discusses the potential effects of the WSIP on potential future-occurring steelhead. Following this expanded discussion, specific text revisions to the Draft PEIR are identified.

The analysis of the WSIP's contribution to potential, cumulative effects (both positive and negative) on future-occurring steelhead is general because many uncertainties remain regarding how and when steelhead will be restored as well as the future environmental conditions that will be present in Alameda Creek at that time. Uncertainties regarding steelhead restoration include, but are not limited to the following: the way in which existing barriers to passage would be remedied in the future; the extent to which natural features act as barriers; and the extent to which the varying water resource operations of the water agencies in the overall Alameda Creek basin influence flows. Protective measures to address and minimize the WSIP's contribution to future cumulative effects on steelhead are included as part of the WSIP program description (incorporated as changes to the project descriptions of the Alameda Creek Fishery Enhancement, SV-1, and Calaveras Dam Replacement, SV-2, projects). As described in Section 14.9.1, above, such protective measures would include: SFPUC reservoir releases and bypass flows to support minimum instream flow requirements, operational modifications (reservoir diversion and release protocols), and monitoring/studying/surveying steelhead habitat below the ACDD. These measures demonstrate the SFPUC's commitment described in the Draft PEIR and the Comments and Responses documents—that the SFPUC would implement the necessary protective measures for steelhead once they are restored, in compliance with applicable environmental regulations including FESA and CESA.

This section of the master response is organized by the following subtopics:

- Future Cumulative Scenario for Steelhead
  - Introduction

Summary of Issues Raised by Commenters

- The effects of the WSIP combined with proposed fish passage improvement projects and steelhead restoration to the upper watershed are not adequately addressed.
- Additional diversions under the WSIP would result in the "take" of listed species through reduced passage and increased temperatures.
- The Draft PEIR contains insufficient information to support the contention that mitigation measures would reduce impacts to a less-than-significant level.
- Specific flow information is required for adequate mitigation of impacts on steelhead passage, spawning, and juvenile rearing.
- Issues related to releases required under two memoranda of understanding: the 1997 CDFG MOU and 2006 ACFRW MOU.
- Relationship of the Draft PEIR assessments to the Calaveras Dam Replacement project-level assessments is unclear.
- The impacts of Calaveras Dam on steelhead/trout in 2010–2012 are not speculative.

Response

Future Cumulative Scenario for Steelhead

Introduction

As described briefly above, it is possible that steelhead could be restored to the Alameda Creek watershed reaches upstream of the BART weir by 2030, the WSIP planning horizon. More specifically, steelhead could be restored during construction or operation of the Calaveras Dam project. In response to this scenario, the SFPUC has modified the project descriptions for components of the proposed program—the Alameda Creek Fishery Enhancement (SV-1) and Calaveras Dam Replacement (SV-2) projects—to recognize this potential for future steelhead restoration, as summarized in Section 14.9.1, above. The modifications to these projects include project revisions that would be implemented regardless of the success of planned and proposed projects to restore steelhead to the upper Alameda Creek watershed, as well as protective measures that would be implemented in the event that the NMFS and/or CDFG have determined steelhead to be present in Alameda Creek above the BART weir, construction of the Calaveras Dam Replacement project is complete, and the Alameda Watershed HCP has yet to be finalized. As summarized in Section 14.9.1, the protective measures have been incorporated into the

Calaveras Dam Replacement project component of the WSIP to address potential effects on steelhead in the event that planned and proposed projects to remove man-made barriers in Alameda Creek are successfully implemented and anadromous steelhead gain access to the upper Alameda Creek watershed. The WSIP's potential contribution to future cumulative effects on steelhead is evaluated here with respect to steelhead life-stage and habitat requirements in the various reaches of Alameda Creek.

The future cumulative scenario for the steelhead fishery in Alameda Creek assumes implementation of all necessary proposed projects and actions to remove the existing fish passage and migration barriers for steelhead, from the BART weir up to spawning and rearing habitats in the upper reaches of Alameda Creek. Under this future cumulative scenario, steelhead are assumed to be present in Alameda Creek above the BART weir. A more detailed discussion of this potential future scenario follows, including: a summary of the regulations, plans, and programs related to steelhead recovery in the Alameda watershed; a review of steelhead life stages and habitat requirements; and the expected future habitat conditions for steelhead following the removal of passage barriers.

This assessment of future conditions does not describe: the specifics of any barrier removal/bypass projects (since no specific adopted designs/plans are available); what flow requirements for reservoir releases, bypass flows at the ACDD, or flows through fish ladders might be adopted; or when (and if) the projects would be undertaken. Thus, this future cumulative scenario is based on a fair degree of speculation, but the information available at this time allows for a general framing of potential future conditions and discussions of the potential WSIP contribution to future cumulative effects.

Regulations, Plans, and Programs Related to Steelhead Recovery in the Watershed

Draft PEIR Section 5.4.5 (Vol. 3, Chapter 5, p. 5.4.5-4) includes a discussion of the regulatory status of steelhead in the Alameda Creek watershed, and Section 5.2 (Vol. 3, Chapter 5, pp. 5.2-1 to 5.2-26) provides an overview of plans and policies relevant to the management of the SFPUC's water supply and system operations, including regulations, policies, plans, and programs related to steelhead recovery in the watershed. Comments on the Draft PEIR expressed concern regarding the take of listed species (defined below under Federal Endangered Species Act) as a result of WSIP implementation. The following information on regulations, plans, and programs related to steelhead recovery augments the information presented in the Draft PEIR.

Federal Endangered Species Act. Pursuant to FESA, the USFWS and NMFS have authority over projects that may result in the take of a federally listed species. Under FESA, "take" means to "harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct." The USFWS has also interpreted the definition of "harm" to include significant habitat loss or modification. If a project could affect a federally listed species, either an incidental take permit under FESA Section 10(a) or a federal interagency consultation under FESA Section 7 is required. The USFWS has regulatory jurisdiction over freshwater and estuarine fishes as well as all terrestrial vegetation and wildlife, while the NMFS has jurisdiction over anadromous and marine species, including steelhead.

The NMFS has not designated the Alameda Creek watershed as critical habitat for steelhead, and has listed as threatened only those steelhead that currently exist below the lowest impassable barriers in the Alameda Creek watershed (i.e., the BART weir). Thus, the resident rainbow trout that occur in the creek above the BART weir are not designated as a listed species and are not proposed for listing. However, the NMFS has advised that the designation of critical habitat would be open to further evaluation if and when anadromous steelhead obtain passage to upper Alameda Creek (as discussed in Section 14.9.2, above). As noted, this cumulative impact assessment is based on the assumption that steelhead will regain access to the Alameda Creek watershed in the future.

Alameda Creek Fisheries Restoration Workgroup. The ACFRW is a multi-agency stakeholder group formed in 1999 to pursue the restoration of steelhead to Alameda Creek. The ACFRW is composed of numerous community and citizens' groups, local water management and flood control agencies, and state and federal resource agencies, including the SFPUC.

With funding from the ACFCWCD and the California Coastal Conservancy, the ACFRW published a report entitled *An Assessment of the Potential for Restoring a Viable Steelhead Trout Population in the Alameda Creek Watershed* (Gunther et al., 2000). The report found that suitable habitat exists in the watershed to support steelhead spawning and rearing, but that several barriers in the lower portion of the watershed completely prevent adult migration upstream. It concluded that making these barriers passable was essential to steelhead restoration in Alameda Creek, and made recommendations to address migration and other steelhead restoration issues in the watershed.

The ACFRW has identified the need to implement passage barrier modification projects, install positive-barrier fish screens at water diversion points, modify instream flows within the four reaches of Alameda Creek, and implement proposed riparian corridor improvements and possibly a steelhead supplementation program. The Draft PEIR discusses the ACFRW's Memorandum of Understanding (2006 ACFRW MOU) to perform steelhead flow studies, the various phases and elements of the studies, and the development of the Alameda Watershed HCP (Vol. 3, Chapter 5, pp. 5.4.5-10 and 5.4.5-11).

SFPUC Alameda Watershed Habitat Conservation Plan. The SFPUC, working with the CDFG, USFWS, and NMFS, is in the process of developing an HCP for its portion of the Alameda Creek watershed in compliance with FESA and CESA. Steelhead is a covered species in the HCP, which is scheduled for public review in 2009. The plan will require preparation of a joint environmental impact report/environmental impact statement (EIR/EIS) before the SFPUC can consider adoption and begin implementation of the HCP conservation strategies. The HCP will be the primary plan in which the SFPUC and regulatory agencies lay out the program and requirements for the restoration of steelhead and other fish species in the watershed affected by SFPUC operations.

SFPUC Water Enterprise Environmental Stewardship Policy. As described in the Draft PEIR (Vol. 3, Chapter 5, pp. 5.2-24 and 5.2-25), the Water Enterprise Environmental Stewardship Policy was adopted in June 2006 and established the long-term management direction for the City and County of San Francisco's lands and natural resources affected by operation of the SFPUC regional water system within the Tuolumne River, Alameda Creek, and Peninsula watersheds. The policy includes the following points specifically relevant to the fishery issues in the Alameda Creek watershed:

- It is the policy of the SFPUC to operate the SFPUC water system in a manner that protects and restores native fish and wildlife downstream of SFPUC dams and water diversions, within SFPUC reservoirs, and on SFPUC watershed lands.

- Releases from SFPUC reservoirs will (consistent with the SFPUC mission, existing agreements, and applicable state and federal laws) mimic the variation of the seasonal hydrology (e.g., magnitude, timing, duration, and frequency) of their corresponding watersheds in order to sustain the aquatic and riparian ecosystems upon which these native fish and wildlife species depend (consistent with the SFPUC mission, existing agreements, and applicable state and federal laws).

The Environmental Stewardship Policy calls for specific integration of this policy into the WSIP and individual infrastructure projects.

Steelhead Life Stages and Habitat Requirements

A summary of steelhead life stages (e.g., migration, spawning, rearing) and habitat requirements is provided in the Draft PEIR (Vol. 3, Chapter 5, pp. 5.4.5-4 to 5.4.5-7). The following discussion augments the Draft PEIR discussion and focuses on different steelhead life-stage and habitat requirements in the Alameda Creek watershed. This information was derived from studies/ assessments of steelhead recovery in the Alameda Creek watershed, including the following:

- *Alameda Creek Population Recovery Strategies and Instream Flow Assessment for Steelhead Trout* (McBain and Trush, 2007)

- *An Assessment of the Potential for Restoring a Viable Steelhead Trout Population in the Alameda Creek Watershed* (Gunther et al., 2000)

As previously described, steelhead have a highly flexible and complex life history and may follow a variety of life-history patterns and strategies. Historical (pre-1900s) steelhead life-history strategies in the Alameda Creek watershed likely occurred within two broad categories: (1) fry were born in the upper tributaries and reared for one or two years, then migrated rapidly to San Francisco Bay, and (2) following emergence in the upper tributaries, the fry moved downstream and reared in the mainstem and/or Niles Canyon before entering the estuary and San Francisco Bay (McBain and Trush, 2007). The success of a given strategy likely varied from year to year and depended on several factors (e.g., precipitation, flow, temperature, food availability). Historically, headwater tributaries likely contributed large steelhead smolts to San Francisco Bay, especially during consecutive wet years, but many additional large smolts were likely produced by slower migrating juveniles that grew on their way downstream through the mainstem channels before smolting and entering the Alameda Creek estuary and then San Francisco Bay.

A critical period occurs during juvenile freshwater residency. Juvenile fish may remain in the watershed from less than a year to more than two years. Those residing in freshwater and/or an estuary for less than a full year from the time of egg deposition are called “0+ juveniles.”

Juveniles that spend one complete winter in freshwater and/or an estuary are termed "1+ juveniles," and those remaining for two complete winters in freshwater and/or an estuary are called "2+ juveniles." Prior to entering the Pacific Ocean, all juveniles physiologically transform into ocean salt-tolerant smolts. Smolts mature into adults and may remain in the Pacific Ocean from one to three years (or more) before returning to their natal streams to spawn. In California, most adult steelhead returning to spawn have spent at least one full winter rearing as juveniles (i.e., as 1+ juveniles) in their natal watershed (McBain and Trush, 2007).

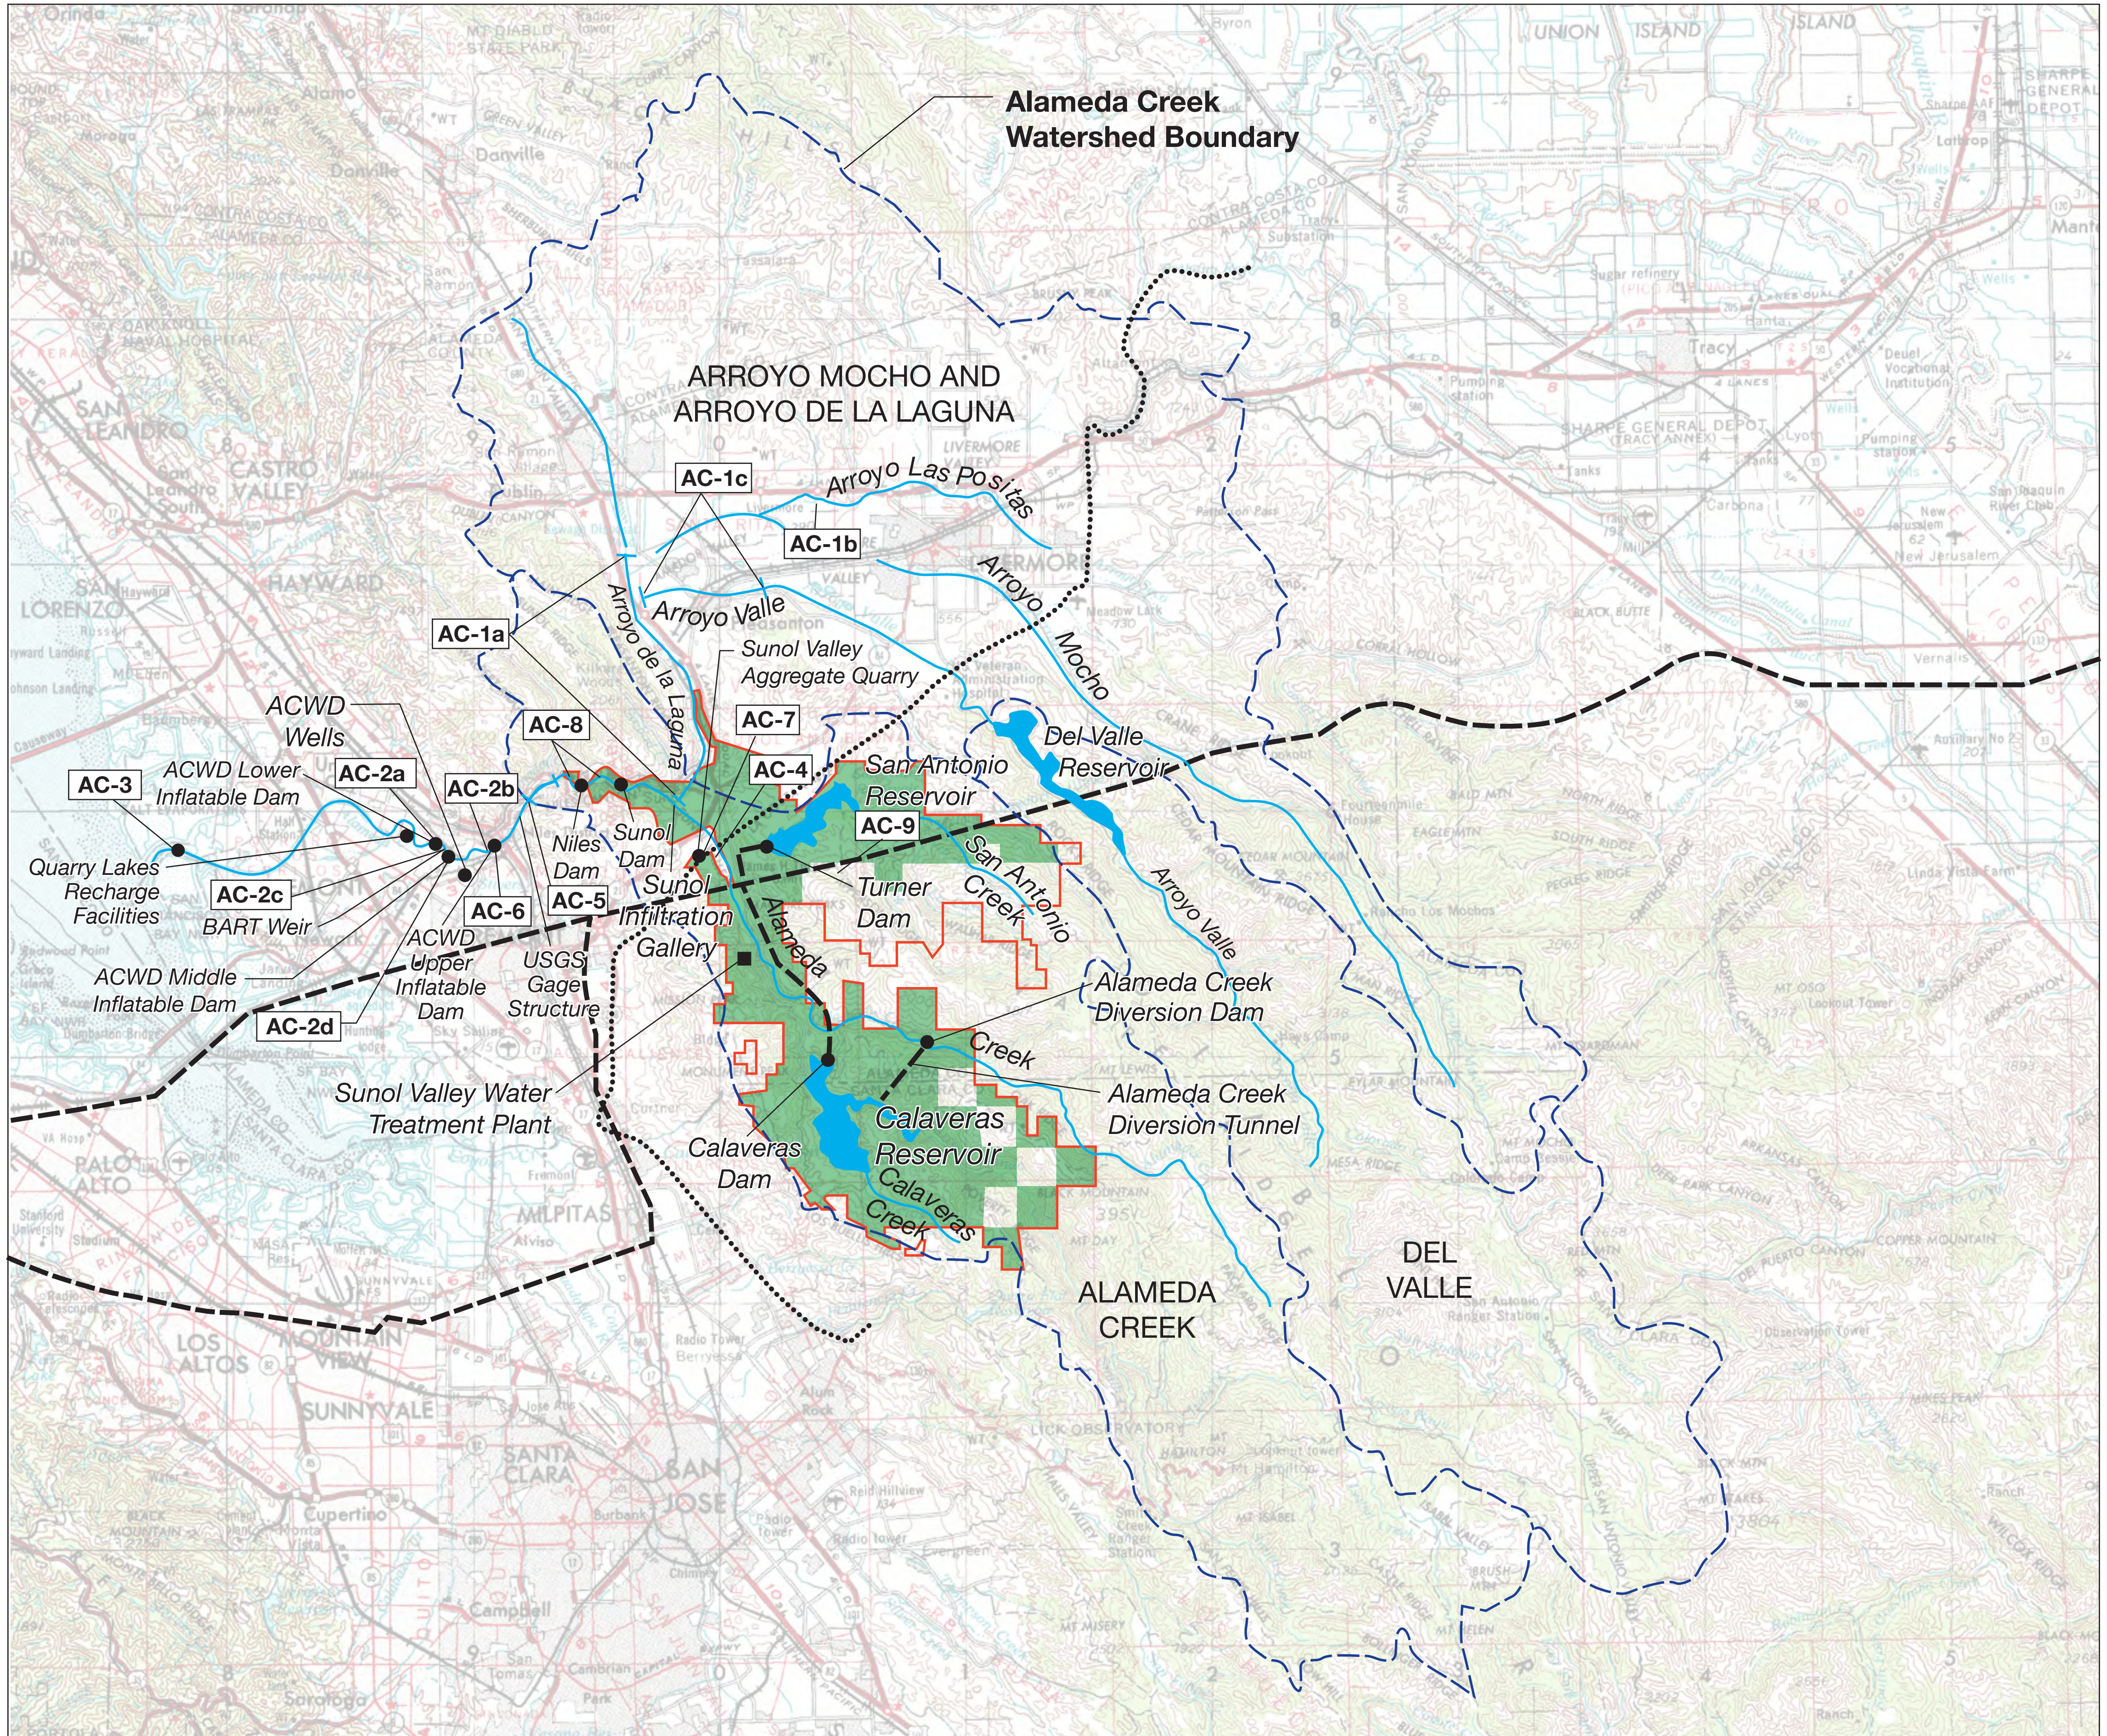
Often, each unique period of juvenile freshwater residency (i.e., staying less than a year, more than one full year, and slightly more than two full years in the watershed) is considered a separate life-history strategy. While these categories are helpful, they do not sufficiently differentiate patterns of watershed use. For example, a juvenile steelhead spending one winter in Alameda Creek (a 1+ juvenile) might reside high in the headwaters then migrate rapidly to San Francisco Bay, or it might move far downstream shortly following emergence to spend the entire winter in Niles Canyon (if suitable conditions exist) before migrating to San Francisco Bay in late spring. Both would enter San Francisco Bay as 1+ smolts, but their strategies for utilizing the watershed would have been fundamentally different (McBain and Trush, 2007).

A key factor in determining steelhead survival and recovery success is the growth of juveniles during freshwater residency and smolt transition. Fish size at smolting is important to steelhead survival, and big smolts are much more likely to return as spawning adults than small smolts (McBain and Trush, 2007). Growth rates during the juvenile rearing period are greatly influenced by both the availability (e.g., access and quantity) and quality (e.g., favorable water temperature and forage availability) of oversummer rearing habitat in the Alameda Creek watershed.

Past and Present Projects Affecting Steelhead

As presented in the Draft PEIR (Vol. 3, Chapter 5, pp. 5.4.5-7 to 5.4.5-10 and pp. 5.7-52 to 5.7-53), a number of existing facilities (i.e., past and present projects) under the jurisdiction of the SFPUC, the ACWD, Zone 7 Water Agency, and the ACFCWCD, among others, affect hydrological and fishery habitat conditions in the Alameda Creek watershed. Many of these structures and facilities have been in existence for well over 80 years and have resulted in substantial changes to the natural conditions that existed prior to the original construction of Calaveras Dam in 1913, when a steelhead run is presumed to have been present throughout the basin. Although built in the past, these facilities (as well as other influences) continue to operate and affect both current habitat conditions and future cumulative scenario conditions for potential future-occurring steelhead in the Alameda Creek watershed. Some of these are direct barriers to fish migration, while others pose various degrees of control/influence over habitat conditions. As shown in Draft PEIR **Figure 5.7-3** (as revised below), the major facilities and other factors affecting fish passage (separated by watershed and/or reach) outlined by Gunther et al. (2000) include:

- *Upper Alameda Creek*:
  - Calaveras Dam and Reservoir
  - Alameda Creek Diversion Dam and Tunnel



- Watershed Boundary
- Existing SFPUC System Corridor
- AP-1 Other SFPUC Project
- AC-1 Non-SFPUC Project
- CCSF Ownership (also project boundary for AP-1, AP-2, AP-3)
- HCP Study Area (also project boundary for AP-1a)
- DWR South Bay Aqueduct

See Draft PEIR Table 5.7-13 for names and descriptions of projects

SFPUC Water System Improvement Program . 203287

Figure 5.7-3 (Revised)
Future Projects in the Alameda Creek Watershed Considered in the Cumulative Analysis

THIS PAGE INTENTIONALLY LEFT BLANK

  - Sunol Valley aggregate quarries and the associated relocation and channelization of Alameda Creek
  - PG&E gas line crossing
  - Turner Dam and San Antonio Reservoir
  - Sunol infiltration galleries

- *Niles Canyon*:
  - USGS gage structure

- *Arroyo de la Laguna watershed*:
  - Del Valle Reservoir/South Bay Aqueduct, including State Water Project releases
  - Livermore/Amador Valley/Quarry Lakes recharge facilities
  - Various channelized and culverted stream segments
  - Expansion of urban development of the Tri-Valley Area

- *Lower Alameda Creek*:
  - ACWD's upper, middle, and lower inflatable dams
  - BART weir
  - Alameda Creek levee reconfiguration

All of these facilities, combined with urbanization and other land use activities, have resulted in substantial alteration of habitat conditions for potential future-occurring steelhead in the watershed. In 2006, the SFPUC removed two historic structures—the Niles and Sunol Dams, both located on Alameda Creek below the Sunol quarries. While some influence on the creek channel due to these dams may remain, they have been removed entirely as barriers to fish migration.

Future Projects Influencing Future Habitat Conditions for Steelhead

The reasonably foreseeable future projects that could affect conditions for potential future-occurring steelhead in the Alameda Creek watershed are presented in Draft PEIR Section 5.7.3 and are summarized in Table 5.7-13 and Figure 5.7-3 (Vol. 3, Chapter 5, pp. 5.7-53 to 5.7-60). These projects include removing/modifying dams, weirs, culverts, and pipelines that block fish passage; installing positive-barrier fish screens at water diversions; constructing slurry cutoff walls in quarry pits to reduce losses to groundwater; and restoring and protecting habitat and instream flows. While these identified future projects are considered reasonably foreseeable for the purposes of this analysis, there remains uncertainty regarding their implementation due to unknowns such as funding or permitting issues. Of particular importance to this analysis are proposals to remove or bypass several fish migration barriers in the watershed. The future projects included in this analysis and their planning status are described in Draft PEIR Section 5.7.3. In response to comments, several revisions and updates have been made to the future projects that would influence habitat conditions for steelhead in the Alameda Creek watershed. These revisions to future projects are presented here and were used in establishing the future baseline condition for assessing the effects of the WSIP on future-occurring steelhead upstream of the BART weir.

A comment received on the Draft PEIR regarding future fish passage improvement projects indicated that, subsequent to publication of the Draft PEIR, the ACFCWCD and ACWD entered into an agreement (on July 31, 2007) to design a fish passage facility over the BART weir and the middle inflatable dam in the Alameda County Flood Control Channel. In response to this comment, the Draft PEIR (Vol. 3, Chapter 5, p. 5.4.5-9, first bullet) is amended as follows:

- Alameda County Flood Control and Water Conservation District's BART Weir – several studies have been conducted regarding potential designs to provide passage at this location. The most recent effort is a report (Wood Rogers, 2006) that outlines options ranging from total removal of the structure ("roughened channel") to three ladder and screen alternatives. The range of low flows estimated to allow suitable passage for adult steelhead among these four options is 10–50 cfs. However, other barriers (e.g., ACWD middle and upper rubber dams, PG&E Drop Structure – see below) within Alameda Creek may be impassable at these low flows. ~~There is currently no schedule or budget for this project, and environmental review has yet to begin.~~ On July 31, 2007, the Alameda County Flood Control and Water Conservation District and the Alameda County Water District entered into an agreement to design a fish passage facility over the BART weir and the middle inflatable dam in the Alameda County Flood Control Channel to improve steelhead passage within the Alameda Creek watershed.

Cumulative Impact Assessment for Potential Future-Occurring Steelhead

The following analysis evaluates the WSIP's potential contribution to effects on future-occurring steelhead in combination with past, present, and probable future projects, including other SFPUC and non-SFPUC projects or activities under the jurisdiction of various federal, state, and local agencies that have the potential to affect steelhead recovery in the watershed. The project description changes summarized above include protective measures for future-occurring steelhead in Alameda Creek above the BART weir that are proposed as part of the Calaveras Dam Replacement project, as well as Mitigation Measures 5.4.1-2 and 5.4.5-3a identified in the Draft PEIR. These protective measures and mitigation measures are summarized in Section 14.9.1, above.

Changes in Habitat Conditions from Future Cumulative Projects

A characterization of habitat conditions for steelhead under existing conditions and the projected future cumulative scenario, based on an analysis of past, present, and probable future projects, is provided below. Alameda Creek has historically been divided into three distinct reaches: lower Alameda Creek, Niles Canyon, and upper Alameda Creek. This section provides a description of habitat conditions within each of these three reaches.

Table 14.9-6 presents a summary of existing conditions along Alameda Creek with the current fish passage barriers in place and with Calaveras Reservoir and the ACDD operating under DSOD-restricted conditions, and summarizes the stream and habitat conditions for three different steelhead life stages under two scenarios:

1. A future scenario *without* implementation of the WSIP (i.e., specifically the Calaveras Dam Replacement and Alameda Creek Fishery Enhancement [recapture facility] projects). This scenario assumes that all planned and proposed projects to improve fish passage in the

TABLE 14.9-6
SUMMARY OF ALAMEDA CREEK STEELHEAD HABITAT USE AND CONDITION
UNDER FUTURE CUMULATIVE WITHOUT WSIP AND FUTURE CUMULATIVE WITH WSIP SCENARIOS

	Existing Condition	Assumed Future Condition without WSIP[a]				Assumed Future Condition with WSIP and Measures to Address Potential Impacts[b]			
			Life Stage Habitat Use and Condition[b]				Life Stage Habitat Use and Condition[c]		
Alameda Creek Reach (moving upstream)	**Stream Condition (Steelhead do not have access to Alameda Creek above the BART weir under the Existing Condition)**	**Stream Condition**	**Migration**	**Spawning**	**Rearing**	**Stream Condition**	**Migration**	**Spawning**	**Rearing**
Lower Alameda Creek (Flood Control Channel) – from San Francisco Bay to mouth of Niles Canyon	• Concrete-lined flood control channel • BART weir acts as complete barrier to migration; ACWD dams are also major migration obstacles • High summer temperatures • Substrate has high silt component • Intermittent flow in summer • High winter flows with limited diversion in normal/wet and wet years	• Fish passage restored upstream of BART weir and ACWD inflatable dams • No change to habitat conditions in this reach • Possible increased surface flow from upstream improvements at Sunol quarries	PRESENT	ABSENT	ABSENT/ LIMITED	• Fish passage restored upstream of BART weir and ACWD inflatable dams • No change to habitat conditions in this reach • Calaveras Dam Replacement project / WSIP would increase diversions to Calaveras Reservoir, implement releases from ACDD or Calaveras Dam consistent with the 1997 MOU, and recapture releases also consistent with the 1997 MOU. It would result in reduced stream flow in lower Alameda Creek in winter months of normal/wet and wet years (up to 18%); minimal change during below-normal and dry years.	PRESENT	ABSENT	ABSENT/ LIMITED
Niles Canyon – from mouth of Niles Canyon to confluence with Arroyo de la Laguna	• Confined channel with steep canyon walls • Well-developed riparian zone • Low-gradient perennial stream • Large deep pools, connected by run and riffle habitat • High summer temperatures • Serves as conveyance for water supply from South Bay Aqueduct • USGS gage acts as obstacle to migration under moderate to low flow conditions	• Fish passage restored at USGS gage for all flow conditions • Possible increased surface flow from upstream improvements at Sunol quarries • Improved rearing habitat through cool-water thermal buffering	PRESENT	PRESENT/ LIMITED	LIMITED	• Fish passage restored at USGS gage for all flow conditions • Calaveras Dam Replacement project / WSIP would increase diversions to Calaveras Reservoir, implement releases from ACDD or Calaveras Dam consistent with the 1997 MOU, and recapture releases also consistent with the 1997 MOU. It would result in reduced stream flow in lower Alameda Creek in winter months of normal/wet and wet years (up to 18%); minimal change during below-normal and dry years. • Improved rearing habitat through cool-water thermal buffering	PRESENT	PRESENT/ LIMITED	LIMITED
Upper Alameda Creek (General) – from confluence with Arroyo de la Laguna and upstream	• Fish passage limited by Turner Dam, Little Yosemite, Alameda Creek Diversion Dam, Calaveras Dam • Spawning and rearing habitat influenced by SFPUC dam operations and releases	• Downstream passage improvements increase potential for migration to upper reaches • Fish passage limited by Turner Dam, Little Yosemite, Alameda Creek Diversion Dam, Calaveras Dam • Spawning and rearing habitat influenced by SFPUC dam operations and releases	(see reach-by-reach below)	(see reach-by-reach below)	(see reach-by-reach below)	• Downstream passage improvements increase potential for migration to upper reaches • Calaveras Dam Replacement project / WSIP would increase diversions to Calaveras Reservoir and implement fish releases consistent with 1997 MOU. WSIP would include downstream recapture of those releases at downstream end of Reach A-1. • Fish passage limited by Turner Dam, Little Yosemite, Alameda Creek Diversion Dam, Calaveras Dam • Spawning and rearing habitat influenced by SFPUC dam operations and releases	(see reach-by-reach below)	(see reach-by-reach below)	(see reach-by-reach below)
A-1 – from confluence with Arroyo de la Laguna to lower Sunol Valley (near Sunol WTP)	• Wide, low-gradient, alluvial valley • Intermittent flows • Natural channel relocated due to gravel mining operations • "Losing" reach – up to 36% seepage of surface water from Alameda Creek to gravel mining pits, infiltration galleries, etc. • Warmwater fish habitat • Trout likely not present in reach • PG&E pipeline crossing acts as obstacle to migration • Migration impeded at several locations (critical riffles) at low flows	• Downstream passage barriers removed and fish passage restored • Historical channel realigned • Improved stream flow conditions due to reduced surface and groundwater losses with construction of slurry cutoff walls (but would remain a naturally "losing" reach) • Fish passage provided at the PG&E pipeline crossing • Critical riffles present within the segment of Alameda Creek adjacent to the Sunol quarry (SMP 30) would be enhanced through restoration of the stream channel associated with Sunol quarry permit renewal	PRESENT	LIMITED	ABSENT/ LIMITED	• Downstream passage barriers removed and fish passage restored • Historical channel realigned • Improved stream flow and habitat conditions due to reduced surface and groundwater losses with construction of slurry cutoff walls (but would remain "losing" reach) and stream habitat restoration • Intermittent stream flow • Warmwater fish habitat • Calaveras Dam Replacement project / WSIP would increase diversions to Calaveras Reservoir and implement fish releases consistent with 1997 MOU. WSIP would include downstream recapture of those releases at downstream end of Reach A-1. This would result in substantially reduced normal/wet and wet year winter stream flows in this reach (up to 45%), which would adversely affect migration.	PRESENT	LIMITED/ PRESENT	ABSENT/ LIMITED

C-1 – Calaveras Creek from confluence with Alameda Creek to Calaveras Dam	• Deep pool, run, and riffle habitat present • Stream flow heavily influenced by Calaveras Dam operations • Water temperature influenced by temperatures of reservoir releases • Habitat values marginal for steelhead due to steep topography, isolated pools, altered stream hydrology • Rainbow trout not present	• No projects planned in this reach • No change to future scenario habitat conditions other than WSIP / Calaveras Dam Replacement project	LIMITED (barrier at dam)	LIMITED	LIMITED/ ABSENT	• Calaveras Dam Replacement project / WSIP implementation would restore operations of Calaveras Dam and include fish releases to achieve flow conditions at confluence consistent with 1997 MOU	LIMITED (barrier at replacement dam)	LIMITED	PRESENT
C-2, AH-1 – Calaveras Creek and Arroyo Hondo upstream of Calaveras Reservoir	• Calaveras Creek lacks hydrologic connection with Calaveras Reservoir at lowermost segment of creek • Calaveras Reservoir provides habitat for trout and warmwater fishes • Arroyo Hondo has good habitat/connectivity for 1.8 miles upstream of the reservoir • Steelhead access precluded by Calaveras Dam	• No projects planned in this reach	N/A (barrier at Calaveras Dam would remain)	N/A (barrier at Calaveras Dam would remain)	N/A (barrier at Calaveras Dam would remain)	• Calaveras Dam Replacement project / WSIP would restore historical operating levels and improve coldwater pool in Calaveras Reservoir • Improved connectivity of Arroyo Hondo and Calaveras Creek with Calaveras Reservoir • Steelhead access still precluded by dam	N/A (barrier at replacement dam)	N/A (barrier at replacement dam)	N/A (barrier at replacement dam)

NOTES: See Figure 14.9-4 for the location of reaches.

[a] Future cumulative condition assumes that planned and proposed projects to improve fish passage in the Alameda Creek watershed would be successfully implemented such that anadromous steelhead have access to the upper Alameda Creek watershed, but flow conditions would be the same as under existing conditions (Alameda Creek Diversion Dam and Calaveras Reservoir operations with DSOD restrictions).

[b] Future cumulative condition assumes that planned and proposed projects to improve fish passage in the Alameda Creek watershed would be successfully implemented such that anadromous steelhead have access to the upper Alameda Creek watershed. In addition, it assumes that the proposed WSIP water supply and system operations modifications would be implemented, including construction and operation of the Calaveras Dam Replacement and Alameda Creek Fishery Enhancement projects. Further, it assumes that identified direct impacts of the WSIP would be mitigated and assumes implementation of Draft PEIR Mitigation Measures 5.4.1-2 (Diversion Tunnel Operation) and 5.4.5-3a (Minimum Flows for Resident Trout on Alameda Creek) and 5.4.5-3b (Alameda Creek Diversion Dam Restrictions or Fish Screens).

[c] ABSENT denotes habitat not present in reach to support life stage. LIMITED denotes habitat present to support life stage during periods of the year, but limited by seasonal low flows and/or high summer temperatures; marginally suitable. PRESENT denotes habitat present to support life stage. N/A = Not Applicable, i.e., not affected by Calaveras Dam Replacement project or WSIP because existing barriers (Calaveras Dam and Alameda Creek Diversion Dam) would remain.

THIS PAGE INTENTIONALLY LEFT BLANK

Alameda Creek watershed have been successfully implemented and anadromous steelhead have access to the upper Alameda Creek watershed, and that stream flow conditions attributable to SFPUC water system operations would be the same as under the existing condition.

2. A future scenario *with* implementation of the WSIP, including the Calaveras Dam Replacement and Alameda Creek Fishery Enhancement projects and associated protective measures. This scenario assumes the same conditions as Scenario 1, except it includes full implementation of the WSIP, which would modify stream flow conditions. Under Scenario 2, full implementation of the WSIP would include increasing diversions at the ACDD to restore historical storage levels in Calaveras Reservoir, providing bypass flows at the ACDD as well as releases from Calaveras Reservoir to augment stream flow to support fisheries consistent with the 1997 CDFG MOU, and, if recaptured, recapturing those releases at a downstream location consistent with the 1997 CDFG MOU.

Table 14.9-6 describes the stream and habitat conditions along the various reaches of Alameda Creek that could be affected by the WSIP, including the Calaveras Dam project, beginning at the downstream end of the watershed in lower Alameda Creek and Niles Canyon, and moving upstream to individual reaches in upper Alameda Creek. **Figure 14.9-4** shows the location of the reaches described in Table 14.9-6.

It should be noted that the WSIP's effect on habitat conditions for steelhead in the reaches downstream of Arroyo de la Laguna (i.e., lower Alameda Creek and Niles Canyon) are linked to a number of uncertainties regarding:

- The way in which existing barriers to passage would be remedied in the future (the design of passage facilities and the timing and amount of flow that would be required to achieve suitable passage conditions at those locations) as well as the effectiveness of the proposed slurry cutoff wall on the perimeter of the quarry on the right bank (looking downstream) of Alameda Creek above the San Antonio Creek confluence to reduce seepage losses from Alameda Creek in the Sunol Valley

- The extent to which natural features act as barriers (e.g., wide/braided channel locations, falls, sediment wedges) under various flow regimes and associated water temperature conditions

- The extent to which varying water resource operations of all water agencies in the overall Alameda Creek basin influence flows needed to establish and sustain appropriate flow and temperature conditions for steelhead and the subsequent effects of the WSIP on these downstream conditions (the contributions of flow from Arroyo del Valle and Arroyo de la Laguna complicate the hydrology further and add to uncertainties)

Understanding and resolving the approach to steelhead habitat restoration in the watershed, including addressing uncertainties regarding habitat requirements in Niles Canyon and lower Alameda Creek, requires a comprehensive, coordinated, basinwide effort and is currently being addressed through the ACFRW, of which the SFPUC is a participant.

Figure 14.9-4
Existing and Future Habitat Conditions for Steelhead on Alameda Creek

Potential Future Cumulative Impacts on Steelhead

The following discussion provides a reach-by-reach analysis of the WSIP's impacts on steelhead in Alameda Creek based on the changes in steelhead life-stage functions: migration (adult and juvenile), spawning, and rearing. The analysis incorporates the project revisions, protective measures, and mitigation measures described in Section 14.9.1, above. The protective measures added to the Calaveras Dam Replacement project description (SFPUC, 2008) include specific operational protocols, seasonal bypass flows at the ACDD and Calaveras Dam, and performance criteria to meet the habitat requirements of steelhead (if present) and other native aquatic species (fish and sensitive amphibians) in upper Alameda Creek in the event that the NMFS and/or CDFG determine that steelhead are present in Alameda Creek above the BART weir, construction of the Calaveras Dam project is complete, and the Alameda Watershed HCP is yet to be finalized. The protective measures also include an interim bypass flow release schedule that would consist of the implementation of flows consistent with the 1997 CDFG MOU, with the additional requirement that these flows be achieved through bypass flows at the ACDD at all times when flows are available, rather than through releases at Calaveras Dam. This interim flow schedule would meet the requirements of the 1997 CDFG MOU point of compliance below the confluence of Alameda and Calaveras Creeks as well as provide additional benefit in the reach between the ACDD and Calaveras Creek. The SFPUC would implement this interim measure until such time that the resource agencies (USFWS, NMFS, and CDFG) develop alternative requirements (i.e., operational protocols, seasonal bypass flows, and performance criteria) through the Alameda Watershed HCP process or other regulatory mechanism to ensure the habitat requirements of steelhead and other native aquatic species are provided at a level that is equal to or better than that provided by this interim measure. Following the development of these protocols, the SFPUC would implement these actions either through the Alameda Watershed HCP or other mechanism developed in consultation with the USFWS, NMFS, and CDFG.

The project revisions and protective measures for steelhead proposed as part of the Calaveras Dam Replacement project (SFPUC, 2008), along with the mitigation measures detailed in the Draft PEIR, have been analyzed by ESA+Orion and EDAW-Turnstone JV (2008) to determine the WSIP's contribution to cumulative effects (both positive and negative) on potential future-occurring steelhead, as discussed below. Implementation of the project revisions, protective measures, and mitigation measures (summarized in the Section 14.9.1, above) would reduce adverse effects of the WSIP on steelhead life stages and habitat in Alameda Creek to a less-than-significant level.

Migration

Upper Alameda Creek (Reaches A-1 through A-5). Implementation of the WSIP would influence stream flow and water temperature in Alameda Creek during steelhead migration periods. Under the WSIP, proposed operation of the ACDD would increase diversions from upper Alameda Creek to Calaveras Reservoir as well as implement protective measures to address steelhead migration downstream of the recapture facility. The protective measures incorporated into the WSIP as part of the Calaveras Dam Replacement and Alameda Fishery Enhancement projects include: (1) in the long term, operational protocols, seasonal bypass flows at the ACDD and Calaveras Dam, and performance criteria to ensure the habitat requirements of steelhead (if present) as implemented through the Alameda Watershed HCP or other regulatory mechanism ensuring compliance with FESA and CESA, and (2) in the short-term until issues associated with the long-term measures are resolved, seasonal flow bypasses at the ACDD and/or Calaveras Dam consistent with the 1997 CDFG MOU but without recapture or with recapture at a point at the downstream end of Reach A-1 below critical riffle locations or lower in the creek. Under this cumulative analysis, it is assumed that Mitigation Measure 5.4.5-3a would be implemented in conjunction with the protective measures

As a result, flows in Alameda Creek downstream of the diversion dam would be substantially reduced from those under existing conditions. Flows passing the diversion dam would include flows above 650 cfs (capacity of the diversion), downstream tributary inflow, and bypass flows when upstream flows are available (from December 1 to April 30) implemented as part of the protective measures and Measure 5.4.5-3a. Natural summer low-flow limitations would not be affected by the bypass flow protective measures, since the bypass flows only address the period from December 1 to April 30, and there is typically no diversion during the summer months.

Because the bypass flows outlined in the 1997 CDFG MOU and Mitigation Measure 5.4.5-3a were developed to meet life-stage habitat suitability requirements for resident rainbow trout, conditions may only be marginally suitable for steelhead migration. As shown in Table 14.9-6, steelhead passage under the existing condition is impeded by natural rock barriers in the steep sections of Alameda Creek within Little Yosemite (Reach A-3, upstream from the Calaveras Creek confluence) under most flow conditions, based on recently completed studies (URS/SWRI, unpublished data). Thus, the effect of the proposed increased diversions on steelhead migration in the reach from the base of the diversion dam to the downstream end of Little Yosemite would only occur during times when flow conditions would have otherwise been adequate for steelhead migration, or if that natural barrier (i.e., falls at Little Yosemite) were to be removed. Removal of the natural Little Yosemite rock barrier is not proposed at this time.

Under the WSIP, flows in the segment of the creek downstream from the confluence of Alameda and Calaveras Creeks would be managed in accordance with the 1997 CDFG MOU through naturally occurring flows, releases from Calaveras Dam, and/or bypass flows at the diversion dam. The resulting stream flows would contribute to potentially suitable migratory conditions at certain times of the year within the reach of Alameda Creek that extends from the Calaveras Creek confluence with Alameda Creek downstream to the water recapture facility. When the bypass flows are released from the diversion dam to meet the terms of the MOU as part of the protective measures incorporated in the Calaveras Dam Replacement project, then the beneficial effects of these flows would also be achieved in Reaches A-3 and A-4, upstream from the Calaveras Creek confluence to the diversion dam.

In the Sunol Valley (Reaches A-1 and A-2), some wide channel areas may limit steelhead passage at lower flows (also known as areas of critical riffles) under existing conditions. In general concept, higher flows would enable upstream migrating adults and downstream migrating adult and juvenile steelhead to pass these areas and the remaining “natural” migration obstacles (following removal of the human-made barriers) in the Sunol Valley and farther downstream.

Stream flow and fish migration assessments conducted in Reach A-1, the stream reach with primary critical riffles adjacent to the Sunol quarry (SMP 30) (ENTRIX, 2006; URS/SWRI, unpublished data), have determined that a total of seven critical riffles are present that could potentially limit fish passage. The assessments determined that a wide range of low to moderate flows would be required to enable fish passage at the individual critical riffle locations. These flow requirements, in order of magnitude, are: 74, 17, 6, 5, 4, 2, and 1 cfs. The flow assessment results indicate that fish passage could be enabled through the provision of minimum flows equal to the highest flow requirement (i.e., 74 cfs) or through physical modification of the creek channel at the critical riffle locations to improve the specific conditions (e.g., wide channel, shallow depths, high velocities, steep gradient, etc.) that impede fish passage, and which, in general, would reduce the flow requirements for suitable fish passage.

While WSIP implementation would result in increased diversions in upper Alameda Creek at the diversion dam, the implementation of releases and/or bypass flows at Calaveras Dam and the ACDD, consistent with the 1997 CDFG MOU (per protective measures incorporated into the Calaveras Dam Replacement project) and Mitigation Measure 5.4.5-3a, would augment migration flows and assure project impacts on fishery habitat as far downstream as the proposed recapture facility are reduced to a less-than-significant level. As part of the project revisions incorporated into the Alameda Fishery Enhancement project, the SFPUC would either not implement recapture until the long-term regulatory mechanism for steelhead protection is resolved, or would locate the recapture facility at a point approximately at the downstream end of Reach A-1 below the areas of critical riffles. Thus, implementation of the 1997 MOU flows would enhance migratory conditions in this area.

Under the assumed future conditions with construction of a slurry cutoff wall and stream habitat restoration at the Sunol quarry pit (i.e., SMP 30 in Reach A-1),[3] downstream losses in stream flow from percolation into these pits in the Sunol area would be reduced; physical conditions at critical riffles is assumed to be improved; and there would be a resulting beneficial effect on steelhead migration in this area. While the remaining stream flow losses due to infiltration and the actual stream flow increase resulting from a future cutoff wall at the Sunol quarry are unknown at this time, it is assumed that increases in stream flows would be achieved and stream habitat restoration would improve physical conditions at critical riffles. Previous assessments of the critical riffles (ENTRIX, 2006; URS/SWRI, unpublished data) determined that passage is enabled at five of the seven critical riffles at relatively low flows (i.e., 1 to 6 cfs). Based on these results, it

[3] The SFPUC's Sunol Valley Sand and Aggregate Quarry Operations (SMP 30) includes projects to be undertaken by the quarry operator to correct losses of water into quarry pits and to enhance riparian vegetation. There is limited fish passage and degraded habitat value in this reach due to past mining-related realignment of the creek channel (noted above), which results in mining pit capture of a significant amount of Alameda Creek flows at the head of the realigned creek. The SFPUC proposes to coordinate planning for an Alameda Creek channel restoration project at this location as part of its negotiation with the selected operator of its Sunol quarry and to include aspects of the restoration project as part of the lease conditions. The SFPUC desires the operator to construct a slurry cutoff wall to reduce inflow to the pit as well as provide restoration of riparian habitat on the right bank of Alameda Creek and the left bank of San Antonio Creek (looking downstream). A plan for these actions has not yet been developed. The selected entity will be required to provide funds towards these efforts. CEQA/NEPA environmental review has yet to begin, but will include planning information for fish passage at the PG&E pipeline drop structure.

is assumed that physical conditions (e.g., channel width and form, gradient) would be improved at the critical riffles that require the highest flows (i.e., 74 and 17 cfs) and these improvements would enable fish passage at low flows, similar to the other critical riffle locations (1 to 6 cfs). These actions combined with minimum flow releases/bypasses consistent with the 1997 CDFG MOU (range of flows between 5 and 20 cfs during migration periods) would achieve suitable steelhead migration conditions in the Sunol Valley downstream to the recapture facility.

In summary, under the future conditions with the WSIP, the total combined stream flow from both regulated and unregulated sources, coupled with the assumed stream flow and habitat improvements at the Sunol Quarry, would sustain some winter flows in Alameda Creek that could facilitate fish migration. Location of the recapture facility downstream of critical riffles (Reach A-1) would assure suitable steelhead migration conditions. With the proposed program modifications described above, the WSIP would have a *less-than-significant* impact on steelhead migration in upper Alameda Creek (ESA+Orion and EDAW-Turnstone JV, 2008).

Lower Alameda Creek and Niles Canyon. At present, steelhead have access only to the segment of lower Alameda Creek below the BART weir because the BART weir acts as a complete barrier to steelhead migration under all flow conditions. In combination with other projects that could provide steelhead access through lower Alameda Creek and Niles Canyon to upper Alameda Creek in the future (including the provision of a fish bypass at the BART weir), the WSIP could result in a cumulative effect on steelhead migration.

Additional stream flow analysis was conducted subsequent to publication of the Draft PEIR (summarized above in Section 14.9.3 and included in Vol. 8, **Appendix N**) in order to address comments regarding the WSIP's impacts on steelhead passage and fishery habitat in lower Alameda Creek and Niles Canyon. This analysis determined that, based on the historical hydrology from 2000 to 2007, flows in Alameda Creek in Niles Canyon and downstream, on average, would occasionally be reduced under the WSIP. Reductions of up to 18 percent in average monthly flow could occur in winter months of years similar to the past eight years of record. The maximum flow reduction would occur during January of an above-normal year; however, the average calculated flow during this period remains relatively high (171 to 216 cfs). A flow increase of up to 13 percent would occur in April of that same hydrologic year type. The average monthly reduction that would occur from December through March of these year types is approximately 20 cfs, with a remaining calculated average flow of 313 cfs (range of 28 to 562 cfs). No changes in flow would occur in below-normal and dry years, when naturally low flow conditions would potentially result in the most substantial passage impediments.

Because the WSIP's effect on flows would only occur during above-normal hydrologic year types when flow conditions are predicted to remain relatively high (ESA+Orion and EDAW-Turnstone JV, 2008), operation of the WSIP is expected to have a negligible cumulative effect on future (anticipated) habitat conditions for steelhead migration. Therefore, this impact would be *less than significant*.

Spawning

Upper Alameda Creek (Reaches A-1 through A-5). Studies recently completed by Hagar and Payne (ETJV, 2008) identified suitable habitat for steelhead spawning in the reach of Alameda Creek immediately downstream of the Calaveras Creek confluence (Reach A-2) and between the Calaveras Creek confluence and the ACDD (Reaches A-3 and A-4). Implementation of the Calaveras Dam Replacement project (SV-2) component of the WSIP would alter stream flow in Alameda Creek during steelhead spawning periods. At present, steelhead do not have access to upper Alameda Creek. However, in combination with other projects that would provide steelhead access to upper Alameda Creek in the future, operation of the Calaveras Dam project could affect steelhead spawning.

Upstream of the Calaveras Creek confluence, Alameda Creek flows are predominantly influenced by operation of the diversion dam and tunnel. At present, Alameda Creek between the diversion dam and the confluence with Calaveras Creek provides habitat for spawning resident rainbow trout as well as other native species. As discussed above, passage conditions are extremely limited under most flow conditions at Little Yosemite and likely impede steelhead access to the majority of this reach, and therefore the effects of the Calaveras Dam project on steelhead spawning may only practically be realized in Alameda Creek downstream of Little Yosemite. Implementation of the WSIP would substantially reduce flows in Alameda Creek compared to existing conditions; however, implementation of PEIR Mitigation Measure 5.4.5-3a would address spawning and egg incubation habitat needs for resident rainbow trout as well as breeding habitat for other native stream-dependent amphibian species present in the creek and would require the SFPUC to monitor fish and sensitive amphibian populations and aquatic habitats. With the addition of the protective measures incorporated into the Calaveras Dam Replacement project, the implementation of the 1997 CDFG MOU flow releases from the ACDD when flow is available in upper Alameda Creek would reduce the WSIP's effect on steelhead spawning in this reach.

While steelhead generally require increased flow (compared to rainbow trout) to meet spawning habitat suitability requirements (e.g., water depth and flow velocity conditions), the bypass flows developed for rainbow trout spawning have been modeled so they would also be adequate for anadromous steelhead spawning. Preliminary studies by Hagar and Payne (ETJV, 2008) to assess flow requirements for steelhead spawning indicate that flows in Alameda Creek between the diversion dam and the Calaveras Creek confluence in the range of 18 to 60 cfs provide the *most* suitable[4] quantity and quality of steelhead spawning habitat. For Alameda Creek downstream of the Calaveras Creek confluence, the studies indicate that flows in the range of 21 to 80 cfs provide the *most* suitable quantity and quality of steelhead spawning habitat. Bypass flows to support spawning in Alameda Creek would be most effective if implemented from approximately January through March, and based on different hydrologic year types and aligned with the timing of precipitation in the upper watershed. It is noted that the 1997 CDFG MOU flows range up to 20 cfs and thus are at or near the lower ranges noted above for the most suitable habitat quantity and quality for steelhead.

4 80 percent or greater of maximum usable area based on the relationship between stream flow and spawning habitat requirements (i.e., water depth, flow velocity, and substrate type and size).

Under the WSIP, water releases from Calaveras Dam and/or bypasses from the ACDD consistent with the 1997 CDFG MOU would contribute to enhancing steelhead spawning habitat conditions at certain times (18 to 20 cfs from January to March) within the reach of Alameda Creek that extends from the Calaveras Creek confluence downstream through Reach A-2 (extent of suitable spawning habitat). The MOU was developed to address habitat needs for rainbow trout only, but would also be expected, based on the Hagar and Payne study (ETJV, 2008, Appendix A), to provide spawning habitat functions for steelhead (ESA+Orion and EDAW-Turnstone JV, 2008). Incorporation of the protective measures (steelhead bypass flows) into the WSIP program description, as summarized above, would reduce these impacts to a *less-than-significant* level.

As a separate issue related to spawning, the increased diversion of higher flows (up to about 650 cfs at the diversion dam as part of the Calaveras Dam Replacement project) could provide a benefit in above-normal and wet years by reducing the likelihood that steelhead eggs incubating in redds downstream of Little Yosemite would be vulnerable to scour and erosion. As such, in some years the increased diversions occurring with the WSIP would be expected to contribute to improved reproductive success of any steelhead spawning within the reach, provided that a suitable base level of flow (through bypass flow mitigation) would be available for spawning and egg incubation (ETJV, 2008).

Lower Alameda Creek and Niles Canyon. Steelhead spawning habitat in lower Alameda Creek is either absent or very limited, and there are no proposed spawning habitat restoration projects in this reach of Alameda Creek. Therefore, the WSIP would not affect steelhead spawning in lower Alameda Creek.

Potential spawning habitat is present in Niles Canyon; however, the future production of individuals spawned in this reach would be restricted by several factors related to subsequent rearing requirements and existing and future habitat limitations (see discussion below). As described above under the heading Migration, stream flow modeling indicated that the WSIP could result in reductions of up to 18 percent in average monthly flow in winter months of above-normal/wet years. The maximum flow reduction would occur during January of an above-normal year; however, the average calculated flow during this period remains relatively high (171 to 216 cfs). A flow increase of up to 13 percent would occur in April of that same hydrologic year type. The average monthly reduction that would occur from December through March of these year types is approximately 20 cfs, with a remaining calculated average flow of 313 cfs (range of 28 to 562 cfs). No changes in flow would occur in below-normal and dry years, when naturally low flow conditions would potentially result in the most limited habitat conditions for spawning.

Because the WSIP's effect on potential steelhead spawning habitat would only occur during above-normal hydrologic year types (when remaining flow conditions are predicted to still be relatively high), the WSIP is expected to have a negligible effect on future (anticipated) habitat conditions for steelhead spawning (ESA+Orion and EDAW-Turnstone JV, 2008). Therefore, this impact would be *less than significant*.

Rearing

Upper Alameda Creek (Reaches A-1 through A-5). At present, steelhead do not have access to upper Alameda Creek. However, in combination with planned projects that would provide steelhead access to upper Alameda Creek in the future, operation of the proposed program could affect steelhead rearing. Implementation of the WSIP could influence stream flow and water temperatures in Alameda Creek during steelhead rearing periods.

Although no published studies have been conducted that specifically address flow needs for rearing steelhead in reaches of Alameda Creek downstream of Calaveras Dam or the diversion dam, the 1997 CDFG MOU was developed to provide an increase in the amount of coldwater habitat in lower Alameda Creek for the benefit of resident trout. This is especially important in the summer and fall periods, at which times the MOU releases would provide sufficiently cool water to support fish survival through the hot, dry summer period. Resident trout and juvenile steelhead have essentially the same requirements for rearing habitat (e.g., flow, water temperature, physical habitat components). Therefore, under the WSIP, releases from Calaveras Dam and/or bypasses from the diversion dam that meet flow and temperature objectives consistent with the 1997 CDFG MOU would be expected to provide habitat conditions suitable for rearing steelhead in Alameda Creek from the confluence with Calaveras Creek downstream, and, with bypasses made from the diversion dam under the Calaveras Dam Replacement project, upstream in Alameda Creek as well. Releases consistent with the MOU are proposed as part of the WSIP, including summer releases that do not occur under existing conditions. Thus, the WSIP would have a *beneficial* effect on potential steelhead summer rearing habitat in the approximate two-mile segment of Alameda Creek between the Calaveras Creek confluence and the boundary of the Sunol Regional Park (i.e., the creek segment where sufficiently cool water temperatures could be maintained before warming [CDFG, 1997]) (see Figure 14.9-4).

There is the potential for adverse effects on steelhead rearing habitat during the rainy season (i.e., approximately November through March) in the reach of Alameda Creek between the diversion dam and the Calaveras Creek confluence (Reaches A-3 and A-4). However, proposed bypass releases from the ACDD under Measure Mitigation 5.4.5-3a would reduce the WSIP’s contribution to this effect. During the dry season when there is minimal naturally occurring flow in Alameda Creek (i.e., April through November), minimal diversions would be made under the WSIP, similar to the existing condition. Furthermore, Draft PEIR Mitigation Measure 5.4.1-2 (Vol. 4, Chapter 6, pp. 6-51 and 6-52) would formalize a commitment for the SFPUC operators to close the gates to the diversion tunnel once reservoir storage levels are met to provide the maximum possible days of winter and spring flows in Alameda Creek below the diversion dam.

Downstream of the bridge at the Sunol Valley Water Treatment Plant (Reach A-1), habitat conditions in the Sunol Valley do not appear to be suitable for steelhead rearing. Annual fish monitoring from 1998 to present (conducted by the SFPUC and summarized in ETJV, 2008) resulted in no rainbow trout being sampled or observed at locations immediately above this reach. With construction of a slurry cutoff wall at the Sunol quarry pit (SMP 30), downstream losses in stream flow resulting from the percolation of groundwater may be substantially reduced, resulting in a beneficial effect. However, remaining losses in stream flow and the capture efficiency of a future cutoff wall at the Sunol quarry (SMP 30) are unknown. Therefore, while the future viability of reestablished steelhead rearing habitat in the Sunol Valley is still uncertain, releases/bypasses included under the WSIP as part of the 1997 CDFG MOU requirements or as part of the PEIR mitigation requirements for resident trout could result in the limited seasonal enhancement of rearing habitat conditions for steelhead (i.e., late spring and late fall, when water temperatures remain sufficiently cool) compared to the existing condition (ESA+Orion and EDAW-Turnstone JV, 2008). Therefore, the WSIP is unlikely to have an adverse effect on steelhead rearing habitat in Reach A-1. In summary, implementation of the WSIP, including project description changes that provide protective measures, in conjunction with the mitigation measures, would result in a *less-than-significant impact* on steelhead rearing.

Lower Alameda Creek and Niles Canyon. There are several key uncertainties regarding the availability and quality of rearing habitat in lower Alameda Creek and Niles Canyon (McBain and Trush, 2007). The Niles Canyon reach may have historically provided important rearing habitat for juvenile steelhead. Currently, rearing habitat in this reach for steelhead is limited by altered flows and warm water temperatures (ETJV, 2008; McBain and Trush, 2007; Hanson, 2002b). As previously noted, the proposed slurry cutoff wall at the Sunol quarry pits could improve the contributions to stream flow and underflow of shallow groundwater into Niles Canyon.

As described above under the heading Migration, additional stream flow analysis indicated that the WSIP could result in reductions of up to 18 percent in average monthly flow in winter months of above-normal/wet years. The maximum flow reduction would occur during January of an above-normal year; however, the average calculated flow during this period remains relatively high (171 to 216 cfs). A flow increase of up to 13 percent would occur in April of that same hydrologic year type. The average monthly reduction that would occur from December through March of these year types is approximately 20 cfs, with a remaining calculated average flow of 313 cfs (range of 28 to 562 cfs). No changes in flow would occur in below-normal and dry years, when naturally low flow conditions would potentially result in the most limited habitat conditions for rearing.

Because habitat functions for rearing have been greatly diminished in lower Alameda Creek and the WSIP's predicted effect on rearing habitat would only occur during above-normal year types (when remaining flow conditions are predicted to still be relatively high), the WSIP is expected to have a negligible effect on future (anticipated) habitat conditions for steelhead rearing (ESA+Orion and EDAW-Turnstone JV, 2008). Therefore, this impact would be *less than significant.*

PEIR Text Revisions to Include Cumulative Impact on Future-Occurring Steelhead

Based on the analysis of the WSIP's contribution to future cumulative effects on potential future-occurring steelhead presented above, the assessment presented in the Draft PEIR of the WSIP's cumulative impacts in the Alameda Creek watershed has been revised. The Draft PEIR text is revised as follows (Vol. 3, Chapter 5, p. 5.4.5-11, fifth full paragraph):

Potential Steelhead Restoration

For the purposes of full disclosure, the PEIR provides this discussion of steelhead in lower Alameda Creek, and the potential for steelhead to be restored to the upper reaches of Alameda Creek (above the BART weir). However, because this steelhead access does not currently exist and there is no current steelhead migration above the BART weir, ~~there would be no~~ the potential impact on steelhead migration, spawning, or juvenile rearing upstream of the BART weir as a result of WSIP implementation is not analyzed in this section, which addresses WSIP impacts relative to existing conditions, but instead is analyzed as a future, cumulative impact in Section 5.7.3. ~~Further, as described in the preceding discussion, since a number of steps are required before steelhead migration further upstream can occur, it is speculative to assess the specific impacts that system operation under the WSIP might have on the potential future restoration of steelhead. Thus, no impact analysis or conclusion is developed in this PEIR. If and when steelhead are restored, the SFPUC will be required to conform its system operations to comply with the applicable Endangered Species Act requirements.~~

In addition, the Draft PEIR text is revised as follows (Vol. 3, Chapter 5, p. 5.7-65, second paragraph):

Cumulative Effects and WSIP Contribution

Table 5.7-15 summarizes the effects of past and present projects, the impacts of the WSIP, the effects of probable future projects, and the combined impacts of the WSIP plus probable future projects on the Alameda Creek watershed. Past and present projects have substantially altered the hydrology, geomorphology, surface water quality, groundwater, fisheries, and terrestrial biology of this portion of the Alameda Creek watershed compared to pre-Euro-American settlement conditions. Visual and recreational resources have been moderately altered. The existing condition, which serves as the baseline for the analysis of the WSIP, reflects the substantial environmental changes that have occurred as a result of the past projects. Because past and present actions have drastically altered ~~this portion of~~ the Alameda Creek watershed, some of the environmental resources are more sensitive to small adverse changes than they would be if the ~~reach~~ watershed had remained relatively unaltered from pre-Euro-American settlement conditions.

In addition, the Draft PEIR text is revised as follows (Vol. 3, Chapter 5, p. 5.7-66, third paragraph):

Implementation of the WSIP would substantially reduce flows in the reach of Alameda Creek from the diversion dam to below its confluence with Calaveras Creek compared to existing conditions (Impact 5.4.1-2). This impact was determined to be significant and unavoidable, even with implementation of Measure 5.4.1-2 (Diversion Tunnel Operation) and bypass flows included as part of the protective measures in the Calaveras Dam Replacement project (SV-2). However, no other past, present, or future projects were identified that would further reduce the stream flow in this reach of Alameda Creek, and some of the projects listed in Table 5.7-13 could enhance the flow. Thus, there would be no adverse cumulative impact on hydrology associated with past, present, and future projects, and the WSIP's contribution to the cumulative impact on hydrology is not applicable.

Due to agreements and ongoing actions regarding the implementation of fish passage improvement projects in lower Alameda Creek (as described in Section 5.4.5 of the Draft

PEIR), it is possible that steelhead will be restored to the Alameda Creek watershed reaches upstream of the BART weir by 2030. More specifically, steelhead may be restored during construction or operation of the Calaveras Dam Replacement project (SV-2) under the WSIP. In response to this scenario, the SFPUC has modified the WSIP program description—mainly that of the Alameda Creek Fishery Enhancement (SV-1) and Calaveras Dam Replacement (SV-2) projects—to incorporate protective measures for steelhead in the event that man-made barriers in Alameda Creek have been successfully removed and that steelhead migration, spawning, and rearing have been restored in Alameda Creek above the BART weir. The protective measures incorporated into the operations of the Calaveras Dam Replacement project would address future-occurring steelhead and would provide for a range of minimum bypass flows and releases at the Alameda Creek Diversion Dam and Calaveras Dam to support steelhead migration, spawning, and rearing. The program as revised, and with implementation of mitigation measures identified in the Draft PEIR, which together include minimum bypass flows to support the various life stages and habitat requirements for steelhead, would have a less-than-significant contribution to cumulative impacts on fishery resources in the Alameda Creek watershed. Please refer to Chapter 14, Section 14.9, of the Final PEIR for further discussion.

14.9.5 Other Fish Species and Aquatic Habitat in Alameda Creek

Introduction

This section of the master response addresses comments concerning the impact analysis and mitigation for the WSIP's potential effects on fishery resources in Alameda Creek upstream of the BART weir. This section of the master response is organized by the following subtopics:

- Analysis of Chinook Salmon, Coho Salmon, and Pacific Lamprey
- Warmwater Fish Species and their Habitats in Alameda Creek

Comment Summary

This section of this master response responds to all or part of the following comments:

L_ACFCWCD-14	SI_ACA1-08	SI_ACA1-19
L_ACWD-19	SI_ACA1-09	SI_ACA1-20
SI_ACA1-05	SI_ACA1-10	SI_GWWF2-02

Summary of Issues Raised by Commenters

- Need to acknowledge the historical range of Chinook salmon, coho salmon, and Pacific lamprey.
- Need to perform analyses to determine mitigation for impacts of flow diversions on Chinook salmon and Pacific lamprey.
- The mitigation measures target rainbow trout and may not mitigate impacts on steelhead, Pacific lamprey, and Chinook salmon.

- Inadequate discussion of warmwater and coldwater fish species and their habitats in the lower Alameda Creek reach.
- Lower Alameda Creek flow diversions would affect fisheries and habitat in the flood control channel.

Chinook Salmon, Coho Salmon, and Pacific Lamprey

Chinook Salmon

Chinook salmon are addressed in the Draft PEIR as part of the environmental setting for Alameda Creek fisheries (Vol. 3, Chapter 5, pp. 5.4.5-11 and 5.4.5-12). While small runs of Chinook salmon may have historically occurred within Alameda Creek, in recent years only a small number of individual Chinook salmon adults have been recovered in the flood control channel downstream of the BART weir. As presented in the Draft PEIR, it is believed that hatchery-produced salmon have strayed into streams that did not traditionally (and do not currently) support them (Gunther et al., 2000).

Although Chinook salmon are occasionally observed and documented below the BART weir, these few individuals are not currently able to migrate upstream of this barrier. If the migration barriers were absent, as discussed above in Section 14.9.3, seasonal high temperatures and low stream flow conditions during both the adult and juvenile migration and rearing periods would likely limit successful Chinook salmon production in most years.

As described above, the discussion of existing conditions presented in the Draft PEIR does not include Chinook salmon as a species of concern in the program area upstream of the BART weir. Impacts on Chinook salmon due to reduced flows below the BART weir have not been determined to be significant based on hydrological modeling of flow changes in the lower portion of Alameda Creek. Further discussion of WSIP-related flow impacts in the flood control channel is provided above in Section 14.9.3, under the heading Impacts on Stream Flow and Fisheries Downstream of the BART Weir. It should be noted, however, that Chinook salmon will be included in the SFPUC's Alameda Watershed HCP.

Coho Salmon

The geographic range for the CCC coho salmon DPS extends from Punta Gorda in northern California south to and including the San Lorenzo River in central California (NMFS, 2006). Evidence presented by Leidy (2007) shows the Alameda Creek watershed historically supported a run of coho salmon. Although there is evidence to support the historical presence of coho salmon in tributaries and coastal streams in and around San Francisco Bay, current findings on the geographic distribution of coho salmon conclude the species is absent from San Francisco Bay and its tributaries and is limited locally to a small number of tributaries in Marin County (NMFS, 2005).

A report by the NMFS (2005) on the status of federally listed DPS of west coast salmon and steelhead summarized a range of surveys and reports on the occurrence of coho salmon in tributaries and coastal streams in and around San Francisco Bay. In assessing historical data and discussing decreasing population numbers for coho salmon in this region, the report identified extremely low contemporary abundance compared to historical abundance, widespread local extinctions, clear downward trends in abundance, extensive habitat degradation, and associated decreases in the carrying capacity of Alameda Creek. The NMFS (2005) presented findings that salmon stocks in small coastal streams north of San Francisco were at moderate risk of extinction, and those in coastal streams south of San Francisco Bay were at high risk of extinction. The report indicated that coho salmon were not present in San Francisco Bay and its tributaries. The results of presence-absence analyses for the CCC coho salmon ESU as a whole estimated that coho salmon were present in only 42 percent of streams historically known to contain coho salmon (NMFS, 2005). Data presented as part of these analyses (CDFG findings, as presented in NMFS, 2005) estimated occupancy was highest in Mendocino County (62 percent), followed by Marin County (40 percent), Sonoma County (4 percent), and San Francisco Bay tributaries (0 percent).

In summary, there is no documentation indicating the presence of coho salmon within Alameda Creek. Therefore, the Draft PEIR does not include an analysis of impacts on coho salmon as a species of concern in the program area.

Pacific Lamprey

Pacific lamprey is addressed in the Draft PEIR as part of the environmental setting for Alameda Creek fisheries (Vol. 3, Chapter 5, p. 5.4.5-12). Additionally, Leidy (2007) presents records for the upper Alameda Creek watershed suggesting that lamprey are able to ascend some formidable migration barriers to reach spawning habitat in the upper Sunol Valley, including the BART weir and the PG&E gas line crossing, as well as more transitory obstacles such as the ACWD inflatable dams in the Alameda Creek flood control channel downstream of Niles Canyon.

Moyle (2002) suggests the possibility that some upstream populations of Pacific lamprey may contain individuals that remain resident, rather than migrating to sea (much like rainbow trout), and it is therefore possible that the sampled population in the program area is resident. There are no known observations of either Pacific lamprey or river lamprey spawning in Alameda Creek, and no recorded observations of lamprey attached to other fish or of scars on fish from lamprey attacks. If adult Pacific lamprey can ascend barriers in the lower creek and reach Sunol Park, it is unclear how often they are successful at doing so.

The Draft PEIR identified sensitive habitat and listed species in the program area. The PEIR description of existing conditions does not include anadromous Pacific lamprey as a species of concern in the program area due to the lack of conclusive data indicating that this form of Pacific lamprey occurs within the upper Alameda Creek watershed. Impacts on Pacific lamprey due to reduced flows below the BART weir (where individual lamprey have recently been netted in the flood control channel section) have not been determined to be significant based on hydrological modeling of flow changes in the lower portion of Alameda Creek. Further discussion of WSIP-related flow impacts in the flood control channel is provided above in Section 14.9.3 under the heading “Impacts on Stream Flow and Fisheries Downstream of the BART Weir.” It should be noted, however, that Pacific lamprey will be included in the SFPUC’s Alameda Watershed HCP.

Warmwater Fish Species and their Habitats in Alameda Creek

Comments on the Draft PEIR requested consideration of warmwater fish habitat in the lower portion of Alameda Creek. A discussion of species present within Alameda Creek, including warmwater species, is presented in Section 5.4.5 of the Draft PEIR (Vol. 3, Chapter 5, p. 5.4.5-12) and summarized in Table 5.4.5-1 (Vol. 3, Chapter 5, pp. 5.4.5-13 to 5.4.5-15).

The CDFG has outlined recreational fishing resources in the San Francisco Bay Area and classifies Alameda Creek as habitat for federally listed steelhead as well as for many native non-game warmwater fish and native and introduced game fish species (CDFG, 2008). According to Skinner (1962), while Alameda Creek may not be a typical warmwater stream, it does support a number of warmwater fish species, including largemouth bass, small-mouth black bass, crappie, catfish, panfish, and roughfish.

The impacts of the WSIP on all fishery resources, including the warmwater species discussed in Table 5.4.5-1, are presented in the Draft PEIR (Vol. 3, Chapter 5, pp. 5.4.5-16 to 5.4.5-22). These impacts were determined to be either beneficial or less than significant in all cases (except for Impact 5.4.5-3, which would be potentially significant, but could be mitigated to a less-than-significant level with implementation of Mitigation Measures 5.4.5-3a and 5.4.5-3b).

14.9.6 Climate Change and Cumulative Effects on Future Fish Passage and Fish Habitat

Introduction

This section of the master response addresses comments concerning the WSIP's potential effects on fish passage and fishery resources in the Alameda Creek watershed when the effects of climate change are taken into consideration.

Comment Summary

This section of this master response responds to all or part of the following comments:

L_ACFCWCD-05

Summary of Issues Raised by Commenters

- The combined effects of the WSIP and climate change on flows and fish passage over the BART weir and middle inflatable dam are not adequately addressed.

Response

Comments received on the Draft EIR included concern regarding climate change effects on flows as they relate to fish passage over the BART weir. A number of habitat studies identify the BART weir as a total barrier to anadromous fish passage (Gunther et al., 2000). As described above in Section 14.9.4, passage improvement projects in Alameda Creek must be successfully completed for fish passage to be possible at the BART weir, and other barriers to passage will need to be removed as well for steelhead to become restored to the upper watershed. For this reason, impacts related to fish passage at the BART weir within the context of climate change were not analyzed in the Draft PEIR. Potential cumulative impacts on fish passage are discussed in Section 14.9.4, which describes the impacts of the WSIP on potential future-occurring anadromous fish under the future cumulative scenario, which assumes the implementation of passage improvement projects and minimum flow releases for the protection of listed species. Impacts on anadromous salmonid migration and fishery habitat in lower Alameda Creek below the recapture facility due to implementation of the WSIP are presented above in Section 14.9.3.

Additional concern was raised that climate change could affect flows in the upper watershed and thus affect future fish passage and habitat connectivity. Potential impacts of climate change on the regional water system, precipitation patterns, and local hydrology are discussed in **Section 14.11, Master Response on Climate Change** (Vol. 7, Chapter 14, Section 14.11.4); this master response provides a qualitative assessment of WSIP impacts in the Alameda Creek watershed with consideration of climate change effects, and therefore addresses effects of climate change on Alameda Creek flows.

Potential impacts on habitat and habitat connectivity from climate-change-induced temperature effects are discussed here. The results of temperature monitoring in Alameda Creek conducted as part of habitat survey work (Hanson, 2002a, 2002b; McBain and Trush, 2007) demonstrate that current habitat conditions in Alameda Creek are on the threshold for steelhead suitability. Temperatures in mid-April already exceeded the smoltification success threshold, and by mid-June had exceeded the assumed juvenile growth threshold in Niles Canyon and farther downstream. Summer water temperatures within the lower reaches of the tributaries and mainstem Alameda Creek were characterized as stressful and/or unsuitable for juvenile steelhead rearing under the environmental conditions monitored during 2001 and 2002 (Hanson, 2002a, 2002b).

Under future climate change scenarios, increased summer temperatures could cause Alameda Creek to exceed the range for viable steelhead summer rearing habitat, particularly in the middle and lower reaches of the creek. Cooler waters are also more likely to favor high juvenile growth rates. Instream flow releases can generate physical juvenile rearing habitat, but abundant habitat that is too warm is not viable for steelhead. However, greater stream flow generally produces cooler water temperatures, especially instream flows released from the hypolimnion[5] of reservoirs (McBain and Trush, 2007). Instream flow releases will be an important management tool for extending favorable water temperatures into spring and summer. In addition, as discussed above in Section 14.9.4, under the future cumulative scenario, the proposed improvements at the Sunol quarry pits could improve the contributions to stream flow and underflow of shallow groundwater into Niles Canyon, improving rearing habitat through cool-water thermal buffering.

5 The bottom portion of a thermally stratified lake or reservoir; water in the hypolimnion is generally cool and has a low oxygen concentration.

Under proposed WSIP operations, peak winter flows of up to 650 cfs would be diverted from Alameda Creek to Calaveras Reservoir through the diversion tunnel. These proposed diversions would not adversely affect summer temperatures or rearing habitat, as no diversions occur during the summer (dry) months. The project revisions described in Section 14.9.1, above, provide detailed discussion of the various strategies for instream flow releases, designed as protective measures for fishery and native stream-dependent biological resources in Alameda Creek. The protective measures include ongoing monitoring and adaptive management of bypass flows such that the SFPUC would modify and adjust flows as needed to address steelhead habitat and life-stage requirements. The ongoing monitoring and adaptation would include operational and flow modifications to address possible climate change effects.

14.10 Master Response on Modified WSIP Alternative

14.10.1 Introduction

Overview

This master response addresses the issues commenters raised on the Modified WSIP Alternative, which was identified in the Draft PEIR as the environmentally superior alternative. Several commenters requested that the Final PEIR further describe and analyze the Draft PEIR's Modified WSIP Alternative. Commenters expressed support for the Modified WSIP Alternative because it would result in fewer impacts on natural resources than the proposed program. This master response is organized by the following subtopics:

14.10.2 Modified WSIP Alternative – Additional Details
14.10.3 Additional Water Conservation/Recycling and the Modified WSIP Alternative
14.10.4 Modified WSIP Alternative – Additional Information on Environmental Impacts

It was apparent from the comments that the Modified WSIP Alternative concept needed clarification. This alternative was devised to avoid the significant adverse impacts on fisheries and terrestrial biological resources in the reach of the Tuolumne River below La Grange Dam that were identified to occur with the WSIP. It incorporates some, but not all, of the mitigation measures that were designed to lessen or eliminate the significant impacts of the WSIP (see Draft PEIR, Vol. 4, Chapter 6). If the Modified WSIP Alternative were to be implemented, mitigation measures would still be needed to avoid significant adverse impacts, as described below in Section 14.10.4.

Summary of Issues Raised by Commenters

- The PEIR should provide a more detailed description of the Modified WSIP Alternative.

Response

As described in the Draft PEIR (Vol. 4, Chapter 9, pp. 9-78 to 9-82), the Modified WSIP Alternative incorporates changes into the proposed WSIP primarily to modify the proposed water supply and system operations so as to minimize environmental effects on resources in the

Tuolumne River, Alameda Creek, San Mateo Creek, and Pilarcitos Creek watersheds. This alternative incorporates many (but not all) of the mitigation measures identified in the Draft PEIR to reduce potentially significant or significant impacts. It consists of the same facility improvement projects and water supply sources as the WSIP, but would also include additional conservation, water recycling, and local groundwater development and certain system operation modifications that would reduce environmental impacts. The Modified WSIP Alternative would meet 2030 customer purchase requests and achieve all of the WSIP goals and level of service objectives, and its performance would be essentially identical to that of the WSIP based on the drought-year shortages and the amount of rationing that would be required during the design drought (see Table 14.10-3, below).

The Modified WSIP Alternative is similar to the proposed WSIP and would consist of the following elements:

- Water supply sources during all years (nondrought and drought periods):
  - Local supplies from the Peninsula and Alameda Creek watersheds (similar to the WSIP)
  - Tuolumne River (similar to existing conditions)
  - Transfer of water conserved in the TID and MID service areas and/or in the service area of another water agency (not part of the WSIP)
  - Recycled water/groundwater/increased conservation in San Francisco (same as the WSIP)
  - Increased recycled water/conservation/local groundwater in the regional wholesale customer service area (not part of the WSIP)

- Supplemental dry-year water supply sources:
  - Westside Groundwater Basin conjunctive use (same as the WSIP)
  - Dry-year water transfer of conserved water from TID and MID (similar to the WSIP, but with transfer made from conserved water)

- System operations under the Modified WSIP Alternative would be the same as with the WSIP, except for the following additional measures designed to minimize environmental effects:
  - Alameda Creek bypass flows between the Alameda Creek Diversion Dam and the confluence with Calaveras Creek to provide minimum flows for resident trout
  - Modified operations of Pilarcitos facilities to reduce effects on water quality, biological resources, and fisheries
  - Modified operations of Crystal Springs Reservoir to reduce effects on biological resources

Table 14.10-1 presents a comparison of the Modified WSIP Alternative and the proposed program, and updates information on the Modified WSIP Alternative shown in Table 9.5 of the Draft PEIR (Vol. 4, Chapter 9, p. 9-11). As shown in the table, the Modified WSIP Alternative would have essentially the same water supply sources as the proposed program, with the notable

TABLE 14.10-1
(SIMILAR TO DRAFT PEIR TABLE 9.4)
COMPARISON OF PROPOSED PROGRAM AND MODIFIED WSIP ALTERNATIVE

Program Element	Existing Condition	Proposed Program	Modified WSIP Alternative
Planning Year	2005	2030	2030
Target Delivery Level (annual average)	265 mgd	300 mgd	300 mgd
Water Supply Sources (during nondrought and drought periods)	▪ Local watersheds (with Calaveras and Lower Crystal Springs Reservoirs operating at reduced levels based on Division of Safety of Dams restrictions) ▪ Tuolumne River	▪ Local watersheds (with Calaveras and Lower Crystal Springs Reservoirs restored) ▪ Tuolumne River, with increased average annual diversions ▪ Recycled water/groundwater/additional conservation in San Francisco, 10 mgd	▪ Local watersheds (with Calaveras and Lower Crystal Springs Reservoirs restored, but with reduced maximum operating levels for Crystal Springs Reservoir) ▪ Tuolumne River, with increased average annual diversions between Hetch Hetchy and Don Pedro Reservoirs but with no increase in diversions below La Grange Dam ▪ Recycled water/groundwater/additional conservation in San Francisco, 10 mgd ▪ Regional recycled water/groundwater/additional conservation in wholesale service area, 10 mgd ▪ Transfer of conserved water in the TID and MID service area and/or in the service area of another water agency
Supplemental Dry-Year Water Supply Sources (for implementation during drought periods only)	None	▪ Additional Tuolumne River diversions from Turlock and Modesto Irrigation District (TID and MID) transfers of 25 mgd (average over design drought) ▪ Westside Basin conjunctive use, 6 mgd (average over design drought)	▪ Transfer of conserved water from TID and MID (17.5 mgd average over design drought) ▪ Westside Basin conjunctive use, (6 mgd average over design drought)
Maximum Drought Rationing Policy	No defined limit, but assumed incidental rationing of up to 25%	20%	20%
System Firm Yield	219 mgd	256 mgd	248 mgd
WSIP PEIR Facility Improvement Projects	None	All projects	All projects
Other Facility Improvements	None	None	▪ Low-head pumping station and permanent aeration system at Pilarcitos Reservoir ▪ Facilities associated with water conservation project(s) in TID, MID, and/or other water agency service area ▪ Facilities associated with additional water conservation, recycling, and groundwater projects in the wholesale service area
Delivery, Operations, and Maintenance	As described in Chapter 2, Section 2.3 (Vol. 1)	Improved to meet WSIP goals and objectives (as described in Vol. 1, Chapter 3, Section 3.8)	Similar to proposed program but with: bypass flows for resident trout at Alameda Creek Diversion Dam; revised operations at Pilarcitos Reservoir; reduced maximum operating levels in Crystal Springs Reservoir; habitat monitoring and compensation at Pilarcitos Reservoir; and establishing flow criteria, monitoring, and augmenting flows below Stone Dam

TABLE 14.10-1 (Continued)
COMPARISON OF PROPOSED PROGRAM AND MODIFIED WSIP ALTERNATIVE

Program Element	Existing Condition	Proposed Program	Modified WSIP Alternative
Permits, Approvals, and other Decisions/Actions	As described in Chapter 2, Sections 2.4 and 2.5 (Vol. 1)	▪ San Francisco Planning Commission certifies Final PEIR ▪ SFPUC adopts CEQA findings/mitigation monitoring and reporting program and approves and adopts the WSIP ▪ Water transfer agreements with TID and MID ▪ Operating agreements with Daly City, San Bruno, and California Water Service Company for Westside Basin conjunctive-use program ▪ Water sales agreements with retail and wholesale customers (see Vol. 1, Chapter 3, Section 3.13)	Same as proposed program except: ▪ Transfer agreements with TID and MID and/or other water agency for conserved water ▪ Agreements for participation in regional recycled water/ conservation/local groundwater projects that could offset SFPUC supply
Mitigation Measures needed to reduce significant and potentially significant impacts	N/A	▪ All programmatic mitigation measures identified for impacts associated with facility improvement projects (Measures 4.3-2 to 4.17-8) ▪ All mitigation measures identified for water supply and system operations impacts (Measures 5.3.6-4 to 5.6-5)	▪ All programmatic mitigation measures for facility improvement projects (Measures 4.3-2 to 4.17-8) ▪ All mitigation measures identified for water supply and system operations impacts (Measures 5.3.6-4 to 5.6-5), except for the following, which would be incorporated into this alternative: - Measure 5.3.6-4a, Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water - Measure 5.3.6-4b, Fishery Habitat Enhancement - Measure 5.3.7-6, Lower Tuolumne River Riparian Habitat Enhancement - Measure 5.4.5-3a, Minimum Flows for Resident Trout on Alameda Creek - Measure 5.4.5-3b, Alameda Diversion Dam Diversion Restrictions or Fish Screens - Measure 5.5.3-2a, Low-Head Pumping Station at Pilarcitos Reservoir - Measure 5.5.3-2b, Aeration System at Pilarcitos Reservoir - Measure 5.5.3-2c, Habitat Monitoring and Compensation at Pilarcitos Reservoir - Measure 5.5.5-5, Establish Flow Criteria, Monitor and Augment Flow below Stone Dam

difference that the alternative would implement increased levels of conservation and water recycling. Section 14.10.3, below, presents a detailed description of the water conservation and recycling proposed under the Modified WSIP Alternative to supplement water supply sources, including agricultural conservation in the San Joaquin Valley and increased conservation/water recycling/local groundwater projects in the wholesale service area. The additional water conservation and recycling efforts incorporated into the Modified WSIP Alternative would enable the SFPUC to reduce diversions from the Tuolumne River compared to the levels proposed under the WSIP while still achieving all of the WSIP's level of service objectives, including serving customer purchase requests to 2030. As indicated in the table, the Modified WSIP Alternative would incorporate some, but not all, of the mitigation measures identified for the WSIP in the Draft PEIR. This alternative is designed to reduce the water-supply-related impacts of the WSIP, but would still require implementation of many of the same mitigation measures as the proposed program to reduce other identified impacts to a less-than-significant level. As described below in Section 14.10.4, the Modified WSIP Alternative was determined to be the environmentally superior alternative.

The Draft PEIR (Vol. 1, Chapter 3) provides detailed descriptions of the proposed facility improvement projects (pp. 3-48 to 3-72) that would be implemented under both the WSIP and the Modified WSIP Alternative. However, since publication of the Draft PEIR in June 2007, the SFPUC has conducted additional studies that would result in slight modifications to the facility improvement projects and system operations under the Modified WSIP Alternative. These changes would affect Alameda Creek bypass flows, Pilarcitos facilities operations, and Crystal Springs Reservoir operations, as described below.

Facility Improvement Project Updates and Alameda Creek Fishery Releases

As described in Section 13.2, Program Description Changes Affecting System Operations (Vol. 7, Chapter 13), as well as in **Section 14.9, Master Response on Alameda Creek Fishery Issues** (Vol. 7, Chapter 14), the SFPUC modified the project descriptions of the Alameda Creek Fishery Enhancement (SV-1) and Calaveras Dam Replacement (SV-2) projects after publication of the Draft PEIR. These modifications would reduce the environmental impacts on fishery, recreational, and visual resources in the Alameda Creek watershed and would also affect regional system operations. The modifications to the Calaveras Dam project include construction of a new bypass structure at the Alameda Creek Diversion Dam and implementation of releases from this structure to meet the requirements of the 1997 California Department of Fish and Game Memorandum of Understanding when flow is available in Alameda Creek. This proposed measure to implement flow releases at the Alameda Creek Diversion Dam would reduce the effects of the WSIP on resident trout between the diversion dam and the confluence with Calaveras Creek and on recreational and visual resources in the Sunol Regional Wilderness. It would also serve as an interim measure to reduce potential impacts on future-occurring steelhead in Alameda Creek to a less-than-significant level, until such time that the Alameda Watershed Habitat Conservation Plan is completed.

Under both the WSIP and the Modified WSIP Alternative, the SFPUC would incorporate these modifications and implement them as part of the Calaveras Dam Replacement project (SV-2).

The Modified WSIP Alternative would also incorporate the specific requirements included in Mitigation Measure 5.4.5-3a (see Vol. 7, Chapter 16, Section 16.2, Measure 5.4.5-3a, as revised), which call for the SFPUC to conduct the necessary site-specific studies to determine the minimum flow requirements needed to support resident trout spawning and egg incubation, and to implement an operations plan that provides for adaptation of the minimum flows based on the monitoring results and best available scientific information.

Modified Pilarcitos Facilities Operations and Related Measures

As described in the Draft PEIR (Vol. 4, Chapter 9, p. 9-79), the Modified WSIP Alternative incorporates Mitigation Measure 5.5.3-2, Revised Operations Plan for Pilarcitos Watershed Facilities, to avoid impacts on multiple Pilarcitos watershed resources, including water quality, terrestrial biological resources, and fisheries. However, as described in Section 13.3 (Vol. 7, Chapter 13), the SFPUC conducted further analysis and modeling of Pilarcitos facilities subsequent to Draft PEIR publication and determined that this proposed mitigation measure would be technically challenging and that other more practical solutions are available. As a result, multiple substitute mitigation measures have been developed to replace Measure 5.5.3-2 that would reduce the impacts of the WSIP on all resources in the Pilarcitos Creek watershed to a less-than-significant level. The replacement measures are described in Section 13.3 (Vol. 7, Chapter 13) and are presented as revised text in Section 16.2 (Vol. 7, Chapter 16). The replacement/substitute measures for the Pilarcitos watershed consist of the following: Measure 5.5.3-2a, Low-Head Pumping Station at Pilarcitos Reservoir; Measure 5.5.3-2b, Aeration System at Pilarcitos Reservoir; Measure 5.5.3-2c, Habitat Monitoring and Compensation; and Measure 5.5.5-5, Establish Flow Criteria, Monitor and Augment Flow.

Therefore, the Modified WSIP Alternative as currently proposed incorporates these replacement mitigation measures. Under the Modified WSIP Alternative, the SFPUC would:

- Install a permanent low-head pumping station at Pilarcitos Reservoir, which would enable the SFPUC to augment flow in Pilarcitos Creek with water from the reservoir when the WSIP would cause releases from Pilarcitos Reservoir to Pilarcitos Creek to be reduced to reservoir inflow earlier in the summer than would occur under the existing condition—about 25 percent of years in the hydrologic record (see Measure 5.5.3-2a)

- Install a permanent aeration system at Pilarcitos Reservoir, which the SFPUC would operate as necessary to avoid anoxic conditions and maintain good water quality conditions at the reservoir (see Measure 5.5.3-2b)

- Develop and implement an adaptive management plan for managing and maintaining freshwater marsh and other wetlands around the periphery of Pilarcitos Reservoir, and compensate for the reduced productivity and diversity of San Francisco garter snake and California red-legged frog wetland habitat that could occur as a result of the greater variability, extent, and duration of drawdowns at Pilarcitos Reservoir associated with operation of the proposed low-head pumping station (see Measure 5.5.3-2c)

- Develop and implement a monitoring and operations plan for Stone Dam to ensure WSIP-related flow reductions downstream of Stone Dam do not impair steelhead passage and spawning during the winter months of normal and wetter hydrologic years and, if needed, release bypass flows from Stone Dam when flow is available to meet the minimum stream flow for steelhead passage in Pilarcitos Creek in the reach between Stone Dam and Albert Canyon (see Measure 5.5.5-5)

Modified Crystal Springs Reservoir Operations

Since publication of the Draft PEIR, the SFPUC has completed studies on Crystal Springs Reservoir as part of the development of the Lower Crystal Springs Dam Improvements project (PN-4). These studies included topographic LiDAR surveys, detailed review of historical water surface elevations and operating procedures, mapping of existing habitat, and analysis of future conditions under the WSIP and the Modified WSIP Alternative using the Hetch Hetchy/Local Simulation Model (HH/LSM) (SFPUC, 2008; Entrix, 2008). The studies identified the maximum operating water surface elevation and corresponding maximum storage capacity in Crystal Springs Reservoir under various conditions, as shown in **Table 14.10-2**, below:

TABLE 14.10-2
CRYSTAL SPRINGS RESERVOIR WATER SURFACE ELEVATION AND STORAGE CAPACITY

Condition	Maximum Water Surface Elevation (feet, NGVD)	Maximum Storage Capacity (billion gallons)
Existing Condition, with DSOD restrictions imposed since 1982	283.8	18.5
WSIP, proposed program analyzed in the Draft PEIR	291.8	22.2
Modified WSIP Alternative	287.8	20.3

NGVD = National Geodetic Vertical Datum of 1929; DSOD = California Department of Water Resources, Division of Safety of Dams.

SOURCE: SFPUC, 2008.

In determining the maximum operating water surface elevation and corresponding storage capacity under the Modified WSIP Alternative, the SFPUC considered numerous factors that would reduce impacts on biological resources, including existing vegetation, the potential for areas to revegetate with other vegetation/habitat if operating water elevations are raised, and the estimated frequency and duration of various inundation conditions, among others. This revised definition of operating parameters for Crystal Springs Reservoir under the Modified WSIP Alternative would set a maximum water surface elevation for most of the year, below the maximum capacity of the future reservoir, to reduce impacts on various habitats and related biological resources while still allowing the SFPUC to achieve the WSIP level of service objectives. It assumes that proposed system operations would not affect the daily rates of change in water surface elevation (which are based on storms and customer demand) or minimum elevations during drought periods (which are based on supply limitations). The major change in operating assumptions under the WSIP and the Modified WSIP Alternative compared to the existing condition is that Crystal Springs Reservoir would be fuller longer, subject to the maximum water surface elevation and corresponding storage level specified above.

The above assumptions constitute a refinement and improvement of the proposed Crystal Springs Reservoir operations under the Modified WSIP Alternative described in the Draft PEIR, which suggested that the SFPUC could regulate seasonal fluctuations within the maximum reservoir capacity rather than restricting the maximum storage level (Vol. 4, Chapter 9, p. 9-9). The refined operating assumptions for the Modified WSIP Alternative would reduce the magnitude of impacts on biological resources compared to the WSIP, but would not eliminate the impacts, which would remain potentially significant under the Modified WSIP Alternative. Therefore, implementation of the following mitigation measures would still be required to reduce impacts to a less-than-significant level: Measure 5.5.6-1a, Adaptive Management of Freshwater Marsh and Wetlands; Measure 5.5.6-1b, Compensation for Impacts on Terrestrial Biological Resources; and Measure 5.5.6-1c, Compensation for Serpentine Seep-Related Special-Status Plants (Vol. 4, Chapter 6, pp. 6-57 and 6-58). However, these impacts and mitigation measures will be reevaluated in detail at a project level and refined as part of the environmental review of the Lower Crystal Springs Dam Improvements project (PN-4).

14.10.3 Additional Water Conservation/Recycling and the Modified WSIP Alternative

Comment Summary

This section of this master response responds to all or part of the following comments:

Summary of Issues Raised by Commenters

- The PEIR should provide a more detailed description of how the proposed conserved water transfer from the Turlock Irrigation District (TID) and the Modesto Irrigation District (MID) (i.e., reduction in demand for water from Don Pedro Reservoir) is to be achieved.

- The PEIR should explore the feasibility of increasing agricultural conservation beyond that proposed to develop the conserved water dry-year water transfer element of the WSIP, with the goal of no net decrease in flows released to the lower Tuolumne River or even an increase; this could result in *more* water (a net increase) remaining in Don Pedro Reservoir (and released to the lower Tuolumne) than is currently the case, even after taking the proposed increased diversions for the SFPUC regional system into account. Possible mechanisms to increase agricultural water conservation to be explored include: Bay Area water agencies provide economic incentives and/or financial support to encourage and fund agricultural conservation.

- The PEIR should provide more detail on future water recycling efforts by the wholesale customers.
- The preferred alternative identified in the Draft PEIR (the proposed program) does not maximize water conservation and recycling in lieu of additional water diversions from the Tuolumne River.
- The SFPUC and Bay Area Water Supply and Conservation Agency (BAWSCA) should work together to establish more effective regional conservation and recycling programs.

Response

Proposed Transfer of Conserved Water Included in Modified WSIP Alternative

Under the WSIP, the SFPUC would increase the amount of water it would divert from the Tuolumne River at Hetch Hetchy Reservoir. The increased diversion of water at Hetch Hetchy Reservoir needed to serve increased purchase requests by 2030 would be partially facilitated by a proposed dry-year water transfer from TID and MID to the SFPUC. The dry-year water transfer is included in the WSIP in order to avoid water rationing of more than 20 percent systemwide during a prolonged drought. For more information on the proposed dry-year water transfer, see **Section 14.3, Master Response on Proposed Dry-Year Water Transfer** (Vol. 7, Chapter 14).

Because more water would be diverted at Hetch Hetchy Reservoir with the WSIP (including the dry-year transfer), less water would flow down the river between O'Shaughnessy Dam and Don Pedro Reservoir, and inflow to Don Pedro Reservoir would be reduced. Decreased inflow would reduce storage in Don Pedro Reservoir compared to the existing condition. Because storage in Don Pedro Reservoir with the WSIP would be reduced, more of the late spring/early summer snowmelt runoff would be needed to refill the reservoir. As a result, less water would be released to the Tuolumne River below La Grange Dam than is released under the existing condition. Releases would still be in compliance with the Federal Energy Regulatory Commission's minimum required releases, but the HH/LSM results indicate that minimum releases would be made in 734 months of the 984-month hydrologic record with the WSIP compared to 717 months under the existing condition. The reduction in late spring/early summer releases attributable to the WSIP would have significant adverse impacts on fisheries and terrestrial biological resources in the reach of the river below La Grange Dam, as described in the Draft PEIR (Vol. 3, Chapter 5, Sections 5.3.6 and 5.3.7).

Draft PEIR Mitigation Measure 5.3.6-4a describes a "conserved water transfer" (Vol. 4, Chapter 6, p. 6-48) to reduce the impacts of the WSIP on fisheries and terrestrial biological resources in the Tuolumne River below La Grange Dam to a less-than-significant level. Measure 5.3.6-4a would involve a water transfer from TID/MID and/or another water agency to the SFPUC, in a manner similar to the dry-year water transfer that is already part of the WSIP. The water for Measure 5.3.6-4a would be developed through conservation in the service areas of TID, MID, and/or another water agency. In this context, conservation could include water savings achieved through altered irrigation methods or planting of less water-intensive crops; improved delivery efficiency; an interagency transfer of conserved water; or use of an alternative supply such as groundwater. Measure 5.3.6-4a was incorporated into the Modified WSIP Alternative, as described in Chapter 9 of the Draft PEIR (Vol. 4, pp. 9-78 to 9-81), but with the condition that the water for the mitigation measure would be developed through conservation only. Unlike Measure 5.3.6-4a, this alternative would not include as an option the use of alternative water sources.

As described in the Draft PEIR (Vol. 1, Chapter 3, pp. 3-36 to 3-39), and expanded upon in **Section 14.3, Master Response on Proposed Dry-Year Water Transfer** (Vol. 7, Chapter 14), the dry-year transfer would be made between TID/MID and the SFPUC. The conserved water transfer included in Measure 5.3.6-4a and the Modified WSIP Alternative differs from the dry-year transfer in that it could be made between TID/MID and the SFPUC or between another water agency and the SFPUC. From a practical standpoint, only a water agency in reasonable proximity to the TID and MID service areas could serve as the source of the conserved water transfer to the SFPUC. The Modified WSIP Alternative, incorporating Measure 5.3.6-4a with water developed through conservation only, would result in less-than-significant adverse impacts on fisheries and terrestrial biological resources in the Tuolumne River below La Grange Dam because it would have little effect on storage in Don Pedro Reservoir compared to the existing condition. Storage in Don Pedro Reservoir with the Modified WSIP Alternative would be similar to storage under the existing condition, and, consequently, releases to the river from La Grange Dam with the Modified WSIP Alternative would be similar to those under the existing condition. Under the Modified WSIP Alternative, the WSIP-caused reduction in inflow to Don Pedro Reservoir would be offset by a reduction in Don Pedro Reservoir outflow, thus maintaining storage in the reservoir at close to the existing condition. Outflow from the reservoir (i.e., water diverted to the Modesto and Turlock Canals) would be reduced through conservation in the TID and MID service areas, or in the service areas of neighboring irrigation districts. The conserved water would be transferred to the SFPUC.

If the source of the conserved water transfer were to be TID and MID, those agencies would conserve water in their service areas and transfer the conserved water directly to the SFPUC. If the source of the conserved water transfer were to be an agency other than TID and MID, the transfer would still involve TID and MID and would occur as follows. The transferring agency would reduce water use in its service area by implementing conservation measures and would transfer the conserved water to TID and MID. TID and MID would use the conserved water in their service areas, thereby reducing the need to divert water from the Tuolumne River. The reduction in diversions of Tuolumne River water by TID and MID, and the consequent reduction in outflow from Don Pedro Reservoir, would offset the reduction in inflow to the reservoir produced by the SFPUC's increased diversions from the Tuolumne River at Hetch Hetchy Reservoir. As noted in the Draft PEIR, the details of the proposed water transfers have not been developed, and no agreements have been made with MID/TID or another water agency with respect to the transfers. The proposed water transfers could themselves have environmental impacts and may need additional environmental review, as described in the Draft PEIR (Vol. 4, Chapter 6, p. 6-63) and Section 14.10.4 of this master response, once the details of such transfers are known.

A commenter on the Draft PEIR, BAWSCA, supports the conserved water transfer concept but notes that decisions regarding crop choice and irrigation water pricing are the responsibility of the irrigation districts and their members. Furthermore, BAWSCA states that it does not support the fallowing of land as a means of water conservation. The San Francisco Planning Department acknowledges the views expressed by BAWSCA. The SFPUC intends to work with TID, MID, and/or other water agencies to develop a transfer of conserved water that is acceptable to all parties to the transfer. Any conserved water transfer agreement is likely to involve the implementation of water conservation measures selected and implemented by the transferring agency and paid for by the SFPUC and the wholesale customers. BAWSCA has expressed its willingness to contribute to the cost of agricultural water conservation measures that reduce environmental impacts on the Tuolumne River.

Many experts believe that water could be used more efficiently in California's cities and agricultural areas, and that it would be if appropriate financial incentives were provided. (See the comment letter from BAWSCA dated February 21, 2008 and the attached materials authored by Professor Brent Haddad, Director of the Center for Integrated Water Research at the University of California, and Peter Gleick, President of the Pacific Institute [Vol. 8, **Appendix M**].) Even without financial incentives, farmers in California are slowly but consistently moving toward more efficient irrigation methods. For example, data from surveys conducted by the California Department of Water Resources indicate that the percentage of land in California irrigated by the more efficient methods—sprinkler and drip/micro irrigation—increased from about 20 percent in the early 1970s to 50 percent in 2000.

The adoption of more efficient irrigation methods could be accelerated through the provision of appropriate financial incentives. Currently, TID and MID divert an average of 867,000 acre-feet of water annually from the Tuolumne River at La Grange Dam. If the SFPUC and TID/MID agreed to a conserved water transfer, TID and MID would only have to increase their water use efficiency slightly to offset the effects of the Modified WSIP Alternative. With appropriate financial incentives, it is assumed that additional agricultural water conservation and improvements in water use efficiency on this scale in the service areas of TID, MID, and/or other water agencies would be feasible.

It should be noted that the Modified WSIP Alternative would lessen but not entirely eliminate the impacts of the WSIP on flow, fisheries, and terrestrial biological resources in the Tuolumne River below La Grange Dam. With the conserved water transfer, average annual releases to the river below La Grange Dam would increase slightly with the Modified WSIP Alternative compared to the existing condition, which would be marginally beneficial for fisheries and terrestrial biological resources. With the Modified WSIP Alternative, there would still be occasional delays in the late spring/early summer releases from La Grange Dam (those releases in excess of minimum requirements), but the magnitude and frequency of the delays would be much less than with the WSIP. The delays would not be completely eliminated under the Modified WSIP Alternative because the timing of changes in Don Pedro Reservoir inflow attributable to increased water demand could not be perfectly matched with the timing of changes in reservoir outflow attributable to the conserved water transfer. Nevertheless, the impacts of the occasional delays in spring releases on fisheries and terrestrial biological resources that would occur under the

Modified WSIP Alternative would be reduced to a less-than-significant level with implementation of the conserved water transfer.

The conserved water transfer that is a part of the Modified WSIP Alternative could have an indirect effect on surface and groundwater resources in the lower Tuolumne River watershed and neighboring watersheds, as noted in the Draft PEIR (Vol. 4, Chapter 6, p. 6-64). Conservation measures and measures to improve the efficiency of agricultural water use could reduce groundwater recharge and the volume of irrigation tailwater discharges to surface streams. The environmental effects of the measures would depend on their nature and location, but would be expected to be relatively minor because any reductions in groundwater recharge or tailwater discharge would be small compared to total groundwater storage capacity or river flow.

Water Conservation in Agricultural Areas Beyond that Included in the Modified WSIP Alternative

BAWSCA and some of its member agencies have proposed the implementation of additional agricultural water conservation beyond that included in the Modified WSIP Alternative. According to these proposals, the water saved would accumulate in Don Pedro Reservoir and could be used to increase flows in the Tuolumne River below La Grange Dam or could be conveyed to water users in the Bay Area via a water exchange agreement with TID and MID. The SFPUC regards any project intended to increase agricultural water conservation beyond the level needed to reduce the impacts of the WSIP to a less-than-significant level to be separate from the WSIP. If the Modified WSIP Alternative is selected as the preferred course of action, the SFPUC would work with TID, MID, or another water agency to develop the transfer of conserved water that is included in the Modified WSIP Alternative. BAWSCA could choose to pursue a separate agricultural water conservation project to augment this transfer, but if the SFPUC were to participate in the project, it would be considered a distinct action from the WSIP or any alternative/variant of the WSIP.

Increased Conservation, Water Recycling, and Local Groundwater Use by Wholesale Customers Included in the Modified WSIP Alternative

The WSIP would increase the average annual diversion of water from the Tuolumne River by 24 million gallons per day (mgd) compared to the existing condition, based on updated HH/LSM results (see **Table 14.10-3**). The Modified WSIP Alternative includes features that would both increase and decrease average annual diversions of water from the Tuolumne River compared to the WSIP, but would result in a net reduced level of Tuolumne River diversions compared to the proposed program. The components of the Modified WSIP Alternative that would increase average annual diversions include the measures to lessen the impacts of the WSIP on natural resources in the Alameda Creek and Peninsula watersheds. They include the release of water from the diversion dam on Alameda Creek to support resident trout, modified operations in the Pilarcitos Creek watershed, and restrictions on the use of storage in Crystal Springs Reservoir. Implementation of these measures would reduce the amount of water available to the regional system from the Alameda Creek and Peninsula watersheds by an annual average of 1 mgd. In order to meet its level of service goals under the Modified WSIP Alternative, the SFPUC would have to increase diversions from the Tuolumne River by an annual average of about 1 mgd compared to the WSIP to compensate for the loss of water from the local watersheds.

TABLE 14.10-3
(SIMILAR TO DRAFT PEIR TABLE 9.5)
AVERAGE ANNUAL TUOLUMNE RIVER DIVERSIONS AND DROUGHT-YEAR SHORTAGES FOR THE MODIFIED WSIP ALTERNATIVE[a]

Scenario	Estimated Tuolumne River Diversions Over the 82-Year Period of Hydrologic Record[b]		Drought-Year Shortages Based on 82-Year Period of Hydrologic Record				Drought-Year Shortages During Design Drought (8.5 years)		
	Average Annual Increase by the SFPUC (mgd)	Average Annual Diversions by the SFPUC (mgd)	Years of Shortages (10% Shortage)	Years of Shortages (20% Shortage)	Years of Shortages >20% Shortage)	No. of Years Drought-Year Supplies Triggered	Years of Shortages (10% Shortage)	Years of Shortages (20% Shortage)	Years of Shortages (25% to 30% Shortage)
Existing Conditions	N/A	221	6 out of 82 (1 in 14 years)	8 out of 82 (1 in 10 years)	None	N/A	1	5	1.5
Proposed Program (WSIP)	24	245	6 out of 82 (1 in 14 years)	2 out of 82 (1 in 41 years)	None	24	3	3.5	None
Modified WSIP Alternative, between Hetch Hetchy and Don Pedro Reservoirs	15	236	6 out of 82 (1 in 14 years)	2 out of 82 (1 in 41 years)	None	23	3	3.5	None
Modified WSIP Alternative, below La Grange Dam	0	221[c]	6 out of 82 (1 in 14 years)	2 out of 82 (1 in 41 years)	None	23	3	3.5	None

a Results from the 2008 HH/LSM analysis using updated and refined model input assumptions. The numbers are not directly comparable to those in Draft PEIR Table 9.5, which are based on the 2007 HH/LSM analysis.
b Diversion levels represent the average annual amount modeled over the 82-year historical hydrology, but do not represent year-to-year variation in diversions. Thus, even with a zero average annual increase in diversions, there would still be year-to-year variations in diversions compared to the existing condition, due primarily to modified system operations for maintenance and implementation of the conjunctive-use program.
c This represents the net effect of SFPUC diversions below La Grange Dam with conserved water transfers implemented.

The components of the Modified WSIP Alternative that would decrease average annual diversions include increased local water conservation, recycling, and groundwater use within the wholesale customer service area of 5 to 10 mgd compared to the WSIP (see Draft PEIR, Vol. 4, Chapter 9, p. 9-80). Studies completed by BAWSCA and the SFPUC indicate that opportunities exist to develop more water conservation, recycling, and groundwater projects within the wholesale customers' service areas than were reflected in the purchase request estimates for the WSIP (Vol. 4, Chapter 9, pp. 9-47 to 9-59). These projects alone would not meet the full projected wholesale customer need for additional water delivery in 2030, but they could meet more of the demand than was assumed in the Draft PEIR.

Increasing local conservation, water recycling, and groundwater use within the wholesale customer service area by 5 to 10 mgd under the Modified WSIP Alternative would decrease the SFPUC's diversion of water from the Tuolumne River by an annual average of 5 to 10 mgd compared to the WSIP. As noted above, the mitigation measures in the Alameda and Peninsula watersheds that are part of the Modified WSIP Alternative would increase the SFPUC's diversion of water from the Tuolumne River by an annual average of 1 mgd compared to the WSIP. Thus, the reduction in diversions associated with additional local conservation, water recycling, and groundwater use would more than offset the increase in diversions attributable to the mitigation measures in the Alameda and Peninsula watersheds.

Modeling performed for the Modified WSIP Alternative—assuming an additional 10 mgd of regional water conservation, recycling, and groundwater use—indicates that the SFPUC's diversion of water from the Tuolumne River at Hetch Hetchy Reservoir would be reduced by an annual average of 9 mgd compared to the WSIP. As shown in Table 14.10-3, the SFPUC's annual average diversion of water from the Tuolumne River at Hetch Hetchy Reservoir under the existing condition is 221 mgd. Annual diversions would average 245 mgd with the WSIP and 236 mgd with the Modified WSIP Alternative. Flow in the Tuolumne River below O'Shaughnessy Dam would be reduced under the Modified WSIP Alternative, but to a lesser extent than under the WSIP.

As described above, the Modified WSIP Alternative includes a transfer of conserved water, which on balance would offset the effects of the SFPUC's increased diversion of water from the Tuolumne River at Hetch Hetchy Reservoir in the reach of the river below La Grange Dam. With the Modified WSIP Alternative, annual average releases from La Grange Dam would be greater than under the WSIP and similar to those made under the existing condition. The environmental effects of the Modified WSIP Alternative on fisheries and terrestrial biological resources in the reach of the river below La Grange Dam would be much less than those of the WSIP.

BAWSCA supports additional conservation, water recycling, and groundwater use within the wholesale customer service area as part of the Modified WSIP Alternative (see Comment L_BAWSCA1-51, Vol. 6, Chapter 12, Section 12.3). In March 2008, the BAWSCA Board of Directors authorized a study of additional water conservation, recycling, and groundwater use opportunities within its service area, and in July 2008, BAWSCA released a Request for Proposals for preparation of a water conservation/recycling implementation plan. Building on the work presented in the *Investigation of Regional Water Supply Option No. 4 Technical*

Memorandum (SFPUC, 2007, Appendix D), this current effort is expected to provide more detailed information about specific near-term projects that BAWSCA and its member agencies can pursue to develop additional local supplies and/or offset demand with conservation and/or water recycling.

14.10.4 Modified WSIP Alternative – Additional Information on Environmental Impacts

Comment Summary

Summary of Issues Raised by Commenters

- The PEIR should further analyze the Modified WSIP Alternative.
- The PEIR should more fully explore the environmentally superior alternative.

Response

The Draft PEIR includes a qualitative/comparative assessment of the environmental impacts of the Modified WSIP Alternative compared to those of the WSIP (Vol. 4, Chapter 9, pp. 9-82 to 9-84). Since publication of the Draft PEIR, the SFPUC has conducted a review of the Modified WSIP Alternative and has refined the assumptions for measures included in it, as described above in Sections 14.10.2 and 14.10.3. This section provides further discussion and analysis of the environmental impacts of the Modified WSIP Alternative, including the results of additional HH/LSM modeling. The impacts of this alternative on resources in the Tuolumne River, Alameda Creek, and Peninsula watersheds are summarized in **Tables 14.10-4**, **14.10-5,** and **14.10-6**; the tables include only those impacts that were determined to be significant or potentially significant under the WSIP, and present a comparison of those impacts between the WSIP and the Modified WSIP Alternative. The impacts of the Modified WSIP Alternative are discussed below under three categories: facility impacts, supply and system operations impacts, and growth-inducement impacts.

Facility Impacts

The environmental impacts of the facility improvement projects proposed under the Modified WSIP Alternative would be the same as those of the WSIP, as described in the Draft PEIR (Vol. 2, Chapter 4), and the same mitigation measures identified for the WSIP's impacts would also apply

TABLE 14.10-4
SUMMARY OF SIGNIFICANT WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP AND MODIFIED WSIP ALTERNATIVE
TUOLUMNE RIVER WATERSHED

Impact	Impact Description	Proposed Program	Modified WSIP Alternative
Section 5.3.6, Fisheries			
Impact 5.3.6-4: Effects on fishery resources along the Tuolumne River below La Grange Dam.			
	In wet or above-normal years when Don Pedro Reservoir is being filled, changes in the timing and duration of releases from the reservoir would decrease average monthly flows along the lower Tuolumne River beneath La Grange Dam. The greatest average flow reductions would occur during June and could result in elevated water temperatures. Changes in stream flow and water temperature would result in a reduction in the linear extent of suitable habitat for rearing Chinook salmon and oversummering steelhead/rainbow trout, potentially causing adverse affects on these fish populations in the lower Tuolumne River.	PSM	Similar to but much less than proposed program (LS) due to conserved water transfer
Section 5.3.7, Terrestrial Biological Resources			
Impact 5.3.7-2: Impacts on meadow/alluvial features along the Tuolumne River below O'Shaughnessy Dam.			
▪ Sensitive habitats	Delayed snowmelt releases, reductions in flow, and the resulting reduction in groundwater recharge would result in an incremental reduction in the extent and diversity of wetland and riparian habitats, including sensitive wetland and riparian habitats in the Poopenaut Valley.	PSM	Similar to but slightly less than proposed program (PSM)
▪ Key special-status species	A reduction in wetland and riparian habitat would reduce suitable breeding habitat for key special-status species potentially occurring along this reach (e.g., foothill yellow-legged frog, California red-legged frog, and willow flycatcher), the populations of which are already critically reduced in the Sierra Nevada.	PSM	Similar to but slightly less than proposed program (PSM)
▪ Other species of concern	A reduction in the extent and diversity of wetland and riparian habitats would reduce habitat quality and extent for animal and plant species of concern.	PSM	Similar to but slightly less than proposed program (PSM)
▪ Common habitats and species	All habitats affected by the WSIP are considered sensitive. The WSIP could affect a large number of common animal species that depend on sensitive meadows and larger riparian areas for food and cover.	PSM	Similar to but slightly less than proposed program (PSM)
Impact 5.3.7-6: Impacts on biological resources along the Tuolumne River below La Grange Dam.			
▪ Sensitive habitats	Delayed spring releases and reductions in average and total flow (particularly during and following an extended drought) below La Grange Dam would reduce or eliminate suitable conditions for the recruitment of some riparian species along the river.	PSM	Similar to but much less than proposed program (LS) due to conserved water transfer

TABLE 14.10-4 (Continued)
SUMMARY OF SIGNIFICANT WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP AND MODIFIED WSIP ALTERNATIVE
TUOLUMNE RIVER WATERSHED

Impact	Impact Description	Proposed Program	Modified WSIP Alternative
Section 5.3.7, Terrestrial Biological Resources (cont.)			
▪ Key special-status species	Because of the known presence of key special-status species and the very limited amount of remaining suitable habitat along this reach of the Tuolumne River, this incremental impact would be potentially significant.	PSM	Similar to but much less than proposed program (LS) due to conserved water transfer
▪ Other species of concern	Species of concern that would be adversely affected by changes in the extent and quality of suitable riparian habitat include western pond turtle, several bat species, and a wide variety of riparian- and marsh-associated bird species.	PSM	Similar to but much less than proposed program (LS) due to conserved water transfer
▪ Common habitats and species	The populations of common species that depend on riparian habitat could be adversely affected by the alteration of habitat.	PSM	Similar to but much less than proposed program (LS) due to conserved water transfer

LS = Less than Significant, no mitigation required
SM or PSM = Significant or Potentially Significant, can be Mitigated to less than significant
SU or PSU = Significant Unavoidable or Potentially Significant Unavoidable, cannot be mitigated to less than significant

TABLE 14.10-5
SUMMARY OF SIGNIFICANT WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP AND MODIFIED WSIP ALTERNATIVE
ALAMEDA CREEK WATERSHED

Impact	Impact Description	WSIP	Modified WSIP Alternative
Section 5.4.1, Stream Flow and Reservoir Water Levels			
Impact 5.4.1-2: Effects on flow along Alameda Creek below the diversion dam.			
	In all year types, system operations under the WSIP would increase diversions from Alameda Creek to Calaveras Reservoir between the months of December and May, nearly eliminating low and moderate (1 to 650 cubic feet per second) flows in Alameda Creek downstream of the diversion dam and substantially reducing many higher (greater than 650 cubic feet per second) flows that have occurred since 2002. The resultant reduction in stream flows and alteration of the stream hydrograph is considered an adverse effect.	SU	Similar to proposed program (SU)
Section 5.4.5, Fisheries			
Impact 5.4.5-3: Effects on fishery resources.			
	Following implementation of the Calaveras Dam Replacement project (SV-2), operation of Calaveras Reservoir and the Alameda Creek Diversion Dam would be restored to pre-2002 conditions. A substantial increase in diversions from Alameda Creek to Calaveras Reservoir would reduce flows in this stretch of the creek, despite proposed bypass flows at the diversion dam. Diversion of most or all flows during late winter and spring months would reduce the ability of resident rainbow trout to spawn and for eggs to incubate; additional monitoring would be needed to determine the effectiveness of proposed bypass flows. In addition, the increased diversion of flows to the reservoir would divert fish from Alameda Creek to the reservoir, prevent fish passage to downstream reaches of the creek, and increase the potential for fish entrainment since there are currently no screens on the diversion.	PSM	Much less than proposed program (LS) due to bypass flows for resident trout from Alameda Creek Diversion Dam
Section 5.4.6, Terrestrial Biological Resources			
Impact 5.4.6-1: Impacts on riparian habitat and related biological resources in Calaveras Reservoir.			
▪ Sensitive habitats	Increased reservoir storage elevations would result in inundation and permanent loss of seasonal wetlands, seeps, perennial freshwater marsh, and riparian habitat that have established since 2002.	PSM	Same as proposed program (PSM)
▪ Key special-status species	Since 2002, foothill yellow-legged frogs have occupied approximately 10,000 linear feet of stream channel along Arroyo Hondo between the maximum reservoir elevation mandated by the Division of Safety of Dams and the spillway elevation. Higher maintained reservoir levels would reduce the length of this high-quality habitat along the creek and adversely affect existing populations of foothill yellow-legged frog.	PSM	Same as proposed program (PSM)
Impact 5.4.6-2: Effects on riparian habitat and related biological resources along Alameda Creek from below the diversion dam to the confluence with Calaveras Creek.			
▪ Key special-status species	A reduction in the frequency, duration, and magnitude of flows below the diversion dam would reduce the total available aquatic breeding habitat and food sources for California red-legged frog and foothill yellow-legged frog populations that currently occupy this reach of Alameda Creek.	PSM	Much less than proposed program (LS) due to bypass flows for resident trout from Alameda Creek Diversion Dam

TABLE 14.10-5 (Continued)
SUMMARY OF SIGNIFICANT WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP AND MODIFIED WSIP ALTERNATIVE
ALAMEDA CREEK WATERSHED

Impact	Impact Description	WSIP	Modified WSIP Alternative
Section 5.4.6, Terrestrial Biological Resources (cont.)			
Impact 5.4.6-3: Effects on riparian habitat and related biological resources along Calaveras Creek from Calaveras Reservoir to the confluence with Alameda Creek.			
▪ Key special-status species	Future outlet works at Calaveras Dam would have the capacity to make higher volume releases than under existing conditions. Depending on the timing and volume of operational releases, they could adversely affect the reproductive success of special-status amphibian species along this reach (e.g., California red-legged frog and foothill yellow-legged frog).	PSM	Similar to proposed program (PSM)
Impact 5.4.6-4: Effects on riparian habitat and related biological resources along Alameda Creek from Calaveras Creek to San Antonio Creek.			
▪ Key special-status species	Depending on annual rainfall and localized site conditions along this creek segment, changes in winter and summer flows along this reach could result in both beneficial and adverse impacts on habitat for California red-legged frog and foothill yellow-legged frog populations.	PSM	Similar to proposed program (PSM)
Section 5.4.7, Recreational and Visual Resources			
Impact 5.4.7-1: Effects on recreation.			
	Operations under the WSIP would substantially reduce flows along Alameda Creek in the Sunol Regional Wilderness during winter and early spring months and adversely affect the recreational experience for hikers. *(Note: The Draft PEIR determined this impact to be PSM, but due to the change in the project description of the Calaveras Dam Replacement project (SV-2), this impact determination is revised to LS.)*	LS	Same as proposed program (LS)
Impact 5.4.7-2: Visual effects.			
	WSIP-induced reductions in stream flows along Alameda Creek would substantially change the quality of visual resources in the Sunol Regional Wilderness. *(Note: The Draft PEIR determined this impact to be PSM, but due to the change in the project description of the Calaveras Dam Replacement project (SV-2), this impact determination is revised to LS.)*	LS	Same as proposed program (LS)

LS = Less than Significant, no mitigation required
SM or PSM = Significant or Potentially Significant, can be Mitigated to less than significant
SU or PSU = Significant Unavoidable or Potentially Significant Unavoidable, cannot be mitigated to less than significant

TABLE 14.10-6
SUMMARY OF SIGNIFICANT WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP AND MODIFIED WSIP ALTERNATIVE
PENINSULA WATERSHED

Impact	Impact Description	WSIP	Modified WSIP Alternative
Section 5.5.3, Surface Water Quality			
Impact 5.5.3-2: Water quality in Pilarcitos Reservoir and along Pilarcitos Creek.			
	Proposed operations would generally be within the same range as existing conditions, although replacement Measure 5.5.3-2a would cause Pilarcitos Reservoir to be drawn down earlier in the summer compared to existing conditions. Water temperature could increase and dissolved oxygen could be reduced. *(Note: The Draft PEIR determined this impact to be PSM, and with the refined impact analysis for the Pilarcitos Creek watershed, implementation of a replacement mitigation measure would result in this impact determination remaining PSM.)*	PSM	Effects offset by aeration system (LS)
	During dry years, summertime releases from Pilarcitos Reservoir to Pilarcitos Creek would be reduced to reservoir inflow at an earlier date than they are under the existing condition. This would increase the temperature of instream flows between Pilarcitos Creek and Stone Dam and reduce the creek's ability to support designated cold freshwater habitat along this reach.	PSM	Similar to existing condition (LS) due to releases from low-head pump station
	During wet and above-normal years, the volume of spills over Stone Dam would be reduced compared to the existing condition.	LS	Similar to proposed program (LS)
Section 5.5.5, Fisheries			
Impact 5.5.5-1: Effects on fishery resources in Crystal Springs Reservoir.			
	Elevated water levels in Crystal Springs Reservoir would inundate approximately 1,500 linear feet of trout spawning habitat upstream of the reservoir along Laguna and San Mateo Creeks.	PSU	Similar to but less than proposed program (PSU)
Impact 5.5.5-4: Effects on fisheries resources in Pilarcitos Reservoir.			
	Proposed operations would be within the same range as existing conditions, although replacement Measure 5.5.3-2a would cause Pilarcitos Reservoir to be drawn down earlier in the summer compared to existing conditions. This would reduce the volume and quality of coldwater habitat available for resident fish species. *(Note: The Draft PEIR determined this impact to be PSM, and with the refined impact analysis for the Pilarcitos Creek watershed, implementation of a replacement mitigation measure would result in this impact determination remaining PSM.)*	PSM	Effects offset by aeration system (LS)
Impact 5.5.5-5: Effects on fisheries resources along Pilarcitos Creek below Pilarcitos Reservoir.			
	Under the WSIP, the extended period of no or very little flow in Pilarcitos Creek below Pilarcitos Reservoir during summer months of dry years would result in significant impacts on resident trout, other resident fish species and aquatic resources, and habitat quality and availability for anadromous steelhead. Increased drawdown of Pilarcitos Reservoir would increase the temperature of releases in summer and fall and reduce the quality and availability of habitat for coldwater fish species.	PSM	Similar to existing condition (LS) due to releases from low-head pump station
	A reduction in the frequency and magnitude of spills over Stone Dam would reduce flows along the lower reach. Reduced instream flows during winter months would adversely affect migratory fish habitat.	PSM	Similar to proposed program (PSM)

TABLE 14.10-6 (Continued)
SUMMARY OF SIGNIFICANT WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP AND MODIFIED WSIP ALTERNATIVE
PENINSULA WATERSHED

Impact	Impact Description	WSIP	Modified WSIP Alternative
Section 5.5.6, Terrestrial Biological Resources			
Impact 5.5.6-1: Impacts on biological resources in Upper and Lower Crystal Springs Reservoirs.			
▪ Sensitive Habitats	Implementation of the Lower Crystal Springs Dam Improvements project (PN-4) would raise average monthly water levels in Crystal Springs Reservoir and result in a short-term reduction in the overall extent of freshwater marsh as the reservoir fills. Proposed changes in operations would maintain maximum reservoir levels during summer for longer periods than under existing conditions, which could affect the composition and structure of riparian habitats. In addition, sensitive upland habitats that are unable to tolerate these longer periods of inundation would be lost.	PSM	Similar to but less than proposed program (PSM)
▪ Key special-status species	Elevated reservoir levels would inundate existing populations of special-status plant species, including serpentine-associated fountain thistle and Marin western flax, and their habitat could be permanently lost. The extent of available habitat for San Francisco garter snake and California red-legged frog would be temporarily reduced during reservoir refill, but wetland habitat that would establish at higher elevations could be more extensive. Raised reservoir levels would provide greater opportunities for largemouth bass and other predators to access frogs and snakes. Periodic drawdown during planned maintenance could adversely affect San Francisco garter snake foraging habitat.	PSM	Similar to but less than proposed program (PSM)
▪ Other species of concern	Changes in wetland habitat due to reservoir refill and proposed operations would adversely affect reptile and bird species of concern, particularly if permanent changes in the composition of wetland vegetation occur. Permanent loss of upland habitat, including upland trees, grassland, and coastal scrub, would result in significant impacts on several bird and mammal species of concern. Serpentine- and grassland-associated plant species unable to tolerate extended periods of inundation would be lost.	PSM	Similar to but less than proposed program (PSM)
▪ Common Habitats and species	Due to the extent of area involved, impacts on common habitats and species would be significant.	PSM	Similar to but less than proposed program (PSM)
Impact 5.5.6-4: Impacts on biological resources in Pilarcitos Reservoir.			
▪ Key special-status species	Proposed operations would be within the same range as existing conditions, although replacement Measure 5.5.3-2a would cause Pilarcitos Reservoir to be drawn down earlier in the summer compared to existing conditions. This would affect the extent of suitable habitat for California red-legged frog and San Francisco garter snake. Special-status species that utilize adjacent upland vegetation would not be affected. *(Note: The Draft PEIR determined this impact to be PSM, and with the refined impact analysis for the Pilarcitos Creek watershed, implementation of a replacement mitigation measure would result in this impact determination remaining PSM.)*	PSM	Effects offset by monitoring and compensation program (LS)
Impact 5.5.6-5: Impacts on biological resources along Pilarcitos Creek.			
▪ Sensitive habitats	In summer months of dry years, an extended period of no or little flow in Pilarcitos Creek between Pilarcitos Reservoir and Stone Dam could stress riparian vegetation, but existing vegetation appears to be adapted to periods of dryness. *(Note: The Draft PEIR determined this impact to be PSM, but due to the refined impact analysis for the Pilarcitos Creek watershed, this impact determination is revised to LS.)*	LS	Similar to existing condition (LS)

LS = Less than Significant, no mitigation required
SM or PSM = Significant or Potentially Significant, can be Mitigated to less than significant
SU or PSU = Significant Unavoidable or Potentially Significant Unavoidable, cannot be mitigated to less than significant

to the Modified WSIP Alternative. However, the Modified WSIP Alternative would include some additional facilities that could have environmental impacts in addition to those identified for the WSIP, as shown in Table 14.10-1, above. New or modified water management facilities in the service areas of TID, MID, or another water agency would likely be needed to enable the conserved water transfer that is part of the Modified WSIP Alternative. New or modified facilities might include sprinkler and drip irrigation systems, tailwater recycling systems, and lined canals. Under the Modified WSIP Alternative, the increased conservation, water recycling, and groundwater use in the wholesale customer service area could require the construction of new facilities such as wastewater reclamation plants and groundwater wells and associated pipelines and transmission facilities (Vol. 4, Chapter 9, pp. 9-35 and 9-93). These facilities would be subject to separate CEQA review; however, in general, it is expected that these facilities would be constructed in previously disturbed areas (within either agricultural or urban lands) and that all construction and operational impacts could be mitigated to a less-than-significant level.

Supply and System Operations Impacts

After publication of the Draft PEIR, the SFPUC conducted updated and refined water supply modeling using the HH/LSM, and quantitative data became available to allow a more detailed analysis of the potential impacts of the Modified WSIP Alternative than the qualitative assessment presented in the Draft PEIR. As described in Section 13.3 (Vol. 7, Chapter 13), the updated HH/LSM results included refinements in the input assumptions, so data from the updated analyses are not always directly comparable to the HH/LSM results presented in the Draft PEIR. However, the updated model results enable a direct comparison of the effects of the WSIP and the Modified WSIP Alternative to those under the existing condition. **Appendix O** (Vol. 8) provides supporting information on the updated HH/LSM assumptions and results for the WSIP and Modified WSIP Alternative.

Tuolumne Watershed Impacts

As shown in Table 14.10-3, diversions from the Tuolumne River at Hetch Hetchy Reservoir under the Modified WSIP Alternative would increase by an annual average of 15 mgd compared to the existing condition. This amount is 9 mgd less than would occur with the WSIP. The reduction in flow in the upper Tuolumne River below Hetch Hetchy Reservoir as a result of increased diversions by the SFPUC would manifest itself as a delay in the spring releases from Hetch Hetchy Reservoir. As described in the Draft PEIR (Vol. 3, Chapter 5, pp. 5.3.7-21 and 5.3.7-22), the delay in the spring releases from Hetch Hetchy Reservoir attributable to the WSIP would have a significant adverse impact on terrestrial biological resources in the streamside meadows and riparian corridor downstream of O'Shaughnessy Dam. Although the delay would be less with the Modified WSIP Alternative than with the WSIP, it would still have a potentially significant adverse effect on terrestrial biological resources in the Poopenaut Valley downstream of the dam; the same mitigation measure, Measure 5.3.7-2, Controlled Releases to Recharge Groundwater in Streamside Meadows, would reduce this impact to a less-than-significant level.

As described in the Draft PEIR (Vol. 3, Chapter 5, pp. 5.3.1-21 to 5.3.1-37), the SFPUC's increased diversions of water from the Tuolumne River would result in a decrease in flow in the river below

La Grange Dam. Again, the decrease would manifest itself as a delay in the late spring/early summer releases from La Grange Dam, together with a reduction in episodic releases from the dam in the fall and winter. As described in Sections 5.3.3, 5.3.6, and 5.3.7 of the Draft PEIR (Vol. 3, Chapter 5), increased water temperature, the delay in late spring/early summer releases, and the reduction in average flow attributable to the WSIP would have a significant adverse impact on fisheries and terrestrial biological resources in the Tuolumne River downstream of La Grange Dam. However, the Modified WSIP Alternative includes a transfer of conserved water from TID, MID, or another water agency (as described in Section 14.10.2, above) that would offset the effects of the SFPUC's increased diversions of water from the Tuolumne River. As a result, the Modified WSIP Alternative would have a less-than-significant impact on fisheries and terrestrial biological resources in the Tuolumne River below La Grange Dam.

The conserved water transfer that is a part of the Modified WSIP Alternative could result in impacts on local groundwater or surface water resources, but conservation projects typically have minor environmental impacts with some tradeoffs in environmental effects. However, those impacts cannot be fully assessed until the characteristics of the projects needed to enable the conserved water transfer are defined. If an agreement for the conserved water transfer were to be made between TID/MID and the SFPUC, additional project-level CEQA review may not be required. The transferring agencies, TID and MID, would serve as the responsible agencies for CEQA compliance and could use the PEIR to make their own findings, as required by CEQA Guidelines Section 15096. If it became apparent that the projects needed to enable the conserved water transfer could have environmental impacts that were not described and analyzed in the Draft PEIR, then additional CEQA review would likely be required. TID and/or MID would be the lead agency for the subsequent, project-specific CEQA review.

If the agreement for a conserved water transfer were to be made between another water agency and the SFPUC, it is expected that the impacts on the Tuolumne River would be less than those described in the Draft PEIR, although impacts could occur in neighboring watersheds. In this case, either the SFPUC or the transferring agency would serve as lead agency for CEQA compliance, and impacts on neighboring watersheds would be evaluated in a project-level CEQA document prior to any discretionary action required for the transfer. Whether the PEIR could be used to provide general background information would be determined at that time and in light of contemporaneous facts and circumstances.

Alameda Watershed Impacts

With the exception of the reach of Alameda Creek between the diversion dam and the confluence with Calavaras Creek, the impacts of the Modified WSIP Alternative in the Alameda Creek watershed would be essentially the same as those of the WSIP, as described in the Draft PEIR (Vol. 3, Chapter 5, Section 5.4). Under the Modified WSIP Alternative, the only difference in system operations in the Alameda Creek watershed would be the incorporation of Mitigation Measure 5.4.5-3a, Minimum Flows for Resident Trout on Alameda Creek (as revised due to changes in the project description of the Calaveras Dam Replacement project [SV-2], Vol. 7, Chapter 13, Section 13.2); this measure requires a monitoring program and site-specific studies to determine if proposed bypass flows would be adequate to support trout spawning and egg incubation, as well as an operations plan that would ensure the bypass flows are adapted as needed based on monitoring results and best available scientific information. For both the WSIP and the Modified WSIP Alternative, incorporation of this measure would reduce potentially significant impacts on fishery and biological resources (key special-status species) along Alameda Creek below the diversion dam (Impacts 5.4.5-3 and 5.4.6-2, respectively, Vol. 3, Chapter 5, pp. 5.4.5-18 to 5.4.5-20 and 5.4.6-18 to 5.4.6-19) to a less-than-significant level.

The impact on flow along Alameda Creek below the diversion would be similar for the Modified WSIP Alternative and the WSIP, and for both would be significant and unavoidable. Other potentially significant impacts on biological resources identified in the Draft PEIR for the WSIP (Impacts 5.4.6-1, 5.4.6-3, and 5.4.6-4 [Vol. 3, Chapter 5, pp. 5.4.6-14 to 5.4.6-23] related to biological resources in Calaveras Reservoir, Calaveras Creek, and Alameda Creek between Calaveras and San Antonio Creeks, respectively) would be the same for the Modified WSIP Alternative, and implementation of Draft PEIR Measure 5.4.6-1, Compensation for Impacts on Terrestrial Biological Resources, and Measure 5.4.6-3, Operational Procedures for Calaveras Dam Releases (Vol. 4, Chapter 6, pp. 6-54 and 6-55) would reduce these impacts to a less-than-significant level.

Peninsula Watershed Impacts

Crystal Springs Reservoir. As described above in Section 14.10.2, the Modified WSIP Alternative would alter the proposed operations of Crystal Springs Reservoir compared to the proposed operations under the WSIP. The Modified WSIP Alternative would impose a maximum water surface elevation for most of the year that is 4 feet lower than the maximum elevation under the WSIP, thus reducing the area of inundation and reducing the magnitude of impacts on habitat and related biological resources around the periphery of the reservoir. However, the operating assumptions for the Modified WSIP Alternative would not eliminate the impacts on biological resources, and the potentially significant impact identified in the Draft PEIR (Impact 5.5.6-1, Vol. 3, Chapter 5, pp. 5.5.6-14 to 5.5.6-17) would also be potentially significant under the Modified WSIP Alternative. Implementation of Measure 5.5.6-1a, Adaptive Management of Freshwater Marsh and Wetlands at Upper and Lower Crystal Springs Reservoir, and Measure 5.5.6-1b, Compensation for Impacts on Terrestrial Biological Resources, would still be required, though to lesser degree, to reduce this impact to a less-than-significant level.

Similarly, the Draft PEIR identified a potentially significant, unavoidable impact on fishery resources in Crystal Springs Reservoir (Impact 5.5.5-1, Vol. 3, Chapter 5, pp. 5.5.5-6 and 5.5.5-7) due to elevated water levels, which would inundate trout spawning habitat upstream of the reservoir along Laguna and San Mateo Creeks. While the Modified WSIP Alternative would reduce the maximum water surface elevation in the reservoir and reduce the magnitude of the impact compared to the WSIP, this impact would remain potentially significant and unavoidable.

These impacts will be evaluated in detail at a project-level as part of the environmental review of the Lower Crystal Springs Dam Improvements project (PN-4).

Pilarcitos Watershed. The WSIP would result in significant adverse effects on water quality, fisheries, and terrestrial biological resources in the Pilarcitos Creek watershed, as described in

Sections 5.5.3, 5.5.5, and 5.5.6 of the Draft PEIR (Vol. 3, Chapter 5), and recommended mitigation measures would reduce all impacts to a less-than-significant level. As described above in Section 14.10.3, the Modified WSIP Alternative would incorporate Measure 5.5.3-2a, Low-Head Pumping Station at Pilarcitos Reservoir; Measure 5.5.3-2b, Aeration System at Pilarcitos Reservoir; Measure 5.5.3-2c, Habitat Monitoring and Compensation; and Measure 5.5.5-5, Establish Flow Criteria, Monitor and Augment Flow. Thus, the impacts of the Modified WSIP Alternative in the Pilarcitos Creek watershed would be the same as those of the WSIP after the inclusion of the mitigation measures.

Growth-Inducement Impacts

The growth-inducement impacts of the Modified WSIP Alternative would be the same as those of the WSIP.

Environmentally Superior Alternative

As described in the Draft PEIR (Vol. 4, Chapter 9, pp. 9-95 and 9-96), the Modified WSIP Alternative is considered the environmentally superior alternative. This conclusion is further supported by the detailed analysis presented above. The Modified WSIP Alternative would reduce key impacts of the WSIP on natural resources along the lower Tuolumne River, along Alameda Creek below the diversion dam, at Pilarcitos Reservoir and along Pilarcitos Creek, and in Crystal Springs Reservoir. Importantly, it would also achieve the WSIP's goals and level of service objectives.

As stated above, compared to the proposed program, the Modified WSIP Alternative could result in additional facilities-related impacts associated with increased conservation, water recycling, and local groundwater projects, including conservation projects within agricultural areas. However, while the construction of new facilities would cause temporary disruption and related environmental impacts, the long-term implementation of these conservation, water recycling, and local groundwater projects would substantially reduce long-term impacts on the Tuolumne River. The impacts associated with these projects would occur in previously disturbed areas in either agricultural or urban use, and could likely be mitigated with standard mitigation measures.

Depending on the extent to which increased conservation, water recycling, and local groundwater projects could be implemented in the wholesale customers' service areas, the SFPUC's need to divert water from the Tuolumne River would be reduced. The Modified WSIP Alternative includes 5 to 10 mgd of regional conservation, water recycling, and local groundwater projects in the wholesale customers' service areas. Assuming that projects resulting in 10 mgd are implemented by 2030, the SFPUC's diversion of water from the Tuolumne River at Hetch Hetchy Reservoir would be reduced by an annual average of 9 mgd compared to the WSIP. In addition, by implementing a transfer of conserved water under the Modified WSIP Alternative, the SFPUC would be able to offset the WSIP's increased diversions from the upper reaches of Tuolumne River such that the average annual releases below La Grange Dam would be similar to those under existing conditions.

14.11 Master Response on Climate Change

14.11.1 Introduction

Overview

This master response addresses issues raised by commenters concerning the discussion on climate change and global warming presented in the Draft PEIR. Commenters primarily raised questions about how the PEIR addresses the effects of climate change on the SFPUC's water supply sources and how those effects would combine with WSIP-related impacts; some commenters also referred to the WSIP's potential to increase greenhouse gas emissions and contribute to global climate change. This master response is organized by the following subtopics:

14.11.2 Update of Climate Change Studies on Water Resources in California and Climate Change Regulatory Framework

14.11.3 Review of Water Agencies' Water Supply Management Approach to Climate Change

14.11.4 Climate Change and the SFPUC Regional Water System

14.11.5 SFPUC's Actions to Address Climate Change

Commenters

Comments on climate change/global warming were received from the following entities:

Federal Agencies

- National Park Service, Yosemite National Park – F_NPS-YOS

State Agencies

- Regional Water Quality Control Board, San Francisco Bay Region – S_RWQCBSF

Local/Regional Agencies

- Alameda County Flood Control and Water Conservation District – L_ACFCWD
- Modesto Irrigation District and Turlock Irrigation District – L_MID-TID
- Tuolumne County – L_Tuol1

Groups

- Acterra – SI_ACT
- Citizens Advisory Committee to PUC – SI_CAC1, SI_CAC2
- California Native Plant Society, East Bay Chapter – SI_CNPS-EB1
- Center for Resource Solutions – SI_CRS
- Clean Water Action – SI_CWA2
- Greenpeace – SI_GreenP
- Pacific Institute – SI_PacInst

- Sierra Club – SI_SierraC2, SI_SierraC3, SI_SierraC7
- San Francisco Planning and Urban Research Association – SI_SPUR
- Tuolumne River Trust – SI_TRT7, SI_TRT8
- Tuolumne River Trust/Clean Water Action/Sierra Club, San Francisco Bay Chapter – SI_TRT-CWA-SierraC

Citizens

PEIR Section Reference

The Draft PEIR (Vol. 2, Chapter 4, Section 4.9, pp. 4.9-14 to 4.9-20 and pp. 4.9-42 to 4.9-47) addresses the potential impacts of the WSIP facility improvement projects relative to greenhouse gas (GHG) emissions and presents a program-level analysis of GHG emissions. This information is also discussed in the following sections: Vol. 1, Summary, Section S.3, pp. S-28 and S-63; and Vol. 1, Chapter 3, Section 3.10, p. 3-82. The analysis concluded that construction and operation of the facility improvement projects would not conflict with the state's goal of reducing GHG emissions to 1990 levels by 2020 because WSIP-related GHG emissions would not result in a substantial contribution to a global climate change. This determination was based on the ongoing implementation of GHG reduction actions by the City and County of San Francisco (CCSF) and the SFPUC and additional GHG reduction actions that the SFPUC would implement as part of the WSIP (see the Draft PEIR, Vol. 1, Chapter 3, p. 3-82). Furthermore, implementation of mitigation measures related to exhaust controls, criteria pollutant emissions, waste reduction, and energy efficiency would further reduce GHG emissions associated with construction and operation of the facility improvement projects.

The Draft PEIR (Vol. 4, Chapter 7, pp. 7-60, 7-61, and 7-76) addresses the potential impacts of the WSIP-related growth inducement, which could indirectly result in increases in GHG emissions. No comments were received regarding the adequacy of the GHG emissions analysis in Draft PEIR Chapters 4 and 7, and commenters did not identify any other significant issues related to GHG emissions associated with facility construction and operations. Therefore, this master response does not provide any further discussion of WSIP-generated GHG emissions beyond that provided in Chapters 4 and 7.

The Draft PEIR addresses the potential effects of global climate change on the SFPUC's water resources in the following location: Vol. 3, Chapter 5, Section 5.7.6, pp. 5.7-92 to 5.7-96.

Comments received on the Draft PEIR related to climate change were focused almost exclusively on issues addressed in Chapter 5 of the Draft PEIR; therefore, this master response provides further discussion to update and augment the analysis of climate change issues presented in Chapter 5.

14.11.2 Update of Climate Change Studies on Water Resources in California and Climate Change Regulatory Framework

Comment Summary

This section of this master response responds to all or part of the following comments:

F_NPS-YOS-01	SI_PacInst-18	SI_TRTCWA-SierraC-78
S_RWQCBSF-16	SI_SierraC2-03	SI_TRTCWA-SierraC-130

SI_GreenP-04	SI_TRTCWA-SierraC-77	C_Unreadable1-01

Summary of Issues Raised by Commenters

- The PEIR lacks up-to-date research.
- The California Department of Water Resources (DWR) has made predictions related to climate change effects on state water resources that should be included in the impact analysis.
- Projections by the Intergovernmental Panel on Climate Change (IPCC) should be addressed.
- The PEIR only addresses one of many possible patterns of global climate change.
- The PEIR does not consider climate science in the impact analysis.
- The PEIR impact analysis does not consider that studies indicate global warming will reduce the Sierra snowpack by 5 percent by 2030 and 33 percent by 2060.

Response

Climate Change Literature Review

The following review of climate change literature relevant to the WSIP and the Draft PEIR was prepared by CH2M HILL (2007) and the SFPUC (2008) to augment and update the annotated bibliography presented in the Draft PEIR (Vol. 3, Chapter 5, pp. 5.7-93 and 5.7-94). The literature review focuses on information related to climate change effects on California water supplies and water management, including many of the references cited in comments received on the Draft PEIR. The key findings of this literature review are briefly summarized below, followed by an annotated review of relevant climate change science and policy/guidance literature in Tables 14.11-1 and 14.11-2. The findings from this literature review are then used in Section 14.11.4, below, to assess the effects of climate change on the impact analysis of water resources presented in the Draft PEIR.

Summary of Literature Review

In California and throughout the West the signs of climate change are evident. During the last 50 years, trends have shown a slight increase in winter and spring temperatures, snow levels in the Sierra Nevada mountains have moved to a higher average elevation, and snowmelt has been occurring earlier in the season. Observed temperature increases in California are higher than the global average. The causes of these recent climate changes are complex and are in part due to the levels of GHG emissions throughout the globe. Climate scientists are studying possible future conditions under a range of future GHG emissions. Under all future emission scenarios, the level of warming is expected to increase and would significantly accelerate under higher emission scenarios. Temperature increases in the range of 1.7 to 5.8 degrees Celsius (°C) are possible by 2100 with a mid-range estimate of 3.1 to 4.3 °C. However, despite the general consensus on future warming for California (and the globe), the scientific studies show no clearly discernible trend in precipitation changes in California over the next century. There is a wide range of differences in model projections for precipitation changes due to global warming, with some models projecting increases in precipitation and others predicting no increase or decreases over the century; still other studies indicate that even with no change in annual precipitation, the number of days with precipitation could decline, resulting in more intense precipitation on those fewer days with precipitation.

A number of analyses have been performed over the past 5 to 10 years to assess the hydrologic impacts of climate change on California's water resources. Some of the more robust findings among the studies listed in Table 14.11-1 are presented below:

- The Sierra Nevada spring snowpack is expected to continue to decrease due to an increase in the elevation of the freezing line, more precipitation falling as rain rather than snow, and an earlier snowmelt (DWR, 2006; California Climate Change Center, 2006; Mote et al., 2005; Roos, 2005).
- Rivers and streams fed by mountain watersheds are expected to exhibit an increase in stream flow in winter and early spring and a decrease in late spring and summer (Hamlet et al., 2005; Maurer and Duffey, 2005; Hayhoe et al., 2004).
- Greater conflicts among water supply, hydropower, and flood control in reservoir operations are anticipated (DWR, 2006).
- Warmer temperatures are expected to reduce some reservoir coldwater pools, which could affect the temperature of reservoir releases and increase stream temperatures, potentially disrupting aquatic species (DWR, 2006).

- Warmer temperatures could cause increases in water demand in both agricultural and municipal regions (DWR, 2006; Kiparsky and Gleick, 2003).
- Sea level rise will affect coastal areas and estuaries and could threaten levees (IPCC, 2007; DWR, 2006).

These six major findings are further discussed below in Section 14.11.4 (see Table 14.11-3) with respect to how climate change may be expected to affect the SFPUC regional water system and how climate change considerations would affect the WSIP impacts presented in the Draft PEIR.

In summary, the literature review (Table 14.11-1) indicated that quantitative assessments of potential climate change effects have been developed for the major watersheds in the Central Valley, and these studies have provided information useful to the SFPUC regional water system. These studies indicate a potential loss in Sierra spring snowpack of 12 to 50 percent by mid-century, depending on the degree of warming. The DWR's most recent climate change study (DWR, 2006) evaluated a range of future climate conditions on water resources in the Central Valley using output from two climate models and four climate change scenarios selected from the IPCC studies; DWR found that under three of the four climate change scenarios (those assuming a modest decline in total precipitation), water deliveries to State Water Project (SWP) and Central Valley Project (CVP) contractors would significantly decrease by 2050. The water resources in lower to mid-elevation basins, such as the upper Sacramento River and Feather River basins, would be substantially affected due to a reduction in snowpack and changes in runoff. Higher elevation basins, such as those providing inflow to Hetch Hetchy Reservoir, would be less sensitive to warming and would not lose as much winter-season snowpack as those with average elevations near the freezing line. The DWR reported that when these climate change scenarios are applied to Don Pedro Reservoir, there would be a reduction in Tuolumne River annual inflow to the reservoir as well as a shift in the timing of inflow by 2050. No focused studies of the upper Tuolumne River basin were identified in this literature review (outside of the initial modeling efforts performed by the SFPUC of the Hetch Hetchy system, as summarized in the Draft PEIR and described further below), although many researchers have analyzed the broad effects of climate change on the Sierra drainages, including the Tuolumne River watershed.

Various researchers and agencies have used different approaches and applied different climate change scenarios to assess the impacts and vulnerabilities of water resource systems to future climate change. One approach used by the DWR and the California Climate Change Center applies a range of future emission scenarios coupled with two general circulation models to quantify possible impacts. The quantitative assessments performed using this approach have utilized results from the research community as inputs to existing operational models. The applications of this approach vary from the use of specific scenarios to multi-model ensemble scenarios to perform the assessments. Another approach recently used by the U.S. Bureau of Reclamation in the Colorado River basin relies on paleoclimatological (tree ring) data over several centuries to characterize hydrologic variability and to predict future climate trends. A third approach used by several entities including the East Bay Municipal Utility District (EBMUD) evaluates system vulnerability to climate change and rates future management options based on flexibility to adapt to a changed climate. The approach being used by the SFPUC to address climate change is described in Sections 14.11.4 and 14.11.5 of this master response.

Tables 14.11-1 and **14.11-2** summarize the recent literature on climate change science and policy relevant to California water supplies and water management that was reviewed for this PEIR.

Regulatory Framework – Climate Change

This section summarizes recent California statues and executive orders that specifically pertain to global climate change, and augments the regulatory framework included in the Draft PEIR (Vol. 2, Chapter 4, pp. 4.9-14 and 4.9-15). The additional regulatory framework information provides a more comprehensive basis for evaluating climate change policy issues related to the SFPUC regional water system, but does not change the analysis in the Draft PEIR. It should be noted that all regulatory policy and guidance related to climate change pertain to GHG emissions.

Assembly Bill 1493

Approved in 2002, Assembly Bill 1493 addresses GHG emissions from motor vehicles. It requires that the California Air Resources Board (CARB) develop and adopt, by January 1, 2005, regulations that achieve "the maximum feasible reduction of GHGs emitted by passenger vehicles and light-duty truck and other vehicles determined by the CARB to be vehicles whose primary use is noncommercial personal transportation in the state."

Executive Order S-3-05

Approved on June 1, 2005 by Governor Schwarzenegger, Executive Order S-3-05 formally recognizes California's vulnerability to the impacts of climate change, including the fact that increased temperatures threaten to reduce snowpack in the Sierra Nevada, which serves as one of the state's primary sources of water. Additionally, the order notes that climate change could influence human health, coastal habitats, microclimates, and agricultural yield. To address these potential impacts, the order mandates the following GHG emission reduction targets: by 2010, reduce GHG emissions to 2000 levels; by 2020, reduce GHG emissions to 1990 levels, and by 2050, reduce GHG emissions to 80 percent below 1990 levels. In addition, the order requires biannual reports starting in January 2006 describing: progress made toward meeting GHG emission targets; global warming impacts in California on water supply, public health, agriculture, the coastline, and forestry; and mitigation and adaptation plans to combat these impacts.

Assembly Bill 32 – California Global Warming Solutions Act

Approved in 2006, the California Global Warming Solutions Act (Assembly Bill 32) establishes a timetable for the CARB to adopt emission limits, rules, and regulations designed to achieve, among other objectives, a statewide GHG emissions cap for 2020 that is equivalent to the 1990 emissions levels. The act requires the CARB to adopt regulations to require the reporting and verification of statewide GHG emissions as well as regulations to achieve the maximum technologically feasible and cost-effective reductions in GHGs. Refer to the Draft PEIR (Vol. 2, Chapter 4, pp. 4.9-14 and 4.9-15) for further description of this act.

Reference	Summary
Barnett, T.P., D.W. Pierce, H.G. Hidalgo, C. Bonfils, B.D. Santer, T. Das, G. Bala, A.W. Wood, T. Nozawa, A.A. Mirin, D.R. Cayan, and M.D. Dettinger, Human-Induced Changes in the Hydrology of the Western United States, in: *Science* 319:1080-1082, 2008.	This study provides statistical validation that observed changes in the hydrological cycle in the western United States from 1950 to 1999 are due to human-caused climate changes related to GHGs and aerosols. The authors conducted a regional, multivariable climate change detection and attribution study using a high-resolution hydrologic model combined with global climate models and sophisticated data analysis. The results show that up to 60 percent of the climate-related trends of river flow, winter air temperature, and snow-pack between 1950 and 1999 are human-induced.
Intergovernmental Panel on Climate Change (IPCC), *Climate Change 2007: The Physical Science Basis, Summary for Policymakers,* 2007.	This brief report provides a summary of the IPPC Working Group I findings in its Fourth Assessment Report (AR4). The report summarizes the most current scientific consensus-based findings regarding recent observations of climate change, a paleoclimate perspective, and projections of future climate change.
Christensen, J.H., B. Hewitson, A. Busuioc, A. Chen, X. Gao, I. Held, R. Jones, R.K. Kolli, W.T. Kwon, R. Laprise, V. Magaña Rueda, L. Mearns, C.G. Menéndez, J. Räisänen, A. Rinke, A. Sarr, and P. Whetton, *Regional Climate Projections*, in: *Climate Change 2007: The Physical Science Basis, Contribution of Working Group I to the Fourth Assessment Report of the Intergovern-mental Panel on Climate Change,* 2007.	This chapter of the IPCC Assessment Report 4 provides a summary of the most recent regional climate projections and attempts to synthesize the most overarching issues. North America is considered as one region, although some greater geographical detail is provided. An assessment is provided regarding the general skill (capability of simulating observed climate) of the current suite of AOGCMs. General conclusions regarding temperature increases, precipitation changes, extreme events, atmospheric circulation, and snowpack-snowmelt-runoff are provided. In addition to the findings reported elsewhere of temperature increases and precipitation uncertainty, the report indicates greater climate variability during the 21st century. It indicates both a greater frequency in extreme temperature events and diurnal range, as well as greater frequency of extreme precipitation events (both wet and dry).
California Department of Water Resources (DWR), *Progress on Incorporating Climate Change into Planning and Management of California's Water Resources,* Technical Memorandum Report, July 2006.	This report is DWR's response to the governor's 2005 order establishing targets for GHG emissions and requiring biennial reporting by state agencies. This report describes the progress made to incorporate climate change into water resources planning and management. The report describes potential changes in precipitation and runoff, sea level, water demand, and fisheries. Based on research by Knowles and Cayan (2002) and the 2001 IPCC findings, the report projects the following loss of April snowpack averaged across the entire Sierra in snow-water-equivalent. Snow-water-equivalent is a measure of the volume of water that would be produced by melting snow and is used to translate snowpack to water volume. • 0.6 °C rise, ~5 percent loss • 1.6 °C rise, ~33 percent loss • 2.1 °C rise, ~50 percent loss These three levels of average temperature rise were projected by Knowles and Cayan to occur by 2030, 2060, and 2090, respectively. The water supply analyses included in this report utilized the results from four climate change scenarios described below in CalEPA (2006): PCM A2, GFDL A2, PCM B1, and GFDL B1. All four of these scenarios show a warming trend by the end of the 21st century; three of the four scenarios show a modest drying trend in precipitation with the fourth scenario showing a weak precipitation increase. There was no consistent trend for precipitation. Due to the coarse scale of the AOGCMs, the results from these climate change scenarios were "downscaled," a process of translating AOGCM output to a smaller regional or watershed scale (such as the major watersheds of the Central Valley) using the statistical methods described by Wood et al (2002, 2004) and Maurer et al. (2007). After downscaling, hydrological analyses were performed using the macro-scale Variable Infiltration Capacity model for each major watershed. The effects on runoff were analyzed for a historical period centered around 1976 (1961–1990) and for a climate change future period centered around 2050 (2035–2064). The fractional changes in runoff from historical gage measurements and future scenarios were then applied as monthly perturbation ratios to adjust the inflows to the CALSIM II Hydrology and Operations model to reflect

TABLE 14.11-1 (Continued)
CLIMATE CHANGE SCIENCE REFERENCES

Reference	Summary
	the climate change future. The perturbation ratios are simply multipliers applied to historical inflows to reflect the effects of climate change. For example, the historical inflow to Oroville Reservoir for July 1985 was approximately 2,189 cubic feet per second (cfs), and the perturbation ratio for July under the GFDL A2 scenario is 0.68. The inflow to Oroville for this simulated month under the GFDL A2 climate change scenario would then be 1,489 cfs (2,189 cfs multiplied by 0.68). For the major watersheds contributing stream flow to the Central Valley (including Tuolumne River inflow to Don Pedro Reservoir), the DWR found there was generally an increase in runoff from December through April and a decrease in May through November due to: more precipitation falling as rain rather than snow and, a reduced snowpack in the warmer climate. This shift occurred regardless of whether the climate change scenario was considered wetter or drier than historical records due to the temperature effect on the snowpack. The long-term average annual inflows to Shasta, Oroville, and Folsom Reservoirs were found to be decreased in three of the four scenarios (those assuming a decline in total precipitation). Only the PCM B1 scenario, the less-sensitive AOGCM combined with the lower emissions, produced increased annual inflows to these reservoirs. The DWR performed model simulations to analyze the long-term potential impacts on State Water Project (SWP) and Central Valley Project (CVP) delivery capability and found that total project impacts ranged from virtually no change to up to 10 percent, depending on the climate change scenario. The DWR also reported potential changes in monthly patterns of Tuolumne River inflow to Don Pedro Reservoir. The shift in the *fraction* of monthly inflows ranged from an increase of 6 to 25 percent for the December through April period and a decrease of 4 to 29 percent for the May through November period. Note that these percentages are an average of the fractional changes and are not equivalent to volumetric shifts in inflow. Volumetric changes in inflow were not documented in the DWR report. However, using the perturbation factors presented in this report and historical inflows to Don Pedro Reservoir, average annual inflow would also decrease for three of the four climate change scenarios (those assuming a decline in total precipitation). Only the wetter PCM B1 scenario produces increased average annual inflow. The report, however, did not specifically analyze climate change effects on the Hetch Hetchy system.
California Environmental Protection Agency (CalEPA), *Climate Action Team Report to Governor Schwarzenegger and the Legislature,* March 2006.	This report provides a general overview of climate processes and summarizes a broad range of climate change impacts on various resources in California. Strategies for controlling GHG emissions and potential adaptation measures are provided. Importantly, the report summarizes climate change scenarios used in the analysis of each of the resource areas. The report uses the results from three emission scenarios developed by the IPCC: a higher emission scenario (A1Fi), a medium-high emission scenario (A2), and a lower emission scenario (B1). To capture the range of uncertainty among climate models, the report relies on projections of the climate changes under these emission scenarios from three atmosphere-ocean general circulation models (AOGCM): the low-sensitivity Parallel Climate Model (PCM) from the National Center for Atmospheric Research (NCAR) and Department of Energy (DOE), the medium-sensitivity Geophysical Fluids Dynamic Laboratory (GFDL) CM2.1 model from the National Oceanic and Atmospheric Administration (NOAA), and the slightly higher-sensitivity Hadley Centre Climate Model, Version 2 (HadCM3) from the U.K. Met Office Hadley Center. The range of scenarios considered in this report exhibits projected temperature increases for the period of 2000 to 2100 of 1.7 to 3.0 °C for the lower range, 3.1 to 4.3 °C in the medium range, and 4.4 to 5.8 °C in the higher range. Despite the consensus among scenarios in projecting warming for California (and the globe), there is no clear trend for overall precipitation results for California over the next century. Only one scenario (PCM B1) projected an increase in precipitation, while all others indicated no change or a decrease.
California Climate Change Center, *Scenarios of Climate Change in California: An Overview,* February 2006.	This white paper was largely incorporated into the March 2006 CalEPA report to Governor Schwarzenegger. It describes the basis of climate change scenarios and gives an overview of the potential impacts on various resources in California. The impacts on water resources are briefly summarized. Hydrologic modeling performed for California was used to estimate changes in snowpack throughout the century. These studies projected reductions in Sierra snowpack with increased temperature and showed large snowpack losses associated with the higher ranges of temperature increases. The paper indicates that in the Sierra Nevada, by the 2035–2064 period, snowpack could be reduced by 12 to 47 percent from historical levels under the lower range of warming and 26 to 40 percent under the higher range of warming. By the end of the century, snowpack may be reduced by as much as 90 percent at the higher end of warming.

TABLE 14.11-1 (Continued)
CLIMATE CHANGE SCIENCE REFERENCES

Reference	Summary
	Two modeling approaches were applied to evaluate the effects on water supply in the Central Valley. The first approach is that described in DWR (2006) using the CALSIM model with climate change "perturbed" inflows. The second approach uses the Water Evaluation and Planning (WEAP) model with direct temperature and precipitation inputs. Both methods indicate a likely decrease in stream flows by mid-century, with more dramatic changes by the end of the century. In addition, the analyses indicate a greater propensity for "critically dry" year classification (using unadjusted indices) than the historical hydrology. Analyses using the CALSIM model indicated that by the end of the century deliveries to the SWP and CVP could be reduced by 15 to 30 percent under the lower warming scenarios and by as much as 40 to 50 percent under the medium and higher warming scenarios. These studies did not include the effects of increased agricultural or outdoor urban demands, but suggested that these could increase by 2 to 13 percent by the end of the century.
California Climate Change Center, *Our Changing Climate, Assessing the Risks to California*, A Summary Report from the California Climate Change Center, 2006.	This brief report is a summary of the "Climate Scenarios" project, which analyzed a range of impacts that would likely result with rising temperatures in California. It is largely a summary of other work. In summarizing the potential effects on the Sierra snowpack, the reports states that "if heat-trapping emissions continue unabated, more precipitation will fall as rain instead of snow, and the snow that does fall will melt earlier, reducing the Sierra Nevada spring snowpack by as much as 70 to 90 percent." The report also indicates there is continued uncertainty regarding the future changes in precipitation, which would affect the magnitude of the snowpack loss. It indicates that if emissions are significantly curbed and temperatures remain in the lower range of projections, the loss of snowpack will likely be half that expected if temperatures reach the higher range of projections.
Sansone, Amy and Pascal Storck, *The Implications of Climate Change on a Snow Melt Dominated Watershed in Western Washington,* 3TIER Environmental Forecast Group Inc., HydroVision, 2006.	The goal of this paper was to evaluate the effect of global warming by 2025 and 2045 on the snowpack in the watershed that supplies a portion of the city of Seattle's water supply. The results from eight global climate simulations were evaluated, and the analysis showed a 1.5 °C change over a 30-year period from 1995 to 2025. The study also showed a shift in runoff from the months of April, May, and June to the months of January, February, and March.
Maurer, E., *Uncertainty in Hydrologic Impacts of Climate Change in the Sierra Nevada Mountains, California under Two Emissions Scenarios,* April 2005.	This manuscript reports on an evaluation of hydrologic impacts in the Sierra Nevada with climate projected by 11 different AOGCMs under two emission scenarios. The intent of the study was to identify the projected hydrologic changes that have high statistical confidence for the period of 2071–2100. High statistical confidence was found under the projections for increasing winter stream flow and decreasing late spring and summer flow. Less snow at the end of winter and earlier arrival of the annual flow volume were identified as confident projections. The two emission pathways investigated, SRES A2 and B1, showed differing impacts with high confidence, leading to the author's conclusion that future emission scenarios play a significant role in the degree of impacts on water resources in California.
Dettinger, Michael D., *From Climate-Change Spaghetti to Climate-Change Distributions for 21st Century California,* San Francisco Estuary and Watershed Science, U.S. Geological Survey, March 2005.	The goal of this paper was to derive a statistically based conclusion from the variable results from runs of many differing Global Circulation Models (GCMs). The paper uses the same figure (temperature change over time from a variety of GCMs) that is used in the Cayan 2004 Ground Water Conference presentation, but it explores a statistical resampling technique to construct projection distribution functions to reduce the variance in the results. When North American GCM results are emphasized in the resampling process, an increase of 3 °C by 2050 and 6 °C by 2100 temperature change is found.
Mote, P.W., A.F. Hamlet, M.P. Clark, and D.P. Lettenmaier, *Declining Mountain Snowpack in Western North America*. Bulletin of the American Meteorological Society, January 2005.	This article presented the results of research utilizing 824 snow stations from the Natural Resources Conservation Service, DWR, and Ministry of Sustainable Resource Management for British Columbia. The authors found decreases in April 1 snow water equivalent between 1950 and 1977 at the majority of the sites, with the largest decreases found in western Oregon and Washington and northern California. Some upward trends in snow water equivalent were found for the Southwest, including the southern Sierra. Some of the increasing trend was attributed to long-term climatic signals such as the Pacific Decadal Oscillation and the El Niño Southern Oscillation.

TABLE 14.11-1 (Continued)
CLIMATE CHANGE SCIENCE REFERENCES

Reference	Summary
Maurer, E and P.B. Duffy, *Uncertainty in Projections of Streamflow Changes due to Climate Change in California,* Geophysical Research Letters, Vol. 32, L03704, 2005.	This paper examines the effects of stream flow under a range of climate projections with the goal of analyzing uncertainty between models and confidence in hydrologic impacts. The effects of climate change on stream flow at three northern Sacramento Valley rivers (Sacramento River at Shasta Dam, Feather River at Oroville, American River at Folsom) and four San Joaquin Valley rivers (Stanislaus River at New Melones, Tuolumne River at New Don Pedro, and Merced River at Lake McClure) were examined under a range of carbon dioxide increase scenarios. The AOGCMs applied were those available for the Coupled Model Intercomparison Project, but are not comparable to those used by Maurer to support the DWR (2006) analyses. This paper confirmed the robust result of increases in stream flow in December through March and decreases in June through October. In addition, the authors found that the March–April flows in the higher elevation south basins were more highly influenced by projected temperature changes than in the lower elevation north basins. This appears to contradict findings by Hamlet et al. (2005), who found that trends in snow water equivalent at high-elevation basins were less affected by warming than lower basins; however, Hamlet's study covered the entire western United States, whereas this study focuses on California. The perturbed climate scenarios utilized in this study indicated a shift in stream flow timing for the Tuolumne River at New Don Pedro, but also indicated an increase in overall annual runoff due to increased precipitation projections.
Roos, M., *Accounting for Climate Change,* California Water Plan Update 2005, Vol. 4, 2005.	This report by Maurice Roos, State Hydrologist for California, examines the broad implications of climate change on California water resources. It provides a good narrative of historical trends in temperature, sea level rise, and water resource systems. The report states that the "most important parameter in determining runoff and therefore water supply is precipitation" and that "regional precipitation predictions in the huge general circulation models of the atmosphere have not been reliable, and vary greatly among the different models." Roos states that on a global scale, warming would increase evaporation, and thus increase overall precipitation, but highlights that "where and when the precipitation falls is all-important." The report discusses initial efforts by the DWR that indicated a much greater trend for warming impacts on northern Sierra snowpack and runoff decreases compared to southern Sierra snowpack and runoff, due to the elevation of these watersheds. Roos reports that with recent models it is possible to project increases in southern Sierra snowmelt runoff under wetter climate scenarios (although from less area), while this phenomenon is not shown for the northern Sierra. Roos also discusses implications for water resources in the state and concludes that not all basins would be equally affected. The report references the differences in the ratio of storage to average annual inflow in watersheds as an indicator of the level of impact. Due to a greater capacity to store runoff, the Stanislaus River with a ratio of 2.5 (storage to inflow) would be expected to have a smaller impact than the American River, where the ratio is about 0.64. Roos also analyzed the past hydrologic record for the Sacramento River and identified declining trends in April–July runoff. The trend was found to exist for most major drainages to the Central Valley, with smaller declines in the southern Sierra. This report also mentions work by researchers that has shown an increased risk for large storms and flood events for several AOGCM scenarios. An increase in flood control space would conflict with operations for water supply, power, and recreation for many of the reservoirs in California. Roos suggests that if increased winter flood control capacity were required, then one would expect greater difficulty in filling reservoirs in the spring. Finally, Roos discusses potential changes (increases) in agricultural water use with increasing temperature and difficulties in managing cold–water pools for anadromous fish. Cold-water pools in reservoirs, and within the watershed, would be expected to decrease, and river water temperatures could warm beyond the tolerable limits for salmon and steelhead in the summer. Roos suggests that multi-level outlets in reservoirs should be considered for more effective cold-water release management.
Hamlet, A., P.W. Mote, M.P. Clark, and D.P. Lettenmaier, *Effects of Temperature and Precipitation Variability on Snowpack Trends in the Western United States,* Journal of Climate, 2005.	This paper summarizes hydrologic simulation studies that were used to examine trends in snow water equivalent for the western U.S. The authors found that widespread warming occurred during 1916–2003, resulting in downward trends in April 1 snow water equivalent for large areas of the western U.S. However, as in previous work, the authors indicate upward trends in snow water equivalent in the Southwest and southern Sierra. Importantly, the paper finds that almost all upward trends in snow water equivalent are due to modest upward trends in precipitation, while all downward trends are associated with widespread warming. Decadal variability (such as the Pacific Decadal Oscillation) is reported to account for the winter trends of precipitation. Trends for stations at high elevations are less affected by warming than those at lower elevations.

CLIMATE CHANGE SCIENCE REFERENCES

Reference	Summary
Hayhoe, K., D. Cayan, C.B. Field, P.C. Frumhoff, E.P. Maurer, N.L. Miller, S.C. Moser, S.H. Schneider, K.N. Cahill, E.E. Cleland, L. Dale, R. Drapek, R.M. Hanemann, L.S. Kalkstein, J. Lenihan, C.K. Lunch, R.P. Neilson, S.C. Sheridan, and J.H. Verville, *Emissions Pathways, Climate Change, and Impacts on California*, 2004.	This study represents one of the earlier versions of the “scenarios” project for California, in which a broad range of climate impacts were analyzed under various emission pathways. The study found that California temperature increases nearly double from the lower to the higher emission scenarios and three of four simulations showed greater summer increases than winter increases. By the end of the century, Sierra snowpack was projected to decrease by 30 to 70 percent under the lower emission scenario and up to 90 percent under the higher emission scenario. The study found that the main differences between scenarios were apparent in the second half of the century, but were strongly dependent on emissions from the preceding decades.
Cayan, Dan, *Climate Change: A Challenge Looming for California*, 2004.	This reference is for a presentation given at the Ground Water Conference, Sacramento, California on October 26, 2004 by Dan Cayan, Scripps Institution of Oceanography, Climate Research Division and the U.S. Geological Survey with input from Mike Dettinger, Iris Stewart, and Noah Knowles, sponsored by the NOAA OGP RISA element, California Energy Commission PIER program. The presentation showed modeled temperature changes for Northern California that range from 1.5 to 4.5 °C by 2050 and from 2 to 10 °C by 2100. A midpoint in these ranges was selected for each date: 3 °C by 2050 and 6 °C by 2100. The presentation concluded that: • Humans have altered the atmospheric composition and thus are altering the earth’s climate; greenhouse gases have long lifetimes, so choices made now and in the future will determine future climate. Warming is already underway and coming fast. • California temperature projections are broadly in consensus (increases from 2 to 6 °C by 2100). • Warming would produce more rain, less snow, earlier flows, more floods, higher sea level, and drier summers. • California precipitation projections are scattered, with most projections showing small changes. • “Shoulders” of watershed elevations at 6,000–8,000 feet would generate more immediate runoff. • Better monitoring and modeling is crucially needed.
Kiparsky, M. and P.H. Gleick, *Climate Change and California Water Resources: A Survey and Summary of Literature*, California Water Plan, Vol. 4, Reference Guide, 2003.	This report summarizes the research and studies (as of 2003) of climate change effects on various California resources. It also highlights areas of greater uncertainty and provides recommendations for further research. The report concludes with suggested strategies for adapting to potential climate change impacts. This report provides a good summary of research, but is somewhat outdated with the rapid advance of climate change analyses in recent years.
Miller, N.L. and K.E. Bashford, *Climate Change Sensitivity Study of California Hydrology: A Report to the California Energy Commission*, Lawrence Berkeley National Labs Technical Report No. 49110, 2001.	This report describes the methodology and results of a study to analyze the effects of climate change on the major drainages of the Central Valley. The study utilized two AOGCM projections from the IPCC Third Assessment Report to analyze temperature and precipitation changes, and eventually snowpack, snowmelt, and runoff. Of particular note in this study, the authors utilized a range of temperature shifts and precipitation ratios to the Sacramento Soil Moisture Accounting Model and Anderson Snow Model in order to determine hydrologic sensitivities. Climate temperature shifts and precipitation ratios were utilized to constrain the changes from the historical climate in order to use existing operational models and “increase credibility and public acceptance” of hydrologic response. Such an approach was deemed valid, although it removed the variance in the time-series that may indicate extreme events. Results indicated that a larger proportion of the streamflow volume will occur earlier in the year and that the amount and timing is dependent on the characteristics of each basin, particularly the elevation of the freezing line. In general, higher elevation basins are less sensitive and do not lose as much winter season snowpack as those with centroid elevations near the freezing line. The paper also reported that there would likely be an increase in high flow days under the scenarios analyzed.

TABLE 14.11-2
SELECTED CLIMATE CHANGE POLICY AND GUIDANCE REFERENCES

Reference	Summary
Natural Resources Defense Council (NRDC), *In Hot Water: Water Management Strategies to Weather the Effects of Global Warming,* 2007.	This recent report highlights the potential effects of climate change on water resources and ecosystems and suggests approaches for future water management. Potential impacts on water supply, flood management, aquatic ecosystems, water quality, and hydropower are summarized largely through reference to other studies. The foundation of the report, however, is in identifying approaches for incorporating climate change into water planning and management. The report suggests the following strategies for water managers: (1) evaluate the vulnerability of water systems to global warming impacts, (2) develop response strategies to reduce future impacts of global warming, (3) prevent future impacts by reducing greenhouse gas emissions, and (4) increase awareness of global warming and water impacts. The report also provides an assessment of the performance of various water management strategies after considering global warming effects. This report is included here as it was referenced by a commenter on the Draft PEIR.
California Department of Water Resources (DWR), *State Water Project Delivery Reliability Report-2005,* April 2006.	The 2005 State Water Project (SWP) Delivery Reliability Report addressed the need to incorporate some of the uncertainties of global warming with regard to planning and operation of the SWP. “Until the impacts of climate change on precipitation and runoff patterns in California are better quantified, future weather patterns are usually assumed to be similar to those of the past, especially where there is a significant historical rainfall record. The State Water Project analyses contained in this report are based upon 73 years of historical records (1922 to1994) for rainfall and runoff that have been adjusted to reflect the current and future levels of development in the source areas by analyzing land use patterns and projecting future land and water use. These series of data are then used to forecast the amount of water available to the SWP under current and future conditions. The assumption that past rainfall-runoff patterns will be repeated in the future has an inherent uncertainty, especially given the evolving information on the potential effects of global climate change.” Note: This report has been updated in 2007 to incorporate recent interim changes in fishery protection actions required by court decisions. The report also presents SWP reliability information with consideration given to the climate change scenarios described in DWR July 2006 above.
Gleick, P.H., H. Cooley, and D. Groves, *California Water 2030: An Efficient Future*. Pacific Institute, September 2005.	This report is not specifically on climate change, but investigates the water “scenarios” approach to decision-making as applied to the California Water Plan. The report argues that the scenarios approach allows for robust decision-making without explicitly quantifying all ranges of uncertainty. This report is included here as it was referenced by a commenter on the Draft PEIR.

Senate Bill 1368

Approved in 2006 as the companion bill of Assembly Bill 32, Senate Bill 1368 requires the California Energy Commission, in consultation with the California Public Utilities Commission and the CARB, to establish and adopt by June 2007 a GHG emission performance standard and implementing regulations for all long-term baseload generation commitments made by electric utilities. The legislation requires the California Energy Commission to reevaluate and continue, modify, or replace the GHG emission performance standard when an enforceable GHG emissions limit is established and in operation.

Executive Order S-1-07

Executive Order S-1-07, the Low Carbon Fuel Standard, was issued on January 18, 2007 and calls for a reduction of at least 10 percent in the carbon intensity of California's transportation fuels by 2020. The order instructs the California Environmental Protection Agency to coordinate activities among the University of California, the California Energy Commission, and other state agencies to develop and propose a draft compliance schedule to meet the 2020 target. Furthermore, the order directs the CARB to consider initiating regulatory proceedings to establish and implement the Low Carbon Fuel Standard. In response, the CARB identified the Low Carbon Fuel Standard as an early action item with a regulation to be adopted and implemented by 2010.

Senate Bill 97

Senate Bill 97 was signed into law in August 2007. This bill requires the Office of Planning and Research to prepare, develop, and transmit to the State of California Resources Agency guidelines for the feasible mitigation of GHG emissions or the effects of GHG emissions by July 1, 2009. The Resources Agency would be required to certify and adopt those guidelines by January 10, 2010. The Office of Planning and Research is required to periodically update the guidelines to incorporate new information or criteria established by the CARB pursuant to the California Global Warming Solutions Act of 2006 (described above). The Office of Planning and Research recently released a technical advisory on CEQA and climate change. The technical advisory offers "informal guidance regarding the steps lead agencies should take to address climate change in their CEQA documents" (OPR, 2008).

14.11.3 Review of Water Agencies' Water Supply Management Approach to Climate Change

Summary of Issues Raised by Commenters

- The PEIR should follow an approach to climate change similar to that used by EBMUD, which has quantified possible climate change impacts and developed operation models.

- Turlock Irrigation District (TID) staff conducted preliminary modeling of global warming effects on the Tuolumne River and the PEIR needs to address the impacts of global warming on this river system.

Response

East Bay Municipal Utility District

EBMUD has been actively monitoring the progress of climate change research to understand and predict potential future impacts on its water supply and operations and has used the results from climate change studies to analyze these impacts (Sykes, 2006). In general, the results have indicated only a modest impact on the utility's water supply reliability. EBMUD used its water supply model to simulate the 80-year historical hydrologic record under a changed climate scenario to analyze the potential effects on water supply reliability at a 2020 level of development. These simulations assumed no change in total annual precipitation, but assumed that a warmer climate (3 °C increase in temperature) would cause 28 percent of the historical runoff to occur earlier in the year. The results of the study indicated that an earlier runoff would have little impact on EBMUD's water deliveries for four main reasons: the large percentage of spring runoff in the system's water supply watershed, the steepness of the area-elevation curve (see Figure 14.11-2), the timing and amount of demands, and the reservoir storage-to-runoff ratio. The climate change scenario used in their model resulted in fewer flood control releases due to decreased spring runoff and no significant effect on carryover storage. In addition, the amount of demand under this scenario is less than the average annual runoff, and the storage volume is greater than the average annual runoff. Nonetheless, EBMUD has taken actions to prepare for climate change, including diversifying its water supply portfolio to reduce vulnerability to geographical variation in precipitation and reinforcing its system to prepare for the effects of a 3-foot sea level rise on its Delta facilities. It is also promoting water conservation and water reclamation and a reduction in emissions of GHGs.

EBMUD has embarked on an evaluation of water supply management options through the year 2040. The focus of EBMUD's initial climate change plan is on the vulnerability of its system to climate change. As part of this effort, the district will conduct sensitivity analyses to evaluate and score the flexibility of each water supply portfolio considered in the Water Supply Management Plan 2040 to respond to climate change. The district will also consider secondary (or backup) elements for use under the predicted worsening climate conditions. This proposed approach represents a "bottom-up" methodology that would initially be limited to climate change scenarios and would not rely on the results of the "downscaled" atmosphere-ocean general circulation models (AOGCM) being used by the DWR (see the description in Table 14.11-1, above, under DWR's *Progress on Incorporating Climate Change into Planning and Management of California's Water Resources*, 2006).

As described in more detail below, many of EBMUD's strategies to address climate change are similar to those being implemented by the SFPUC. The SFPUC used one of the same key assumptions as EBMUD in its near-term planning for climate change (i.e., no change in the total annual precipitation but a shift in runoff patterns to earlier in the year that would be expected to result from warmer climate). However, unique aspects of the EBMUD and SFPUC systems necessitated some differences in the analyses of climate change effects on the systems' water resources and deliveries as well as in the long-term planning approaches. For example, the SFPUC conducted preliminary modeling of near-term climate change effects (to 2030) using temperature projections that were consistent with those of the IPCC, while EBMUD's period of analysis was to 2020 and used different temperature figures. As described below in Section 14.11.4, the SFPUC analysis used a potential mean annual temperature increase of 1.5 °C by 2025–2030, based on climate change studies that forecast a mean annual temperature increase of 3 °C by 2050 (Dettinger, 2005; Sansone and Storck, 2006). EBMUD's use of a 3 °C temperature increase by 2020 accelerates the projected temperature increase compared to the findings of current climate change studies and thus represents a very conservative assumption. The SFPUC's long-term water supply planning to prepare for the effects of climate change (as described in Section 14.11.5, below) has some of the same elements as EBMUD's program, including diversifying its water supply portfolio.

Turlock Irrigation District

TID has conducted some preliminary analyses of the possible impacts of global warming on Tuolumne River watershed runoff. The ongoing study, performed in collaboration with the SFPUC, uses a physical process model—the Hydrologic Forecasting Analysis Model—calibrated to the Tuolumne River basin for the period 1931 to 2000. The model is designed to explicitly analyze evapotranspiration,[1] snowpack, precipitation as rain or snow, and heat budget to determine effects on runoff timing and volume. This initial work compares the existing temperature (base case) with increasing temperature inputs of 0.6 and 1.7 °C (1 and 3 °F). The SFPUC is currently working with TID in reviewing the model assumptions and preliminary results. However, the work is still in progress, and no conclusions have been reached to date. As described in Section 14.11.5 below, the SFPUC is working with TID to further develop this model for use in long-term planning for climate change effects.

California Department of Water Resources

The DWR's climate change planning efforts are described above in Table 14.11-1. The SFPUC is using information provided by the DWR as general guidance in addressing climate change effects on its water system, although the results of specific DWR modeling do not address the Hetch Hetchy system and therefore are not directly applicable. (Please refer to Table 14.11-1 for descriptions of DWR's climate change planning documents.)

Sacramento Municipal Utility District

Because the Sacramento Municipal Utility District (SMUD) system includes reservoirs in the Sierra Nevada at elevations similar to those in the Hetch Hetchy system, the SFPUC contacted SMUD regarding its ongoing actions related to climate change. SMUD is following the scientific literature and DWR's analyses on climate change, particularly with respect to potential effects on the runoff patterns and quantities that could affect its system. Although SMUD does not provide water supply services, it operates and maintains hydroelectric facilities that are dependent on

1 The return of water from the soil and from plants to the atmosphere by evaporation and transpiration.

runoff patterns that could be altered by climate change. SMUD's hydroelectric project in the upper American River watershed includes three major reservoirs, at elevations of approximately 4,500, 5,500, and 6,300 feet. Because the drainage basin includes areas at 9,000-foot elevations, climate change effects associated with rising snowlines would not be expected to affect SMUD's system in the near future. SMUD has not conducted modeling or other analyses to determine any special issues for its reservoirs and watershed (McFadden, 2008).

Summary of Issues Raised by Commenters

- The PEIR should analyze the effects of increased diversions coupled with the effects stemming from climate change and global warming, including impacts on biological resources.
- The PEIR should analyze the effects on the Tuolumne River watershed, including the SFPUC's Tuolumne River system firm yield, due to climate change and associated effects on the SFPUC's system operations and water yield.
- The PEIR should analyze the effects of climate change on demand, water use patterns, and the frequency of future rationing.

- Use of historical hydrology in the impact analysis overestimates water availability and underestimates the impacts of removing water from the Tuolumne River. Changes within the historical range are not the same as no impact, and modeling shown in the PEIR does not capture the range of impacts.
- The analysis should be expanded to include the effects resulting from changes in the frequency and duration of extreme climatic events.
- The water system needs to be robust enough to withstand any future climate scenario.

Response

Chapter 5 of the Draft PEIR (Vol.3, pp. 5.7-92 to 5.7-96) describes the SFPUC's initial modeling of potential climate change effects, which indicated that warming of 1.5 °C would effectively raise the snowline by 500 feet and transfer a portion of each year's runoff from spring/summer to fall/winter. This initial modeling of the SFPUC's regional water system indicates that, by 2025, about 7 percent of the current runoff to Hetch Hetchy Reservoir would occur earlier in the year. The Draft PEIR indicates that this degree of change is within the interannual variation in runoff, and that the potential impacts of global warming on the SFPUC's regional system would not affect the proposed WSIP operations through 2030. Consistent with the approach presented in the Draft PEIR, the analysis presented in this master response relies on the best available scientific information to provide further discussion and assessment of potential climate change effects on water resources and the SFPUC regional water system in the context of the environmental impacts of the WSIP.

SFPUC's Current Studies of Climate Change Effects

Background

The SFPUC manages three reservoirs in the Sierra Nevada mountains and five local reservoirs in the Bay Area to provide water supplies for customers in the Bay Area. The mountain watersheds typically have substantial snowmelt runoff from about March through June, filling the three Sierra reservoirs by late in the spring season. The supply from the Sierra reservoirs supplements the water supply provided by the local reservoirs, and in most years it is adequate to meet customer demand through the summer as well as to provide longer term reservoir storage in case subsequent years are dry.

The historical variability of hydrologic year types includes a broad range of annual runoff volumes in the mountain watersheds, ranging from at least 40 to 200 percent of the average annual runoff, and each winter's pattern of storms is different. The SFPUC operates the Hetch Hetchy system based on the "water first" protocol (see the Draft PEIR, Vol. 1, Chapter 2, p. 2-18), and discretionary drafts of the reservoir do not occur until forecasting tools confirm that snowmelt runoff will fill the reservoirs. This policy is designed to protect against water supply shortages in the foreseeable future.

The Hetch Hetchy basin above O'Shaughnessy Dam covers 459 square miles. About 87 percent of the area is above 6,000 feet in elevation, and about 76 percent is above 7,000 feet. The Cherry

Creek drainage basin above Lake Lloyd is 116 square miles; about 76 percent is above 6,000 feet, and about 52 percent is above 7,000 feet. The Eleanor Creek drainage basin above Lake Eleanor is 79 square miles, and about 60 percent is above 6,000 feet and 26 percent is above 7,000 feet.

Based on preliminary modeling of global warming effects, the SFPUC has estimated that the elevation of the snowline in the Sierra watersheds will increase from 6,000 to about 6,500 feet by 2025 (see the Draft PEIR, Vol. 3, Chapter 5, p. 5.7-94). This change means that in the future with climate change more of the precipitation in the SFPUC's Sierra watersheds will fall as rain than as snow due to the increased occurrence of warmer storms compared to historical conditions. It also means that the snowpack, on average, will contain less water and produce less snowmelt runoff. While the total runoff volume is likely to stay about the same, the pattern of the runoff will change. The November-through-March fraction of the runoff is expected to increase, and the April-through-July fraction of the runoff is expected to decrease.

Preliminary Modeling of Near-Term Climate Change Effects

The Draft PEIR (Vol. 3, Chapter 5, pp. 5.7-94 to 5.7-96) summarizes the SFPUC's initial evaluation of climate change effects on the regional system, and a more detailed description of that study is presented in this master response. The SFPUC conducted a preliminary analysis of global warming effects using the Water Supply Forecast Model (WSFM), a statistical model based on a 48-year record of daily temperature and precipitation (Hannaford, 1997). The SFPUC currently uses the WSFM as a tool to assist in the planning and operation of the Hetch Hetchy system to predict unimpaired stream flow conditions, and adapted this model to estimate stream flow effects of near-term temperature increases in the Tuolumne River watershed that appear likely in the next few decades based on the climate change literature. However, because the WSFM is a statistical model based on historical data, the SFPUC is working with TID to develop a different model—a physical process model—for studying long-term climate change effects (see Section 14.11.5, below).

The WSFM makes forecasts using prior precipitation and runoff, the water stored as snowpack in the basin, and future precipitation. The basin's snowpack is quantified by 35 snow courses (snow measuring stations) located throughout the Merced, Tuolumne, and Stanislaus River basins. Historical precipitation is used to estimate the likely range of future precipitation, and historical temperature is used to estimate future snow melt quantity and timing. An advanced statistical procedure is employed to develop equations that are then used, together with current conditions and 48 years of historical temperature and precipitation data, to make monthly forecasts of future runoff volumes.[2]

The database used in the model includes public data collected by state, federal, and cooperating organizations and individuals. Snow course data are coordinated by the California Cooperative Snow Survey Program based in Sacramento. Precipitation and temperature data originate from a variety of sources, including the Snow Survey, the National Weather Service and their

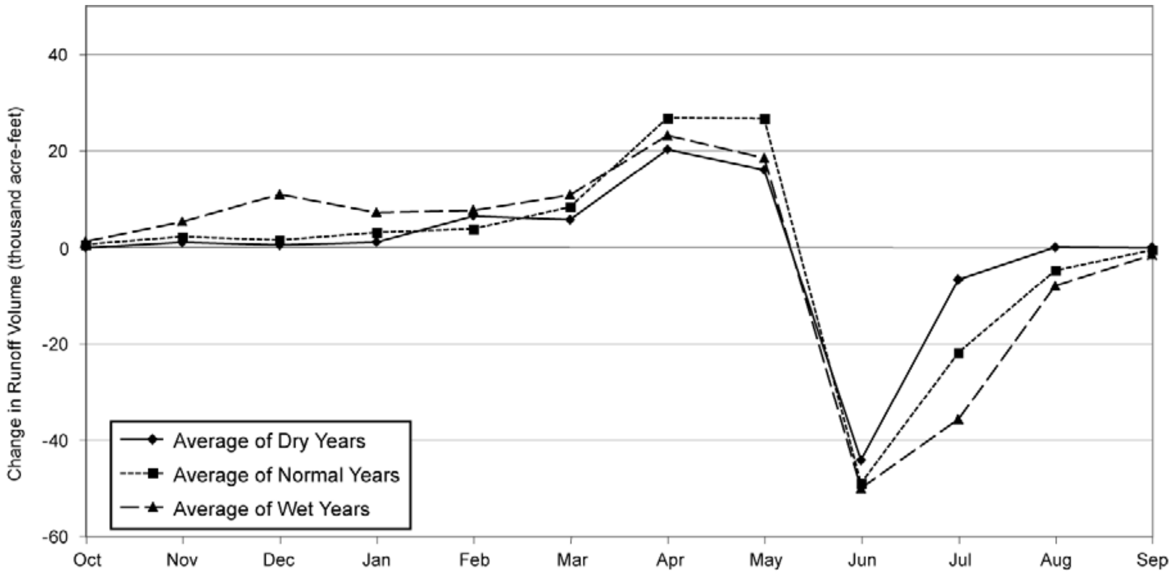
[2] Based on standard errors, the accuracy of the WSFM in predicting total annual runoff is within approximately 5 percent.

cooperators, and irrigation and water supply districts. Runoff data for the model originate from sources such as the U.S. Geological Survey, TID, and MID.

Climate change studies indicate that there will be an increase of 3 °C mean annual temperature from 2000 to 2050 (Dettinger, 2005; Sansone and Storck, 2006). Because the PEIR period of analysis is through 2030, a projected temperature increase of 1.5 °C (about 3 °F) by 2025 was selected for analysis, which is assumed to approximate the 2030 condition. Thus, a 1.5 °C warming factor was added to historical temperatures, and the SFPUC calculated runoff volumes by month for the 1948–1995 period using the WSFM to depict a climate change scenario. Differences in the monthly volumes between the historical and climate change scenarios were analyzed for the entire analysis period, and the years were also sorted into wet, normal, and dry categories to determine if differences were evident for the various wetness regimes. This analysis assumed that no changes in annual precipitation would occur, even though the scientific literature has reported a range of differences in various model projections for precipitation changes due to global warming. Since the scientific literature indicates no clear trend for precipitation changes in California over the next century (see the description in Table 14.11-1, above, under CalEPA's *Climate Action Team Report to Governor Schwarznegger and the Legislature*, 2006), it was determined that no change in annual precipitation from historical/existing conditions was a reasonable assumption for the purposes of this near-term analysis (i.e., use of this assumption would be sufficient to characterize the general nature of effects that may be expected through 2030 due to climate change). The analysis is not intended to provide the full range of possible outcomes that could occur under the various climate change scenarios, but rather to encompass a reasonable range of effects. In the absence of scientific consensus on a quantifiable change in precipitation, the assumption of no change avoids speculation as to whether precipitation would decrease, increase, or occur at the same level, or whether it would occur on fewer days but at more intense levels.

Preliminary results from the WSFM confirmed that a shift in the timing of runoff from late winter months to early winter months could occur between 2000 and 2025, and inflow to all three of the SFPUC's Sierra reservoirs shows an average shift in runoff of about 7 percent. For the 48-year period, about 7 percent of the runoff shifted from the April–July period to the November–March period. In dry years, the runoff volume is smaller, and 8.5 percent shifted, corresponding to a volume of about 35,000 acre-feet out of 410,000 acre-feet as an average runoff volume for that year type. For normal years, 7 percent shifted, corresponding to a volume of about 50,000 acre-feet out of 677,000 acre-feet as an average runoff volume. For wet years, 6 percent shifted, corresponding to a volume of about 70,000 acre-feet out of 1,410,000 acre-feet. **Figure 14.11-1** graphically depicts the shift in the volume and timing of runoff that would be expected to occur by 2025 compared to historical conditions based on a 1.5 °C increase in temperature.

The capacity of Hetch Hetchy Reservoir is 360,000 acre-feet, and in normal and wet years over 700,000 acre-feet of water flows into the reservoir, resulting in large spills/releases to the Tuolumne River. Modest amounts of spill occur even in dry years. The WSFM results indicate that a shift in the timing of runoff volumes ranging from 35,000 to 70,000 acre-feet could occur by 2025 due to global warming. These predicted changes are well within the range of current and



Note: Zero represents average historical conditions from 1948 to 1995.

SFPUC Water System Improvement Program ▪ 203287

SOURCE: SFPUC, 2008.

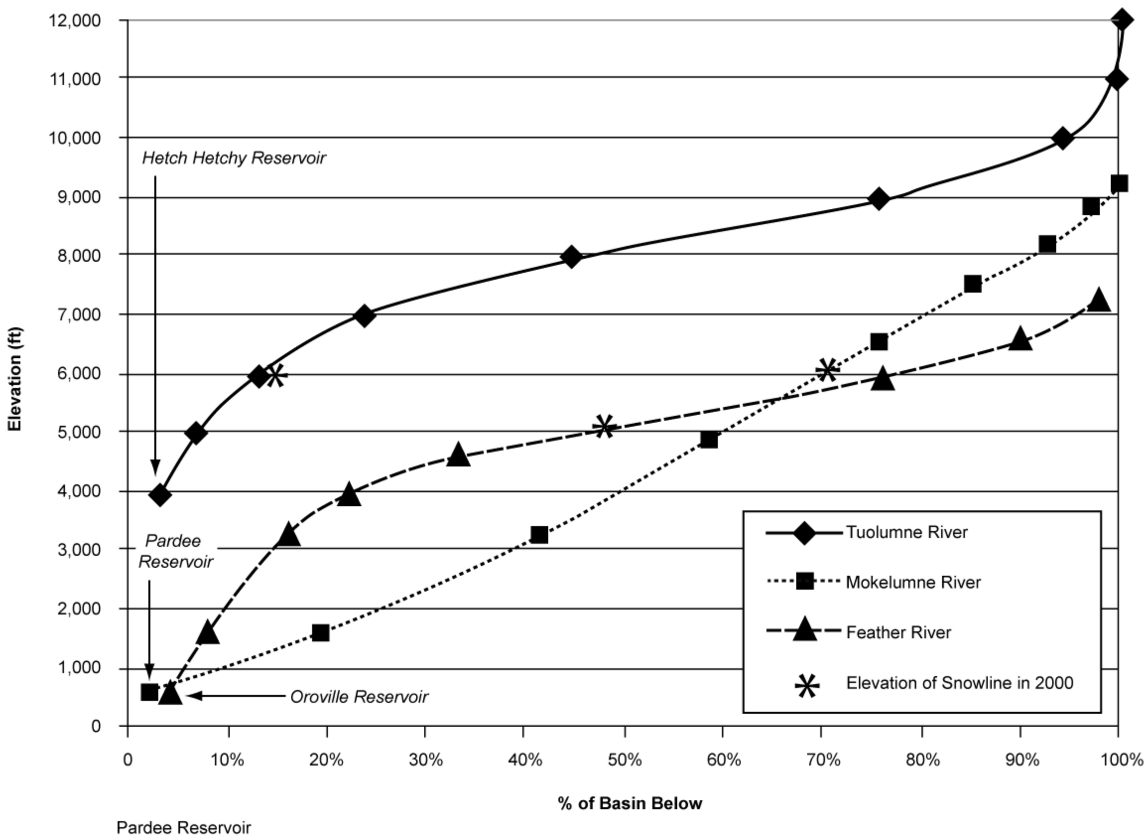
Figure 14.11-1
Modeled Shift in Runoff to Hetch Hetchy Reservoir
Comparing Historical Patterns with a Global Warming Scenario
of 1.5 °C Increase in Temperature

historical variability in annual runoff patterns. Year-to-year historical variability has shown much larger shifts between early and late winter runoff than the 2025–2030 global warming effect projected by the WSFM. Therefore, while global warming is projected to result in changes in runoff patterns in the Hetch Hetchy watershed, the SFPUC operators have determined that the magnitude of the predicted near-term changes is within the range of current/historical runoff patterns, and therefore it is not expected that substantial changes in SFPUC management practices or operations would be required through 2030. In dry years, if runoff ends earlier than in normal or wet years, the SFPUC has established operational procedures to minimize spills or discretionary power releases. A shift in the timing of runoff volumes (ranging from 35,000 to 70,000 acre-feet) to earlier in the season could cause releases/spills from the reservoir to cease a few days earlier each year. For current Hetch Hetchy Reservoir operations, the period when spills cease typically ranges from June 1 to August 15 depending on the hydrologic conditions of any given year. Under global warming conditions in the 2025–2030 timeframe, any change in the timing of when spills from Hetch Hetchy Reservoir cease would be minor compared to current/historical year-to-year variability. For these reasons, the SFPUC operators have determined that the change in runoff timing due to near-term global warming is not expected to cause substantial operational changes in the SFPUC's water supply system or its reliability.

The critical factor behind the relatively small shift in runoff timing and volume due to the predicted 1.5 °C warming at Hetch Hetchy Reservoir is the high elevation of the Hetch Hetchy watershed. The higher the elevation of a snow-covered basin, the greater the warming needed to change a large fraction of the snow-covered area and alter runoff patterns significantly.

Figure 5.7-5 in the Draft PEIR (Vol. 3, Chapter 5, p. 5.7-95) depicts the estimated decrease in snowpack in the Hetch Hetchy watershed due to predicted temperature increases by 2030 associated with global climate change.

Thus, the expected near-term climate change effects on the SFPUC regional system are different from those predicted for other California water supply and hydroelectric systems with reservoirs at much lower elevations. For example, EBMUD's Mokelumne River watershed and the SWP's Feather River watershed contain much lower proportions of their overall drainage basin as high-elevation snowpack compared to the Tuolumne River watershed. As shown in **Figure 14.11-2**, the overall basin elevation and the shape (steepness) of the area-elevation curve are indicative of a system's sensitivity to temperature change. The Feather River basin, for example, is sensitive to temperature change because its area-elevation curve is very flat, and for modest temperature changes, large areas of the basin could shift from snow-covered to rain-influenced lands.



SFPUC Water System Improvement Program ▪ 203287

SOURCE: SFPUC, 2008.

Figure 14.11-2
Relationship between Area and Elevation for the Tuolumne, Mokelumne, and Feather River Basins

Reservoirs at higher elevations, such as Hetch Hetchy, are less likely to be affected by increased air temperatures from global warming in the next 25 to 30 years than those at lower elevations in terms of reservoir water temperatures and stream flow releases. A shift in the timing of runoff would not likely cause a substantial change in the magnitude or schedule of the minimum stream flow releases from reservoirs at higher elevations, since these releases are routinely made from the bottom of the reservoir (i.e., below the upper layer of water in the reservoir that is affected by air temperature). If summer air temperatures become significantly higher with global warming, streams may warm more rapidly than under historical conditions; however, air temperature is dynamic and highly variable, and thermal refuges such as cool, deep pools exist in most stream reaches.

In conclusion, the preliminary WSFM results indicate that the near-term effects of climate change through 2030 are not expected to affect the current water supply planning or operations of the SFPUC regional water system.

Since the planning horizon for the WSIP is 2030, the results of the preliminary WSFM modeling are adequate for the purposes of the PEIR environmental analysis. A description of the SFPUC's long-term planning with respect to climate change is provided in Section 14.11.5, below, for informational purposes. Further detail on the effects of climate change as they relate to the proposed WSIP is presented below using the results of the WSFM modeling.

It should be noted that the current state of atmospheric science and global circulation models is not yet advanced enough to provide specific information on phenomena such as changes in total precipitation, seasonal precipitation allocation, or the more frequent or more intense droughts or larger storm events that some scientists believe may occur. Thus, at this time, it would be speculative to predict the magnitude and characteristics such events and attempt to analyze them with operational planning models. The SFPUC now uses a design drought in its operational planning models that is longer and more intense than any drought on record, and is thereby planning for the more intense droughts predicted to occur under some climate change scenarios using prudent judgment and the best available scientific information.

Qualitative Assessment of WSIP Impacts with Consideration of Climate Change Effects

In response to the numerous comments on the Draft PEIR related to climate change, this master response presents a qualitative assessment of potential WSIP impacts in the context of potential climate change effects in order to confirm the impact analysis of proposed WSIP water supply and system operations presented in the Draft PEIR (Vol. 3, Chapter 5).

In the 2005 *State Water Project Delivery Reliability Report*, the DWR stated:

> Until the impacts of climate change on precipitation and runoff patterns in California are better quantified, future weather patterns are usually assumed to be similar to those of the past, especially where there is a significant historical rainfall record.

Consistent with this statement, the impact analysis of the WSIP water supply and system operations presented in Chapter 5 of the Draft PEIR is largely based on results obtained from the Hetch Hetchy/Local Simulation Model (HH/LSM), which simulates system operations over an 82-year period of historical hydrology (from 1920 to 2002). Although there is inherent uncertainty regarding whether historical hydrology will be repeated in the future—especially given the evolving information on the potential effects of global climate change—the use of historical data over 82 years provides a wide enough range of inter-annual variation to address the climate change effects expected by 2030. The HH/LSM represents the best available tool for depicting overall regional system operations and predicting potential future effects on resources downstream of SFPUC water system facilities. The validity of this methodology to account for the future effects of climate change through 2030 was corroborated by the results of the WSFM modeling described above, which indicated that, independent of WSIP implementation, the existing SFPUC system operations and management practices provide adequate flexibility to accommodate the projected effects of climate change through the WSIP planning year of 2030.

Nevertheless, in response to comments received on the Draft PEIR, a qualitative analysis was conducted to determine how climate change might affect the environmental impacts of the WSIP identified in the Draft PEIR. The qualitative assessment was conducted by first reviewing the key findings from the scientific literature (summarized in Section 14.11.2, above) and assessing the applicability of each finding to the SFPUC regional water system. The qualitative analysis then reexamined the impacts of the WSIP assuming that a certain climate change scenario would occur between now and 2030 using the findings from the WSFM modeling described above. The qualitative analysis was based on an understanding of regional system operations and operating constraints combined with an understanding of the changes in system operations that would result from WSIP implementation as identified through the HH/LSM.

Table 14.11-3 lists the key findings from the literature review on climate change variables and describes how each variable relates to the HH/LSM assumptions and how those assumptions could be adjusted to account for climate change. The table indicates that, with the exception of the shift in the seasonal timing of runoff to the Hetch Hetchy system reservoirs and Don Pedro Reservoir, no other adjustments to the assumptions used in the HH/LSM or the Draft PEIR impact analysis would be required, either because any revised assumption would be too speculative at this time or because the existing operational protocols and planning process include adequate flexibility to account for expected climate change effects through 2030.

Methods and Assumptions for Qualitative Assessment

This qualitative analysis was based on a reasonable prediction of climate change effects in the next few decades as they pertain to the SFPUC regional water system. Although it does not encompass the wide range of climate change projections and variability described in the scientific literature, this approach provides a reasonable basis for the purposes of the PEIR for estimating the nature and magnitude of the environmental impacts of the WSIP while accounting for climate change through 2030. This qualitative assessment assumed global climate change would increase air temperatures in California by an average of 1.5 °C by 2030, but that no change in average annual precipitation would occur. These assumptions are generally consistent with the results of

TABLE 14.11-3
CLIMATE CHANGE VARIABLES AND THE SFPUC REGIONAL WATER SYSTEM

Climate Change Variable	Existing HH/LSM Modeling Assumptions That Could Be Affected	Adjusted Assumptions to Account for Climate Change Variable for the Qualitative Assessment
1. Sierra snowpack will likely decrease due to an increase in snowline elevation, resulting in increased amount of precipitation falling as rain rather than snow and an earlier snowmelt. Since there is no clear trend for precipitation changes in California, this variable assumes no change in total average annual precipitation.	• Unimpaired runoff to Hetch Hetchy system reservoirs and to Don Pedro Reservoir • Tuolumne River entitlements among CCSF, TID, and MID • Forecasted runoff procedures and operation protocols	Shift in monthly distribution of inflow within a year: • Increased inflow to reservoirs in fall, winter, and spring (approximately October to May) • Decreased inflow to reservoirs in late spring and summer (approximately June to September)
2. Rivers and streams fed by mountain watersheds are expected to exhibit an increase in stream flow in fall, winter, and spring, and a decrease in late spring and summer.	Instream flow requirements are based on hydrology and fishery needs that establish releases from: • Lake Lloyd (Cherry Reservoir) • Lake Eleanor • Hetch Hetchy Reservoir • Don Pedro Reservoir	No change in current mandated minimum releases for fisheries from affected reservoirs. At this time, it would be speculative to assume that future resource objectives and flow requirements would be different from the existing condition.
3. Warmer air temperatures are expected to increase water temperature in reservoirs, potentially increasing temperature of releases to streams; instream water temperatures may increase.	Instream flow requirements are based on hydrology and fishery needs that establish releases from: • Lake Lloyd (Cherry Reservoir) • Lake Eleanor • Hetch Hetchy Reservoir • Don Pedro Reservoir	No change in current mandated minimum releases for fisheries from affected reservoirs (see above). There would be negligible changes in SFPUC reservoirs during all but the most extreme droughts due to the size of the coldwater pool in the reservoirs and minimal changes in reservoir operations.
4. Conflicts among water supply, hydropower, and flood control in reservoir operations are expected.	Reservoir operations	No change in protocols for SFPUC reservoir operations. Protocols would continue to prioritize water supply. No change in protocols for Don Pedro Reservoir operations by TID and MID.
5. Warmer temperatures could cause increases in water demand in both agricultural and municipal regions.	• 300 mgd, 2030 purchase request • Availability of water in Don Pedro Reservoir	No change in delivery assumptions for the SFPUC. While demand of SFPUC customers may increase, delivery is limited to the contractual amount. Agricultural demand of TID and MID may evolve, since warmer conditions could lead to increased demand for irrigation. However, other factors such as land use conversion and agricultural market forces may have a larger effect on demand for irrigation than climate change, making alternative demands too speculative to predict.
6. Sea level rise will affect coastal areas and estuaries.	Not applicable	Not applicable
7. Increased risk for more extreme weather and climate events (i.e., more intense precipitation and drought events) is likely.	• Historical and design drought sequences included in the HH/LSM to establish system firm yield and rationing needs • Flood control studies have been performed for regulatory requirements	No change in existing SFPUC operation protocols, which were developed to address a wide range of conditions, including extreme weather events. The SFPUC planning process already incorporates a more extreme drought scenario than any from historical hydrology (i.e., the design drought). No change in SFPUC operations related to flooding because the SFPUC facilities have no flood control functions. Assume no change for TID and MID flood control operations for Don Pedro Reservoir.

the literature review presented above in Section 14.11.2, with the understanding that an increase of 1.5 °C by 2030 may be on the high side (and is therefore a conservative assumption with respect to determining potential impacts). The following analysis considers the effects of this temperature increase on hydrology within the SFPUC regional water system based on the WSFM results, and compares the environmental effects that would stem from this hydrologic change with the impact analysis presented in the Draft PEIR.

The WSFM, described above, was used to estimate inflow into reservoirs on the Tuolumne River under this climate change scenario (an average of 1.5 °C warming by 2030). As noted earlier, the primary effect of the climate-change-induced temperature rise would be to increase precipitation falling as rain, decrease precipitation falling as snow, and cause snowmelt to occur earlier in the season. Using the numerical reservoir inflow estimates provided by the WSFM, the qualitative analysis was performed by tracking the movement of water through the SFPUC regional water system, noting where reservoir storage and releases to rivers would increase or decrease due to climate change effects compared to the analysis presented in Chapter 5 of the Draft PEIR. The general scale of increases and decreases was also noted. However, due to the broad assumptions used in the analysis regarding climate change effects, no numerical values for increases or decreases of reservoir storage and releases are presented, since they would give a misleading impression of the precision of this assessment.

The following assessment is organized by watersheds and reflects a three-step process. First, it summarizes the environmental impacts of the WSIP compared to existing conditions as presented in Chapter 5 of the Draft PEIR. It then describes how climate change could affect reservoir storage and releases by 2030. Finally, the impacts of the WSIP presented in the Draft PEIR are discussed in light of possible climate change effects.

Upper Tuolumne River Watershed

Under the existing condition, only the required minimum stream flow releases are made to the Tuolumne River from Hetch Hetchy Reservoir for most months of the year. In the late spring, snowmelt runoff fills the reservoir and releases in excess of the minimum required are made to the river (typically in May and June). With the WSIP in 2030, the SFPUC would draw down Hetch Hetchy Reservoir farther prior to the snowmelt period than it does under the existing condition in order to serve the increased purchase requests, thus lowering the water level in the reservoir. As a result, a greater proportion of the snowmelt runoff would be needed to refill the reservoir, and spring stream flow releases in excess of the minimum required would be delayed by a few to several days, and the total volume of releases over that time period would be reduced. Terrestrial biological resources in the Poopenaut Valley would be adversely affected by the delay and reduced volume of the spring release (see Draft PEIR, Impact 5.3.7-2, Vol. 3, Chapter 5, pp. 5.3.7-21 and 5.3.7-22).

With climate change effects in 2030, snowmelt is expected to occur earlier in the year. Assuming no change in annual precipitation, the total volume of the spring release would not be altered but its seasonal timing would be. Hetch Hetchy Reservoir would have lower water levels due to serving the increased purchase requests under the WSIP, and it would fill with snowmelt runoff earlier in the year due to climate change; thus, releases to the river in excess of the minimum would begin earlier. Thus, it is possible that the delay in spring releases to the river (by a few to several days) that was identified as a consequence of the WSIP might not occur when the combined effects of climate change and the WSIP are considered together. If this were to happen, terrestrial biological resources in the Poopenaut Valley would not be subjected to a delay in spring releases, and the Poopenaut Valley would probably experience the greatest release several weeks earlier than under the existing condition. When climate change is considered, the effect on biological resources in the Poopenaut Valley would be the same as, or possibly less than, that described in Draft PEIR Impact 5.3.7-2.

The WSIP and climate change combined could still adversely affect terrestrial biological resources if peak flows were reduced compared to the existing condition and opportunities for groundwater recharge in the Poopenaut Valley were reduced. However, as identified in the Draft PEIR for the impacts of the WSIP, the combined effects of the WSIP and climate change on these resources could be reduced through the operational strategies described in Mitigation Measure 5.3.7-2 (Vol. 4, Chapter 6, pp. 6-49 and 6-50). These strategies involve shaping the releases from Hetch Hetchy Reservoir to maximize opportunities for inundation of the valley in an effort to achieve the necessary groundwater recharge, and, as specified in the measure, can be modified as needed to achieve the mitigating effect of sustaining the existing meadow communities.

The Draft PEIR determined that the WSIP would have a less-than-significant effect on whitewater river recreation in the upper Tuolumne River watershed (Impact 5.3.8-2, Vol. 3, Chapter 5, pp. 5.3.8-27 to 5.3.8-32). With the WSIP in 2030, the delay in spring releases could slightly reduce the number of days when flow in the river is suitable for rafting in some years; however, when climate change effects are also considered, the earlier snowmelt could cause releases to the river to begin earlier, possibly offsetting the effects of the WSIP. When climate change is considered, the effect on whitewater river recreation would be the same as, or possibly less than, that described in Draft PEIR Impact 5.3.8-2.

Lower Tuolumne River Watershed

Under the existing condition, only the minimum required stream flow releases are made to the Tuolumne River from La Grange Dam in most months. During the summer and fall, Don Pedro Reservoir is drawn down to meet water supply needs. One of the goals of dam operators is to fill the reservoir in the following winter and spring with rainfall and snowmelt runoff by the end of the snowmelt period. The operators' ability to meet this goal is constrained by the requirement that space must be retained in Don Pedro Reservoir to accommodate flood flows and reduce the risk of downstream flooding. Water in excess of the minimum required is typically released from La Grange Dam to the Tuolumne River in a number of pulses. During large winter storms, operators may have to release water to maintain the flood reservation in the reservoir, creating a pulse release of a few days to a few weeks. The need to maintain the flood reservation declines in the late spring, and the operators use snowmelt runoff to fill Don Pedro Reservoir. If more water is available than is needed to fill the reservoir, releases in excess of the minimum required are made to the Tuolumne River below La Grange Dam. In many years, the release from the reservoir during the snowmelt period is the largest of the pulse releases.

With the WSIP in 2030, increased purchase requests in the SFPUC service area would cause Don Pedro Reservoir to be drawn down farther prior to the snowmelt period than it is under the existing condition. As a result, a greater proportion of reservoir inflow from winter rainfall and snowmelt runoff would be needed to fill the reservoir. Because the reservoir would be drawn down farther than under the existing condition, runoff from winter storms could be more easily contained in the reservoir without encroaching on the flood reservation. As a result, some of the wintertime pulse releases to the Tuolumne River from La Grange Dam that occur under the existing condition would be eliminated or reduced in volume with the WSIP. The increased reservoir drawdown with the WSIP would also delay (by several days or weeks) the larger pulse release in the snowmelt period and reduce its total volume. The delay and reduction in the spring pulse release would have adverse effects on anadromous fish in the Tuolumne River and biological resources along the river below La Grange Dam (see Draft PEIR, Impacts 5.3.6-4 and 5.3.7-6, Vol. 3, Chapter 5, pp. 5.3.6-28 to 5.3.6-32 and pp. 5.3.7-25 to 5.3.7-26).

With climate change effects in 2030, rainfall and snowmelt runoff would enter Don Pedro Reservoir earlier in the season than it does under the existing condition. As the dam operators would be unable to accommodate the earlier wintertime runoff in the reservoir because of the flood control reservation, they would have to release water in excess of the minimum required to the Tuolumne River. The earlier runoff could offset the effects of the WSIP on reservoir water levels. When the effects of WSIP and climate change are considered together, the wintertime pulse releases could occur much as they do under the existing condition.

Based on the assumptions and results from the WSFM analysis, climate change is not expected to have much effect on the total average annual volume of water released from La Grange Dam by 2030.[3] As noted above, the WSIP would delay the spring pulse release by several days or weeks compared to the existing condition. The WSIP and climate change together would delay the spring release and also reduce its volume because a higher proportion of inflow to the reservoir would be in the winter and be released to the stream at that time.

The adverse effects of the WSIP on anadromous fish would be attributable to the delay and reduction in volume of the spring release from La Grange Dam and would not be much affected by the WSIP-caused reductions in wintertime pulse releases. When the WSIP and climate change are considered together, the reduction in spring release would be greater than with the WSIP alone, and therefore the effects on anadromous fish could be greater. If increases in spring water temperatures due to climate change are also considered, the effects on anadromous fish could be even more severe. Implementation of Mitigation Measure 5.3.6-4a, Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water, or Mitigation Measure 5.3.6-4b, Fishery Habitat Enhancement (Vol. 4, Chapter 6, pp. 6-48 and 6-49), would avoid the impacts attributable

[3] As described in Section 14.11.2, above, the DWR reported that when some climate change scenarios are applied to Don Pedro Reservoir, there would be a reduction in Tuolumne River annual inflow to the reservoir as well as a shift in the timing of the inflow by 2050. The results of this qualitative assessment corroborate the DWR prediction that climate change will cause a shift in the timing of runoff; however, unlike the DWR results, due to differences in the assumptions used in the climate change scenarios, this qualitative assessment assumes the total annual inflow to Don Pedro Reservoir would remain the same.

to the WSIP. Since implementation of this measure would fully mitigate the adverse effects of the WSIP, the effects of climate change on anadromous fish would be independent of the WSIP.

The identified adverse effects of the WSIP on terrestrial biological resources along the Tuolumne River below La Grange Dam are primarily attributable to the reduction in average peak flows and total flows in the river. Thus, the effects on biological resources due to the WSIP and climate change combined could be essentially the same as those due to the WSIP alone (as described in Draft PEIR Impact 5.3.7-6), since climate change effects are not expected to result in much change in the total volume of winter and spring releases from La Grange Dam based on the assumptions used in the WSFM. Implementation of Mitigation Measure 5.3.6-4a (Vol. 4, Chapter 6, p. 6-48) would avoid the impacts attributable to the WSIP.

The shift in the timing of snowmelt and runoff in the Tuolumne River watershed due to climate change is not expected to affect SFPUC system deliveries to the San Joaquin Pipelines and Bay Area customers.

Alameda Creek Watershed

Climate change effects by 2030 are not expected to change the total volume of water the SFPUC diverts from the Tuolumne River. Since this analysis assumed no change in total annual precipitation, and since the Alameda Creek watershed is at a much lower elevation than the Sierra watersheds and is not affected by snowmelt, there would be no change in local hydrology and runoff patterns due to increasing snowline elevations. While some studies indicate that climate change could result in more extreme weather or climate events, there are insufficient data to make any assumptions regarding how these extreme weather events might affect a specific watershed or operation of local SFPUC facilities. None of the SFPUC reservoirs in the Alameda Creek watershed currently provide or are proposed to provide flood control functions under the WSIP, so any operational changes attributable to extreme flooding events due to climate change would occur independent of the WSIP. Similarly, SFPUC operational practices during drought events would remain the same, regardless of whether the WSIP is implemented, and the SFPUC would continue to meet all legal requirements for the protection of fish and other wildlife habitat. Consequently, the 2030 operations of water supply facilities in the Alameda Creek watershed with the WSIP and with the WSIP and climate change considered together would likely be the same. Therefore, the environmental effects of SFPUC water system operations in the Alameda Creek watershed with the WSIP and with the WSIP and climate change combined would also likely be the same, as described in the Draft PEIR (Vol. 3, Chapter 5, Section 5.4).

Peninsula Watershed

As stated above, climate change would not affect the total volume of water the SFPUC would divert from the Tuolumne River by 2030. Since this analysis assumed no change in total annual precipitation, and since the San Mateo Creek and Pilarcitos Creek watersheds are at much lower elevations than the Sierra watersheds and are not affected by snowmelt, there would be no change in local hydrology and runoff patterns due to increasing snowline elevations. While some studies indicate that climate change could result in more extreme weather or climate events, there are insufficient data to make any assumptions regarding how these extreme weather events might affect a specific watershed or operation of local SFPUC facilities. None of the SFPUC reservoirs in the Peninsula watershed currently provide or are proposed to provide flood control functions under the WSIP,[4] so any operational changes attributable to extreme flooding events due to climate change would occur independent of the WSIP. Similarly, SFPUC operational practices during drought events would remain the same, regardless of whether the WSIP is implemented, and the SFPUC would continue to meet all legal requirements for the protection of fish and other wildlife habitat. Consequently, the 2030 operations of water supply facilities in the Peninsula watershed with the WSIP and with the WSIP and climate change considered together would likely be the same. Therefore, the environmental effects of SFPUC water system operations in the Peninsula watershed with the WSIP and with the WSIP and climate change combined would also likely be the same, as described in the Draft PEIR (Vol. 3, Chapter 5, Section 5.5).

Summary of Qualitative Assessment of WSIP Impacts and Climate Change

The assessment demonstrates that, in all cases, the impacts of the WSIP through 2030 on resources in the Tuolumne River, Alameda Creek, and Peninsula watersheds identified in the Draft PEIR remain valid when climate change effects are also considered. In most cases, when WSIP effects are considered in combination with a climate change scenario, the resulting impacts are either comparable to those described in the Draft PEIR or possibly less severe due to an offsetting effect of the timing of snowmelt compared to the WSIP-induced changes in reservoir storage or releases. In all cases, mitigation measures identified in the Draft PEIR would apply whether or not climate change is considered. Thus, the impact analysis of WSIP water supply and system operations presented in Chapter 5 of the Draft PEIR provides a reasonable, and sometimes conservative, assessment of environmental effects that accounts for potential climate change through the SFPUC planning horizon of 2030.

[4] The Lower Crystal Springs Dam Improvements project (PN-4) would include improvements to protect downstream areas from the probable maximum flood; however, the Lower Crystal Springs Dam is generally not operated as a flood control facility. Crystal Springs Reservoir reduces peak flow in San Mateo Creek most of the time, and the SFPUC operates the reservoir to allow space for floodwaters when major storms are expected.

Summary of Issues Raised by Commenters

- Proactive climate change management strategies should be the first priority.

Response

SFPUC Water Supply Management Approach to Climate Change

As part of its ongoing operations and management of the regional water system, the SFPUC is addressing climate change with respect to both the near-term and long-term implications for the system. While some short-term trends over the next 20 to 25 years are discernible to a degree, the uncertainty associated with the range of climate conditions that could develop late in the 21st century from the continued accumulation of greenhouse gases in the atmosphere presents a greater challenge to water supply management.

The SFPUC is now taking steps to evaluate its water supply planning with respect to climate change effects. In addition, the SFPUC is working at a broader level to organize the utility community around climate change issues, to advocate for improved climate science, and to help develop better decision support tools that can address uncertainties related to long-term climate change effects.

Planning for Long-Term Climate Change Effects

The SFPUC is investigating the effects of global warming on the Tuolumne River basin water supply at time scales that extend well beyond the planning horizon for the WSIP and the PEIR. At these longer time scales (such as by 2100), a potential 6 °C change would have a range of effects that are more significant than the effects estimated to occur by 2025 or 2030. Physical processes subject to long-term climate change effects, such as evapotranspiration (ET), the lack of permanent snow cover, and midwinter melting, could change runoff timing in a significant way and even alter runoff volumes due to increased ET losses.

The SFPUC has begun collaborative research with TID (as described above in Section 14.11.3) and plans to assess the longer time-scale changes with a physical process model that TID has had calibrated to the Tuolumne River basin. The TID model is an explicit physics-based simulation model that incorporates the physical processes that occur during the accumulation and ablation (loss) of a watershed’s snowpack and that produce runoff, and is thus better suited to examining the large changes in temperature and other variables that could occur between 2025 and 2100. The TID model analyzes ET and snowpack accumulation by allocating precipitation (as rain or snow) on 800 sub-watersheds based on elevation and other factors, and then performs heat budget calculations for the snowpack. It is expected that the model will depict representative effects of long-term climate change on runoff timing and volume. The TID model output can then be used as the input to an operations or planning model to investigate changes in operations, firm yield, and other issues of interest for the period from 2050 to 2100 and beyond. Operations models using these new inflow time series can be changed to assess ways of adapting current project operations to compensate for the expected larger changes in runoff timing and volume in this longer timeframe. As regional downscaling of global circulation models begins to provide better projections of climate change effects in the Tuolumne River basin, the TID model will be used to refine the analysis of changes in temperature and precipitation on runoff timing and quantity.

SFPUC Climate Change Activities

In August 2006, the SFPUC Commission held a special public hearing to begin outlining the local and regional steps needed to prepare the utility and its customers for the expected impacts of global climate change on the SFPUC's water, wastewater, and power services. In January and February 2007, the SFPUC convened the Water Utility Climate Change Summit, which was attended by managers and board members from 30 water utilities from eight states; representatives from 17 regional, state, and federal agencies; leaders from non-governmental organizations and business communities; and members of the public. The summit was designed for the utility community with a focus on adaptation to climate change ("adaptation" is the term used to describe efforts to respond to the effects of climate change rather than to address the causes). For two days, top experts from around the country discussed the implications of climate change with respect to water supply, operations, and sea level rise, as well as the state of climate science in determining the nature of climate change impacts. The second day was focused on brainstorming action items, such as enhancing technical tools to help better predict climate change impacts, increasing funding for data gathering related to snowpack, streamflow, and related issues, and developing a collective voice for the water utility community.

Eight of the attending utilities have since formed a coalition, called the Water Utility Climate Alliance, to build on the recommendations that emerged from the summit. Chaired by the SFPUC, the alliance also includes Seattle Public Utilities, Metropolitan Water District of Southern California, New York City Department of Environmental Protection, San Diego County Water Authority, Southern Nevada Water Authority, Portland Water Bureau, and Denver Water. Combined, these utilities deliver water to over 36 million Americans. Thus far, the focus has been on addressing adaptation concerns while also enhancing mitigation programs. The group has identified the following two priorities: (1) lobbying for more funding for climate research, and greater focus on regional climate forecasting, in order to improve the ability to predict the effects of climate change on water supply and infrastructure; and (2) adapting decision support tools that might assist utilities in developing frameworks for long-term planning in the face of the extensive uncertainties regarding the scope of climate change effects. Utilities in the alliance are also learning from one another in developing adaptation programs, gathering information on federal initiatives such as the Climate Change Science Program (and commenting in an integrated fashion on that program), educating each other about efforts to downscale global circulation models to improve forecasting at a regional level, and tracking federal legislation. Guest speakers representing the Western Water Assessment in Colorado, National Center for Atmospheric Research, Association of Metropolitan Water Agencies, American Water Works Association

Research Foundation, and U.S. Environmental Protection Agency have participated in the activities of the Water Utility Climate Alliance.

In addition to these efforts, the SFPUC participated in the American Water Works Association Research Foundation (AwwaRF) Climate Change Research Needs Workshop on January 8 and 9, 2008. The SFPUC's water quality manager, Andrew DeGraca, served as chair of the workshop and is chairing a new strategic initiative at AwwaRF focused on improving climate change research to assist water utility planning efforts.

Other activities at the SFPUC include: (1) in May 2007, SFPUC General Manager Susan Leal represented Mayor Gavin Newsom at the international C40 Large Cities Climate Summit hosted by Mayor Michael Bloomberg in New York; and (2) during 2007, SFPUC staff presented their climate change-related work on panels at the Association of Metropolitan Water Agencies fall conference, the Colorado Water Congress annual meeting, the annual California Water Policy Conference of Public Officials for Water and Environmental Reform (POWER), and at a workshop on Climate Change, Urban Drainage, and Adaptation sponsored by Seattle Public Utilities.

Reducing the SFPUC's Carbon Footprint

In addition to the steps the CCSF and the SFPUC are taking to reduce GHG emissions described in the Draft PEIR (Vol. 2, Chapter 4, pp. 4.9-16 to 4.9-20), the SFPUC is taking other actions as well. The SFPUC is developing a comprehensive Sustainability Plan, which will incorporate consideration of the agency's carbon footprint and adaptation of system operations to adjust for climate change effects.

As a clean power generator whose water supply is largely gravity fed, the SFPUC currently has a small carbon footprint compared to that of most utility districts. Nonetheless, the SFPUC Power Enterprise manages a number of programs that develop renewable energy facilities and energy efficiency programs for the CCSF.

Two key programs managed by the Power Enterprise—renewable energy generation and energy efficiency—are helping the SFPUC contribute to San Francisco's effort to reduce its carbon footprint. By the end of 2007, a total of 2 megawatts of peak solar capacity had been installed on city facilities (including Moscone Center, San Francisco International Airport, the SFPUC's City Distribution Division, and other locations), generating an estimated 2.5 million kilowatt-hours of electricity per year, or approximately 1,000 tons of carbon-dioxide-equivalent[5] per year.

On the energy efficiency front, the SFPUC has an aggressive program in several city departments; projects include lighting and HVAC (heating, ventilation, and air conditioning) upgrades at San Francisco General Hospital, and conversion of the city's traffic signals to LED technology. The resulting energy savings of these projects is an estimated 24 million kilowatt-

5 Carbon dioxide equivalency is a quantity that describes, for a given mixture and amount of greenhouse gas, the amount of carbon dioxide that would have the same global warming potential when measured over a specified timescale (generally 100 years).

hours of electricity and 300,000 therms of natural gas per year, a GHG emissions reduction of approximately 11,000 tons of carbon-dioxide-equivalent per year.

The SFPUC recycles a substantial amount of potential GHG at its wastewater treatment plants. Methane gas produced in the anaerobic digesters at both wastewater treatment plants (Southeast and Oceanside) is used to fuel the engine generators and boilers, which in turn produce the energy used in plant operations. The engine generators produce electrical power, and the engine generators and boilers both produce hot water to heat the digesters and run the plant's HVAC system. Without this system, this methane gas—a more damaging GHG than carbon dioxide—would be released into the atmosphere.

The CCSF's newly adopted Green Building Ordinance (Chapter 7 of the Environment Code) requires city construction projects over 5,000 square feet in size to be built to Leadership in Energy and Environmental Design (LEED) Silver standards and to be certified by the U.S. Green Building Council. The San Francisco Municipal Green Building Program is mandatory for most aboveground buildings, including those proposed under the WSIP, regardless of whether or not they are used to house facilities or people. The San Francisco Department of the Environment has also been working with the SFPUC and other CCSF departments on certain municipal projects that are not required to obtain LEED Silver Certification (such as pipelines) to try to ensure these projects are constructed with recycled, environmentally friendly building materials that are sourced locally to minimize transportation fuel. City officials estimate this ordinance could reduce carbon dioxide emissions in the city by 60,000 tons and save 220,000 megawatt-hours of power by 2012.

Finally, the CCSF is a member of the California Climate Action Registry and became the first city to certify its emissions with the Registry in 2006. The SFPUC's emissions were certified as part of the overall city/county certification process using the Registry's Power Utility Protocol.

Email	F_USFWS	G. Mendel Stewart	Manager	U.S. Department of the Interior, Fish and Wildlife Service, San Francisco Bay National Wildlife Refuge Complex	15.1-11

National Park Service, Golden Gate National Recreation Area, Brian O'Neill, General Superintendent, 11/06/07

F_NPS-GGNRA-01 The commenter requests that the reference to Cañada Road be deleted. In response to this comment, the Draft PEIR is revised as follows (Vol. 2, Chapter 4, p. 4.2-7, first paragraph):

> In 1969, the CCSF granted two easements over the vast majority of the Peninsula watershed to the Department of the Interior. The easements were granted to the federal government in order to obtain a change in the route of Interstate 280 (I-280) (and an increase in the federal share of costs) to a less environmentally damaging location further east of Crystal Springs Reservoir. The approximately 19,000-acre Scenic Easement covers the lands west of Crystal Springs and San Andreas Reservoirs. The approximately 4,000-acre Scenic and Recreation Easement applies to lands in the vicinity of I-280. ~~Cañada Road demarcates these easements: t~~The CS/SA Transmission project (PN-2), Lower Crystal Springs Dam project (PN-4), and the Pulgas Channel and sediment catch basin components of the Pulgas Balancing Reservoir project (PN-5) are within the Scenic Easement, while the Pulgas Balancing Reservoir itself is within the Scenic and Recreation Easement. The easements cover nearly all of the CCSF-owned Peninsula watershed lands and place restrictive covenants on use of the lands that are unrelated to the SFPUC's overall management of the land for utility purposes. The provisions of the easement include:

F_NPS-GGNRA-02 Due to an agreement established between the SFPUC and the GGNRA, the commenter requests that the GGNRA be considered a stakeholder agency during the planning phases for the subsequent WSIP projects. Please refer to **Section 14.4, Master Response on PEIR Appropriate Level of Analysis** (Vol. 7, Chapter 14, Section 14.4.3) for detailed discussion of the issues raised by this comment. The GGNRA's request to be consulted and notified has been added to Draft PEIR Table C.6 (Vol. 5, Appendix C, p. C-26) for consideration during the project-level CEQA review for the following projects: Crystal Springs/San Andreas Transmission Upgrade (PN-2), HTWTP Long-Term Improvements (PN-3), Lower Crystal Springs Dam Improvements (PN-4), and Pulgas Balancing Reservoir Rehabilitation (PN-5).

F_NPS-GGNRA-03 The commenter expresses concern regarding the potentially significant but mitigable impacts related to existing land uses, visitor access and experience, visual character, wetland and aquatic resources, historic resources, and traffic safety hazards, as well as the unavoidable significant impacts on sensitive biological and historic resources. Please refer to

Section 14.4, Master Response on PEIR Appropriate Level of Analysis (Vol. 7, Chapter 14, Section 14.4.2) for detailed discussion of the issues raised by this comment. This master response provides information on the appropriate level of detail of an impact analysis at the program level versus the project level. The Draft PEIR generally addresses the potential types of land use, visual/aesthetic, biological resource, historic resource, and recreation impacts identified by the commenter, and they are discussed on the following pages of the Draft PEIR:

Land Use: Impact 4.3-2 (Vol. 2, Chapter 4, p. 4.3-26) indicates that permanent displacement or long-term disruption of existing land uses would not be expected under any of the Peninsula projects, because these projects would not involve the acquisition of additional land, with the possible exception of the Crystal Springs/San Andreas Transmission Upgrade project (PN-2). In general, the lands that would be affected by WSIP projects are already owned by the City and County of San Francisco (CCSF) and are currently used for or designated for use as water infrastructure. Only those projects requiring the acquisition of non-CCSF-owned land would have the potential to cause permanent land use changes. The programmatic impact analysis in the Draft PEIR determined that a potentially significant land use impact could result from the Crystal Springs/San Andreas Transmission Upgrade project, but identifies this impact as potentially significant and unavoidable since facility locations have not yet been determined. As noted in the impact discussion, if it is determined during subsequent project development and project-level environmental review that land acquisition is required, this impact could be mitigated to a less-than-significant level by implementing facility siting studies (Mitigation Measure 4.3-2; Vol. 4, Chapter 6, p. 6-7), which may identify alternative sites and designs to avoid land use impacts.

Visual/Aesthetics: Impact 4.3-4 (Vol. 2, Chapter 4, p. 4.3-41 and Table 4.3-4, p. 4.3-34) identifies potentially significant permanent impacts on scenic vistas or visual character under all projects of concern to the commenter: Crystal Springs/San Andreas Transmission Upgrade (PN-2), HTWTP Long-Term Improvements (PN-3), Lower Crystal Springs Dam Improvements (PN-4), and Pulgas Balancing Reservoir Rehabilitation (PN-5). The Draft PEIR indicates that all of these projects, except for the HTWTP Long-Term Improvements, are located in the Peninsula Watershed Management Plan (WMP) boundary and therefore will be subject to WMP design guidelines. In addition, all four projects will be required to implement Draft PEIR mitigation measures addressing architectural design, landscaping plans, landscape screens, and tree removal (Measures 4.3-4a through 4.3-4d; Vol. 4, Chapter 6, p. 6-7) to reduce potential visual impacts to a less-than-significant level.

Biological Resources: Impact 4.6-1 (Vol. 2, Chapter 4, p. 4.6-50) identifies potentially significant impacts on wetlands and aquatic resources for three projects of concern to the commenter: Crystal Springs/San Andreas Transmission Upgrade (PN-2), Lower Crystal Springs Dam Improvements (PN-4), and Pulgas Balancing Reservoir Rehabilitation (PN-5). Implementation of SFPUC Construction Measure #8, which requires performance of a biological screening survey, will determine if sensitive wetland and aquatic resources are present; if such resources are present, Mitigation Measures 4.6-1a and 4.6-1b (Vol. 4, Chapter 6, p. 6-11) will be implemented as necessary to reduce identified impacts to a less-than-significant level.

Historic Resources: Impact 4.7-3 (Vol. 2, Chapter 4, p. 4.7-74) identifies potentially significant impacts on historic resources for two projects of concern to the commenter: Crystal Springs/San Andreas Transmission Upgrade (PN-2) and Lower Crystal Springs Dam Improvements (PN-4). Implementation of Mitigation Measures 4.7-3 and 4.7-4a through 4.7-4f (Vol. 2, Chapter 6, p. 6-26) could reduce potential impacts on historic resources to a less-than-significant level, but impacts associated with the Crystal Springs/San Andreas Transmission Upgrade project could remain significant after mitigation.

Recreation: Impact 4.12-1 (Vol. 2, Chapter 4, p. 4.12-25) identifies potentially significant temporary conflicts with established recreational uses during construction of the Crystal Springs/San Andreas Transmission Upgrade project (PN-2); however, implementation of SFPUC Construction Measures #1, #3, #5, and #6 (Neighborhood Notice, Air Quality, Traffic, and Noise) and Mitigation Measure 4.12-1 (Vol. 2, Chapter 4, p. 6-44; Coordination with Facility Managers) would reduce identified temporary conflicts to a less-than-significant level. SFPUC Construction Measures would also reduce potential impacts on recreational uses to a less-than-significant level for the Lower Crystal Springs Dam Improvements (PN-4) and Pulgas Balancing Reservoir Rehabilitation (PN-5) projects.

National Park Service, Yosemite National Park, Michael Tollefson, Superintendent, 10/15/07

F_NPS-YOS-01 The Draft PEIR (Vol. 3, Chapter 5, pp. 5.3.1-1 to 5.3.1-40) provides a comprehensive analysis of the WSIP's impacts on stream flow in the Tuolumne River and water levels in the SFPUC's reservoirs. The impacts of WSIP-induced changes in stream flow and reservoir water levels on the riverine ecosystem are described in Section 5.3.2 (Geomorphology), Section 5.3.3 (Water Quality), Section 5.3.6 (Fisheries), and Section 5.3.7 (Terrestrial Biological Resources). The analysis of WSIP impacts on stream flow was conducted using the SFPUC's Hetch Hetchy/Local Simulation Model (HH/LSM). The HH/LSM uses monthly stream flow monitoring data for the 82-year period from 1920 to 2002, which includes several multiple-year droughts and extremely dry years.

Please refer to **Section 14.11, Master Response on Climate Change** (Vol. 7, Chapter 14) for detailed discussion of climate change effects, including a literature review on climate change effects on California water supplies and water management and a qualitative assessment of WSIP impacts with consideration of climate change effects.. Please refer to **Section 14.5, Master Response on Water Resources Modeling** (Vol. 7, Chapter 14) for more information on the SFPUC's use of a design drought that is more severe than any droughts in the historical record.
