SUBJECT: Final Program Environmental Impact Report on the San Francisco Public Utilities Commission's Water System Improvement Program (Case No. 2005.0159E)

The Final Program Environmental Impact Report (PEIR) on the San Francisco Public Utilities Commission's (SFPUC) Water System Improvement Program (WSIP) was certified by the San Francisco Planning Commission as adequately fulfilling the requirements of the California Environmental Quality Act (CEQA) on October 30, 2008. Subsequent to the certification action, the SFPUC approved the Phased WSIP and adopted the CEQA Findings, including a statement of overriding considerations and the WSIP Mitigation Monitoring and Reporting Program. Copies of the certification motion and CEQA Findings are attached to this memorandum.

This document is the consolidated Final PEIR; it consists of eight volumes that contain the full Draft PEIR (Volumes 1 through 5) and the Comments and Responses document (Volumes 6 through 8), but also incorporates text revisions described in the Comments and Responses document. This consolidated Final PEIR does not contain any new information from that presented in the Draft PEIR (published on June 29, 2007) and the Comments and Responses document (published on September 30, 2008). The text revisions include those prepared in response to comments received on the Draft PEIR as well as corrections and relevant updates. The document also provides cross-references to information in the Comments and Responses document, updates information on the CEQA process, and consolidates the tables of contents for the eight volumes. This document is intended to facilitate use of the Final PEIR as a reference document, which should be cited based on the certification date of October 30, 2008 and referenced as follows:

> San Francisco Planning Department, 2008. *Final Program Environmental Impact Report on the San Francisco Public Utilities Commission's Water System Improvement Program*. State Clearinghouse No. 2005092026. Certified October 30, 2008.

To assist the reader in identifying the text changes that were incorporated subsequent to publication of the Draft PEIR, this consolidated Final PEIR includes a vertical line along the outside margin of the pages where changes have been made; new and revised figures are labeled as *New* or *Revised*, respectively, in the figure title. Other than the vertical line along the margin, deleted text is not shown, except where an entire paragraph was deleted, in which case the deletion is noted in square brackets and italics. The consolidated Final PEIR preserves the same pagination as was used in the Draft PEIR so that any cross-references remain accurate; thus, where the text changes involved inserting lengthy new text, the new page numbers are labeled with *a, b, c*, etc. following the original page number (e.g., pp. 4.7-24a and 4.7-24b follow p. 4.7-24 and come before p. 4.7-25).

In response to some comments on the Draft PEIR, it was necessary to provide supplemental discussion of certain issues to confirm and validate the original analysis or discussion presented in the Draft PEIR, but in these instances the comments did not warrant a change or correction in the text of the Draft PEIR. In these cases, the consolidated Final PEIR includes cross-references and explanatory notes, which are called out in square brackets and italics in the revised text in Volumes 1 through 5 to refer the reader to the additional information presented in the Comments and Responses document (Volumes 6 though 8).

This consolidated Final PEIR also provides guidance for the reader in locating the description of the Phased WSIP and its environmental effects. The Phased WSIP is a variation of the proposed program described and analyzed in the Draft PEIR, and, as indicated in the Comments and Responses document, its potential environmental effects fall within the range of impacts previously evaluated in the Draft PEIR for the originally proposed program and alternatives. The SFPUC ultimately adopted the Phased WSIP, as described above.

The user's guide below is intended to help the reader navigate through the Final PEIR and to find relevant cross-references between the Draft PEIR and Comments and Responses document. It indicates where changes were made to the Draft PEIR as part of the Comments and Responses document, provides cross-references for information on the Phased WSIP, and shows the interrelationships among the various sections of the PEIR.

USER'S GUIDE TO CHANGES IN THE WSIP FINAL PEIR

Section	Name	Description	Changes from the Draft PEIR?	Other Relevant PEIR Sections
VOLUME 1				
Summary	**Summary**	Summary of the proposed program, impacts, mitigation measures, variants, and alternatives	Yes, changes made due to project description updates, updates to impacts and mitigation measures, and introduction of the Phased WSIP Variant	Refer to all chapters of the PEIR for full discussions
Chapter 1	**Introduction**	Purpose of proposed program and CEQA process	Yes, changes made to correct editorial errors	Refer to Chapter 11 for updates to the CEQA process for the PEIR
Chapter 2	**Existing Regional Water System**	Existing facilities, operations, regulatory requirements	Yes, changes made to update information on existing facilities and SFPUC policies	
Chapter 3	**Program Description**	Location, objectives, background, proposed water supply strategy and facilities, required actions and approvals	Yes, changes made due to revisions in some facility project descriptions and to include cross-reference to information on the Phased WSIP Variant	Refer to the following sections for supplemental discussions: Section 13.2 for project revisions; Section 13.4 for the Phased WSIP; Section 14.1 for the need for the program; Section 14.2 for demand projections, conservation, and recycling assumptions; and Section 14.3 for the dry-year water transfer
VOLUME 2				
Chapter 4	**WSIP Facility Projects – Setting and Impacts**			
Section 4.1	Overview	Approach used to analyze program-level impacts and to develop programmatic mitigations for key regional facility improvement projects	No changes	Refer to Appendix C for the assumptions used for facility improvement projects and Section 14.4 for additional discussion of the appropriate level of detail for the program-level analysis
Section 4.2	Plans and Policies	Plans and policies relevant to facility projects and plan consistency evaluation	Yes, changes made to update the setting to include the San Francisco Municipal Green Building Program	
Section 4.3	Land Use and Visual Quality	Setting and impacts	No changes	Refer to Section 6.3 for mitigation measures
Section 4.4	Geology, Soils, and Seismicity	Setting and impacts	No changes	Refer to Section 6.3 for mitigation measures
Section 4.5	Hydrology and Water Quality	Setting and impacts	Yes, changes made to update the regulatory framework to clarify three impacts	Refer to Section 6.3 for mitigation measures
Section 4.6	Biological Resources	Setting and impacts	Yes, changes made to clarify the setting and two impacts	Refer to Section 6.3 for mitigation measures, to Section 14.4 for supplemental discussion, and to Appendix D for supporting details

USER'S GUIDE TO CHANGES IN THE WSIP FINAL PEIR (Continued)

Section	Name	Description	Changes from the Draft PEIR?	Other Relevant PEIR Sections
VOLUME 2 (cont.)				
Section 4.7	Cultural Resources	Setting and impacts	Yes, changes made to clarify and refine the historical resources analysis	Refer to Section 6.3 for mitigation measures and to Section 15.3 for supplemental discussion
Section 4.8	Traffic, Transportation, and Circulation	Setting and impacts	Yes, changes made to clarify one impact	Refer to Section 6.3 for mitigation measures and to Appendix F for supporting details
Section 4.9	Air Quality	Setting and impacts	Yes, changes made to update setting to include the Greenhouse Gas Reduction Ordinance	Refer to Section 6.3 for mitigation measures
Section 4.10	Noise and Vibration	Setting and impacts	No changes	Refer to Section 6.3 for mitigation measures and to Appendix F for supporting details
Section 4.11	Public Services and Utilities	Setting and impacts	Yes, changes made to update the setting	Refer to Section 6.3 for mitigation measures
Section 4.12	Recreational Resources	Setting and impacts	Yes, changes made to update the setting, clarify one impact, and augment the references	Refer to Section 6.3 for mitigation measures
Section 4.13	Agricultural Resources	Setting and impacts	No changes	Refer to Section 6.3 for mitigation measures
Section 4.14	Hazards	Setting and impacts	No changes	Refer to Section 6.3 for mitigation measures and to Appendix G for supporting details
Section 4.15	Energy Resources	Setting and impacts	No changes	Refer to Section 6.3 for mitigation measures
Section 4.16	Collective Impacts of WSIP Facilities	Combined impacts of multiple facility projects under the proposed program	No changes	Refer to Section 6.3 for mitigation measures
Section 4.17	Cumulative Effects	Impacts of the proposed program in combination with other projects	No changes	Refer to Section 6.3 for mitigation measures
VOLUME 3				
Chapter 5	**WSIP Water Supply and System Operations – Setting and Impacts**			
Section 5.1	Overview	Approach used to analyze water supply impacts and mitigation measures; includes a description of hydrologic modeling	Yes, changes made due to refinement and update of hydrologic modeling	Refer to Sections 13.3 and 14.5 for supplemental discussion of hydrologic modeling and to Appendices H and O for supporting details
Section 5.2	Plans and Policies	Plans and policies relevant to water supply system operations and plan consistency	Yes, changes made to clarify applicability of plans and policies

		evaluation		
VOLUME 3 (cont.)				
Section 5.3	**Tuolumne River System and Downstream Water Bodies** – Setting and impacts on the Tuolumne River, the San Joaquin River, and the Sacramento–San Joaquin Delta watersheds and associated resources			
Section 5.3.1	Stream Flow and Reservoir Water Levels	Setting and impacts on stream flow and reservoir levels along the Tuolumne River, San Joaquin River, and Sacramento–San Joaquin Delta	Yes, changes made to clarify impact analysis	Refer to Section 13.3 for supplemental discussion of hydrologic modeling and to Sections 14.6, 14.7, and 14.8 for supplemental discussion of stream flow in the Tuolumne River and downstream water bodies
Section 5.3.2	Geomorphology	Setting and impacts on the geomorphology of the Tuolumne River	No changes	Refer to Sections 14.6 and 14.7 for supplemental discussion of the geomorphology along the Tuolumne River
Section 5.3.3	Surface Water Quality	Setting and impacts on surface water quality in the Tuolumne River, the San Joaquin River, and the Sacramento–San Joaquin Delta	Yes, changes made to clarify regulatory framework	Refer to Sections 14.6, 14.7, and 14.8 for supplemental discussion of surface water quality in the Tuolumne River and downstream water bodies
Section 5.3.4	Surface Water Supplies	Setting and impacts on surface water supplies along the lower Tuolumne River, the San Joaquin River, and the Sacramento–San Joaquin Delta	Yes, changes made to clarify one impact	Refer to Section 14.8 for supplemental discussion of issues related to the San Joaquin River and Delta
Section 5.3.5	Groundwater	Setting and impacts on groundwater resources in the Tuolumne River watershed	Yes, changes made to clarify the regulatory setting	
Section 5.3.6	Fisheries	Setting and impacts on fishery resources along the Tuolumne River, the San Joaquin River, and the Sacramento–San Joaquin Delta and	Yes, changes made to clarify two impacts	Refer to Section 6.4 for mitigation measures and to Section 14.7 for supplemental discussion of fisheries in the lower Tuolumne River
Section 5.3.7	Terrestrial Biological Resources	Setting and impacts on terrestrial biological resources along the Tuolumne River, the San Joaquin River, and the Sacramento–San Joaquin Delta	No changes	Refer to Section 6.4 for mitigation measures and to Section 14.6 for supplemental discussion of biological resources along the upper Tuolumne River
Section 5.3.8	Recreational and Visual Resources	Setting and impacts on recreational and visual resources along the Tuolumne River	Yes, changes made to clarify the setting and one impact	
Section 5.3.9	Energy Resources	Setting and impacts on energy resources related to water supply and	No changes

		system operations		
VOLUME 3 (cont.)				
Section 5.4	**Alameda Creek Watershed Streams and Reservoirs** – Setting and impacts on the Alameda Creek watershed and associated resources			
Section 5.4.1	Stream Flow and Reservoir Water Levels	Setting and impacts on stream flow and reservoir levels in the Alameda Creek watershed	Yes, changes made due to revisions in some facility project descriptions, updated modeling, and refined impact analysis	Refer to Section 6.3 for mitigation measures and to Section 14.9 for supplemental discussion of revisions to facility project descriptions and refined analysis; refer to Appendices H, N, and O for supporting details of the hydrologic analysis
Section 5.4.2	Geomorphology	Setting and impacts on the geomorphology of Alameda Creek	Yes, changes made to clarify impact analysis	
Section 5.4.3	Surface Water Quality	Setting and impacts on surface water quality in the Alameda Creek watershed	Yes, changes made to clarify the setting and one impact	
Section 5.4.4	Groundwater	Setting and impacts on groundwater resources in the Alameda Creek watershed	Yes, changes made to clarify one impact	
Section 5.4.5	Fisheries	Setting and impacts on fishery resources in the Alameda Creek watershed	Yes, changes made due to revisions in some facility project descriptions, updated modeling, and refined impact analysis	Refer to Section 6.3 for mitigation measures, to Section 14.9 for supplemental discussion of Alameda Creek watershed fishery issues, and to Appendix N for supporting details
Section 5.4.6	Terrestrial and Biological Resources	Setting and impacts on terrestrial biological resources in the Alameda Creek watershed	Yes, changes made to clarify three impacts	Refer to Section 6.3 for mitigation measures
Section 5.4.7	Recreational and Visual Resources	Setting and impacts on recreational and visual resources in the Alameda Creek watershed	Yes, changes made to clarify the setting and to refine the impact analysis due to revisions in some facility project descriptions	Refer to Section 13.2 for revisions to facility project descriptions
Section 5.5	**San Francisco Peninsula Streams and Reservoirs** – Setting and impacts on the Peninsula watershed (San Mateo and Pilarcitos Creek watersheds) and associated resources			
Section 5.5.1	Stream Flow and Reservoir Water Levels	Setting and impacts on stream flow and reservoir levels in the watersheds of San Mateo and Pilarcitos Creeks	Yes, changes made due to updated hydrologic modeling and refined Pilarcitos watershed impact analysis	Refer to Section 13.3 for a description of the updated hydrologic modeling and refined Pilarcitos watershed impact analysis
Section 5.5.2	Geomorphology	Setting and impacts on the geomorphology of San Mateo and Pilarcitos Creeks	No changes	
Section 5.5.3	Surface Water Quality	Setting and impacts on surface water quality in the San Mateo and Pilarcitos Creek watersheds	Yes, changes made due to updated hydrologic modeling and refined Pilarcitos watershed impact analysis	Refer to Section 6.4 for mitigation measures and to Section 13.3 for a description of the updated hydrologic modeling and refined Pilarcitos watershed impact analysis

USER'S GUIDE TO CHANGES IN THE WSIP FINAL PEIR (Continued)

Section	Name	Description	Changes from the Draft PEIR?	Other Relevant PEIR Sections
VOLUME 3 (cont.)				
Section 5.5.4	Groundwater	Setting and impacts on groundwater resources in the San Mateo and Pilarcitos Creek watersheds	No changes	
Section 5.5.5	Fisheries	Setting and impacts on fishery resources along San Mateo and Pilarcitos Creeks	Yes, changes made due to updated hydrologic modeling and refined Pilarcitos watershed impact analysis	Refer to Section 6.4 for mitigation measures and to Section 13.3 for a description of the updated hydrologic modeling and refined Pilarcitos watershed impact analysis
Section 5.5.6	Terrestrial Biological Resources	Setting and impacts on terrestrial biological resources in the San Mateo and Pilarcitos Creek watersheds	Yes, changes made due to updated hydrologic modeling and refined Pilarcitos watershed impact analysis	Refer to Section 6.4 for mitigation measures and to Section 13.3 for a description of the updated hydrologic modeling and refined Pilarcitos watershed impact analysis
Section 5.5.7	Recreational and Visual Resources	Setting and impacts on recreational and visual resources along San Mateo and Pilarcitos Creeks	Yes, changes made to clarify the setting	
Section 5.6	Westside Groundwater Basin Resources	Setting and impacts on the north and south portions of the groundwater basin	Yes, changes made to clarify and update the setting and to clarify one impact	Refer to Section 6.4 for mitigation measures
Section 5.7	Cumulative Effects	Cumulative impacts on affected water resources and a discussion of global climate change on the water supply sources	Yes, changes made to update information on cumulative projects and to refine the cumulative analysis of Alameda Creek watershed resources	Refer to Section 14.9 for supplemental discussion of the cumulative analysis of Alameda Creek fisheries and to Section 14.11 for supplemental discussion of global climate change
VOLUME 4				
Chapter 6	**Mitigation Measures**	Detailed description of mitigation measures and discussion of the impacts of mitigation measures	Yes, changes made to refine and clarify several mitigation measures	Refer to Sections 14.7, 14.9, 14.10, 15.2, and 15.4 for supplemental discussion related to clarification and refinement of mitigation measures
Chapter 7	**Growth-Inducement Potential and Indirect Effects of Growth**	Water demand projections and analyses of growth-inducement impacts and secondary effects of growth	Yes, changes made to correct editorial errors and to clarify the discussion	Refer to Appendix E for supporting details
Chapter 8	**WSIP Variants and Impact Analysis**	Description and analysis of variants requested by the SFPUC	Yes, changes made to introduce the Phased WSIP Variant	Refer to Section 13.4 for supplemental discussion of the Phased WSIP Variant
Chapter 9	**CEQA Alternatives**	Description, analysis, and comparison of CEQA alternatives, the alternatives screening process, and the	Yes, changes made due to refined analysis of Pilarcitos watershed resources and to clarify the Modified WSIP	Refer to Section 13.3 for refined Pilarcitos watershed impact analysis and to Section 14.10 for supplemental discussion of the Modified

ADOPTING FINDINGS RELATED TO THE CERTIFICATION OF A FINAL PROGRAM ENVIRONMENTAL IMPACT REPORT FOR A PROPOSED WATER SYSTEM IMPROVEMENT PROGRAM FOR THE SAN FRANCISCO PUBLIC UTILITIES COMMISSION.

MOVED, that the San Francisco Planning Commission (hereinafter "Commission") hereby CERTIFIES the Final Program Environmental Impact Report identified as Case No. 2005.0159E for the Water System Improvement Program (WSIP), including a series of facilities improvement projects, in Alameda, Santa Clara, San Francisco, San Joaquin, San Mateo, Stanislaus, and Tuolumne Counties (hereinafter "Project"), based upon the following findings:

1. The City and County of San Francisco, acting through the Planning Department (hereinafter "Department") fulfilled all procedural requirements of the California Environmental Quality Act (Cal. Pub. Res. Code Section 21000 *et seq.*, hereinafter "CEQA"), the State CEQA Guidelines (Cal. Admin. Code Title 14, Section 15000 *et*

seq., (hereinafter "CEQA Guidelines") and Chapter 31 of the San Francisco Administrative Code (hereinafter "Chapter 31").

A. The Department determined that a Program Environmental Impact Report (hereinafter "PEIR") was required and in accordance with Sections 15063 and 15082 of the CEQA Guidelines, the Department prepared a Notice of Preparation (NOP) of an EIR and conducted scoping meetings (see Draft PEIR, Appendix A). The NOP was circulated to local, state, and federal agencies and to other interested parties on September 6, 2005, initiating a public comment period that extended through October 24, 2005. Pursuant to CEQA Guidelines Section 15083, the San Francisco Planning Department held five public scoping meetings, one each in Sonora, Modesto, Fremont, Palo Alto and San Francisco, between October 5, 2005 and October 19, 2005. The purpose of the meetings was to present the proposed WSIP to the public and receive public input regarding the proposed scope of the Program EIR analysis. A scoping report was prepared to summarize the public scoping process and the comments received in response to the NOP, and the main body of the report is included in Appendix A of the Draft Program EIR.

B. On June 29, 2007, the Department published the Draft Program Environmental Impact Report (hereinafter "DPEIR") and provided public notice in a newspaper of general circulation of the availability of the DPEIR for public review and comment and of the date and time of the Planning Commission public hearings on the DPEIR; this notice was mailed to the Department's list of persons requesting such notice and other interested parties.

C. Notices of availability of the DPEIR and of the date and time of the public hearing were posted near the project site at O'Shaughnessy Dam in Tuolumne County by Department staff on July 25, 2007, and posting of the Notice of Availability were made by Department staff at a public library in each of the counties potentially affected by the Program (i.e., Alameda, San Francisco, San Joaquin, San Mateo, Santa Clara, Stanislaus, and Tuolumne Counties) in July 2007.

D. On June 29, 2007, copies of the DPEIR were mailed or otherwise delivered to a list of persons requesting it, to those noted on the distribution list in the DPEIR, and to government agencies, the latter both directly and through the State Clearinghouse. The DPEIR was posted on the Department's website.

E. Notice of Completion was filed with the State Secretary of Resources via the State Clearinghouse on June 29, 2007.

2. The DPEIR was circulated to local, state, and federal agencies and to interested organizations and individuals for review and comment on June 29, 2007 for a 90-day public review period. The public review period was subsequently extended and closed on October 15, 2007, for a total of 108 days. Six duly advertised public

hearings on the Draft PEIR to accept written or oral comments were held in Sonora, Modesto, Fremont, Palo Alto, and San Francisco (two hearings) between September 5, 2007 and October 11, 2007. All of the public hearings transcripts are in the Project record.

3. The Department prepared responses to comments on environmental issues received at the public hearings and in writing during the public review period for the DPEIR, prepared revisions to the text of the DPEIR in response to comments received or based on additional information that became available during the public review period, and corrected errors in the DPEIR. This material was presented in a Draft Comments and Responses document, published on September 30, 2008, distributed to the Commission and all parties who commented on the DPEIR, and made available to others upon request at Department offices and on the Department's website.

4. A Final Program Environmental Impact Report (hereinafter "FPEIR") has been prepared by the Department, consisting of the Draft Program Environmental Impact Report, any consultations and comments received during the review process, any additional information that became available, and the Comments and Responses, all as required by law.

5. Project files on the FPEIR have been made available for review by the Commission and the public. These files are available for public review at the Department offices at 1650 Mission Street, and are part of the record before the Commission. Linda Avery is the custodian of records. Copies of the DPEIR and associated reference materials as well as the C&R document are also available for review at public libraries in each of the following counties: Alameda, San Francisco, San Joaquin, San Mateo, Santa Clara, Stanislaus, and Tuolumne.

6. The San Francisco Public Utilities Commission, the Project Sponsor, has indicated that the presently preferred program is the Phased WSIP Variant, which is described and analyzed in the FPEIR.

7. The FPEIR added new information to the DPEIR, as detailed in the Department Staff Memorandum dated October 16, 2008. This additional information does not involve a new significant environmental impact, a substantial increase in the severity of a significant environmental impact, or a feasible alternative or mitigation measure considerably different from others previously analyzed that would clearly lessen the significant environmental impacts of the Program and that the Project Sponsor declines to adopt. No information indicates that the DPEIR was inadequate or conclusory. Therefore, recirculation of the PEIR is not required or necessary because: (1) no new significant environmental impact would result from the Program (the Phased WSIP Variant as well as the originally preferred Program) or from a new mitigation measure proposed to be implemented; (2) no substantial increase in the severity of an environmental impact would result; (3) no feasible program

alternative or mitigation measure considerably different from others previously analyzed would clearly lessen the environmental impacts of the Phased WSIP Variant, but the project's proponents decline to adopt it; and (4) the Draft PEIR was not so fundamentally and basically inadequate and conclusory in nature so that meaningful public review and comment were precluded.

8. The Commission, in certifying the completion of said FPEIR, hereby does find that the Phased WSIP Variant described in the FPEIR and preferred by the Project Sponsor, will have the following significant and unavoidable effects on the environment.

Significant and Unavoidable Water Supply/System Operations Impacts:

- The proposed water supply and system operations would reduce stream flows and alter the stream hydrograph along Alameda Creek below the Alameda Creek Diversion Dam in the Alameda Creek watershed in Alameda County and result in a significant and unavoidable impact on stream flow in Alameda Creek between the diversion dam and the confluence with Calaveras Creek;
- The proposed water supply and system operations would result in a potentially significant and unavoidable impact in the Peninsula watershed on fishery resources in Crystal Springs Reservoir in San Mateo County; and
- The Program would indirectly contribute to potentially significant and unavoidable environmental impacts caused by growth in the SFPUC service area, as identified in the planning documents and associated environmental documents for the affected jurisdictions.

Potentially Significant and Unavoidable WSIP Facility Improvement Project Impacts:

The WSIP may have significant and unavoidable impacts on the environment in the following ways based on programmatic information provided in the FPEIR about the WSIP facilities improvement projects. These impacts will be reevaluated in subsequent CEQA documentation based on site-specific, project-level information. Until more detailed project-level assessments are completed to determine the significance of impacts, these impacts are conservatively considered to be potentially significant and unavoidable. The impacts include:

Land Use and Visual Quality

- Temporary disruption or displacement of land uses during construction periods.

- Existing land uses could be displaced to accommodate proposed facilities at some locations.

- Removal of a large area of existing oak woodland cover as part of the Calaveras Dam Replacement project would permanently alter a scenic vista.

Cultural Resources

- Alteration or demolition of existing or potential historic facilities.

- Substantial adverse effects on existing or potential historic districts.

Noise and Vibration

- Excessive construction noise could occur in close proximity to sensitive receptors and audible construction noise could occur during the more noise-sensitive nighttime hours.

- Construction activities could generate vibration in proximity to sensitive receptors during the nighttime hours with implementation of some WSIP facility projects.

Biological Resources

- Multiple facility improvement projects in the Sunol Valley would have a potentially significant and unavoidable collective impact on biological resources because of the number of WSIP projects in this region and the extent of overlap in terms of construction activity timing and location.

- Potentially significant and unavoidable collective impacts on special-status plant species could occur during construction of the Crystal Springs/San Andreas Transmission Upgrade and Lower Crystal Springs Dam projects.

Impacts Due to Implementation of Multiple WSIP Projects (Collective Impacts)

- Temporary impacts on existing land uses near the Irvington Tunnel portal in Fremont could occur during construction if staging and access under both the New Irvington Tunnel and Bay Division Pipeline Reliability Upgrade projects overlap in this vicinity.

- Impacts on biological resources in Sunol Valley because of the number of WSIP projects in this region and the extent of overlap in terms of construction activity timing and location.
- Impacts on biological resources (special-status plant species) on the Peninsula during construction of the Crystal Springs/San Andreas Transmission Upgrade and Lower Crystal Springs Dam projects.
- Impacts on historical resources due to implementation of multiple projects in areas with water system facilities more than 45 years old.
- Truck traffic impacts due to the numerous potentially-affected roadways, including regional roadways.
- Multi-regional effects on air quality from ozone and particulate matter emissions during construction of multiple projects.
- Noise impacts from construction of multiple WSIP projects the San Joaquin, Bay Division, Peninsula, and San Francisco regions.

Impacts Due to Implementation of all WSIP Projects Combined with Non-WSIP Projects (Cumulative Impacts)

- Impacts on individual historic resources or on potential historic districts in the Sunol Valley and Peninsula regions.
- Regionwide traffic impacts from construction-related traffic (e.g., increased travel times).
- Regionwide air quality impacts due to the nonattainment status for ozone and particulate matter in both the San Francisco Bay Area and San Joaquin Valley Air Basins as well as the Program's contribution to construction-related diesel particulate matter emissions.
- Construction-related noise impacts on local and regional roadways.

9. On October 30, 2008, the Commission reviewed and considered the FPEIR and hereby does find that the contents of said report and the procedures through which the FPEIR was prepared, publicized and reviewed comply with the provisions of

CEQA, the CEQA Guidelines and Chapter 31 of the San Francisco Administrative Code.

10. The Planning Commission hereby does find that the FPEIR concerning File No. 2005.0159E, Water System Improvement Program, reflects the independent judgment and analysis of the City and County of San Francisco, is adequate, accurate and objective, and that the Comments and Responses document contains no significant revisions to the DPEIR, and hereby does CERTIFY THE COMPLETION of said FPEIR in compliance with CEQA and the CEQA Guidelines.

I hereby certify that the foregoing Motion was ADOPTED by the Planning Commission at its regular meeting of October 30, 2008.

AM FOR

ADOPTED: October 30, 2008

ATTACHMENT A

WATER SYSTEM IMPROVEMENT PROGRAM

CALIFORNIA ENVIRONMENTAL QUALITY ACT FINDINGS: FINDINGS OF FACT, EVALUATION OF MITIGATION MEASURES AND ALTERNATIVES, AND STATEMENT OF OVERRIDING CONSIDERATIONS

SAN FRANCISCO PUBLIC UTILITIES COMMISSION

In determining to approve the Phased Variant of the Water System Improvement Program ("Phased WSIP Variant" or the "Program"), the San Francisco Public Utilities Commission ("SFPUC") makes and adopts the following findings of fact and decisions regarding mitigation measures and alternatives, and adopts the statement of overriding considerations, based on substantial evidence in the whole record of this proceeding and under the California Environmental Quality Act ("CEQA"), California Public Resources Code Sections 21000 et seq., particularly Sections 21081 and 21081.5, the Guidelines for Implementation of CEQA ("CEQA Guidelines"), 14 California Code of Regulations Sections 15000 et seq., particularly Sections 15091 through 15093, and Chapter 31 of the San Francisco Administration Code.

This document is organized as follows:

Section I provides a description of the Program proposed for adoption (the Phased WSIP Variant), the environmental review process for the Program, the approval actions to be taken and the location of records;

Section II identifies the impacts found not to be significant that do not require mitigation;

Section III identifies potentially significant impacts that can be avoided or reduced to less-than-significant levels through mitigation and describes the disposition of the mitigation measures;

Section IV identifies significant impacts that cannot be avoided or reduced to less-than significant levels and describes any applicable mitigation measures as well as the disposition of the mitigation measures;

Section V evaluates the different Program alternatives and the economic, legal, social, technological, and other considerations that support approval of the Phased WSIP Variant and the rejection of the alternatives, or elements thereof, analyzed; and

Section VI presents a statement of overriding considerations setting forth specific reasons in support of the Commission's actions and its rejection of the alternatives not incorporated into the Program.

The Mitigation Monitoring and Reporting Program ("MMRP") for the mitigation measures that have been proposed for adoption is attached with these findings as **Attachment B**. The MMRP is required by CEQA Section 21081.6 and CEQA Guidelines Section 15091. Attachment B provides a table setting forth each mitigation measure listed in the Final Program Environmental Impact Report for the WSIP ("Final PEIR" or "PEIR") that is required to reduce or avoid a significant adverse impact. Attachment B also specifies the agency responsible for implementation of each measure and establishes monitoring actions and a monitoring schedule. The full text of the mitigation measures is set forth in Attachment B.

These findings are based upon substantial evidence in the entire record before the Commission. The references set forth in these findings to certain pages or sections of the Draft Program Environmental Impact Report ("Draft PEIR" or "DEIR") or the Comments and Responses document ("C&R") in the Final PEIR are for ease of reference and are not intended to provide an exhaustive list of the evidence relied upon for these findings.

I. APPROVAL OF THE PROGRAM

A. Program Description

By this action, the SFPUC adopts and implements substantially the Program identified as the Phased WSIP Variant in Chapter 13, Section 13.4 of the PEIR, to increase the reliability of the regional water system that serves 2.4 million people in San Francisco and the San Francisco Bay Area; the Phased WSIP Variant is a variation of the original WSIP described in Chapter 3 of the PEIR. The Phased WSIP Variant involves *full implementation of all proposed WSIP facility improvement projects* as described in Chapter 3 of the Draft EIR to insure that the public health, seismic safety and delivery reliability goals are achieved as soon as possible *and phased implementation of a water supply program to meet projected water purchases through 2030*. Under the Phased WSIP Variant, the SFPUC establishes an interim mid-term planning horizon – 2018. The Commission is making a decision about providing water supply to the water customers through 2018 only, and is deferring a decision regarding long-term water supply after 2018 and through 2030 until it undertakes further water supply planning and demand analysis. All non-water supply related goals and system performance objectives identified for the original WSIP would be achieved under the Phased WSIP Variant and all individual WSIP facility improvement projects proposed in the original WSIP would be constructed.

Under the Phased WSIP Variant, the SFPUC will construct and operate all the regional water system WSIP facility improvement projects while (1) limiting water sales to an average annual of 265 million gallons per day (mgd) from the watersheds through 2018; and (2) improving water supply reliability to meet the goals and objectives of the WSIP including no greater than 20 percent rationing systemwide in any one year of a drought. The Phased WSIP Variant would not provide water supply to meet 300 mgd average annual water sales in 2030 as proposed under the WSIP. Rather, the SFPUC would limit deliveries to no more than an annual average of 265 mgd from the watersheds through 2018, and the SFPUC and wholesale customers would collectively develop 20 mgd in conservation, recycled water, and groundwater to meet or offset the projected regional water system purchase request of 285 mgd in 2018. This 20 mgd of conservation, recycled water, and groundwater includes development of 10 mgd of conservation, recycled water and groundwater in San Francisco as proposed under the WSIP and 10 mgd of conservation, recycled water and groundwater developed by the wholesale customers, which is in addition to 15 mgd of conservation, recycled water and groundwater already assumed by the wholesale customers in preparing their regional water system purchase requests.

There is no change between the WSIP and the Phased WSIP Variant in the average annual water delivery proposed for the SFPUC's retail customers; the current average annual retail customer demand is approximately 91 mgd and this same amount would be provided to the retail customers through 2018, although 10 mgd of this amount would be provided through conservation, recycled water, and groundwater developed in San Francisco. While the WSIP proposed to provide the full 2030 projected wholesale customer average annual purchase requests of 209 mgd, the Phased WSIP Variant instead is designed to meet a projected 2018 wholesale customer average annual purchase request of 194 mgd in 2018, although 10 mgd of this amount would be provided through conservation, recycled water, and groundwater projects.

Under the Phased WSIP Variant, the SFPUC also would implement the delivery and drought reliability elements of the WSIP, including the Westside Basin Conjunctive Use Project and proposed dry-year transfers from the Modesto Irrigation District ("MID") and the Turlock Irrigation District ("TID"), which would increase average annual diversions from the Tuolumne River by about 2 mgd over existing conditions.

Before 2018, the SFPUC would engage in a new planning process to re-evaluate water system demands and water supply options. As part of the process, San Francisco would conduct additional environmental studies and CEQA review as appropriate to address the SFPUC's recommendation regarding water supply and proposed water system deliveries after 2018. This Commission would review and consider approval of the terms of any new master Water Sales Agreement that would take effect after 2018.

As originally proposed, the WSIP established program goals for improvements to the regional water system and system performance objectives in the areas of water quality, seismic reliability, delivery reliability, and water supply through the year 2030. The facility improvement projects and the proposed water supply option included in the WSIP as originally proposed were designed to: (1) ensure compliance with existing and anticipated future water quality standards under all operating conditions; (2) upgrade the seismic standards of critical facilities to improve seismic reliability and to reduce the system's vulnerability to earthquakes; (3) improve water delivery reliability under a variety of operating conditions by improving overall operations of the system; and (4) assure that the SFPUC has an adequate supply of water available to deliver to customers during both non-drought and drought periods through 2030.

The SFPUC initially proposed the draft WSIP in early 2005 as the result of long-term planning and in response to legislative mandates, including a 2002 voter-approved bond measure. The draft WSIP is described in PEIR Chapter 3. For budgeting and management purposes, the SFPUC categorized as part of the WSIP all capital improvements and projects that will receive financing from the 2002 voter-approved bond measure. Some, but not all, of the activities and projects that the SFPUC has identified for financing purposes as part of the WSIP are analyzed in the Program EIR as explained in PEIR Section 3.4. (CEQA Guidelines section 15168.) Other proposed WSIP activities that are not evaluated in the PEIR are undergoing independent project-level CEQA review as explained in EIR Section 3.4.6. For purposes of these CEQA findings, the facility projects included under the "Program," "WSIP," or "Variant" refer only to the facility improvement projects included in the PEIR. WSIP facility improvement projects included in the PEIR will also undergo independent project-level CEQA review.

In March 2008, the SFPUC determined that it would like the option to consider approval and implementation of a variation of the WSIP. The program variation is called the Phased WSIP Variant and is a hybrid combination of the WSIP program as originally proposed and the No Purchase Request Increase Alternative analyzed in the Draft EIR at pages 9-7 through 9-16, 9-40 through 9-47 and 9-84 through 9-96, as well as the Modified WSIP Alternative analyzed in the Draft PEIR at pages 9-7 through 9-16 and 9-78 through 9-96 and in the C&R pages 14.10-1 through 14.10-26. The Phased WSIP Variant also includes some elements of the Aggressive Conservation and Recycling Alternative analyzed in the Draft EIR at pages 9-7 through 9-16, 9-47 through 9-59, and 9-84 through 9-96.

The Phased WSIP Variant includes the following key program elements:

- Full implementation of all of the 17 proposed WSIP facility improvement projects described in the PEIR (Draft EIR Sections 3.4.6 and 3.8; C&R Chapter 16, pages 16-14 to 16-17).
- Water supply delivery to regional water system customers through 2018 only of 265 mgd average annual target delivery originating from the Tuolumne, Alameda and Peninsula watersheds. This includes 184 mgd for the wholesale customers (including 9 mgd for the cities of San Jose and Santa Clara), and 81 mgd for the retail customers.
- Development of 20 mgd of conservation, recycled water and groundwater within the service area (10 mgd retail; 10 mgd wholesale).
- Dry year transfer from MID and/or TID of about 2 mgd coupled with the Westside Groundwater Basin conjunctive-use project to meet the drought year goal of limiting rationing to no more than 20 percent on a systemwide basis.
- Re-evaluation of 2030 demand projections, potential regional water system purchase requests, and water supply options by 2018 and a separate SFPUC decision in 2018 regarding regional water system water deliveries after 2018.
- Financial incentives to limit water sales to an annual average of 265 mgd from the watersheds.

The SFPUC will deliver to customers up to 265 mgd from the SFPUC watersheds on an average annual basis. While average annual deliveries from the SFPUC watersheds would be limited to 265 mgd such that there would be no increase in diversions from the Tuolumne River to serve additional demand, there would be a small increase in average annual Tuolumne River diversions of about 2 mgd over existing conditions in order to meet the delivery and drought reliability elements through 2018. As part of adoption of this Program, the SFPUC will implement the mitigation measures identified for the Phased WSIP Variant in the Final PEIR, including measures addressing interim impacts from potential increases in deliveries from the SFPUC watersheds over the total average annual of 265 mgd in the event that conservation, recycled water and groundwater projects are not completed prior to the increase in customers' demand.

The SFPUC must maintain water deliveries to all its customers for the protection of public health and safety. Therefore, the SFPUC will work with its customers to develop financial incentives to limit water sales to an average annual amount of 265 mgd from the watersheds through 2018.

With the projected 20 mgd of conservation, recycled water and groundwater projects, the system would meet average daily demand of 285 mgd in 2018.

Summaries of the WSIP facility improvement projects and the WSIP water supply under the Phased WSIP Variant are provided in the SFPUC staff memorandum dated September 30, 2008, and summaries of the WSIP facility improvement projects are set forth in PEIR Chapter 3, pages 3-48 through 3-73 and Appendix C, and are listed below. The projects are analyzed in the PEIR, Chapter 4. This approval action slightly modified the staff recommendation as set forth in the Resolution.

Phased WSIP Variant Facility Improvement Projects

The size and design of the WSIP facility improvement projects are driven by the system performance objectives and would not change as a result of the water supply decision proposed in the Phased WSIP Variant. The SFPUC prepared a memorandum describing the factors affecting facilities capacity, dated July 29, 2008, and the information from that memorandum is incorporated by reference here. The draft WSIP included multiple program goals for improving seismic reliability and water delivery reliability, meeting current and future water quality regulations, and meeting water supply reliability goals through the year 2030. Design and capacity of the WSIP facility improvement projects is driven by all four of the WSIP objectives -- the need to improve system performance for seismic reliability and water delivery reliability as well as maintaining high water quality standards and meeting water supply goals. All four of these objectives are factored into the decision on how to size the WSIP's individual facilities. As is explained in the SFPUC memorandum, even if the goal of meeting projected increases in water supply demands were dropped from the mix of program objectives, the other program goals would cause the SFPUC to design WSIP facility improvement projects of the same size. The sizing of the facilities is necessary to reliably deliver an average annual amount up to 300 mgd in light of the regional system's needs for seismic and delivery reliability during both drought and non-drought periods, and to meet water quality requirements.

The Phased WSIP Variant includes the following facility improvement projects:

San Joaquin Region
SJ-1, Advanced Disinfection
SJ-2, Lawrence Livermore Supply Improvements
SJ-3, San Joaquin Pipeline System
SJ-5, Tesla Portal Disinfection Station

Sunol Valley Region
SV-1, Alameda Creek Fishery Enhancement
SV-2, Calaveras Dam Replacement
SV-3, Additional 40-mgd Treated Water Supply
SV-4, New Irvington Tunnel
SV-5, SVWTP – Treated Water Reservoirs
SV-6, San Antonio Back-Up Pipeline

Bay Division Region
BD-1, Bay Division Pipeline Reliability Upgrade

Peninsula Region
PN-2, Crystal Springs/San Andreas Transmission Upgrade
PN-3, HTWTP Long-Term Improvements
PN-4, Lower Crystal Springs Dam Improvement:

San Francisco Region
SF-1, San Andreas Pipeline No. 3 Installation
SF-2, Groundwater Projects
SF-3, Recycled Water Projects

B. Program Objectives

The SFPUC developed the WSIP to address several problems and issues that it had identified with its regional water system. In developing the WSIP goals and objectives, the SFPUC incorporated two fundamental principles pertaining to the existing regional system: (1) maintaining a clean, unfiltered water source from the Hetch Hetchy system, and (2) maintaining a gravity-driven system.

Among the considerations leading to identification of the WSIP were the following:

• *Aging Infrastructure.* The SFPUC regional water system is old. Many of its components were built in the 1800s and early 1900s; parts of the regional water system were built using now-outdated construction materials and/or methods and are currently in need of major repair. As the system ages, its reliability decreases and the risk of failure increases.

• *Exposure to Seismic and Other Hazards.* The 167-mile-long system crosses five active earthquake faults. Many of the SFPUC regional water system components are located on or in the immediate vicinity of major earthquake faults. Due to the age of the system, many facilities do not meet modern seismic standards. To protect public safety, the California Department of Water Resources, Division of Safety of Dams has imposed operating restrictions on Calaveras and Crystal Springs Reservoirs, reducing the local storage capacity and impairing normal system operations; this storage capacity needs to be restored.

• *Maintain Water Quality.* The regional water system currently meets or exceeds existing water quality standards. However, system upgrades are needed to improve the SFPUC's ability to continue to maintain compliance with current water quality standards and to meet anticipated future water quality standards under a range of operating conditions, including such events as a major earthquake, without reducing system reliability.

• *Improve Asset Management and Delivery Reliability.* In order to implement a feasible asset management program in the future that will provide continuous maintenance and repairs to facilities, the regional water system requires redundancy (i.e., backup) of some critical facilities necessary to meeting day-to-day customer water supply needs. Without adequate redundancy of critical facilities, the SFPUC has limited operational flexibility in the event of an emergency or a system failure, as well as constraints on conducting adequate system inspection and maintenance.

• *Meet Customer Water Demands.* Additional supplies are needed to satisfy current demand in drought years and projected 2030 demand in all years. The experience of the last 150 years of record as well as recent studies on California's climate show the region is susceptible to droughts. Two of the most severe droughts occurred during the past 30 years. The regional water system currently has insufficient water supply to meet customer demand during a prolonged drought, and this situation will worsen in the future.

To address these challenges to the reliability of the regional water system, the SFPUC must replace or upgrade numerous components of the system and add some new components—thus the need for the WSIP and its associated facility improvement projects.

Goals and objectives were established for the WSIP described and analyzed in the PEIR. Because of the decision to phase implementation of a water supply program to meet projected water purchases through 2030, the water supply objective for the Phased WSIP Variant is slightly different from the water supply objective originally proposed, as revised below. The goals and objectives of the Phased WSIP Variant are presented below.

Phased WSIP GOALS AND OBJECTIVES

Program Goal	System Performance Objective
Water Quality – *maintain high water quality*	• Design improvements to meet current and foreseeable future federal and state water quality requirements. • Provide clean, unfiltered water originating from Hetch Hetchy Reservoir and filtered water from local watersheds. • Continue to implement watershed protection measures.
Seismic Reliability – *reduce vulnerability to earthquakes*	• Design improvements to meet current seismic standards. • Deliver basic service to the three regions in the service area (East/ South Bay, Peninsula, and San Francisco) within 24 hours after a major earthquake. Basic service is defined as average winter-month usage, and the performance objective for design of the regional system is 229 mgd. The performance objective is to provide delivery to at least 70 percent of the turnouts in each region, with 104, 44, and 81 mgd delivered to the East/South Bay, Peninsula, and San Francisco, respectively. • Restore facilities to meet average-day demand of up to 300 mgd within 30 days after a major earthquake.

Program Goal	System Performance Objective
Delivery Reliability – *increase delivery reliability and improve ability to maintain the system*	• Provide operational flexibility to allow planned maintenance shutdown of individual facilities without interrupting customer service. • Provide operational flexibility to minimize the risk of service interruption due to unplanned facility upsets or outages. • Provide operational flexibility and system capacity to replenish local reservoirs as needed. • Meet the estimated average annual demand of up to 300 mgd under the conditions of one planned shutdown of a major facility for maintenance concurrent with one unplanned facility outage due to a natural disaster, emergency, or facility failure/upset.
Water Supply – *meet customer water needs in non-drought and drought periods*	• Meet average annual water demand of 265 mgd from the SFPUC watersheds for retail and wholesale customers during non -drought years for system demands through 2018. • Meet dry-year delivery needs through 2018 while limiting rationing to a maximum 20 percent system-wide reduction in water service during extended droughts. • Diversify water supply options during non-drought and drought periods. • Improve use of new water sources and drought management, including groundwater, recycled water, conservation, and transfers.
Sustainability – *enhance sustainability in all system activities*	• Manage natural resources and physical systems to protect watershed ecosystems. • Meet, at a minimum, all current and anticipated legal requirements for protection of fish and wildlife habitat. • Manage natural resources and physical systems to protect public health and safety.
Cost-effectiveness – *achieve a cost-effective, fully operational system*	• Ensure cost-effective use of funds. • Maintain gravity-driven system. • Implement regular inspection and maintenance program for all facilities.

C. Environmental Review

In accordance with Sections 15063 and 15082 of the CEQA Guidelines, the San Francisco Planning Department, as lead agency, prepared a Notice of Preparation (NOP) of an EIR and conducted scoping meetings (see Draft PEIR, Appendix A). The NOP was circulated to local, state, and federal agencies and to other interested parties on September 6, 2005, initiating a public comment period that extended through October 24, 2005.

As indicated in the NOP, the Program EIR addresses the full range of environmental impacts of the WSIP. The NOP included a preliminary list of the potential environmental impacts related to the following resource topics: surface water resources; groundwater resources; fisheries and aquatic resources; terrestrial vegetation and wildlife; geology, soils, and seismicity; cultural resources; land use, plans, and policies; recreation; agricultural resources; traffic, transportation, and circulation; air quality; noise and vibration; public services, utilities, and energy; hazards and public safety; visual quality; socioeconomics; growth-inducement potential and secondary effects of growth; and cumulative effects. The NOP provided a general description of the proposed action, the need for the program and program benefits, the proposed facilities, and the program location.

Pursuant to CEQA Guidelines Section 15083, the San Francisco Planning Department held five public scoping meetings, one each in Sonora, Modesto, Fremont, Palo Alto and San Francisco, between October 5, 2005 and October 19, 2005. The purpose of the meetings was to present the proposed WSIP to the public and receive public input regarding the proposed scope of the Program EIR analysis. Attendees were provided an opportunity to voice comments or concerns regarding potential effects of the WSIP.

A scoping report was prepared to summarize the public scoping process and the comments received in response to the NOP, and the main body of the report is included in Appendix A of the Draft Program EIR. Based on sign-in sheets at each of the meetings, 260 participants attended the scoping meetings, with 75 of those participants providing oral comments. Transcripts of each scoping meeting are included in the full scoping report on file with the San Francisco Planning Department.

The San Francisco Planning Department also held a scoping meeting for resource agencies on Thursday, November 3, 2005 in San Francisco. Representatives from the following agencies attended: U.S. Army Corps of Engineers, San Francisco Bay Regional Water Quality Control Board, California Department of Fish and Game, and U.S. Fish and Wildlife Service. Representatives of the U.S. Environmental Protection Agency and the National Marine Fisheries Service were invited but unable to attend. Additional coordination with public agencies through informal consultation and telephone interviews was conducted throughout the EIR process.

In addition to comments received during scoping meetings, comments on the NOP were received by letter sent via mail, email, or fax (104, including 5 form letters counted once each but submitted multiple times), orally by speakers at the scoping meetings (79), and by phone (187 voicemail messages left with the San Francisco Planning Department). The comments addressed concerns regarding the full range of potential environmental issues as well as program alternatives and the CEQA process.

The San Francisco Planning Department then prepared the Draft Program EIR, which describes the WSIP and the environmental setting for the proposed program, identifies potential impacts, presents mitigation measures for impacts found to be significant or potentially significant, and evaluates program alternatives. It also includes an analysis of three variants to the proposed WSIP, as requested by the SFPUC. The analysis of environmental impacts is divided into three main groups: (1) construction and operational impact of the WSIP facility improvement projects; (2) water supply and system operational impacts of the WSIP; and (3) growth-inducing impacts. In assessing construction and operational impacts of the facility improvement projects, the Program EIR considers impacts of individual projects, the "collective" construction and operational impacts from multiple WSIP facility improvement projects, and cumulative impacts associated with construction and operation of WSIP projects in combination with other past, present, and future actions with potential for similar impacts on the same resources as those affected by the WSIP. Similarly, in assessing water supply and system operations impacts, the Program EIR includes analysis of cumulative impacts associated with the WSIP water supply and system operations in combination with other past, present, and future actions with potential for impacts on the same resources as those affected by the WSIP.

Each environmental issue presented in this Draft PEIR is analyzed with respect to significance criteria that are based on the San Francisco Planning Department Major Environmental Analysis Division (MEA) guidance regarding the environmental effects to be considered significant. MEA guidance is, in turn, based on CEQA Guidelines Appendix G with some modifications. In cases where potential environmental issues associated with the WSIP are identified but are not clearly addressed by MEA's standard Initial Study checklist, additional impact significance criteria are presented. (Draft EIR, Appendix B.)

The Draft EIR was circulated to local, state, and federal agencies and to interested organizations and individuals for review and comment on June 29, 2007 for a 90-day public review period, which was extended once and closed on October 15, 2007, for a total of 108 days. Six public hearings on the Draft PEIR to accept written or oral comments were held in Sonora, Modesto, Fremont, Palo Alto, and San Francisco (two hearings) between September 5, 2007 and October 11, 2007. During the public review period, the San Francisco Planning Department received approximately 1,500 written comments sent through the mail or by hand-delivery, fax, or email as well as approximately 200 oral comments made at six public hearings. A court reporter was present at each of the public hearings, transcribed the oral comments verbatim, and prepared written transcripts. Appendix J of the PEIR includes a summary of the Draft PEIR notification and public hearing process.

The Comments and Responses ("C&R") document was published on September 30, 2008 and it provides copies of all of the comments received on the Draft PEIR as well as individual responses to those comments. In some cases, the responses to individual comments are presented as master responses, which consist of comprehensive discussions of issues that received numerous comments. In addition, the C&R includes descriptions of changes in the WSIP that were proposed by the SFPUC after publication of the Draft PEIR, and it includes a description and analysis of the Phased WSIP Variant.

The C&R provided additional, updated information and clarification on issues raised by commenters, as well as consultant, SFPUC and Planning Department experts. The Final PEIR incorporates information obtained and produced after the Draft PEIR was completed, and contains additions, clarifications, and modifications, including a description and analysis of the Phased WSIP Variant. The Planning Commission reviewed and considered the Final PEIR and all of the supporting information. The Final PEIR provided augmented and updated information on many issues presented in the Draft PEIR, including (but not limited to) the following topics: revisions to the Hetch Hetchy/Local Simulation Model; additional analysis of the Tuolumne River impacts; changes and clarifications on the Pilarcitos Watershed analysis and impact conclusions; an analysis of the Alameda Creek Fisheries issues, including future potentially occurring steelhead in the Alameda Creek watershed; updated information on the San Joaquin River and the San Francisco Bay Delta; an update to the information provided on climate change issues; and WSIP facility improvement projects updates. In certifying the Final PEIR, the Planning Commission found that the Final PEIR does not add significant new information to the Draft EIR that would require recirculation of the PEIR under CEQA because the Final PEIR contains no information revealing (1) any new significant environmental impact that would result from the Phased WSIP Variant or from a new mitigation measure proposed to be implemented, (2) any substantial increase in the severity of a previously identified environmental impact, (3) any feasible project alternative or mitigation measure considerably different from others previously analyzed that would clearly lessen the environmental impacts of the Phased WSIP Variant, but that was rejected by the project's proponents, or (4) that the Draft EIR was so fundamentally and basically inadequate and conclusory in nature that meaningful public review and comment were precluded. This Commission concurs in that determination.

D. Environmental Analysis of the Phased WSIP Variant

The Final PEIR included a description and analysis of the Phased WSIP Variant, as discussed in the C&R, Chapter 13, Section 13.4. The C&R analysis concluded that the potential environmental effects of the Phased WSIP Variant fall within the range of impacts already evaluated in the Draft PEIR for the WSIP and the alternatives. This Variant is similar to the No Purchase Request Increase Alternative analyzed in the Draft EIR. Also relevant are the analyses of the No Program Alternative, the Aggressive Conservation/Water Recycling and Local Groundwater Alternative, and the Modified WSIP Alternative.

The Phased WSIP Variant would have the same impacts associated with proposed facility construction and operation as the WSIP. The 17 facility improvement projects proposed under the WSIP and analyzed in the Program EIR would also be implemented under the Phased WSIP Variant to meet the intent of the water quality, seismic reliability, delivery reliability, and water supply goals of the WSIP.

The Phased WSIP Variant would have impacts associated with its proposed water supply program similar to those described in the Draft PEIR for the alternatives where the wholesale customer purchase requests for 2030 would not be provided by the regional water system. Under those alternatives, the Draft PEIR assumed that the wholesale customers might pursue other types of projects to either reduce demand and/or to supplement the surface water supplies delivered by the regional water system from the SFPUC watersheds. The potential facility and operations impacts associated with such projects are discussed in the Draft EIR in Section 9.2.2, No Program Alternative (Vol. 4, Chapter 9, pp. 9-34 to 9-37), Section 9.2.3, No Purchase Request Increase Alternative (Vol. 4, Chapter 9, pp. 9-40 to 9-45), and Section 9.2.4, Aggressive Conservation/Water Recycling and Local Groundwater Alternative (Vol. 4, Chapter 9, pp. 9-55 to 9-57).

Similar to the Modified WSIP Alternative and the Aggressive Conservation/Water Recycling and Local Groundwater Alternative, the Phased WSIP Variant, which envisions developing additional local conservation, recycled water and groundwater projects, could result in construction and operation of additional recycled water and groundwater facilities in the wholesale customer service areas; thus, collective impacts in the Bay Division and Peninsula Regions and associated cumulative effects would occur. The types of impacts associated with implementation of the local recycled water and groundwater projects are summarized in Table

13.9 (which is the same as Draft EIR Table 9.12) in C&R Section 13.4 (C&R, page 13-34) and generally relate to construction of new infrastructure, water quality, and groundwater resources, and operational uses of energy and long-term air quality emissions.

In the event local conservation, recycled water or groundwater projects are not sufficient or cannot be developed in time to meet the demands of each of the wholesale customers, SFPUC customers could be expected to pursue alternative water supply sources. The types of impacts associated with water supply acquisition projects are summarized in Table 13.8 (which is the same as Draft EIR Table 9.10) in C&R Section 13.4 (C&R, pages 13-31 to 13-32). Depending on the facilities needed to convey the supplemental supplies to the wholesale customer service areas, the construction and operation of such facilities could result in a full range of construction and operational impacts similar to those described in Draft EIR Chapter 4 for the WSIP facility improvement projects in the South Bay and Peninsula areas (such as traffic, air quality, noise, energy use, waste disposal, and vibration). In general, certain types of impacts are common to water supply transfers/acquisition and include: the cessation of water application to lands irrigated by the water being transferred; changes related to flows, fisheries, and water quality; and impacts caused by the use of existing or the construction of new infrastructure. If water is transferred from agricultural customers, without implementation of agricultural conservation measures, the transfer can result in the conversion of agricultural land to nonagricultural land. Beneficial environmental effects (related to retiring drainage-impaired lands, reducing the application of pesticides, etc.) can also occur. The need for new facilities and/or changes in the operations of existing facilities depend on the source of supply (e.g., the Tuolumne River through transfers with TID and MID, water-rights holders north of the Delta, in the Delta, or south of the Delta), the quantity of supply, the means of conveyance, and any additional storage requirements. Construction or expansion of interties or connecting pipelines could be required, potentially resulting in impacts similar to those described for the WSIP pipeline projects.

If desalination technologies were used to supplement potable water supplies, implementation of a desalination project to augment wholesale customer water supplies would result in the full range of construction impacts at the proposed facility location (such as traffic, air quality, noise, and vibration) as well as operational impacts related to aquatic resources, water quality, energy consumption, air quality, visual resources, land use and planning, traffic, and greenhouse gas emissions. The programmatic impacts of construction and operation of a desalination facility are described in the Draft EIR under WSIP Variant 2, Regional Desalination for Drought (Draft EIR, Chapter 8, pp. 8-24 to 8-32).

The water supply impacts of the Phased WSIP Variant would be similar to those analyzed in Chapter 9 of the Draft PEIR for the No Purchase Request Increase Alternative, and overall the impacts of the Phased WSIP Variant through 2018 would be less than the water supply impacts of the WSIP set out in Chapter 5 of the PEIR. With a few exceptions, the water supply impacts identified as potentially significant and mitigable for the proposed WSIP remain potentially significant and mitigable for the Phased WSIP Variant. Two impacts on the lower Tuolumne River were determined to be less than significant as long as the SFPUC does not increase deliveries to customers above 265 mgd from the watersheds: Impact 5.3.6-4, effects on fishery resources along the Tuolumne River below La Grange Dam; and, Impact 5.3.7-6, impacts on terrestrial biological resources along the Tuolumne River below La Grange Dam. Although the

Phased WSIP Variant is designed to keep deliveries from exceeding an annual average level of about 265 mgd, in the event the SFPUC must deliver more than 265 mgd to its customers from the watersheds, the SFPUC shall implement the mitigation measures associated with these impacts in proportion to the extent of the exceedance. In implementing the Phased WSIP Variant, the need could arise to temporarily increase deliveries from the Tuolumne River and local watersheds over the 265 mgd average annual target levels to meet customer water delivery needs in the near term, because of public health and safety considerations and because it might not be possible to implement all of the local conservation, recycling and groundwater projects and actions in time to meet increasing customer demands. Although avoidance of these impacts on the lower Tuolumne River is not assured, the magnitude, frequency, and duration of the impacts are likely to be less than the originally proposed WSIP. The impact analysis for the Phased WSIP Variant recognized that, between now and 2018, deliveries from the Tuolumne River and local watersheds might increase above the 265 mgd average annual level (to a possible 275 mgd average annual) for up to a few years. By 2018, and perhaps well before, it is expected that local projects would provide sufficient local supply and conservation to bring SFPUC watershed deliveries back down to current levels, average annual 265 mgd.

Under the Phased WSIP Variant, the SFPUC would monitor sales to ensure that sales delivered from the SFPUC watersheds are limited to an average annual of 265 mgd through 2018. The SFPUC would measure and review average annual sales at the close of each fiscal year. Mitigation Measures 5.3.6-4a or 5.3.6-4b, as well as Mitigation Measure 5.3.7-6, will be implemented when the average annual sales exceed 265 mgd from the watersheds. The SFPUC would continue to implement the necessary measure(s) until the average annual SFPUC watershed deliveries are 265 mgd or less. Similar to the WSIP, implementation of Measure 5.3.6-4a is the preferred mitigation approach, and for the Phased WSIP Variant, the amount of conserved water required to reduce the impact to less than significant would be proportional to the amount of increased diversions from the Tuolumne River contributing to exceeding the 265 mgd deliveries restriction.

Four impacts in the Pilarcitos watershed were determined to be potentially significant and mitigable for the originally proposed WSIP, but are considered less than significant for the Phased WSIP Variant through 2018: Surface Water Quality Impact 5.5.3-2, effects on water quality in Pilarcitos Creek between Pilarcitos Reservoir and Stone Dam; Fisheries Impacts 5.5.5-4, effects on fishery resources in Pilarcitos Reservoir, and 5.5.5-5, effects on fishery resources along Pilarcitos Creek below Pilarcitos Reservoir and below Stone Dam; and, Terrestrial Biology Impact 5.5.6-4, impacts on biological resources in Pilarcitos Reservoir. With the Phased WSIP Variant, operations for Pilarcitos Reservoir and releases to Pilarcitos Creek will be similar to existing conditions resulting in a less than significant impact. Thus no mitigation is required. (DEIR pages 5.5.3-5 through 5.5.3-7; C&R pages 13-39 and 13-44; DEIR page 5.5.5-7; C&R pages 13-39 and 13-44; DEIR pages 5.5.6-17 through 5.5.6-22; C&R pages 13-39, 13-44 and 16-80 to 16-82.)

E. Changes to Facility Improvement Projects in the Alameda Creek Watershed

Since publication of the Draft PEIR in June 2007, SFPUC staff proposed modifications to the project descriptions of two of the facility improvement projects—the Alameda Creek Fishery

Enhancement (SV-1) and Calaveras Dam Replacement (SV-2) projects—and these proposed changes would affect overall system operations.[1] These modifications were made due to the numerous comments received on the potential impacts on future steelhead fishery resources in the Alameda Creek watershed as well as to actions taken in July 2007 by other agencies in the watershed. The SFPUC has incorporated project revisions and protective measures into these two projects to reduce the WSIP's potential to affect habitat conditions for potential future-occurring steelhead in the upper watershed. The project revisions would occur regardless of steelhead presence or absence in the upper watershed, while the protective measures are designed to reduce the WSIP's potential to affect habitat conditions for potential, future-occurring steelhead in the Alameda Creek watershed in the event that man-made barriers in Alameda Creek are removed and steelhead gain access to the upper watershed. The following project revisions have been incorporated into the Alameda Creek Fishery Enhancement (SV-1) and Calaveras Dam Replacement (SV-2) projects:

- The Calaveras Dam Replacement project would include facility modifications at the Alameda Creek Diversion Dam (ACDD) to construct a new bypass structure needed to implement bypass stream flows.

- If a structural alternative involving construction of a recapture facility is selected under the Alameda Creek Fishery Enhancement project, the recapture facility would be located at the downstream end of the reach of Alameda Creek between the lower Sunol Valley and the confluence with Arroyo de la Laguna. As an alternative to the recapture facility, the SFPUC may coordinate with other water agencies to develop and implement other means of recapturing fishery enhancement flows consistent with the 1997 California Department of Fish and Game Memorandum of Understanding (CDFG MOU).[2]

The project components designed to provide protective measures for future-occurring steelhead in the upper Alameda Creek watershed will include the following:

- An operational plan to provide minimum stream flows to support steelhead spawning below the ACDD to the confluence with Calaveras Creek when precipitation naturally generates runoff and flow in the creek, including the site-specific studies needed to determine the specific minimum stream flow requirements to support steelhead spawning in this reach of the creek.

- A detailed monitoring plan to survey and document steelhead spawning, subject to review and comment by the appropriate resource agencies.

- Interim minimum flows would be implemented consistent with the 1997 CDFG MOU, with the additional requirement that these flows would be achieved through bypass flows

---

1 See Memorandum from Michael Carlin to the Planning Department dated July 16, 2008.

2 Under the 1997 CDFG MOU, the SFPUC and CDFG reached agreement on the magnitude and timing of flows to be released from Calaveras Reservoir for the purposes of improving fishery habitat conditions. The MOU includes provisions for the SFPUC to divert flows from Alameda Creek to the SFPUC regional system at a suitable downstream location equivalent to the magnitude and timing of these releases; the MOU refers to this as "recapture."

at the ACDD at all times when flows are available in upper Alameda Creek, rather than through releases at Calaveras Dam, and with the following conditions:

- The SFPUC would provide seasonal flow bypasses at the ACDD and/or flow releases from Calaveras Dam, either (1) without recapture or (2) with recapture at a point approximately at the downstream end of the reach of Alameda Creek between the lower Sunol Valley and the confluence with Arroyo de la Laguna, below critical riffle locations or lower in the creek, between December 1 and June 30 (combined adult and juvenile migration period) in an amount equivalent to the flow release schedule provided in the 1997 CDFG MOU.

- As an alternative to the recapture facility, the SFPUC would coordinate with other water agencies to develop and implement other means of recapturing enhancement flows consistent with the 1997 CDFG MOU at a location downstream of the reach of Alameda Creek between the lower Sunol Valley and the confluence with Arroyo de la Laguna.

The C&R also proposed a minor revision to an existing mitigation measure (Mitigation Measure 5.4.5-3a, Minimum Flows for Resident Trout on Alameda Creek) to address other native stream species, including steelhead. The mitigation measures are set forth in the MMRP attached to these Findings as Attachment B. The project description modifications would generally reduce the impacts identified in the Draft PEIR, and, in some cases, would reduce impacts from potentially significant to less than significant (i.e., Impacts 5.4.7-1 and 5.4.7-2). Implementation of the project revisions and protective measures, along with the mitigation measures designed to reduce impacts on resident trout, would be effective in assuring that if in the future steelhead successfully migrate above the BART weir, that the Phased WSIP Variant will not result in a significant adverse effect on steelhead life stages and habitat in Alameda Creek.

F. Approval Actions

1. Planning Commission Actions

On October 30, 2008, the Planning Commission certified the Final PEIR.

2. Public Utilities Commission Actions

The San Francisco Public Utilities Commission is taking the following actions and approvals to implement the Program.

- Adopt these CEQA findings and the attached Mitigation Monitoring and Reporting Program.
- Approve the Water System Improvement Program, the Phased WSIP Variant, as described herein.
- Endorse the selected Water Supply Elements of a new Water Sales Agreement (“Elements”) and authorize the General Manager to negotiate such Agreement with the wholesale customers in substantial conformance with the water supply principles.

3. San Francisco Board of Supervisors Actions

- The Planning Commission's certification of the EIR may be appealed to the Board of Supervisors. If appealed, the Board of Supervisors will determine whether to uphold the certification or to remand the EIR to the Planning Department for further review.

- The San Francisco Board of Supervisors approves an allocation of bond monies to pay for mitigation measures necessary to implement the Program.

4. Other -- Federal, State, and Local Agencies

Implementation of the water supply mitigation measures will involve consultation with/required approvals by other local, state and federal regulatory agencies, including:

- Modesto Irrigation District
- Turlock Irrigation District
- California Water Resources Control Board
- California Department of Fish and Game
- California Department of Health Services (for approval and permits required for drinking water source assessments for groundwater wells)
- U.S. Army Corps of Engineers
- U.S. Fish and Wildlife Service
- NOAA Fisheries- National Marine Fisheries Service
- U.S. Department of the Interior, National Park Service, Yosemite National Park (for consultation on and sharing data from ongoing studies in the Poopenaut Valley)

To the extent that the identified mitigation measures require consultation or approval by these other agencies, this Commission urges these agencies to assist in implementing, coordinating or approving the mitigation measures, as appropriate to the particular measure.

There will be further project approvals following project-specific environmental review, for each of the individual WSIP projects. The actions described herein contemplate only the approval and implementation of the Program as a whole and not each and every project-specific approval.

G. Content and Location of Record

The record upon which all findings and determinations related to the Program are based includes the following:

- The draft Water System Improvement Program and the Phased WSIP Variant.

- The PEIR, and all documents referenced in or relied upon by the PEIR. (The references in these findings to the Program EIR or the PEIR include both the Draft EIR and the C&R documents.)

- All information (including written evidence and testimony) provided by City staff to the SFPUC and the Planning Commission relating to the PEIR, the WSIP, the proposed Program, and the alternatives set forth in the PEIR.

- All information (including written evidence and testimony) presented to the SFPUC and the Planning Commission by the environmental consultant and sub-consultants who prepared the PEIR, or incorporated into reports presented to the SFPUC.

- All information (including written evidence and testimony) presented to the City from other public agencies relating to the WSIP, the Program or the PEIR.

- All information (including written evidence and testimony) presented at any public hearing or workshop related to the WSIP, the Program and the PEIR.

- For documentary and information purposes, all locally-adopted land use plans and ordinances, including, without limitation, general plans, specific plans and ordinances, together with environmental review documents, findings, mitigation monitoring programs and other documentation relevant to planned growth in the area.

- The Mitigation Monitoring and Reporting Program.

- All other documents available to the SFPUC and the public, comprising the administrative record pursuant to Public Resources Code Section 21167.6(e).

The Public Utilities Commission has relied on all of the documents listed above in reaching its decision on the Program, even if not every document was formally presented to the Commission. Without exception, any documents set forth above not so presented fall into one of two categories. Many of them reflect prior planning or legislative decisions with which the Commission was aware in approving the Program. Other documents influenced the expert advice provided to Planning Department and PUC staff or consultants, who then provided advice to the Commission. For that reason, such documents form part of the underlying factual basis for the Commission's decisions relating to the adoption of the Program.

The public hearing transcript, a copy of all letters regarding the Draft EIR received during the public review period, the administrative record, and background documentation for the Final PEIR, as well as additional materials concerning approval of the Phased WSIP Variant and adoption of these findings are contained in SFPUC files, located at the SFPUC, 1155 Market Street, San Francisco. **Kelley Capone** is the custodian of records for the SFPUC. CEQA files are also available at the San Francisco Planning Department, 1650 Mission Street, San Francisco. **Linda Avery** is the Custodian of Records for the Planning Department. All files have been available to the SFPUC and the public for review in considering these findings and whether to approve the Program.

H. Findings About Significant Environmental Impacts And Mitigation Measures

The following Sections II, III and IV set forth the SFPUC's findings about the Final PEIR's determinations regarding significant environmental impacts and the mitigation measures proposed to address them. These findings provide the written analysis and conclusions of the SFPUC regarding the environmental impacts of the Phased WSIP Variant and the mitigation measures included as part of the Final PEIR and adopted by the SFPUC as part of the Phased WSIP Variant. To avoid duplication and redundancy, and because the SFPUC agrees with, and hereby adopts, the conclusions in the Final PEIR, these findings will not repeat the analysis and conclusions in the Final PEIR, but instead incorporates them by reference herein and relies upon them as substantial evidence supporting these findings.

In making these findings, the SFPUC has considered the opinions of SFPUC staff and experts, other agencies and members of the public. The SFPUC finds that the determination of significance thresholds is a judgment decision within the discretion of the City and County of San Francisco; the significance thresholds used in the PEIR are supported by substantial evidence in the record, including the expert opinion of the PEIR preparers and City staff; and the significance thresholds used in the PEIR provide reasonable and appropriate means of assessing the significance of the adverse environmental effects of the Program. Thus, although, as a legal matter, the SFPUC is not bound by the significance determinations in the PEIR (see Pub. Resources Code, § 21082.2, subd. (e)), the SFPUC finds them persuasive and hereby adopts them as its own.

These findings do not attempt to describe the full analysis of each environmental impact contained in the Final PEIR. Instead, a full explanation of these environmental findings and conclusions can be found in the Final PEIR and these findings hereby incorporate by reference the discussion and analysis in the Final PEIR supporting the Final PEIR’s determination regarding the Phased WSIP Variant’s impacts and mitigation measures designed to address those impacts. In making these findings, the SFPUC ratifies, adopts and incorporates in these findings the determinations and conclusions of the Final PEIR relating to environmental impacts and mitigation measures, except to the extent any such determinations and conclusions are specifically and expressly modified by these findings.

As set forth below, the SFPUC adopts and incorporates all of the mitigation measures set forth in the Final PEIR and the attached MMRP to substantially lessen or avoid the potentially significant and significant impacts of the Phased WSIP Variant. In adopting these mitigation measures, the SFPUC intends to adopt each of the mitigation measures proposed in the Final PEIR for the Phased WSIP Variant. Accordingly, in the event a mitigation measure recommended in the Final EIR has inadvertently been omitted in these findings or the MMRP, such mitigation measure is hereby adopted and incorporated in the findings below by reference. In addition, in the event the language describing a mitigation measure set forth in these findings or the MMRP fails to accurately reflect the mitigation measures in the Final PEIR due to a clerical error, the language of the policies and implementation measures as set forth in the Final PEIR shall control. The impact numbers and mitigation measure numbers used in these findings reflect the impact and mitigation measure numbers used in the Final PEIR.

In the sections II, III and IV below, the same findings are made for a category of environmental impacts and mitigation measures. Rather than repeat the identical finding dozens of times to address each and every significant effect and mitigation measure, the initial finding obviates the need for such repetition because in no instance is the SFPUC rejecting the conclusions of the Final PEIR or the mitigation measures recommended in the Final PEIR for the Phased WSIP Variant. There are determinations of significance regarding the originally proposed WSIP and proposed mitigation measures identified in the PEIR that are not applicable to the Phased WSIP Variant, and therefore, those impacts and mitigation measures are not included in these findings.

II. IMPACTS FOUND TO BE LESS THAN SIGNIFICANT AND THUS REQUIRING NO MITIGATION

A. WSIP Water Supply Impacts

Under CEQA, no mitigation measures are required for impacts that are less than significant. (Pub. Resources Code, § 21002; CEQA Guidelines, §§ 15126.4, subd. (a)(3), 15091.) The Phased WSIP Variant diverts less water than the proposed WSIP and therefore the water supply impacts are generally the same as or less than those of the originally proposed WSIP. (See C&R section 13.4, pp. 13-29 through 13-44.) Based on substantial evidence in the whole record of this proceeding, the SFPUC finds that implementation of the water supply portion of the Phased WSIP Variant will not result in any significant impacts in the following areas and that these impact areas therefore do not require mitigation:

1. Tuolumne River System and Downstream Water Bodies

- **Stream Flow** (**Impacts 5.3.1-1**, effects on flow along the river below O'Shaughnessy Dam; **5.3.1-2**; effects of flow along Cherry Creek below Cherry Dam; **5.3.1-3**; effects of flow along Eleanor Creek below Eleanor Dam; **5.3-1-4**; effects of flow along the river below La Grange Dam; **5-.3-1-5**, effects of flow along the San Joaquin River and the Sacramento-San Joaquin Delta) (DEIR pages 5.3.1-20 through 5.3.1-39; C&R pages 14.6-8 to 14.6-10, 14.7-12 to 14.7-14, 14.8-2 to 14.8-9 and 16-47);
- **Geomorphology** (**Impacts 5.3.2-1**, effects on sediment transport and channel characteristics between O'Shaughnessy Dam and Don Pedro Reservoir; **5.3.2-2**, effects on sediment transport and channel characteristics below La Grange Dam) (DEIR pages 5.3.2-5 through 5.3.2-7; C&R pages 14.6-10 to 14.6-12 and 14.7-15 to 14.7-16);
- **Surface Water Quality** (**Impacts 5.3.3-1**, effects on quality in Hetch Hetchy Reservoir and along the Tuolumne River below O'Shaughnessy Dam; **5.3.3-2**, effects on quality in Don Pedro Reservoir and along the Tuolumne River below La Grange Dam; **5.3.3-3**, effects on quality along the San Joaquin River and the Sacramento-San Joaquin Delta) (DEIR pages 5.3.3-13 through 5.3.3-20; C&R pages 14.6-12 to 14.6-13, 14.7-10 to 14.7-11, and 14.8-2 to 14.8-16);
- **Surface Water Supplies** (**Impacts 5.3.4-1**, effects on Tuolumne River, San Joaquin River, and Stanislaus River water users; **5.3.4-2**, effects on Delta water users) (DEIR pages 5.3.4-5 through 5.3.4-11; C&R pages 14.8-9 to 14.8-16, 15-4-217 to 15.4-218, and 16-48);
- **Groundwater** (**Impacts 5.3.5-1**, alteration of stream flows along the Tuolumne River, which could affect local groundwater recharge and levels; **5.3.5-2**, alteration of stream

flows along the Tuolumne River, which could affect local groundwater quality) (DEIR pages 5.3.5-3 through 5.3.5-5);

- **Fisheries** (**Impacts 5.3.6-1**, impacts on effects on fishery resources in Hetch Hetchy Reservoir; **5.3.6-2**, effects on fishery resources along the Tuolumne River between Hetch Hetchy Reservoir and Don Pedro Reservoir; **5.3.6-3**, effects on fishery resources in Don Pedro Reservoir; **5.3.6-5**, fishery resources along the San Joaquin River) (DEIR pages 5.3.6-24 through 5.3.6-28 and 5.3.6-32 through 5.3.6-33; C&R pages 15.4-226 to 15.4-227 and 16-49);
- **Terrestrial Biology** (**Impacts 5.3.7-1**, impacts on riparian habitat and related biological resources in Hetch Hetchy Reservoir and along the bedrock channel portions of the Tuolumne River from O'Shaughnessy Dam to Don Pedro Reservoir; **5.3.7-3**, impacts on biological resources in Lake Eleanor and along Eleanor Creek; **5.3.7-4,** biological resources in Lake Lloyd and along Cherry Creek; **5.3.7-5**, biological resources in Don Pedro Reservoir; **5.3.7-7**, conflicts with the provisions of adopted conservation plans or other approved biological resource plans for the Tuolumne Wild and Scenic River) (DEIR pages 5.3.7-14 through 5.3.7-27);
- **Recreational and Visual Resources** (**Impact 5.3.8-1**, effects on reservoir recreation due to changes in water system operations; **5.3.8-2**, effects on river recreation due to changes in water system operations; **5.3.8-3**, effects on the aesthetic values of the Tuolumne Wild and Scenic River.) (DEIR pages 5.3.8-23 through 5.3.8-35; C&R pages 16-49);
- **Energy Resources** (**Impact 5.3.9-1**, Effects on hydropower generation at facilities along Tuolumne River (beneficial).) (DEIR pages 5.3.9-2 through 5.3.9-3);
- **Cumulative Impacts (Impacts 5.7.2-1**, cumulative effects on the Tuolumne River from Hetch Hetchy Reservoir to Don Pedro Reservoir; **5.7.2-2**, cumulative effects on the Tuolumne River from Don Pedro Reservoir to the San Joaquin River; and **5.7.2-3**, cumulative effects on the San Joaquin River, Stanislaus River, and Delta) (DEIR pages 5.7-22 through 5.7-52).

2. Alameda Creek Watershed

- **Stream Flow** (**Impacts 5.4.1-1,** effects on flow along Calaveras Creek below Calaveras Reservoir; **5.4.1-3**, effects in San Antonio Reservoir and along San Antonio Creek; **5.4.1-4**, effects on flow along Alameda Creek below the confluence of San Antonio Creek) (DEIR pages 5.4.1-19 through 5.4.1-25 and 5.4.1-35 through 5.4.1-43; C&R pages 16-50 through 16-57);
- **Geomorphology** (**Impacts 5.4.2-1**, effects on channel formation and sediment transport along Calaveras Creek; **5.4.2-2,** effects on channel formation and sediment transport along Alameda Creek downstream of the diversion dam and downstream of the San Antonio Creek confluence; **5.4.2-3,** effects on channel formation and sediment transport along San Antonio Creek downstream of San Antonio Reservoir) (DEIR pages 5.4.2-3 and -4; C&R pages 15.2-29 to 15.2-34, 15.3-15 to 15.3-17 and 16-57 to 16-58);
- **Surface Water Quality** (**Impacts 5.4.3-1**, effects on water quality in Calaveras Reservoir; **5.4.3-2,** effects on water quality in San Antonio Reservoir; **5.4.3-3,** changes in water quality along Calaveras, San Antonio, and Alameda Creeks) (DEIR pages 5.4.3-6 through 5.4.3-12; C&R pages 15.2-34 to 15.2-38 and 16-59 to 16-60);

- **Groundwater Bodies** (**Impact 5.4.4-1**, changes in groundwater levels, flows, quality, and supplies) (DEIR pages 5.4.4-5 through 5.4.4-7; C&R pages15.3-19 and 16-60);
- **Fisheries** (**Impacts 5.4.5-1**, effects on fishery resources in Calaveras Reservoir (beneficial); **5.4.5-2**, Effects on fishery resources along Calaveras Creek below Calaveras Dam and along Alameda Creek below confluence with Calaveras Creek (beneficial); **5.4.5-4**, effects on fishery resources in San Antonio Reservoir (beneficial); **5.4.5-5**, effects on fishery resources along San Antonio Creek below San Antonio Reservoir; **5.4.5-6,** effects on fishery resources along Alameda Creek below confluence with San Antonio Creek) (DEIR pages 5.4.5-16 through 5.4.5-18 and 5.4.5-21 and 22);
- **Terrestrial Biology** (**Impacts 5.4.6-1 Other Species of Concern/Common Habitats and Species,** effects on riparian habitat and related biological resources in Calaveras Reservoir; **5.4.6-2, Sensitive Habitats/Others Species of Concern,** effects on riparian habitat and related biological resources along Alameda Creek, from below the diversion dam to the confluence with Calaveras Creek; **5.4.6-3, Sensitive Habitats/Other Species of Concern/Common Habitats and Species,** effects on riparian habitat and related biological resources along Calaveras Creek, from Calaveras Reservoir to the confluence with Alameda Creek; **5.4.6-4, Sensitive Habitats/Other Species of Concern/Common Habitats and Species,** effects on riparian habitat and related biological resources along Alameda Creek, from the confluence with Calaveras Creek to the confluence with San Antonio Creek; **5.4.6-5,** effects on riparian habitat and related biological resources in San Antonio Reservoir; **5.4.6-6,** effects on riparian habitat and related biological resources along San Antonio Creek between Turner Dam and the confluence with Alameda Creek; **5.4.6-7**, effects on riparian habitat and related biological resources along Alameda Creek below the confluence with San Antonio Creek; **5.4.6-8,** conflicts with the provisions of adopted conservation plans or other approved biological resource plans) (DEIR pages 5.4.6-14 through 5.4.6-26; C&R pages 5.2-13 to 15.2-14, 16-62 to 16-64);

- **Recreational and Visual Impact -- (Impacts 5.4.7-1,** effects on recreational facilities and/or activities; and **5.4.7-2**, visual effects on scenic resources or visual character of water bodies (DEIR, pp. 5.4.7-5 and 5.4.7-6; C&R pp. 13-5 and 16-65 to 16-66). Operations under the Phased WSIP Variant would substantially reduce flows along Alameda Creek in the Sunol Regional Wilderness during winter and early spring months and could affect the recreational experience for hikers. However, protective measures included in the Calaveras Dam Replacement project would include bypass flows at the Alameda Creek Diversion Dam when flow is available, thereby retaining flowing water in the creek and maintain the recreational and visual qualities. On July 16, 2008 the SFPUC revised the project description for the Calaveras Dam Replacement project. The revised project description includes specific operational protocols for seasonal bypass flows at the Alameda Creek Diversion Dam (ACDD) and the Calaveras Dam. Bypassing flow from the ACDD, when such flows are present, results in water in Alameda Creek below the ACDD to the confluence with Calaveras Creek. The addition of the flow releases from ACDD resulted in a determination that this impact is now less than significant for recreation and visual effects.
- **Cumulative Impacts (Impact 5.7.3-1**, cumulative effects on the Alameda Creek watershed). (DEIR, pages 5.7-61 through 5.7-67; C&R, pages 14.9-24 through 14.9-50).

3. Peninsula Watersheds

- **Stream Flow** (**Impacts 5.5.1-1**, effects on flow along the San Mateo Creek; **5.5.1-2**, effects on flow along Pilarcitos Creek) (DEIR pages 5.5.1-12 through 5.5.1-22; C&R pages 16-61 to 16-73);
- **Geomorphology** (**Impact 5.5.2-1**, changes in sediment transport and channel morphology in the Peninsula watershed) (DEIR pages 5.5.2-2 through 5.5.2-4);
- **Surface Water Quality** (**Impacts 5.5.3-1,** effects on water quality in Crystal Springs Reservoir, San Andreas Reservoir, and San Mateo Creek; **5.5.3-2,** effects on water quality in Pilarcitos Creek between Pilarcitos Reservoir and Stone Dam.) (DEIR pages 5.5.3-5 through 5.5.3-7; C&R pages 13-39 and 13-44). (Note: The PEIR determined Impact 5.5.3-2 to be potentially significant and mitigable for the WSIP, but this impact determination is less than significant for the Phased WSIP Variant through 2018.) With the Phased WSIP Variant, operations for Pilarcitos Reservoir and releases to Pilarcitos Creek will be similar to existing conditions, resulting in a less than significant impact;
- **Groundwater** (**Impact 5.5.4-1,** alteration of stream flows along Pilarcitos Creek, which could affect groundwater levels and water quality) (DEIR pages 5.5.4-1 through 5.5.4-3);
- **Fisheries** (**Impacts 5.5.5-2,** effects on fishery resources in San Andreas Reservoir; **5.5.5-3**, effects on fishery resources along San Mateo Creek; **5.5.5-4**, effects on fishery resources in Pilarcitos Reservoir; **5.5.5-5**, effects on fishery resources along Pilarcitos Creek below Pilarcitos Reservoir and below Stone Dam) (DEIR page 5.5.5-7; C&R pages 13-39 and 13-44). (Note: The PEIR determined Impacts 5.5.5-4 and 5.5.5-5 to be potentially significant and mitigable for the WSIP, but these impact determinations are less than significant for the Phased WSIP Variant through 2018.) Proposed operations under the Phased WSIP Variant would be within the same range as existing conditions, resulting in a less than significant impact);
- **Terrestrial Biology** (**Impacts 5.5.6-2**, impacts on biological resources in San Andreas Reservoir; **5.5.6-3**, impacts on biological resources along San Mateo Creek below Lower Crystal Springs Dam; **5.5.6-4**, impacts on biological resources in Pilarcitos Reservoir; **5.5.6-5,** impacts on biological resources along Pilarcitos Creek below Pilarcitos Reservoir; **5.5.6-6,** impacts on biological resources along Pilarcitos Creek below Stone Dam; **5.5.6-7,** conflicts with the provisions of adopted conservation plans or other approved biological resource plans) (DEIR pages 5.5.6-17 through 5.5.6-22; C&R pages 13-39, 13-40, 13-44 and 16-80 to 16-82). (Note: The PEIR determined Impact 5.5.6-4 to be potentially significant and mitigable for special status species for the originally proposed WSIP with implementation of a mitigation measure for the originally proposed WSIP. Since the Phased WSIP Variant does not result in impacts that require mitigation, this impact is less than significant for the Phased WSIP Variant through 2018);
- **Recreational and Visual Resources** (**Impact 5.5.7-1**, effects on recreational facilities and/or activities; **5.5.7-2**, visual effects on scenic resources or the visual character of water bodies.) (DEIR pages 5.5.7-4 through 5.5.7-6);
- **Cumulative Impacts (Impacts 5.7.4-1**, cumulative effects on the San Mateo Creek watershed, **5.7.4-2**, cumulative effects on the Pilarcitos Creek watershed). (DEIR, pages 5.7-74 through 5.7-84).

4. South Westside Groundwater Basin

- **Groundwater** -- **Impacts 5.6-1 --** basin overdraft due to pumping from the Westside Groundwater Basin; **5.6-3 --** seawater intrusion due to decreased groundwater levels in the Westside Groundwater Basin. (DEIR pages 5.6-25 through 5.6-27 and 5.6-29)

5. North and South Westside Groundwater Basin

- **Groundwater -- Impacts 5.6-4,** land subsidence due to decreased groundwater levels in the Westside Groundwater Basin if the historical low water levels are exceeded; **Impact 5.6-6**, drinking water contaminants above maximum contaminant levels and adverse effects of adding treated groundwater to the distribution system.) (DEIR pages 5.6-23 through 5.6-27 and 5.6-28 through 5.6-32)
- **Cumulative Impacts (Impacts 5.7.5-1**, cumulative effects on the North Westside Groundwater Basin, **5.7.5-2,** cumulative effects on the South Westside Groundwater Basin). (DEIR pages 5.7-89 to 5.7-91.)

Each of these topics is analyzed and discussed in detail in the record, including in, but not limited to, the Draft PEIR at Chapter 5, Sections 5.3, 5.4, 5.5, and 5.6 and in the C&R Chapter 13, Section 13.4.

B. WSIP Facility Construction and Operation Impacts

Under CEQA, no mitigation measures are required for impacts that are less than significant. (Pub. Resources Code, § 21002; CEQA Guidelines, §§ 15126.4, subd. (a)(3), 15091.) The Phased WSIP Variant will have the same facility construction and operation impacts as the originally proposed WSIP because the Phased WSIP Variant implements all the same projects as the originally proposed WSIP. (See C&R pages 13-17, 13-30 through 33.) Based on substantial evidence in the whole record of this proceeding, the SFPUC finds that implementation of the Facility Construction and Operations portion of the Phased WSIP Variant will not result in any significant impacts in the following areas and that these impact areas therefore do not require mitigation:

- **Land Use and Visual Quality** (Impact **4.3-3**, Temporary construction impacts on scenic vistas or visual character) (DEIR, pp. 4.3-28 to 4.3-29);
- **Geology, Soils, and Seismicity** (Impacts **4.4-2**, Erosion during construction; **4.4-3**, Substantial alteration of topography; **4.4-5**, Surface fault rupture; **4.4-6**, Seismically induced ground shaking; **4.4-7**, Seismically induced ground failure, including liquefaction and settlement; **4.4-8** Seismically induced landslides or other slope failures) (DEIR, pp. 4.4-27 to 4.4-29, 4.4-31 to 4.4-41);
- **Hydrology and Water Quality** (Impacts **4.5-1**, Degradation of water bodies as a result of erosion and sedimentation or a hazardous materials release during construction; **4.5-3a**, Degradation of water quality due to dewatering discharges; **4.5-3b**, Degradation of water quality due to construction-related discharges of treated water; **4.5-5**, Degradation of water quality and increased flows due to discharges to surface water during operation) (DEIR, pp. 4.5-21 to 4.5-28, 4.5-31 to 4.5-37, 4.5-41 to 4.5-49);

- **Traffic, Transportation and Circulation** (Impact **4.8-6**, Long-term traffic increases during facility operation) (DEIR, pp. 4.8-28 to 4.8-31);
- **Air Quality** (Impacts **4.9-4**, Air pollutant emissions during project operation; **4.9-5**, Odors generated during project operation; **4.9-6**, Secondary emissions at power plants; **4.9-7**, Conflict with implementation of applicable regional air quality plans addressing criteria air pollutants and state goals for reducing greenhouse gas emissions) (DEIR, pp. 4.9-37 to 4.9-47);
- **Noise and Vibration** (Impact **4.10-4**, Disturbance due to long-term noise increases) (DEIR, pp. 4.10-33 to 4.10-38);
- **Hazards** (Impacts **4.14-3**, Risk of fires during construction; **4.14-4**, Gassy conditions in tunnels; **4.14-6**, Accidental hazardous materials release from construction equipment; **4.14-7**, Increased use of hazardous materials during operation; **4.14-8**, Emission or use of hazardous materials within ¼ mile of a school) (DEIR, pp. 4.14-26 to 4.14-31, 4.14-35 to 4.14-42);
- **Collective** (Impacts **4.16-2**, Collective exposure of people or structures to geologic and seismic hazards; **4.16-9**, Collective impacts on utilities and landfill capacity) (DEIR, pp. 4.16-13, 4.16-33);
- **Cumulative** (Impacts **4.17-1**, Cumulative disruption of established communities, changes in existing land use patterns, and impacts on the existing visual character; **4.17-2**, Cumulative exposure of people or structures to geologic and seismic hazards; **4.17-3**, Cumulative impacts related to the degradation of water quality, alteration of drainage patterns, increased surface runoff, and flooding hazards; **4.17-4**, Cumulative loss of sensitive biological resources; **4.17-9**, Cumulative impacts related to disruption of utility service or relocation of utilities; **4.17-10**, Cumulative effects on recreational resources during construction; **4.17-11**, Cumulative conversion of farmland to nonagricultural uses; **4.17-12**, Cumulative effects related to hazardous conditions and exposure to or release of hazardous materials; **4.17-13**, Cumulative increases in the use of nonrenewable energy resources) (DEIR, pp. 4.17-46 to 4.17-52, 4.17-60 to 4.17-64).

Each of these topics is analyzed and discussed in detail in the record, including in, but not limited to, the Draft PEIR at Chapter 4, Sections 4.3, 4.4, 4.5, 4.8, 4.9, 4.10, 4.14, 4.16, and 4.17.

III. FINDINGS OF POTENTIALLY SIGNIFICANT IMPACTS THAT CAN BE AVOIDED OR REDUCED TO A LESS-THAN-SIGNIFICANT LEVEL

CEQA requires agencies to adopt mitigation measures that would avoid or substantially lessen a project's identified significant impacts or potential significant impacts if such measures are feasible (unless mitigation to such levels is achieved through adoption of a project alternative). The findings in this Section III and in Section IV concern mitigation measures set forth in the PEIR. These findings discuss mitigation measures as proposed in the PEIR and recommended for adoption by the SFPUC, which can be implemented by the SFPUC. The mitigation measures proposed for adoption in this section are the same as the mitigation measures identified in the Final PEIR for the Phased WSIP Variant. The full explanation of the potentially significant environmental impacts is contained in Chapters 4, 5, and 13 of the Final PEIR. The full text of the mitigation measures is contained in the Final PEIR and in **Attachment B**, the Mitigation Monitoring and Reporting Program.

As explained previously, **Attachment B** contains the Mitigation Monitoring and Reporting Program required by CEQA Section 21081.6 and CEQA Guidelines Section 15091. It provides a table setting forth each mitigation measure listed in the PEIR that is required to reduce or avoid a significant adverse impact. **Attachment B** also specifies the agency responsible for implementation of each measure, establishes monitoring actions and a monitoring schedule.

The SFPUC adopts all of the mitigation measures proposed for the Phased WSIP Variant. The SFPUC will implement all of the water supply and system operations mitigation measures as part of adoption of the Phased WSIP Variant. The SFPUC will implement the programmatic mitigation measures identified to address WSIP facility improvement projects impacts as part of approval and adoption of individual WSIP projects, and these programmatic mitigation measures will be re-evaluated as part of the project-level CEQA review and will be confirmed, refined or replaced with an equivalent measure, as applicable. The SFPUC finds that all the mitigation measures are appropriate and feasible, and that changes or alterations will be required in, or incorporated into, the Program and the projects that mitigate or avoid the significant environmental effect as identified in the PEIR. Based on the analysis contained in the PEIR, other considerations in the record, and the standards of significance, the SFPUC finds that implementation of all of the proposed mitigation measures will reduce potentially significant impacts to a ***less-than-significant*** level, discussed in this Section III.

A. WSIP Water Supply and System Operations Impacts

1. Tuolumne River System and Downstream Water Bodies

Fisheries

Impact 5.3.6-4 – Fisheries: Effects on fishery resources along the Tuolumne River below La Grange Dam in the event diversions from the Tuolumne River substantially increase over existing conditions. (DEIR, pp. 5.3.6-28 to 5.3.6-32; C&R pp. 14.7-2 to 14.7-7 and 13-43 to 13-44.) Under the Phased WSIP Variant, there may be a short-term increase in deliveries to customers from the watersheds above the existing level of 265 mgd, while the SFPUC and/or BAWSCA and wholesale customers implement the local conservation, recycled water and projects needed to meet demands through 2018. In this interim period, there is a potential for increased diversions from Hetch Hetchy Reservoir to serve SFPUC customers, which in turn would result in flow reductions below La Grange Dam and infrequent water temperature increases, which could adversely affect habitat conditions for juvenile salmonids. Flow changes with the Phased WSIP Variant with the 265 mgd delivery limitation and a small increase in average annual diversions from the Tuolumne River of 2 mgd in order to implement delivery and drought reliability elements of the WSIP through 2018 were determined to be less than significant. However, it is recognized that under the Phased WSIP Variant, deliveries could exceed 265 mgd while the SFPUC and/or wholesale customers implement the local conservation, recycled water and groundwater projects needed to meet increasing demands. Therefore, it was conservatively assumed that total water deliveries above 265 mgd could cause potentially significant impacts on the lower Tuolumne River during these periods until average annual deliveries were reduced to 265 mgd. This impact is less than significant if the annual average deliveries to customers does not exceed 265 mgd from the watersheds and does not require mitigation.

Mitigation Measure 5.3.6-4a, Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water, OR Mitigation Measure 5.3.6-4b, Fishery Habitat Enhancement

This Commission recognizes that mitigation measure 5.3.6-4a is partially within the jurisdiction of MID and TID. The Commission urges MID and TID to assist in implementing this mitigation measure, and finds that MID and TID can and should participate in implementing this mitigation measure.

This Commission also recognizes that mitigation measure 5.3.6-4b is partially within the jurisdiction of other agencies, including the California Department of Fish and Game. The Commission urges this agency to assist in implementing this mitigation measure, and finds that this agency can and should participate in implementing this mitigation measure if measure 5.3.6-4a is determined to be infeasible.

Terrestrial Biological Resources

Impact 5.3.7-2 – Terrestrial Biology: Impacts on alluvial features that support meadow and riparian habitat along the Tuolumne River from O'Shaughnessy Dam to Don Pedro Reservoir. (DEIR, pp. 5.3.7-21 to 5.3.7-22; C&R pages 14.6-4 to 14.6-7.) The alluvial area supporting the largest wetland complex in this section of the Tuolumne River is the Poopenaut Valley, although smaller alluvial areas downstream, where larger tributaries empty into the Tuolumne River, also support riparian and/or wetland habitats. Delayed snowmelt releases, reductions in flow, and the resulting reduction in groundwater recharge would result in an incremental reduction in the extent and diversity of wetland and riparian habitats, including sensitive wetland and riparian habitats in the Poopenaut Valley. A reduction in wetland and riparian habitat would reduce suitable breeding habitat for key special-status species potentially occurring along this reach (e.g., foothill yellow-legged frog, California red-legged frog, and willow flycatcher), the populations of which are already critically reduced in the Sierra Nevada. A reduction in the extent and diversity of wetland and riparian habitats would reduce habitat quality and extent for animal and plant species of concern. All natural habitats affected by the Program are considered sensitive. The Program could affect a large number of common animal species that depend on sensitive meadows and larger riparian areas for food and cover.

Mitigation Measure 5.3.7-2, Controlled Releases to Recharge Groundwater in Streamside Meadows and Other Alluvial Deposits.

Impact 5.3.7-6 – Terrestrial Biology: Impacts on biological resources along the Tuolumne River below La Grange Dam in the event that diversions from Hetch Hetchy Reservoir substantially increase over existing conditions (DEIR, pages 5.3.7-25 to 5.3.7-26; C&R pages 14.4-13 and 13-43 to 13-44). Under the Phased WSIP Variant, there may be a short-term increase in deliveries to customers from the watersheds above the existing level of 265 mgd, while the SFPUC and/or BAWSCA and wholesale customers implement the local conservation, recycled water and projects needed to meet demands through 2018. In this interim period, there is a potential for increased diversions from Hetch Hetchy Reservoir to serve SFPUC customers, which in turn would result in flow reductions below La Grange Dam. Delayed spring releases and reductions in average and total flow (particularly during and following an extended drought) below La Grange Dam would reduce or eliminate suitable conditions for the recruitment of some riparian species along the river. Because of the known presence of key special-status species and the very limited amount of remaining suitable habitat along this reach of the Tuolumne River, this incremental impact would be potentially significant. Flow changes with the Phased WSIP Variant with the 265 mgd delivery limitation and a small increase in average annual diversions from the Tuolumne River of 2 mgd in order to implement delivery and drought reliability elements of the WSIP through 2018 were determined to be less than significant. However, it is recognized that under the Phased WSIP Variant, deliveries could exceed 265 mgd while the SFPUC and/or wholesale customers implement the local conservation, recycled water and groundwater projects needed to meet increasing demands. Therefore, it was conservatively assumed that deliveries above 265 mgd could cause potentially significant impacts on the lower Tuolumne River during these periods until average annual deliveries were reduced to 265 mgd. Species of concern that would be adversely affected by changes in the extent and quality of suitable riparian habitat include western pond turtle, several bat species, and a wide variety of riparian- and marsh-associated bird species. The populations of common species that depend on riparian habitat could be adversely affected by the alteration of habitat. This impact is less than significant if the annual average deliveries to customers does not exceed 265 mgd from the watersheds, and would not require mitigation.

Mitigation Measure 5.3.6-4a, Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water <u>OR</u> Mitigation Measure 5.3.7-6, Lower Tuolumne River Riparian Habitat Enhancement

This Commission recognizes that mitigation measure 5.3.6-4a is the preferred mitigation approach but implementation is partially within the jurisdiction of MID and TID or other water agencies. The Commission urges MID and TID or other water agencies to assist in implementing this mitigation measure, and finds that MID and TID or other water agencies can and should participate in implementing this mitigation measure.

This Commission also recognizes that mitigation measure 5.3.7-6 is partially within the jurisdiction of other agencies, depending on the selected action and could include the California Department of Fish and Game, U. S. Fish and Wildlife Service and U.S. Army Corps of Engineers. The Commission urges these agencies to assist in implementing this mitigation measure, and finds that these agencies can and should participate in implementing this mitigation measure if measure 5.3.6-4a is determined to be infeasible.

2. Alameda Creek Watershed

Fisheries

Impact 5.4.5-3 – Fisheries: Effects on fishery resources along Alameda Creek downstream of Alameda Creek Diversion Dam. (DEIR, pp. 5.4.5-18 to 5.4-20 and C&R, pp. 13-37 and 13-38; 13-44; 16-61 and 16-62.) Following implementation of the Calaveras Dam Replacement project (SV-2) as one of the WSIP facility improvement projects, operation of Calaveras Reservoir and the Alameda Creek Diversion Dam would be restored to pre-2002 conditions. A substantial increase in diversions from Alameda Creek to Calaveras Reservoir would reduce flows in this stretch of the creek, despite proposed bypass flows at the diversion dam. Diversion of most or all flows during late winter and spring months would reduce the ability of resident rainbow trout to spawn and for eggs to incubate; additional monitoring would be needed to determine the effectiveness of proposed bypass flows to sustain trout population. In addition, the increased diversion of flows to the reservoir would prevent fish passage to downstream reaches of the creek, and increase the potential for fish entrainment since there are currently no screens on the diversion dam. If monitoring indicates that resident trout populations are not being sustained, the SFPUC shall either modify the minimum stream flow or implement mitigation measure 5.4.5-3b.

Mitigation Measure 5.4.5-3a, Minimum Flows for Resident Trout on Alameda Creek
Mitigation Measure 5.4.5-3b, Alameda Diversion Dam Diversion Restrictions or Fish Screens

This Commission recognizes that mitigation measures 5.4.5-3a and 5.4.5-3b are partially within the jurisdiction of other agencies, including the California Department of Fish and Game, the California Regional Water Quality Control Board and the U.S. Army Corps of Engineers. The Commission urges these agencies to assist in implementing this mitigation measure, and finds that these agencies can and should participate in implementing this mitigation measure.

Terrestrial Biological Resources

Impact 5.4.6-1 – Terrestrial Biology: Effects on riparian habitat and related biological resources in Calaveras Reservoir. (DEIR, pp. 5.4.6-14 to 5.4.6-17; C&R pp. 13-37 and 13-38; 13-44.) Increased reservoir storage elevations would result in inundation and permanent loss of seasonal wetlands, seeps, perennial freshwater marsh, and riparian habitat that have established since 2002. Since 2002, foothill yellow-legged frogs have occupied approximately 10,000 linear feet of stream channel along Arroyo Hondo between the maximum reservoir elevation mandated by the Division of Safety of Dams and the spillway elevation. Higher maintained reservoir levels would reduce the length of this high-quality habitat along the creek and adversely affect existing populations of foothill yellow-legged frog.

Mitigation Measure 5.4.6-1, Compensation for Impacts on Terrestrial Biological Resources

This Commission recognizes that mitigation measure 5.4.6-1 is partially within the jurisdiction of other agencies, including the California Department of Fish and Game, the California Regional Water Quality Control Board, and the U.S. Army Corps of Engineers. The Commission urges these agencies to assist in implementing this mitigation measure, and finds that these agencies can and should participate in implementing this mitigation measure.

Impact 5.4.6-2 – Terrestrial Biology: Effects on riparian habitat and related biological resources along Alameda Creek, from below the diversion dam to the confluence with Calaveras Creek. (DEIR, pp. 5.4.6.2-18 to 5.4.6-19; C&R pp. 13-37 and 13-38; 13-44; 15.2-12.) A reduction in the frequency, duration, and magnitude of flows below the diversion dam would reduce the total available aquatic breeding habitat and food sources for California red-legged frog and foothill yellow-legged frog populations that currently occupy this reach of Alameda Creek.

Mitigation Measure 5.4.1-2, Diversion Tunnel Operation
Mitigation Measure 5.4.5-3a, Minimum Flows for Resident Trout on Alameda Creek

This Commission recognizes that mitigation measures 5.4.5-3a and 5.4.1-2 are partially within the jurisdiction of other agencies, including the California Department of Fish and Game. The Commission urges these agencies to assist in implementing this mitigation measure, and finds that these agencies can and should participate in implementing this mitigation measure.

Impact 5.4.6-3 – Terrestrial Biology: Effects on riparian habitat and related biological resources along Calaveras Creek, from Calaveras Reservoir to the confluence with Alameda Creek. (DEIR, pp. 5.4.6-19 to 5.4.6-22; C&R pp. 13-37 and 38; 13-44.) Future outlet work at Calaveras Dam would have the capacity to make higher-volume releases than under existing conditions. Depending on the timing and volume of operational releases, they could adversely affect the reproductive success of special-status amphibian species along this reach (e.g., California red-legged frog and foothill yellow-legged frog).

Mitigation Measure 5.4.6-3, Operational Procedures for Calaveras Dam Releases

Impact 5.4.6-4 – Terrestrial Biology: Effects on riparian habitat and related biological resources along Alameda Creek, from the confluence with Calaveras Creek to the confluence with San Antonio Creek. (DEIR, pp. 5.4.6-22 to 5.4.6-23; C&R pp. 13-37 and 13-38; 13-44.) Depending on annual rainfall and localized site conditions along this creek segment, changes in winter and summer flows along this reach could result in both beneficial and adverse impacts on habitat for California red-legged frog and foothill yellow-legged frog populations.

Mitigation Measure 5.4.6-3, Operational Procedures for Calaveras Dam Releases
Mitigation Measure 5.4.5-3a, Minimum Flows for Resident Trout on Alameda Creek

This Commission recognizes that mitigation measures 5.4.6-3 and 5.4.5-3a are partially within the jurisdiction of other agencies, including the California Department of Fish and Game. The Commission urges this agency to assist in implementing this mitigation measure, and finds that this agency can and should participate in implementing this mitigation measure.

3. Peninsula Watersheds

Terrestrial Biological Resources

1. **Impact 5.5.6-1 –** Terrestrial Biology: Impacts on biological resources in upper and Lower Crystal Springs Reservoirs. (DEIR, pp. 5.5.6-14 to 5.5.6-17; C&R pp. 13-39 to 13-41; 13-44.) Implementation of the Lower Crystal Springs Dam Improvements project (PN-4) would raise average monthly water levels in Crystal Springs Reservoir and result in a short-term reduction in the overall extent of freshwater marsh as the reservoir fills. Proposed changes in operations would maintain maximum reservoir levels during summer for longer periods than under existing conditions, which could affect the composition and structure of riparian habitats. In addition, sensitive upland habitats that are unable to tolerate these longer periods of inundation would be lost. Elevated reservoir levels would inundate existing populations of special-status plant species, including serpentine-associated fountain thistle and Marin western

flax, and their habitat could be permanently lost. The extent of available habitat for San Francisco garter snake and California red-legged frog would be temporarily reduced during reservoir refill, but wetland habitat that would establish at higher elevations could be more extensive. Raised reservoir levels would provide greater opportunities for largemouth bass and other predators to access frogs and snakes. Periodic drawdown during planned maintenance could adversely affect San Francisco garter snake foraging habitat. Changes in wetland habitat due to reservoir refill and proposed operations would adversely affect reptile and bird species of concern, particularly if permanent changes in the composition of wetland vegetation occur. Permanent loss of upland habitat, including upland trees, grassland, and coastal scrub, would result in significant impacts on several bird and mammal species of concern. Serpentine- and grassland-associated plant species unable to tolerate extended periods of inundation would be lost. Due to the extent of area involved, impacts on common habitats and species would be significant.

Mitigation Measure 5.5.6-1a, Adaptive Management of Freshwater Marsh and Wetlands at Upper and Lower Crystal Springs Reservoirs
Mitigation Measure 5.5.6-1b, Compensation for Impacts on Terrestrial Biological Resources
Mitigation Measure 5.5.6-1c, Compensation for Serpentine Seep-Related Special-Status Plants
This Commission recognizes that mitigation measure5.5.6-1 is partially within the jurisdiction of other agencies, including the California Department of Fish and Game, the California Regional Water Quality Control Board, the U.S. Army Corps of Engineers and possibly the National Marine Fisheries Service. The Commission urges these agencies to assist in implementing this mitigation measure, and finds that these agencies can and should participate in implementing this mitigation measure.

4. North Westside Groundwater Basin

1. **Impact 5.6-1 – Groundwater**: Basin overdraft due to pumping from the Westside Groundwater Basin. (DEIR, pp. 5.6-23 to 5.6-24; C&R pp. 13-10; 13-29 and 13-30.) The proposed water supply option would include installation of up to four primary production and deep aquifer production wells in San Francisco to provide a total of 2 mgd of annualized production rate, as implemented through Local Groundwater Projects (part of SF-2). With implementation of the Phased WSIP Variant, production of up to 4 mgd (4,500 afy) under the Local Groundwater Projects (SF-2) and continued nonpotable pumping of 0.5 mgd (560 afy) would be the major groundwater use in the North Westside Groundwater Basin once irrigation pumping is replaced with recycled water at the San Francisco Zoo and Golden Gate Park; thus, the maximum total annual pumping by 2018 is estimated to be 5,060 afy. Based on water years 1987 and 1988, the annual recharge to this basin was estimated at 4,850 afy. However, this analysis was done during the first two-years of an on-going drought and therefore is considered to be a low estimate of groundwater recharge to the North Westside Groundwater Basin relative to average conditions. Estimates of recharge to the basin are being refined as part of ongoing groundwater modeling efforts on behalf of the SFPUC, and this analysis indicates that recharge to the basin could range from about 4,850 afy to 6,950 afy. The total proposed pumping rate of 4.5 mgd (5,060 afy) would be within the range of recharge to the groundwater basin. However, because it exceeds the lower end of the range, and the studies indicating the range have not been completed at this program-level of analysis, potential impacts related to depletion of

groundwater resources in the North Westside Groundwater Basin would be considered *potentially significant*.

Mitigation Measure 5.6-1, Groundwater Monitoring to Determine Basin Safe Yield

Impact 5.6-2 – Surface water: changes in water levels in Lake Merced and other surface water features, including Pine Lake, due to decreased groundwater levels in the Westside Groundwater Basin. (DEIR, pp. 5.6-27 to 5.6-28; C&R pp. 13-10; 13-29 and 30.) Because the primary production aquifer is not in direct hydraulic connection with the shallow aquifer in the Lake Merced vicinity or with Lake Merced, proposed pumping from the primary production aquifer under Local Groundwater Projects is not expected to have a direct effect on lake levels, but could potentially cause an indirect effect. Shallow groundwater levels could decline due to flow from the shallow aquifer under Lake Merced toward the primary production aquifer in which future production wells would be completed under the proposed program. Therefore, the potential to adversely affect water levels in Lake Merced and other surface water features would be *potentially significant*.

Mitigation Measure 5.6-1, Groundwater Monitoring to Determine Basin Safe Yield
Mitigation Measure 5.6-2, Implementation of a Lake Level Management Plan

Impact 5.6-3 – Groundwater: Seawater intrusion due to decreased groundwater levels in the Westside Groundwater Basin. (DEIR, pp. 5.6-28 to 5.6-29; C&R pp. 13-10; 13-29 and 13-30.) In the North Westside Groundwater Basin, the shallow aquifer is in direct connection with the ocean from approximately Lake Merced to the north. Because the shallow aquifer is in direct connection with the ocean and groundwater pumping would lower groundwater levels, impacts related to the potential to cause seawater intrusion in the North Westside Groundwater Basin would be *potentially significant*.

Mitigation Measure 5.6-1, Groundwater Monitoring to Determine Basin Safe Yield

5. North and South Westside Groundwater Basins

- **Impact 5.6-5 – Groundwater**: Contamination of drinking water due to groundwater pumping in the Westside Groundwater Basin. (DEIR, pp. 5.6-31 to 5.6-32; C&R pp. 13-10; 13-29 and 30.) During operation, groundwater production wells constructed under the Local and Regional Groundwater Projects could induce migration of chemical or microbiological contamination from sources surrounding the wells, potentially resulting in an exceedance of drinking water standards in the groundwater. However, under the California Department of Public Health Drinking Water Source Assessment Protection (DWSAP) program, the SFPUC would develop a drinking water source assessment. The second step in the DWSAP program is the voluntary development and implementation of a source water protection program. Development of this program is not mandated under the DWSAP program, but protection of water quality is an important component of a complete wellhead protection program for the protection of drinking water quality. Until production well locations are selected and a drinking water source assessment performed, the potential for contamination of a drinking water well cannot be fully evaluated. Therefore, impacts related to potential contamination of a drinking water source are considered *potentially significant* for the Local and Regional Groundwater Projects (SF-2)

Mitigation Measure 5.6.5, Drinking Water Source Assessments for Groundwater Wells

B. WSIP Facility Improvement Projects Construction and Operation Impacts

The Phased WSIP Variant will have the same impacts as the originally proposed WSIP because it implements all facility improvement projects as the originally proposed WSIP. (C&R pp. 13-17; 13-30 – 33.)

1. Land Use and Visual Quality

Impact 4.3-1 – Land Use: Temporary Disruption or Displacement of Existing Land Uses During Construction. Potentially significant land use impacts were identified in association with the following facility improvement projects: SJ-3, BD-1, BD-2, SF-1, SF-2, and SF-3. (DEIR, pp. 4.3-9 to 4.3-20, 6-4 to 6-6, 6-30 to 32, 6-34 to 6-42, 6-44.)

Mitigation Measure 4.8-1a, Traffic Control Plan Measures
Mitigation Measure 4.8-1b, Coordination of Individual Traffic Control Plans
Mitigation Measure 4.9-1a, SJVAPCD Dust Control Measures
Mitigation Measure 4.9-1b, SJVAPCD Exhaust Control Measures
Mitigation Measure 4.9-1c, BAAQMD Dust Control Measures
Mitigation Measure 4.9-1d, BAAQMD Exhaust Control Measures
Mitigation Measure 4.9-2a, Health Risk Screening or Use of Soot Filters
Mitigation Measure 4.9-2b, Vacate SFPUC Land Managers' Residences in Sunol Valley
Mitigation Measure 4.10-1a, Noise Controls
Mitigation Measure 4.10-1b, Vacate SFPUC Caretaker's Residence at Tesla Portal
Mitigation Measure 4.10-2a, Limit Hourly Truck Volumes
Mitigation Measure 4.10-2b, Restrict Truck Operations
Mitigation Measure 4.10-2c, Vacate SFPUC Land Manager's Residence
Mitigation Measure 4.10-3a, Vibration Controls to Prevent Cosmetic or Structural Damage
Mitigation Measure 4.10-3b, Limit Vibration Levels at or Below Vibration Perception Threshold
Mitigation Measure 4.10-3c, Limit Tunnel-Related Detonation to Daylight Hours
Mitigation Measure 4.12-1, Coordination with Golf Course/Recreational Facility Managers

Impact 4.3-4 – Visual Quality: Permanent Adverse Impacts on Scenic Vistas or Visual Character. Potentially significant visual quality impacts were identified in association with the following facility improvement projects: SJ-1, SJ-5, SV-1, SV-4, BD-1, BD-2, PN-2, PN-3, PN-4, SF-1, SF-2, and SF-3. (DEIR, pp. 4.3-29 to 4.3-43, 6-7 to 6-8.)

Mitigation Measure 4.3-4a, Architectural Design
Mitigation Measure 4.3-4b, Landscaping Plans
Mitigation Measure 4.3-4c, Landscape Screens
Mitigation Measure 4.3-4d, Minimize Tree Removal

Impact 4.3-5 – Visual Quality: New Permanent Sources of Light and Glare. Potentially significant glare impacts were identified in association with all of the facility improvement projects. (DEIR, pp. 4.3-43 to 4.3-44, 6-8.)

Mitigation Measure 4.3-5, Reduce Lighting Effects

2. Geology, Soils, and Seismicity

Impact 4.4-1 – Geology, Soils, and Seismicity: Slope instability during construction. Potentially significant geology, soils, and seismicity impacts were identified in association with the following facility improvement projects: SJ-2, SV-1, SV-2, SV-3, SV-4, SV-5, PN-3, SF-2, and SF-3. (DEIR, pp. 4.4-23 to 4.4-27, 6-4, 6-9.)

Mitigation Measure 4.4-1, Quantified Landslide Analysis

Impact 4.4-4 – Geology, Soils and Seismicity: Squeezing Ground and Subsidence During Tunneling. Potentially significant geology, soils and seismicity impacts were identified in association with the following facility improvement projects: SV-4 and BD-1. (DEIR, pp. 4.4-29 to 4.4-31, 6-9.)

Mitigation Measure 4.4-4, Subsidence Monitoring Program

Impact 4.4-9 – Geology, Soils and Seismicity: Expansive or Corrosive Soils. Potentially significant geology, soils and seismicity impacts were identified in association with all of the facility improvement projects. (DEIR, pp. 4.4-42 to 4.4-47, 6-4, 6-9.)

Mitigation Measure 4.4-9, Characterize Extent of Expansive and Corrosive Soil

3. Hydrology and Water Quality

Impact 4.5-2 – Hydrology and Water Quality: Depletion of Groundwater Resources. Potentially significant hydrology and water quality impacts were identified in association with the following facility improvement projects: SV-4. (DEIR, pp. 4.5-28 to 4.5-30, 6-9 to 6-10.)

Mitigation Measure 4.5-2, Site Specific Groundwater Analysis and Identified Measures

Impact 4.5-4 – Hydrology and Water Quality: Flooding or water quality impacts associated with impeding or redirecting flood flows. Potentially significant hydrology and water quality impacts were identified in association with the following facility improvement projects: SJ-3, SV-1, SV-4, BD-1, BD-2, and SF-2. (DEIR, pp. 4.5-37 to 4.5-41, 6-10.)

Mitigation Measure 4.5-4a, Flood Flow Protection Measures
Mitigation Measure 4.5-4b, Site Specific Flooding Analysis and Identified Measures

Impact 4.5-5 – Hydrology and Water Quality: Degradation of water quality and increased flows due to discharges to surface water during operation. Potentially significant hydrology and water quality impacts were identified in association with the following facility improvement projects: SF-2. (DEIR, pp. 4.5-41 to 4.5-49, 6-10.)

Mitigation Measure 4.5-5, Stormwater Treatment and Groundwater Monitoring

Impact 4.5-6 – Hydrology and Water Quality: Degradation of water quality as a result of alteration of drainage patterns or an increase in impervious surfaces. Potentially significant hydrology and water quality impacts were identified in association with the following facility improvement projects: SJ-2. (DEIR, pp. 4.5-49 to 4.5-54, 6-6, 6-10.)

Mitigation Measure 4.5-6, Appropriate Source Control and Site Design Measures

4. Biological Resources

Impact 4.6-1 – Biological Resources: Impacts on wetlands and aquatic resources. Potentially significant impacts to biological resources were identified in association with the following facility improvements: SJ-1, SJ-2, SJ-3, SJ-5, SV-1, SV-2, SV-3, SV-4, SV-5, BD-1, BD-2, PN-2, PN-4, SF-1, SF-2, and SF-3. (DEIR, pp. 4.6-43 to 4.6-51, 6-4 to 6-6, 6-11 to 21.)

Mitigation Measure 4.6-1a, Wetlands Assessment
Mitigation Measure 4.6-1b, Compensation for Wetlands and Other Biological Resources

Impact 4.6-2 – Biological Resources: Impacts on Sensitive Habitats, Common Habitats, and Heritage Trees. Potentially significant impacts to biological resources were identified in association with the following facility improvements: SJ-1, SJ-2, SJ-3, SJ-5, SV-1, SV-2, SV-3, SV-4, SV-5, BD-1, BD-2, PN-2, PN-4, SF-1, SF-2, and SF-3. (DEIR, pp. 4.6-52 to 4.6-59, 6-4 to 6-6, 6-12 to 6-13.)

Mitigation Measure 4.6-1b, Compensation for Wetlands and Other Biological Resources
Mitigation Measure 4.6-2, Habitat Restoration/Tree Replacement

Impact 4.6-3 – Biological Resources: Impacts on key special status species – direct mortality and/or habitat effects. Potentially significant impacts to biological resources were identified in association with the following facility improvements: SJ-1, SJ-2, SJ-3, SJ-5, SV-1, SV-2, SV-3, SV-4, SV-5, BD-1, BD-2, PN-2, and PN-4. (DEIR, pp. 4.6-59 to 4.6-68, 6-4 to 6-6, 6-11 to 6-13.)

Mitigation Measure 4.6-1b, Compensation for Wetlands and Other Biological Resources
Mitigation Measure 4.6-3a, Protection Measures During Construction for Key Special-Status Species and Other Species of Concern
Mitigation Measure 4.6-3b, Standard Mitigation Measures for Specific Plants and Animals

Impact 4.6-4 – Biological Resources: Water discharge effects on riparian and/or aquatic resources. Potentially significant impacts to biological resources were identified in association with the following facility improvements: SJ-3, SV-4, BD-1, and BD-2. (DEIR, pp. 4.6-69 to 4.6-73, 6-13.)

Mitigation Measure 4.6-4, Pipeline and Water Treatment Plant Treated Water Discharge Restrictions

Impact 4.6-5 – Biological Resources: Conflicts with adopted conservation plans, or other approved biological resources plans. Potentially significant impacts to biological resources were identified in association with the following facility improvements: SJ-3. (DEIR, pp. 4.6-73 to 4.6-74, 6-11 to 6-13.)

Mitigation Measure 4.6-1a, **Wetlands Assessment**
Mitigation Measure 4.6-1b, Compensation for Wetlands and Other Biological Resources
Mitigation Measure 4.6-2, Habitat Restoration/Tree Replacement
Mitigation Measure 4.6-3a, Protection Measures During Construction for Key Special-Status Species and Other Species of Concern
Mitigation Measure 4.6-3b, Standard Mitigation Measures for Specific Plants and Animals

5. Cultural Resources

Impact 4.7-1 – Cultural Resources: Impacts on paleontological resources. Potentially significant impacts to cultural resources were identified in association with the following facility improvements: SJ-1, SJ-3, SJ-5, SV-1, SV-2, SV-3, SV-4, SV-5, PN-3, SF-1, SF-2, and SF-3. (DEIR, pp. 4.7-47 to 4.7-55, 6-4 to 6-6, 6-22.)

Mitigation Measure 4.7-1, Suspend Construction Work if Paleontological Resource is Identified

Impact 4.7-2 – Cultural Resources: Impacts on unknown and known prehistoric and historic archaeological resources. Potentially significant impacts to cultural resources were identified in association with all of the facility improvements. (DEIR, pp. 4.7-55 to 4.7-63, 6-4 to 6-6, 6-22 to 6-26.)

Mitigation Measure 4.7-2a, Archeological Testing, Monitoring, and Treatment of Human Remains
Mitigation Measure 4.7-2b, Accidental Discovery Measures

Impact 4.7-3 – Cultural Resources: Impacts on the historical significance of a historic district or a contributor to a historic district. Potentially significant impacts to cultural resources were identified in association with the following facility improvements: SJ-1, SJ-3, SV-4, BD-1, BD-2, PN-4, and SF-1. (DEIR, pp. 4.7-69 to 4.7-75, 6-26 to 6-30.)

Mitigation Measure 4.7-3, Protection of Historic Districts
Mitigation Measure 4.7-4a, Alternatives Identification and Resource Relocation
Mitigation Measure 4.7-4b, Historical Resources Documentation

Mitigation Measure 4.7-4c, Secretary of the Interior's Standards for Treatment of Historic Properties
Mitigation Measure 4.7-4d, Historic Resources Survey and Redesign
Mitigation Measure 4.7-4e, Historic Resources Protection Plan
Mitigation Measure 4.7-4f, Preconstruction Surveys and Vibration Monitoring

Impact 4.7-4 – Cultural Resources: Impacts on the historical significance of individual facilities resulting from demolition or alteration. Potentially significant impacts to cultural resources were identified in association with the following facility improvements: SJ-1, SJ-3, BD-1, BD-2, and SF-1. (DEIR, pp. 4.7-76 to 4.7-83, 6-4 to 6-6, 6-26 to 6-30.)

Mitigation Measure 4.7-4a, Alternatives Identification and Resource Relocation
Mitigation Measure 4.7-4b, Historical Resources Documentation
Mitigation Measure 4.7-4c, Secretary of the Interior's Standards for Treatment of Historic Properties
Mitigation Measure 4.7-4d, Historic Resources Survey and Redesign
Mitigation Measure 4.7-4e, Historic Resources Protection Plan
Mitigation Measure 4.7-4f, Preconstruction Surveys and Vibration Monitoring

Impact 4.7-5 – Cultural Resources: Impacts on adjacent historic architectural resources. Potentially significant impacts to cultural resources were identified in association with the following facility improvements: SJ-3, SJ-5, SV-2, SV-4, BD-1, BD-2, PN-2, PN-4, SF-1, and SF-3. (DEIR, pp. 4.7-83 to 4.7-86, 6-4 to 6-6, 6-26 to 6-30.)

Mitigation Measure 4.7-4a, Alternatives Identification and Resource Relocation
Mitigation Measure 4.7-4b, Historical Resources Documentation
Mitigation Measure 4.7-4c, Secretary of the Interior's Standards for Treatment of Historic Properties
Mitigation Measure 4.7-4d, Historic Resources Survey and Redesign
Mitigation Measure 4.7-4e, Historic Resources Protection Plan
Mitigation Measure 4.7-4f, Preconstruction Surveys and Vibration Monitoring

6. Traffic, Transportation, and Circulation

Impact 4.8-1 – Traffic, Transportation, and Circulation: Temporary reduction in roadway capacity and increased traffic delays. Potentially significant impacts to traffic, transportation, and circulation were identified in association with the following facility improvements: SJ-3, SV-2, BD-1, PN-2, PN-4, SF-1, SF-2, and SF-3. (DEIR, pp. 4.8-10 to 4.8-15, 6-4 to 6-6, 6-30 to 6-31.)

Mitigation Measure 4.8-1a, Traffic Control Plan Measures
Mitigation Measure 4.8-1b, Coordination of Individual Traffic Control Plans

Impact 4.8-2: Short-term traffic increases on roadways due to construction related vehicle trips. Potentially significant impacts to traffic, transportation, and circulation were identified in association with the following facility improvements: SJ-1, SJ-2, SJ-3, SJ-5, SV-1, SV-2, SV-3,

SV-4, SV-5, BD-1, BD-2, PN-2, PN-3, PN-4, SF-1, and SF-3. (DEIR, pp. 4.8-15 to 4.8-20, 6-4 to 6-6, 6-30 to 6-32.)

Mitigation Measure 4.8-1a, Traffic Control Plan Measures
Mitigation Measure 4.8-1b, Coordination of Individual Traffic Control Plans

Impact 4.8-3 – Traffic, Transportation, and Circulation: Impaired access to adjacent roadways and land uses. Potentially significant impacts to traffic, transportation, and circulation were identified in association with the following facility improvements: SJ-3, SV-2, BD-1, BD-2, PN-4, SF-1, SF-2, and SF-3. (DEIR, pp. 4.8-20 to 4.8-24, 6-4 to 6-6, 6-30 to 6-32.)

Mitigation Measure 4.8-1a, Traffic Control Plan Measures

Impact 4.8-4 – Traffic, Transportation, and Circulation: Temporary displacement of on-street parking. Potentially significant impacts to traffic, transportation, and circulation were identified in association with the following facility improvements: BD-1, PN-4, SF-1, SF-2, and SF-3. (DEIR, pp. 4.8-24 to 4.8-27. 6-4 to 6-6, 6-30 to 6-32.)

Mitigation Measure 4.8-1a, Traffic Control Plan Measures
Mitigation Measure 4.8-4, **Accommodation of Displaced Public Parking Supply for Recreational Visitors**

Impact 4.8-5 – Traffic, Transportation, and Circulation**:** Increased potential traffic safety hazards during construction. Potentially significant impacts to traffic, transportation, and circulation were identified in association with all of the facility improvements. (DEIR, pp. 4.8-27 to 4.8-28, 6-4 to 6-6, 6-30 to 6-31.)

Mitigation Measure 4.8-1a, Traffic Control Plan Measures

7. Air Quality

Impact 4.9-1 – Air Quality: Construction emissions of criteria pollutants. Potentially significant impacts to air quality were identified in association with the following facility improvements: SJ-1, SJ-2, SJ-3, SJ-5, SV-1, SV-2, SV-3, SV-4, SV-5, BD-1, and BD-2. (DEIR, pp. 4.9-21 to 4.9-27, 6-4 to 6-6, 6-34 to 6-37.)

Mitigation Measure 4.9-1a, SJVAPCD Dust Control Measures
Mitigation Measure 4.9-1b, SJVAPCD Exhaust Control Measure
Mitigation Measure 4.9-1c, BAAQMD Dust Control Measures
Mitigation Measure 4.9-1d, BAAQMD Exhaust Control Measures

Impact 4.9-2 – Air Quality: Exposure to diesel particulate matter (DPM) during construction. Potentially significant impacts to air quality were identified in association with the following facility improvements: SV-2, SV-5, and BD-1. (DEIR, pp. 4.9-27 to 4.9-34, 6-37 to 6-38.)

Mitigation Measure 4.9-2a, Health Risk Screening or Use of Soot Filters

Mitigation Measure 4.9-2b, Vacate SFPUC Land Managers' Residences in Sunol Valley

Impact 4.9-3 – Air Quality: Exposure to emissions (possibly including asbestos) from tunneling. Potentially significant impacts to air quality were identified in association with the following facility improvements: SJ-3, SV-4, BD-1, PN-2, SF-1, SF-2, and SF-3. (DEIR, pp. 4.9-34 to 4.9-36, 6-38.)

Mitigation Measure 4.9-3, Tunnel Gas Odor Control

8. Noise and Vibration

Impact 4.10-2, Noise and Vibration: Temporary Noise Disturbance Along Construction Haul Routes. Potentially significant noise impacts were identified in association with the following facility improvement project: SV-4. (DEIR, pp. 4.10-23 to 4.10-26, 6-41 to 6-42.)

Mitigation Measure 4.10-2c, Vacate SFPUC Land Manager's Residence

Impact 4.10-3 – Noise and Vibration: Disturbance due to construction related vibration. Potentially significant vibration impacts were identified in association with the following facility improvement project: SV-4. (DEIR, pp. 4.10-27 to 4.10-33, 6-42.)

Mitigation Measure 4.10-1a, Noise Controls
Mitigation Measure 4.10-3a, Vibration Controls to Prevent Cosmetic or Structural Damage

9. Public Services and Utilities

Impact 4.11-1 – Public Services and Utilities: Potential temporary damage to, or disruption of existing regional or local public utilities. Potentially significant impacts to public services and utilities were identified in association with the following facility improvement projects: SJ-3, SV-1, SV-2, SV-3, SV-4, BD-1, BD-2, PN-2, PN-4, SF-1, SF-2, and SF-3. (DEIR, pp. 4.11-10 to 4.11-15, 6-4 to 6-6, 6-43 to 6-44.)

Mitigation Measure 4.11-1a, Notify Neighbors of Potential Utility Service Disruption
Mitigation Measure 4.11-1b, Locate Utility Lines Prior to Excavation
Mitigation Measure 4.11-1c, Confirmation of Utility Line Information
Mitigation Measure 4.11-1d, Safeguard Employees from Potential Accidents Related to Underground Utilities
Mitigation Measure 4.11-1e, Notify Local Fire Departments
Mitigation Measure 4.11-1f, Emergency Response Plan
Mitigation Measure 4.11-1g, Prompt Reconnection of Utilities
Mitigation Measure 4.11-1h, Coordinate Final Construction Plans with Affected Utilities

Impact 4.11-2 – Public Services and Utilities: Temporary Solid Waste Effects on Solid Waste Landfill Capacity. Potentially significant impacts to public services and utilities were identified in association with all of the facility improvement projects. (DEIR, pp. 4.11-15 to 4.11-21, 6-44.)

Mitigation Measure 4.11-2, Waste Reduction Measures

Impact 4.11-3 – Public Services and Utilities: Impacts related to compliance with federal, state, and local statutes and regulations related to solid waste. Potentially significant impacts to public services and utilities were identified in association with all of the facility improvement projects. (DEIR, pp. 4.11-22, 6-44.)

Mitigation Measure 4.11-2, Waste Reduction Measures

Impact 4.11-4 – Public Services and Utilities: Impacts related to the relocation of utilities. Potentially significant impacts to public services and utilities were identified in association with all of the facility improvement projects. (DEIR, pp. 4.11-22 to 4.11-23, 6-4 to 6-6, 6-43 to 6-44.)

Mitigation Measure 4.11-1a, Notify Neighbors of Potential Utility Service Disruption
Mitigation Measure 4.11-1b, Locate Utility Lines Prior to Excavation
Mitigation Measure 4.11-1c, Confirmation of Utility Line Information
Mitigation Measure 4.11-1d, Safeguard Employees from Potential Accidents Related to Underground Utilities
Mitigation Measure 4.11-1e, Notify Local Fire Departments
Mitigation Measure 4.11-1f, Emergency Response Plan
Mitigation Measure 4.11-1g, Prompt Reconnection of Utilities
Mitigation Measure 4.11-1h, Coordinate Final Construction Plans with Affected Utilities

10. Recreational Resources

Impact 4.12-1 – Recreational Resources: Temporary Conflicts with established recreational uses during construction. Potentially significant impacts to recreational resources were identified in association with the following facility improvement projects: SJ-3, SV-4, BD-1, BD-2, PN-2, SF-1, SF-2, and SF-3. (DEIR, pp. 4.12-18 to 4.12-27, 6-4 to 6-6, 6-30 to 6-32, 6-34 to 6-44.)

Mitigation Measure 4.12-1, Coordination with Golf Course/Recreational Facility Managers
Mitigation Measure 4.8-1a, Traffic Control Plan Measures
Mitigation Measure 4.8-1b, Coordination of Individual Traffic Control Plans
Mitigation Measure 4.9-1a, SJVAPCD Dust Control Measures
Mitigation Measure 4.9-1b, SJVAPCD Exhaust Control Measure
Mitigation Measure 4.9-2a, Health Risk Screening or Use of Soot Filters
Mitigation Measure 4.9-2b, Vacate SFPUC Land Managers' Residences in Sunol Valley
Mitigation Measure 4.10-1a, Noise Controls
Mitigation Measure 4.10-1b, Vacate SFPUC Caretaker's Residence at Tesla Portal
Mitigation Measure 4.10-2a, Limit Hourly Truck Volumes
Mitigation Measure 4.10-2b, Restrict Truck Operations
Mitigation Measure 4.10-2c, Vacate SFPUC Land Manager's Residence
Mitigation Measure 4.10-3a, Vibration Controls to Prevent Cosmetic or Structural Damage
Mitigation Measure 4.10-3b, Limit Vibration Levels at or Below Vibration Perception Threshold

Impact 4.12-2 – Recreational Resources: Conflicts with established recreational uses due to facility siting and project operation. Potentially significant impacts to recreational resources were identified in association with the following facility improvement projects: SF-1, SF-2, and SF-3. (DEIR, pp. 4.12-27 to 4.12-28, 6-7 to 6-8, 6-44.)

Mitigation Measure 4.3-4a, Architectural Design
Mitigation Measure 4.3-4b, Landscaping Plans
Mitigation Measure 4.3-4c, Landscape Screens
Mitigation Measure 4.3-4d, Minimize Tree Removal
Mitigation Measure 4.12-2, Appropriate Siting of Proposed Facilities

11. Agricultural Resources

Impact 4.13-1 – Agricultural Resources: Temporary conflicts with established agricultural resources. Potentially significant impacts to agricultural resources were identified in association with the following facility improvement projects: SJ-3, SV-1, SV-2, SV-3, and SV-4. (DEIR, pp. 4.13-11 to 4.13-15, 6-4 to 6-6, 6-45.)

Mitigation Measure 4.13-1a, Supplemental Noticing and Soil Stockpiling
Mitigation Measure 4.13-1b, Avoidance or Soil Stockpiling

Impact 4.13-2 - Agricultural Resources: Conversion of farmlands to non-agricultural uses. Potentially significant impacts to agricultural resources were identified in association with the following facility improvement projects: SJ-3, SV-3, and SV-5. (DEIR, pp. 4.13-15 to 4.13-17, 6-45.)

Mitigation Measure 4.13-2, Siting Facilities to Avoid Prime Farmland

12. Hazards

Impact 4.14-1 – Hazards: Potential to encounter hazardous materials in soil or groundwater. Potentially significant hazards impacts were identified in association with the following facility improvement projects: BD-1, BD-2, SF-1, SF-2, and SF-3. (DEIR, pp. 4.14-16 to 4.14-22, 6-4 to 6-6, 6-45 to 6-46.)

Mitigation Measure 4.14-1a, Site Health and Safety Plan
Mitigation Measure 4.14-1b, Materials Disposal Plan
Mitigation Measure 4.14-1c, Coordination with Property Owners and Regulatory Agencies

Impact 4.14-2 – Hazards: Exposure to naturally occurring asbestos. Potentially significant hazards impacts were identified in association with the following facility improvement project: BD-1. (DEIR, pp. 4.14-23 to 4.14-26, 6-46.)

Mitigation Measure 4.14-2, Health Risk Screening and Airborne Asbestos Monitoring Plan

Impact 4.14-5 – Hazards: Exposure to hazardous building materials. Potentially significant hazards impacts were identified in association with the following facility improvement projects: SJ-3, SJ-5, SV-2, SV-4, BD-1, PN-2, PN-3, PN-4, SF-1, SF-2, and SF-3. (DEIR, pp. 4.14-31 to 4.14-35, 6-46.)

Mitigation Measure 4.14-5, Hazardous Building Materials Surveys and Abatement

13. Energy Resources

Impact 4.15-1 – Energy Resources: Construction related energy use. Potentially significant energy impacts were identified in association with all of the facility improvement projects. (DEIR, p. 4.15-8, 6-34 to 6-37, 6-47.)

Mitigation Measure 4.9-1b, SJVAPCD Exhaust Control Measure
Mitigation Measure 4.9-1d, BAAQMD Exhaust Control Measures

Impact 4.15-2 – Energy Resources: Long-term energy use during operation. Potentially significant energy impacts were identified in association with the following facility improvement projects: SJ-1, SJ-2, SJ-3, SJ-5, SV-1, SV-3, SV-5, BD-1, BD-2, PN-2, PN-3, SF-1, SF-2, and SF-3. (DEIR, pp. 4.15-8 to 4.15-14, 6-47.)

Mitigation Measure 4.15-2, Incorporation of Energy Efficient Measures

14. Collective Facilities Impacts

Impact 4.16-1a – Collective temporary and permanent impacts on existing land uses in the vicinity of the proposed facility site. Potentially significant collective land use impacts were identified in association with the following facility improvement project regions: Peninsula Region Improvements. (DEIR, pp. 4.16-8 to 4.16-11, 6-32.)

Mitigation Measure 4.8.-4, Accommodation of Displaced Public Parking Supply for Recreational Visitors

Impact 4.16-1b – Collective temporary and permanent impacts on the visual character the surrounding area. Potentially significant collective visual quality impacts were identified in association with the following facility improvement project regions: San Joaquin Region, Bay Division Region, Peninsula Region, San Francisco Region. (DEIR, pp. 4.16-11 to 4.16-12, 6-7 to 6-8.)

Mitigation Measure 4.3-4a, Architectural Design
Mitigation Measure 4.3-4b, Landscaping Plans
Mitigation Measure 4.3-4c, Landscaping Screens

Impact 4.16-3 – Collective WSIP impacts related to the degradation of surface waters and flooding hazards. Potentially significant collective hydrology and water quality impacts were identified in association with multi-regional effects as well as the following facility improvement project regions: San Joaquin Region, Sunol Valley Region, Bay Division Region, Peninsula Region and San Francisco Region. (DEIR, pp. 4.16-13 to 4.16-16, 6-10.)

Mitigation Measure 4.5-4a, Flood Flow Protection Measures
Mitigation Measure 4.5-4b, Site-Specific Flooding Analysis and Identified Measures
Mitigation Measure 4.5-5, Stormwater Treatment and Groundwater Monitoring
Mitigation Measure 4.5-6, Appropriate Source Control and Site Design Measure

Impact 4.16-4 – Collective loss of sensitive biological resources. Potentially significant collective biological resource impacts were identified in association with multi-regional effects as well as the following facility improvement project regions: San Joaquin Region and Bay Division Region. (DEIR, pp. 4.16-16 to 4.16-19, 6-11 to 6-21.)

Mitigation Measures 4.6-1a, Wetlands Assessment
Mitigation Measure 4.6-1b, Compensation for Wetlands and Other Biological Resources
Mitigation Measure 4.6-2, Habitat Restoration/Tree Replacement
Mitigation Measure 4.6-3a, Protection Measures During Construction for Key Special-Status Species and Other Species of Concern
Mitigation Measure 4.6-3b, Standard Mitigation Measures for Specific Plants and Animals
Mitigation Measure 4.16-4a, Bioregional Habitat Restoration Measures
Mitigation Measure 4.16-4b, Coordination of Construction Staging and Access

Impact 4.16-5 – Collective increase in impacts related to archaeological, paleontological and historical resources. Potentially significant collective cultural resource impacts were identified in association with multi-regional effects as well as the following facility improvement project regions: San Joaquin Region and Bay Division Region. (DEIR, pp. 4.16-19 to 4.16-22, 6-26 to 6-30.)

Mitigation Measure 4.7-4a, Alternatives Identification and Resource Relocation
Mitigation Measure 4.7-4b, Historical Resources Documentation
Mitigation Measure 4.7-4c, Secretary of the Interior's Standards for Treatment of Historic Properties
Mitigation Measure 4.7-4d, Historic Resources Survey and Redesign
Mitigation Measure 4.7-4e, Historic Resources Protection Plan
Mitigation Measure 4.7-4f, Preconstruction Surveys and Vibration Monitoring

Impact 4.16-6 – Collective traffic increases on local and regional roads. Potentially significant collective traffic impacts were identified in association with the following facility improvement project regions: San Joaquin Region, Sunol Valley Region, Bay Division Region, Peninsula Region and San Francisco Region. (DEIR, pp. 4.16-23 to 4.16-26, 6-30 to 6-33.)

Mitigation Measure 4.8-1a, Traffic Control Plan Measures
Mitigation Measure 4.8-1b, Coordination of Individual Traffic Control Plans
Mitigation Measure 4.16-6a, SFPUC WSIP Projects Construction Coordinator
Mitigation Measure 4.16-6b, Combined San Joaquin Traffic Control Plan
Mitigation Measure 4.16-6c, Combined Sunol Valley Traffic Control Plan

Impact 4.16-7 – Collective increases in construction and/or operational emission in the region. Potentially significant collective air quality impacts were identified in association with the following facility improvement project regions: San Joaquin Region, Sunol Valley Region, and Bay Division Region. (DEIR, pp. 4.16-26 to 4.16-29, 6-37 to 6-39.)

Mitigation Measure 4.9-2a, Health Risk Screening or Use of Soot Filters
Mitigation Measure 4.9-2b, Vacate SFPUC Land Managers' Residences in Sunol Valley
Mitigation Measure 4.16-7a, Dust and Exhaust Control Measures for All WSIP Projects
Mitigation Measure 4.16-7b, Health Risk Screening or Use of Soot Filters for All Projects in the San Joaquin and Sunol Valley Regions
Mitigation Measure 4.16-7c, Vacate SFPUC Land Managers' Residences for All Projects in the Sunol Valley Region

Impact 4.16-8 – Collective increases in construction-related and operational noise. Potentially significant collective noise impacts were identified in association with the following facility improvement project regions: Sunol Valley Region. (DEIR, pp. 4.16-30 to 4.16-33, 42 to 6-43.)

Mitigation Measure 4.16-8b, Vacate Land Manager's Residence for All Projects in Sunol Valley Region

Impact 4.16-9 – Collective impacts on landfill capacity. Potentially significant impacts on landfill capacity were identified in association with all of the facility improvement project regions (Draft PEIR, p. 4.16-33.)

Mitigation Measure 4.11-2, Waste Reduction Measures

Impact 4.16-10 – Collective effect on recreational resources during construction. Potentially significant collective recreational resource impacts were identified in association with the following facility improvement project regions: San Joaquin Region, Sunol Valley Region, Bay Division Region, Peninsula Region and San Francisco Region. (DEIR, pp. 4.16-33 to 4.16-34, 6-44.)

Mitigation Measure 4.12-1, Coordination with Golf Course/Recreational Facility Managers
Mitigation Measure 4.12-2, Appropriate Siting of Proposed Facilities

Impact 4.16-11 – Collective conversion of farmland to nonagricultural uses. Potentially significant collective agricultural resource impacts were identified in association with the following facility improvement project regions: San Joaquin Region and Sunol Valley Region. (DEIR, p. 4.16-34, 6-45.)

Mitigation Measure 4.13-2, Siting Facilities to Avoid Prime Farmland

Impact 4.16-12 – Collective effects related to hazardous conditions and exposure to ore release of hazardous materials. Potentially significant collective hazard impacts were identified in association with the following facility improvement project regions: San Joaquin Region, Sunol

Valley Region, Bay Division Region, Peninsula Region and San Francisco Region. (DEIR, pp. 4.16-35 to 4.16-36, 6-30 to 6-32, 6-46.)

Mitigation Measure 4.8-1a, Traffic Control Plan Measures
Mitigation Measure 4.8-1b, Coordination of Individual Traffic Control Plans
Mitigation Measure 4.14-1b, Materials Disposal Plan

Impact 4.16-13 – Collective increases in the use of nonrenewable energy resources. Potentially significant collective energy resource impacts were identified in association with multi-regional effects as well as the following facility improvement project regions: San Joaquin Region, Sunol Valley Region, Bay Division Region, Peninsula Region, and San Francisco Region. (DEIR, pp. 4.16-36 to 4.16-38, 6-35 to 6-37, 6-47.)

Mitigation Measure 4.9-1b, SJVAPCD Exhaust Control Measures
Mitigation Measure 4.9-1d, BAAQMD Exhaust Control Measures
Mitigation Measure 4.15-2, Incorporation of Energy Efficiency Measures

Conservation, Recycling and Groundwater Programs: The Final PEIR also identified possible impacts and mitigation strategies for facilities potentially developed by the wholesale customers to decrease demand for water or to supplement water supply as well. (See C&R pages 13-30 – 34; see also DEIR pp. 9-34 to 9-37; 9-55 to 9-57.) While it is difficult to predict what facilities will be implemented by the wholesale customers, any decisions to approve new projects or programs will undergo further CEQA review and will be approved by the individual customer or by BAWSCA. This Commission recommends that the wholesale customers approve projects that incorporate the mitigation strategies set forth in the Final PEIR, and finds that the wholesale customers can and should adopt applicable mitigation measures and strategies.

IV. SIGNIFICANT IMPACTS THAT CANNOT BE AVOIDED OR REDUCED TO A LESS THAN SIGNIFICANT LEVEL

Based on substantial evidence in the whole record of these proceedings, the SFPUC finds that, where feasible, changes or alterations have been required, or incorporated into, the Phased WSIP Variant to reduce the significant environmental impacts listed below as identified in the FEIR. The SFPUC finds that the mitigation measures in the PEIR and described below are appropriate, and that changes have been required in, or incorporated into, the Phased WSIP Variant that, to use the language of Public Resources Code section 21002 and CEQA Guidelines section 15091, may substantially lessen, but do not avoid (i.e., reduce to less than significant levels), the potentially significant environmental effect associated with implementation of the individual WSIP facility improvement projects, as described in the Program EIR Chapter 4, and the potentially significant or significant environmental effects associated with implementation of the water supply program, as described in the Program EIR, Chapter 13. The SFPUC adopts all of the mitigation measures proposed in the Program EIR that are relevant to the Phased WSIP Variant and set forth in the MMRP, attached hereto as Attachment B. The SFPUC further finds, however, for the impacts listed below, that no mitigation is currently available to render the effects less than significant. The effects therefore remain significant and unavoidable. Based on the analysis contained within the Program EIR, other considerations in the record, and the standards of significance, the SFPUC finds that because some aspects of the Phased WSIP Variant would cause potentially significant impacts for which feasible mitigation measures are not available to reduce the impact to a less-than-significant level, the impacts are ***significant and unavoidable***.

With respect to the facility improvement projects impacts and those water supply/system operations impacts directly related to one of the WSIP projects, the PEIR provides a program-level of analysis based on preliminary project information. Due to the lack of site-specific details, the impacts are based on reasonable worst-case assumptions, and the feasibility of many mitigation measures is uncertain. Thus, to be conservative, these impacts are considered ***potentially significant and unavoidable***. However, subsequent environmental review and analysis of all WSIP facility improvement projects will occur when more detailed, site-specific information is available, and it may be determined that either the impacts no longer apply or that feasible mitigation measures may be available.

The SFPUC determines that the following significant impacts on the environment, as reflected in the Program EIR, are unavoidable, but under Public Resources Code Section 21081(a)(3) and (b), and CEQA Guidelines 15091(a)(3), 15092(b)(2)(B), and 15093, the SFPUC determines that the impacts are acceptable due to the overriding considerations described in Section VII below. This finding is supported by substantial evidence in the record of this proceeding.

A. WSIP Water Supply and System Operations Impacts

1. Alameda Creek Stream Flow

Impact 5.4.1-2 – Stream Flow: Effects on flow along Alameda Creek below the Alameda Creek Diversion Dam. (DEIR, pp. 5.4.1-25 to 5.4.1-33, C&R page 13-37.) Restoring the levels of the Calaveras Dam reservoir under the Calaveras Dam Replacement Project would increase diversions from Alameda Creek to Calaveras Reservoir, nearly eliminating the low and moderate (1 to 650 cfs) flows in Alameda Creek downstream of the diversion dam that currently occur when the diversion gates are closed, and substantially reducing many higher (greater than 650 cfs) flows. Under the Phased WSIP Variant, flows in Alameda Creek in the reach below the diversion dam to the Calaveras Creek confluence and in the reach below the confluence would be substantially reduced compared to the conditions in existence since December 2001, when the California Department of Water Resources, Division of Safety of Dams imposed storage capacity restrictions on Calaveras Reservoir. This reduction of stream flows and alteration of the stream hydrograph is considered a substantial hydrologic effect and, as a result, this impact is *significant and unavoidable.* Implementation of Measure 5.4.1-2 would reduce the impact by requiring the SFPUC to close the diversion dam and cease Alameda Creek diversions to Calaveras Reservoir as soon as possible each year, once the reservoir is at desired levels, such that the later-season storm flows not needed to refill Calaveras Reservoir are allowed to flow down Alameda Creek past the diversion dam to the lower reaches. This measure would help reduce the impact, but not to a less than significant level.

Mitigation Measure 5.4.1-2, Diversion Tunnel Operation

2. San Francisco Peninsula Fisheries

Impact 5.5.5-1 –Fisheries: Effects on fishery resources in Crystal Springs Reservoir (Upper and Lower). (DEIR, pp. 5.5.5-6 to 5.5.5-7; C&R, pp. 15.2-15 and 15.2-16.) Restoring the levels of the reservoir under the Lower Crystal Springs Dam Improvements project (PN-4) could cause a potential loss of stream channel and potential spawning area in San Mateo Creek. However, upstream areas may provide suitable replacement habitat to support the population and this prospect is currently under evaluation in the project-level CEQA review for the Lower Crystal Springs Dam Improvements project. Thus, implementation of Measure 5.5.5-1, Create New Spawning Habitat Above Crystal Springs Reservoir, if feasible, may reduce this impact to less than significant. The project-level CEQA review for the Lower Crystal Springs Dam Improvements project will further evaluate the severity of this impact and the feasibility and efficacy of Measure 5.5.5-1. To be conservative, at the program-level of analysis, this impact is considered *potentially significant and unavoidable*.

Mitigation Measure 5.5.5-1, Create New Spawning Habitat Above Crystal Springs Reservoir

B. Growth Inducing Impacts

CEQA Guidelines section 15126.2, subdivision (d) requires a discussion of the ways in which projects could be growth inducing, including the ways in which "the proposed project could foster economic and population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment." CEQA also requires a discussion of ways in which a project may remove obstacles to growth, as well as ways in which a project may set a precedent for future growth or encourage and facilitate other activities that could significantly affect the environment, either individually or cumulatively. PEIR Chapter 7 and Appendix E provide detailed analysis of the growth-inducing effects of the originally proposed WSIP in the Draft PEIR and concluded in the C&R document, page 13-45, that the Phased WSIP Variant would have similar growth-inducing impacts through 2018.

Impact 7-1 – By removing the lack of a reliable water supply system as one potential obstacle to growth within the SFPUC service area and providing, and assisting in development of, additional water supply sources such as recycled water and groundwater projects as well as promotion of more efficient use of water through conservation measures, the Phased WSIP Variant would have an indirect growth-inducing effect according to the CEQA definition above. The Phased WSIP Variant would support planned growth in the SFPUC service area through 2018, although it appears that some growth would occur irrespective of the Phased WSIP Variant due to increased water delivery efficiencies (e.g., plumbing code changes), conservation, and other water supply sources. Growth would in turn result in indirect effects. In most cases, the effects of planned population and employment growth have been identified and addressed in the EIRs for the general plans and associated area plans and specific plans adopted by the jurisdictions in the service area. Some of the identified indirect effects of growth are significant and unavoidable; others are significant but can be mitigated.

Potentially significant and unavoidable impacts as a result of planned growth in the SFPUC service area have been identified in the following areas: traffic congestion, air pollution, traffic noise, construction noise, increased demand for public schools and other public services, loss of recreational opportunities and impacts on visual quality resulting from the loss of open space, cumulative effects on over-utilized parks, loss of wildlife habitat and wetlands and impacts on other biological resources, cumulative impacts on cultural resources, increased flooding potential, increased urban runoff pollutants, seismic hazards, induced population growth, failure to meet housing demand for projected population growth, exposure of new development to contaminated soil or groundwater, insufficient water supply, insufficient wastewater disposal capacity, loss of agricultural resources, land use conflicts, conflicts with existing land use plans or policies, and changes in density, scale, and character of an area.

The Phased WSIP Variant would have the same growth-inducement potential through 2018 as the WSIP because the SFPUC (with the cooperation of BAWSCA and the wholesale customers) would provide the additional water supply to meet 2018 purchase requests. The Phased WSIP Variant would support much of the planned growth through 2018 in the jurisdictions served by the SFPUC regional water system. In general, development planned and approved through the general plan process in the SFPUC service area would have environmental impacts. The environmental consequences of this planned growth have been largely addressed in local plans and the associated CEQA review as well as in other, project-specific documentation. In a number of jurisdictions, negative declarations or mitigated negative declarations were prepared for general plans and related planning documents that were found not to have significant environmental effects. (DEIR, pp. 7-1 to 7-78; C&R page 13-45.)

With the exception of the No Purchase Request Alternative, all of the alternatives analyzed in the PEIR contribute in similar ways to growth inducement impacts, since each of the Alternatives provides alternative ways of meeting future water supply demand as one of the WSIP objectives. It is also likely that the water customers would find alternate sources of water to meet future demand under the alternatives that are not effective in meeting demand like the Aggressive Conservation and Recycling Alternative. Under this scenario, the Alternative itself may not be growth-inducing, but growth could still occur. There are no mitigation measures proposed for implementation by the SFPUC that could substantially decrease or eliminate growth-inducing impacts because the SFPUC does not have control over the decisions that each local agency will make with respect to growth in their jurisdictions. Individual agencies' general plans and environmental documents contain actions, limitations and mitigation measures that will be implemented in the individual jurisdictions with local development project or program approvals. These kinds of mitigation measures were identified in the PEIR pages 7-67 through 7-78 and in PEIR Appendix E, Section E.5 and Table E.5.1. This Commission urges the local agencies to implement those mitigation measures already identified as feasible, and finds that these agencies can and should implement those mitigation measures

B. WSIP Facility Construction and Operation Impacts

1. Land Use and Visual Quality

Impact 4.3-1 – Land Use: Temporary disruption or displacement of existing land uses during construction. Potentially significant and unavoidable land use impacts were identified in association with the following facility improvement project: SV-4. (DEIR, pp. 4.3-9 to 4.3-16, 6-4 to 6-6, 6-8, 6-30 to 6-32, 6-34 to 6-42.)

Mitigation Measure 4.16-1a, Construction Coordination at Irvington Portal
Mitigation Measure 4.8-1a, Traffic Control Plan Measures
Mitigation Measure 4.8-1b, Coordination of Individual Traffic Control Plans
Mitigation Measure 4.9-1c, BAAQMD Dust Control Measures
Mitigation Measure 4.9-1d, BAAQMD Exhaust Control Measures
Mitigation Measure 4.9-2a, Health Risk Screening or Use of Soot Filters
Mitigation Measure 4.9-2b, Vacate SFPUC Land Managers' Residences in Sunol Valley
Mitigation Measure 4.10-1a, Noise Controls
Mitigation Measures 4.10-2a, Limit Hourly Truck Volumes
Mitigation Measure 4.10-2b, Restrict Truck Operations
Mitigation Measure 4.10-2c, Vacate SFPUC Land Manager's Residence
Mitigation Measure 4.10-3a, Vibration Controls to Prevent Cosmetic or Structural Damage
Mitigation Measure 4.10-3b, Limit Vibration Levels at or Below Vibration Perception Threshold
Mitigation Measure 4.10-3c, Limit Tunnel-Related Detonation to Daylight Hours

Impact 4.3-2 – Land Use: Permanent Displacement or Long-Term Disruption of Existing Land Uses. Potentially significant and unavoidable land use impacts were identified in association with the following facility improvement projects: SJ-3, SV-3, BD-1, PN-2, SF-2, and SF-3. (DEIR, pp. 4.3-20 to 4.3-28, 6-7.)

Mitigation Measure 4.3-2, Facility Siting Studies

Impact 4.3-4 – Visual Quality: Permanent Adverse Impacts on Scenic Vistas or Visual Character. Potentially significant and unavoidable visual quality impacts were identified in association with the following facility improvement project: SV-2. (DEIR, pp. 4.3-29 to 4.3-39, 6-7 to 6-8.)

Mitigation Measure 4.3-4a, Architectural Design
Mitigation Measure 4.3-4b, Landscaping Plans
Mitigation Measure 4.3-4c, Landscape Screens
Mitigation Measure 4.3-4d, Minimize Tree Removal

2. Cultural Resources

Impact 4.7-3 – Cultural Resources: Impacts on historical significance of a district or a contributor to a historic district. Potentially significant and unavoidable cultural resource impacts were identified in association with the following facility improvement projects: SV-2 and PN-2. (DEIR, pp. 4.7-69 to 4.7-75, 6-7 to 6-8, 6-26, 6-29 to 6-30.)

Mitigation Measure 4.7-3, Protection of Historic Districts
Mitigation Measure 4.7-4a, Alternatives Identification and Resource Relocation
Mitigation Measure 4.7-4b, Historical Resources Documentation

Mitigation Measure 4.7-4c, Secretary of the Interior's Standards for Treatment of Historic Properties
Mitigation Measure 4.7-4d, Historic Resources Survey and Redesign
Mitigation Measure 4.7-4e, Historic Resources Protection Plan
Mitigation Measure 4.7-4f, Preconstruction Surveys and Vibration Monitoring

Impact 4.7-4 – Cultural Resources: Impacts on the historical significance of individual facilities resulting from demolition or alteration. Potentially significant and unavoidable cultural resource impacts were identified in association with the following facility improvement projects: SV-2, SV-4, PN-2, and PN-4. (DEIR, pp. 4.7-76 to 4.7-82, 6-4 to 6-6, 6-26 to 6-30.)

Mitigation Measure 4.7-4a, Alternatives Identification and Resource Relocation
Mitigation Measure 4.7-4b, Historical Resources Documentation
Mitigation Measure 4.7-4c, Secretary of the Interior's Standards for Treatment of Historic Properties
Mitigation Measure 4.7-4d, Historic Resources Survey and Redesign
Mitigation Measure 4.7-4e, Historic Resources Protection Plan
Mitigation Measure 4.7-4f, Preconstruction Surveys and Vibration Monitoring

3. Noise and Vibration

Impact 4.10-1 –Noise: Disturbance from temporary construction-related noise increases. Potentially significant and unavoidable noise impacts were identified in association with all of the facility improvement projects. (DEIR, pp. 4.10-10 to 4.10-23, 6-4 to 6-6, 6-39 to 6-41.)

Mitigation Measure 4.10-1a, Noise Controls
Mitigation Measure 4.10-1b, Vacate SFPUC Caretaker's Residence at Tesla Portal

Impact 4.10-2 – Noise: Temporary noise disturbance along construction haul routes. Potentially significant and unavoidable noise impacts were identified in association with the following facility improvement projects: SJ-1, SJ-3, SJ-5, BD-1, BD-2, PN-3, SF-1, SF-2, and SF-3. (DEIR, pp. 4.10-23 to 4.10-26, 6-41 to 6-42.)

Mitigation Measure 4.10-2a, Limit Hourly Truck Volumes
Mitigation Measure 4.10-2b, Restrict Truck Operations

Impact 4.10-3 –Vibration: Disturbance due to construction-related vibration. Potentially significant and unavoidable vibration impacts were identified in association with the following facility improvement projects: SJ-3, SV-3, BD-1, BD-2, SF-1, SF-2, and SF-3. (DEIR, pp. 4.10-27 to 4.10-33, 6-42.)

Mitigation Measure 4.10-3a, Vibration Controls to Prevent Cosmetic or Structural Damage
Mitigation Measure 4.10-3b, Limit Vibration Levels at or Below Vibration Perception Threshold
Mitigation Measure 4.10-3c, Limit Tunnel-Related Detonation to Daylight Hours

4. Collective Facilities Impacts

Impact 4.16-1a – Collective temporary and permanent impacts on existing land uses in the vicinity of the proposed facility site. Potentially significant and unavoidable collective land use impacts were identified in association with the following facility improvement project regions: Bay Division Region. (DEIR, pp. 4.16-8 to 4.16-11, 6-32.)

Mitigation Measure 4.16-1a, Construction Coordination at Irvington Portal

Impact 4.16-4 – Collective loss of sensitive biological resources. Potentially significant and unavoidable collective biological resource impacts were identified in association with the following facility improvement project regions: Sunol Valley Region and Peninsula Region. (DEIR, pp. 4.16-16 to 4.16-19, 6-11 to 6-21.)

Mitigation Measure 4.6-1a, Wetlands Assessment
Mitigation Measure 4.6-1b, Compensation for Wetlands and Other Biological Resources
Mitigation Measure 4.6-2, Habitat Restoration/Tree Replacement
Mitigation Measure 4.6-3a, Protection Measures During Construction for Key Special-Status Species and Other Species of Concern
Mitigation Measure 4.6-3b, Standard Mitigation Measures for Specific Plants and Animals
Mitigation Measure 4.16-4b, Coordination of Construction Staging and Access

Impact 4.16-5 – Collective increase in impacts related to archaeological, paleontological and historical resources. Potentially significant and unavoidable collective cultural resource impacts were identified in association with the following facility improvement project regions: Sunol Valley Region and Peninsula Region. (DEIR, pp. 4.16-19 to 4.16-22, 6-26 to 6-30.)

Mitigation Measures 4.7-4a, Alternatives Identification and Resource Relocation
Mitigation Measure 4.7-4b, Historical Resources Documentation
Mitigation Measure 4.7-4c, Secretary of the Interior's Standards for Treatment of Historic Properties
Mitigation Measure 4.7-4d, Historic Resources Survey and Redesign
Mitigation Measure 4.7-4e, Historic Resources Protection Plan
Mitigation Measure 4.7-4f, Preconstruction Surveys and Vibration Monitoring

Impact 4.16-6 – Collective impact from multi-regional effects on traffic, transportation, and circulation were identified as potentially significant and unavoidable due to multiple roadways affected by construction activities within one or more regions and/or when construction vehicles use regional roadways. (DEIR, pp. 4.16-23 and 6-32)

Mitigation Measure 4.16-6a, SFPUC WSIP Projects Construction Coordinator

Impact 4.16-7 – Collective impact from multi-regional effects on air quality was identified as potentially significant and unavoidable due to residual contributions to ozone and particulate matter emissions during construction. (DEIR, pp. 4.16-26, 6-34 to 6-38)

Mitigation Measure 4.16-7a, Dust and Exhaust Control Measures for All WSIP Projects

Impact 4.16-8 – Collective increases in construction-related and operational noise. Potentially significant and unavoidable collective noise impacts were identified in association with the following facility improvement project regions: San Joaquin Region, Bay Division Region, Peninsula Region and San Francisco Region. (DEIR, pp. 4.16-30 to 4.16-33, 6-42 to 6-43.)

Mitigation Measure 4.10-1a, Noise Controls
Mitigation Measure 4.10-1b, Vacate SFPUC Caretaker's Residence at Tesla Portal
Mitigation Measure 4.10-2a, Limit Hourly Truck Volumes
Mitigation Measure 4.10-2b, Restrict Truck Operations
Mitigation Measure 4.16-8a, Limiting Hourly Truck Volumes and Restricting Truck Operations on Haul Routes for Multiple WSIP Projects
Mitigation Measure 4.16-8b, Vacate Land Manager's Residence for All Projects in Sunol Valley Region

5. Cumulative Facilities Impacts

Impact 4.17-5 – Cumulative increase in impacts on archaeological, paleontological, and historical resources. Potentially significant and unavoidable cumulative cultural resource impacts were identified in association with all of the following facility improvement project regions. (DEIR, pp. 4.17-52 to 4.17-53, 6-26 to 6-30.)

Mitigation Measure 4.7-4a, Alternatives Identification and Resource Relocation
Mitigation Measure 4.7-4b, Historical Resources Documentation
Mitigation Measure 4.7-4c, Secretary of the Interior's Standards for Treatment of Historic Properties
Mitigation Measure 4.7-4d, Historic Resources Survey and Redesign
Mitigation Measure 4.7-4e, Historic Resources Protection Plan
Mitigation Measure 4.7-4f, Preconstruction Surveys and Vibration Monitoring

Impact 4.17-6 – Cumulative traffic increases on local and regional roads. Potentially significant and unavoidable cumulative traffic impacts were identified in association with all of the following facility improvement project regions. (DEIR, pp. 4.17-54 to 4.17-57, 6-33.)

Mitigation Measure 4.8-1a, Traffic Control Plan Measures
Mitigation Measure 4.8-1b, Coordination of Individual Traffic Control Plans
Mitigation Measure 4.16-6a, SFPUC WSIP Projects Construction Coordinator
Mitigation Measure 4.16-6b, Combined San Joaquin Traffic Control Plan
Mitigation Measure 4.16-6c, Combined Sunol Valley Traffic Control Plan
Mitigation Measure 4.17-6, SFPUC WSIP Projects Construction Coordinator – Other Agencies

Impact 4.17-7 – Cumulative increases in construction and/or operational emissions in the region. Potentially significant and unavoidable cumulative air quality impacts were identified in association with all of the following facility improvement project regions. (DEIR, pp. 4.17-57 to 4.17-59, 6-34 to 6-38.)

Mitigation Measure 4.9-1a, SJVAPCD Dust Control Measures
Mitigation Measure 4.9-1b, SJVAPCD Exhaust Control Measure
Mitigation Measure 4.9-1c, BAAQMD Dust Control Measures
Mitigation Measure 4.9-1d, BAAQMD Exhaust Control Measures
Mitigation Measure 4.11-2, Waste Reduction Measures
Mitigation Measure 4.15-2, Incorporation of Energy Efficient Measures
Mitigation Measure 4.16-7a, Dust and Exhaust Control Measures for All WSIP Projects
Mitigation Measure 4.17-6, SFPUC WSIP Projects Construction Coordinator – Other Agencies

Impact 4.17-8 – Cumulative increases in construction-related and operational noise. Potentially significant and unavoidable cumulative noise impacts were identified in association with all of the following facility improvement project regions. (DEIR, pp. 4.17-59 to 4.17-60, 6-43.)

Mitigation Measure 4.10-2a, Limit Hourly Truck Volumes
Mitigation Measure 4.10-2b, Restrict Truck Operations
Mitigation Measure 4.17-8, Coordination of Truck Traffic on Local Streets

V. EVALUATION OF PROGRAM ALTERNATIVES

This Section describes the Phased WSIP Variant as well as the Program Alternatives and the reasons for approving the Phased WSIP Variant and for rejecting the Alternatives. This Article also outlines the Phased WSIP Variant's purposes and provides a context for understanding the reasons for selecting or rejecting alternatives.

CEQA mandates that an EIR evaluate a reasonable range of alternatives to the Project or the Project location that generally reduce or avoid potentially significant impacts of the Project. CEQA requires that every EIR also evaluate a "No Project" alternative. Alternatives provide a basis of comparison to the Project in terms of their significant impacts and their ability to meet Program objectives. This comparative analysis is used to consider reasonable, potentially feasible options for minimizing environmental consequences of the Project.

A. Reasons for Selection of the 2018 Phased Project Variant

The overall goals of the Phased WSIP Variant for the regional water system are to:

- Maintain high-quality water and a gravity-driven system
- Reduce vulnerability to earthquakes
- Increase delivery reliability
- Meet customer water supply needs through 2018
- Enhance sustainability
- Achieve a cost-effective, fully operational system

The SFPUC staff recommended this Variant in order to fully implement all proposed WSIP facility improvement projects to insure that the public health, seismic safety and delivery reliability goals of the WSIP are achieved as soon as possible while phasing implementation of a water supply program to meet projected water purchases through 2030. Deferring a decision on the 2030 water supply element of the WSIP until 2018 allows the SFPUC and its wholesale customers to focus first on implementing additional local recycled water, groundwater and demand management actions while minimizing additional diversions from the Tuolumne River. Under the Phased WSIP Variant, the SFPUC would establish an interim mid-term planning horizon – 2018. By adopting this Variant, the SFPUC is deferring a decision regarding long-term water supply until 2018 in light of then-current information and updated analysis. Because it remains at present unclear whether in 2018 the SFPUC will approve a water supply scenario for 2030 with adverse environmental effects beyond those associated with the Phased WSIP Variant, the Phased WSIP Variant may, in the long run, have a lesser level of environmental effect than the original WSIP. All non-water supply related WSIP goals and level of service objectives would be achieved under this Variant and all individual WSIP facility improvement projects proposed in the original WSIP would be constructed.

It is necessary to implement all of the WSIP facility improvement projects in order to achieve the program goals of the Phased WSIP Variant, as set forth in Section I of these findings, above. The Phased WSIP Variant is superior to the Alternatives in achieving the urgent goals of the WSIP; it allows the SFPUC to meet its water quality, seismic safety and water delivery reliability goals while minimizing effects on the SFPUC watersheds through 2018. The Phased WSIP Variant also focuses efforts on conservation, recycling and groundwater projects before deciding whether to increase deliveries from the watersheds.

As discussed above, impacts from Phased WSIP Variant would be less than those for the original WSIP because (1) the impact on Tuolumne River would be less and likely of shorter duration, and (2) certain impacts in the Pilarcitos watershed and in the Alameda Creek watersheds would not occur with Phased WSIP Variant.

B. Alternatives Rejected and Reasons for Rejection

The Commission rejects the Alternatives set forth in the Final PEIR and listed below because the Commission finds that there is substantial evidence, including evidence of economic, legal, social, technological, and other considerations described in this Section in addition to those described in Section VII below under CEQA Guidelines 15091(a)(3), that make infeasible such Alternatives. In making these determinations, the Commission is aware that CEQA defines “feasibility” to mean "capable of being accomplished in a successful manner within a reasonable period of time, taking into account economic, environmental, social, legal, and technological factors.” The Commission is also aware that under CEQA case law the concept of “feasibility” encompasses (i) the question of whether a particular alternative promotes the underlying goals and objectives of a project. and (ii) the question of whether an alternative is “desirable” from a policy standpoint to the extent that desirability is based on a reasonable balancing of the relevant economic, environmental, social, legal, and technological factors.

In addition, adoption of the Phased WSIP Variant will reduce many of the water supply impacts associated with increased diversions until at least 2018, and the additional water conservation, recycling and groundwater projects will have the effect of reducing the projected demand for water to be diverted from the SFPUC watersheds through 2018 and beyond. Some of the alternatives are less effective in reducing environmental impacts associated with water supply than the Phased WSIP Variant and are not environmentally superior to the Phased WSIP Variant because they do not attempt to reduce projected demand for water but would look to development of alternative sources of water, each of which has environmental effects. While some of the other alternatives would avoid or lessen certain WSIP impacts, they would also result in substantial additional impacts that the Phased WSIP Variant would not generate, because these alternatives would require substantial additional major facilities and affect other environmental resources in different geographic locations in addition to those affected by the Phased WSIP Variant. There would thus be no basis under CEQA for selecting a particular alternative where this is the case. The Phased WSIP Variant also incorporates elements of three alternatives, the No Purchase Request Alternative, the Aggressive Conservation/Water Recycling and Groundwater Alternative, and the Modified WSIP Alternative, as described below. Therefore, the Commission is not rejecting those alternatives in their entirety.

1. No Program Alternative

Under the No Program Alternative, the SFPUC would implement only those facility improvement projects driven by regulatory requirements or existing agreements with regulatory agencies. The system would meet the water quality goals of the WSIP, but it would fail to meet the seismic and delivery reliability goals and would have limited ability to serve the increase in customer purchase requests through 2018, as both the magnitude and frequency of rationing would increase in response to droughts. The SFPUC would endeavor to meet increasing customer purchase requests by diverting additional Tuolumne River water only when available. It would not secure an additional dry-year supply transfer of Tuolumne River water, implement the Westside Basin groundwater conjunctive-use program, or develop the proposed recycled water and groundwater projects in San Francisco or the wholesale customer service area. The wholesale customers may decide to pursue supplemental supply sources and/or conservation measures to make up for the reduced reliability and the supply shortfall under this alternative, but this would occur outside of and independent of the WSIP. Compared to the Phased WSIP Variant, this alternative would develop less in terms of new water supplies for the regional system and would implement far fewer of the proposed facility improvement projects. (DEIR, pages 9-23 to 9-40.)

Although it appears that fewer facility improvement projects would be implemented under the No Program Alternative and that, as a result, there would be fewer facility construction and operation impacts, it is expected that there would be much more emergency facility repair and replacement projects under this alternative as the system continues to age without proactive improvement. Ultimately, through required repair and replacement efforts, a similar level of facility improvement projects as that proposed under the Phased WSIP Variant might have to be conducted under the No Program Alternative, resulting in much of the same facility impacts as the Phased WSIP Variant; however, these repair and replacement projects would likely occur over a longer period of time and in a less coordinated and comprehensive manner. In addition, implementing system improvements through a piecemeal and largely emergency response approach could result in greater environmental impacts and less mitigation for such impacts;

when projects are implemented under emergency conditions, they often require little or no environmental review (see Pub. Resources Code, § 21080, subds. (b)(2), (b)(4)) and thus could be implemented without the same level of mitigation and mitigation compliance monitoring that would be required for the Phased WSIP Variant. Furthermore, piecemeal implementation could also increase the cumulative effects of multiple, sequential facility repair and replacement projects throughout the system.

The Commission rejects this Alternative because it will not meet the fundamental and most pressing needs of the water system – to improve the seismic safety and reliability of the water system as a means of saving human life and property under a catastrophic earthquake scenario or even a disaster scenario not rising to the level of catastrophic. As the system ages, its reliability decreases and the risk of failure increases. The 167-mile-long system crosses five active earthquake faults. Many of the SFPUC regional water system components are located on or in the immediate vicinity of major earthquake faults. Due to the age of the system, many facilities do not meet modern seismic standards. In order to implement a feasible asset management program in the future that will provide continuous maintenance and repairs to facilities, the regional water system requires redundancy (i.e., backup) of some critical facilities necessary to meeting day-to-day customer water supply needs. Without adequate redundancy of critical facilities, the SFPUC has limited operational flexibility in the event of an emergency or a system failure, as well as constraints on conducting adequate system inspection and maintenance. This Alternative would place the water system at significant risk to seismic hazards, increased facility failures, and increased supply shortages on a day-to-day basis, as well as result in prolonged service disruptions to many customers in the event of an earthquake or other emergency due to inadequate facility redundancy and operational flexibility. This Alternative is rejected as infeasible because it meets none of the vitally important Program objectives.

2. No Purchase Request Increase Alternative

As described in the PEIR, the No Purchase Request Increase Alternative is designed to serve wholesale customers only the amount of water required under the existing Master Water Sales Agreement between the City and County of San Francisco and each of the wholesale customers through 2030. Under the No Purchase Request Increase Alternative, the SFPUC would implement all of the proposed WSIP facility improvement projects. It is expected that the wholesale customers would pursue supplemental supply sources and/or conservation measures to make up the supply shortfall under this alternative, but this would occur outside of and independent of the WSIP. This alternative was included in the alternatives analysis in an effort to avoid or minimize the potential growth-inducing effects and secondary effects of growth associated with providing more water to the regional customers, and the PEIR evaluates the effects of this water supply approach on the SFPUC watersheds.

This Commission acknowledges that the Phased WSIP Variant is similar to this Alternative through the 2018 planning period. However, unlike the No Purchase Request Alternative, the Phased WSIP Variant includes financial incentives to induce the wholesale customers to limit water use and thus minimize increases in diversions from the SFPUC watersheds or other locations, and instead, emphasizes the development of alternative sources of water, including conservation measures, recycling projects and local groundwater development. This Commission adopts those portions of the No Purchase Request Increase Alternative that are the same as those included within the Phased WSIP Variant and rejects the remaining aspects of the No Purchase Request Increase Alternative as infeasible, as they do not incorporate the mitigation measures, the financial incentives or the re-evaluation of the customer demands in 2018. The Commission finds that the Phased WSIP Variant is similar to this Alternative, but the Variant provides a mechanism to re-evaluate the long term water demands and the need to divert more water from the SFPUC watersheds in 2018. The Phased WSIP Variant also provides that the SFPUC and the customers will develop the most effective and financially feasible methods of providing recycled water and implementing conservation measures as a priority in the next ten years.

To the extent that the No Purchase Request Increase Alternative would fail to increase SFPUC water deliveries through 2030 and not just through 2018, the Commission rejects the alternative as infeasible for that reason alone. It is foreseeable that, within the next 22 years, the population and economic trends within the SFPUC service area will create a substantial demand for new water supplies, even with aggressive conservation efforts. Under the Phased WSIP Variant, the SFPUC would wait until 2018 to determine whether and how to address demands arising between 2018 and 2030. This latter approach is more realistic and responsible from a public policy standpoint, in that it (i) acknowledges the likelihood of increasing customer demands between 2018 and 2030 and (ii) does not essentially force existing SFPUC customers to seek other sources for their needed new long-term water supplies, some of which may be more environmentally damaging than increasing the yield from the SFPUC system from averages of 265 mgd annually to an average of 300 mgd annually. Compared with the No Purchase Increase Alternative, the Phased WSIP Variant delays a decision on supply needs between 2018 and 2030 for a decade in order to give SFPUC customers the chance to maximize their conservation efforts and identify any available, environmentally sustainable source alternatives, while not making any irrevocable decision to deny SFPUC supply increases after 2018. In short, after balancing competing policy considerations and the extent to which the No Purchase Request Increase Alternative would address the SFPUC's long-term water supply objective, the Commission rejects as infeasible within the meaning of CEQA those portions of the No Purchase Request Increase Alternative not included within the Phased WSIP Variant.

3. Aggressive Conservation/Water Recycling and Local Groundwater Alternative

As described in the PEIR, under this alternative, the SFPUC would implement all of the proposed WSIP facility improvement projects, but would endeavor to serve the projected increase in customer purchase requests through 2030 using only additional conservation, water recycling, and local groundwater projects. It does not appear feasible, however, to fully meet the 2030 purchase requests with reasonably foreseeable conservation, recycled water, and groundwater projects within the service area. Therefore, under the Aggressive Conservation/Water Recycling and Local Groundwater Alternative, the SFPUC would have to either: (a) limit future customer purchase deliveries to the level that can be met, short of the 2030 requests (approximately 294 mgd under the most optimistic scenario instead of 300 mgd average annual) and increase the level of rationing to 25 percent or more during droughts, or (b) provide a supplemental supply to make up the delivery shortfall to meet the 300 mgd.

The Phased WSIP Variant incorporates the most important elements of this Alternative through 2018. The Variant establishes financial incentives to induce the wholesale customers to develop conservation, recycled water and groundwater projects and thus limit deliveries from the SFPUC watersheds to an average annual 265 mgd. The Phased WSIP Variant allows the SFPUC to re-evaluate water demands and the efficacy of the conservation, recycling and groundwater programs in 2018. In the Phased WSIP Variant, the SFPUC will implement 10 mgd of conservation, recycling and groundwater projects in San Francisco, and the wholesale customers will develop an additional 10 mgd of conservation, recycling and groundwater projects in the wholesale customer service area. This Commission rejects this Alternative insofar as it makes a water supply decision to attempt to meet demand of 300 mgd through 2030 (although it may be ineffective in meeting that demand and force customers to seek water from other entities); instead, the Phased WSIP Variant focuses the SFPUC and the customers on implementation of conservation, recycling and local groundwater projects before 2018. The SFPUC will then re-evaluate the water supply decision in 2018.

To the extent that the Aggressive Conservation/Water Recycling and Local Groundwater Alternative does not include sufficient supplies to deal with foreseeable customer demand through 2030, the Commission rejects those portions of the Aggressive Conservation/Water Recycling and Local Groundwater Alternative not included within the Phased WSIP Variant as infeasible for that reason alone. Under the Phased WSIP Variant, unlike the Aggressive Conservation/Water Recycling and Local Groundwater Alternative, the SFPUC has not refused to supply the amounts of water predicted to be needed by customers in 2030, but rather has delayed any such decision until 2018. The Phased WSIP Variant thus has the virtues of being more realistic and responsible from a public policy standpoint, in that it (i) acknowledges the likelihood of increasing customer demands between 2018 and 2030 and (ii) does not essentially force existing SFPUC customers to seek other sources for their needed new long-term water supplies, some of which may be more environmentally damaging than increasing the yield from the SFPUC system to the levels predicted to be needed in 2030. Compared with the Aggressive Conservation/Water Recycling and Local Groundwater Alternative, the Phased WSIP Variant delays a decision on supply needs between 2018 and 2030 for a decade in order to give all SFPUC customers the chance to maximize their conservation efforts and identify any available, environmentally sustainable source alternatives, while not making any irrevocable decision to deny SFPUC supply increases after 2018. In short, after balancing competing policy considerations and the extent to which the Aggressive Conservation/Water Recycling and Local Groundwater Alternative would address the SFPUC's long-term water supply objective, the Commission rejects as infeasible within the meaning of CEQA those portions of the Aggressive Conservation/Water Recycling and Local Groundwater Alternative not included within the Phased WSIP Variant.

4. Lower Tuolumne River Diversion Alternative

As described in the PEIR, under the Lower Tuolumne River Diversion Alternative, the SFPUC would implement all of the proposed facility improvement projects and would serve the projected increase in customer purchase requests through 2030 through diversions from the lower Tuolumne River near its confluence with the San Joaquin River, assuming it could reach agreement with TID and MID. This alternative would include construction and operation of additional conveyance and treatment facilities to divert, transport, treat, and blend the new supply into the regional system. This Alternative represented an alternative source of supply and was evaluated to address impacts on the Tuolumne River and related resources.

This Commission rejects this Alternative as infeasible. The ability to implement this Alternative is uncertain, given the number of agreements and approvals that would be required to construct the diversion and treatment facilities. Because the Phased WSIP Variant proposes to limit sales of water from the SFPUC watersheds to 265 mgd through 2018, the effects on the Tuolumne River would be substantially less since much less water would be diverted from the Tuolumne River watershed. Through 2018, the Phased WSIP Variant will divert an average annual 2 mgd more than SFPUC currently diverts from the Tuolumne River to meet its delivery and drought reliability objectives. There will be no need to construct additional conveyance and treatment facilities to divert, transport, treat, and blend the new supply into the regional system and incur the financial or the environmental costs that such construction will necessitate, as analyzed by the SFPUC in its Report (SFPUC, Water Supply Options, 2007 [Appendix C, *WSIP Alternative Water Supply Option 3*, prepared by SFPUC and Parsons, June 2006).

The analysis in the Draft PEIR concluded that the environmental impacts of this alternative would result in greater impacts on the Tuolumne River resources than the original WSIP or the Phased WSIP Variant. This Alternative would not meet the SFPUC's most basic objective of maintaining a gravity-driven system. This Alternative would require construction of pumping and treatment facilities in order to divert water from the lower Tuolumne River. This Alternative will result in far more impacts than the Phased WSIP Variant on the watershed and its resources, including fisheries, due to the construction and operation of the facilities that must be constructed to implement this Alternative. The Phased WSIP Variant is superior to this Alternative because the Phased WSIP Variant focuses first on developing more conservation, water recycling and groundwater projects before determining to divert more water from the Tuolumne River on a long-term, extended basis. Therefore, there should be no need to construct a diversion structure prior to 2018.

In short, after balancing competing policy considerations and the extent to which the Lower Tuolumne River Diversion Alternative would result in greater environmental impacts and address the SFPUC’s long-term water supply objective, the Commission rejects the Lower Tuolumne River Diversion Alternative as infeasible within the meaning of CEQA.

5. Year-round Desalination at Oceanside Alternative

As described in the PEIR, under the Year-round Desalination at Oceanside Alternative, the SFPUC would implement all of the proposed WSIP facility improvement projects and would construct a 25-mgd desalination plant in San Francisco to serve the projected increase in customer purchase requests through 2030. This alternative would not involve increased levels of diversions from the Tuolumne River. The desalination plant would provide year-round supplies during all hydrologic year types to blend into the regional system at the Sunset Reservoir in San Francisco. Compared to the originally proposed WSIP, this alternative represents an alternative source of supply and was evaluated to address the potential impacts on the Tuolumne River, Alameda Creek, and Peninsula watersheds, including Pilarcitos Creek, and related resources. (DEIR, pp. 9-66 to 9-74.) Compared to the Phased WSIP Variant, it provides a supply of water that is not yet needed but has significant environmental effects of its own, as discussed below.

This Commission rejects this Alternative as infeasible at this time for the following reasons. Construction and operation of a desalination facility raises unresolved environmental issues, including questions about protecting aquatic resources, water quality and brine disposal issues. The plant would require significant increases in long-term energy use compared to the Phased WSIP Variant. Because in California today, such energy generation typically involves the use of fossil fuels, the energy demands of a desalination facility will exacerbate global climate change by increasing emissions of greenhouse gases (GHGs), in contravention of state policy as embodied in the California Global Warming Solutions Act of 2006, also known as AB 32. This Alternative is also likely to be quite costly for the SFPUC, as analyzed by the SFPUC in its Report (SFPUC, Water Supply Options, 2007 [Appendix C, *WSIP Alternative Water Supply Option 3*, prepared by SFPUC and Parsons, June 2006). Feasibility of the desalination plant is also uncertain at this time; it would require numerous additional permits and approvals from, among other agencies, the California Department of Health Services, the U.S. Army Corps of Engineers, the RWQCB and the California Coastal Commission. It is unlikely that this facility can be approved and constructed in time to meet demand projections in the next 10 years. Thus the Phased WSIP Variant is not only more feasible from technological and timing perspectives but also will have fewer environmental impacts because of its focus on conservation, recycling and local groundwater projects. Instead, this Commission believes that efforts should be made to implement conservation measures, recycling projects and groundwater projects to meet additional water supply demands in the relative short term; following those efforts, demand for water supply can be reassessed in 2018.

In short, after balancing competing policy considerations and the extent to which the Year-round Desalination at Oceanside Alternative would add a great deal of complexity and uncertainty to the satisfaction of the SFPUC's long-term water supply objective, the Commission rejects the Year-round Desalination at Oceanside Alternative as infeasible within the meaning of CEQA.

6. Regional Desalination for Drought Alternative

As described in the PEIR, under the Regional Desalination for Drought Alternative, the SFPUC would implement all of the proposed WSIP facility improvement projects and would partner with other Bay Area water agencies to construct and operate a regional desalination plant that would provide the SFPUC with supplemental supply during drought years. Compared to the originally proposed WSIP, this alternative represents an alternative source of water supply and was evaluated to address the potential impacts on the Tuolumne River.

This Commission does not fully reject this Alternative because the SFPUC is currently exploring a regional desalination plant for drought, as a partial long-term solution to water supply and demand. The SFPUC is participating in the development of feasibility studies and pilot testing to determine the viability of the regional desalination plant. If found to be feasible, the SFPUC would contribute funds towards environmental review, project construction and operation of the plant. Development of this Alternative would require construction of multiple components, cooperation agreements with other agencies, and local, state and federal regulatory approvals. There are many unresolved environmental issues, including questions about protecting aquatic resources, water quality and brine disposal issues. The plant would require significant increases in long-term energy use compared to the Phased WSIP Variant. Because in California today, such energy generation typically involves the use of fossil fuels, the energy demands of a desalination facility will exacerbate global climate change by increasing GHG emissions, in contravention of state policy as embodied in AB 32. Depending on the agreements with other participating agencies, this Alternative could also be quite costly for the SFPUC as analyzed by the SFPUC in the Bay Area Regional Desalination Project Pre-feasibility Study, Final Report, prepared by URS Corporation, 2003. While the desalination may provide a partial solution to diverting more water from the SFPUC watersheds, it does not appear to be environmentally superior to the Phased WSIP Variant through 2018. Instead, this Commission believes that a combination of efforts to be made under the Phased WSIP Variant to limit deliveries from the SFPUC watersheds to approximately 265 mgd, average annual, as well as implementation of conservation measures, recycled water projects and groundwater projects to meet additional water supply demands in the relative short term, presents a better approach to water system management. In the near-term, this Commission considers this Alternative to be infeasible to fulfill dry year or drought water supply needs because of the potential financial and environmental costs and the uncertainty regarding the SFPUC's ability to secure all necessary agreements and approvals to implement the Alternative. This Alternative proposes a desalination facility that is in the beginning stages of feasibility analyses, and many issues remain to be resolved.

After balancing competing policy considerations and the extent to which the Regional Desalination for Drought Alternative would add a great deal of complexity and uncertainty to the satisfaction of the SFPUC’s long-term water supply objective, the Commission presently rejects the Regional Desalination for Drought Alternative as infeasible within the meaning of CEQA. In doing so, however, the SFPUC is by no means closing the door permanently on eventual participation in a regional desalination facility. As part of its assessment in 2018 as to whether to increase Tuolumne River diversions to meet anticipated 2030 demand in its service area, the SFPUC will assess any progress the region has made towards putting in place, on a timely basis and under acceptable environmental conditions, a facility for desalinating seawater as a source of supplemental water supply during droughts. Any such facility is simply too ill-defined and uncertain at present to be adopted at this time.

7. Modified WSIP Alternative

The Modified WSIP Alternative would implement all of the proposed facility improvement projects, but would modify proposed system operations to minimize environmental effects. This alternative would include as part of its "Project description" the implementation of key mitigation measures identified for the originally proposed WSIP in the PEIR, including acquiring a water transfer of conserved water as a supplemental dry-year source, implementing a minimum instream flow requirement for resident fish in a portion of Alameda Creek, incorporating mitigation measures to address impacts in the Pilarcitos Creek watershed**,** managing the inundation levels at Crystal Springs Reservoir to preserve upland habitat to the extent possible, and increasing recycled water, conservation, and local groundwater in partnership with wholesale customers. It also requires that any additional water diverted from the upper Tuolumne River must be offset by conservation efforts for water to be released to the lower Tuolumne River. This Alternative proposes to divert an average annual 15 mgd additional water from the Tuolumne River between Hetch Hetchy and Don Pedro Reservoirs compared to existing conditions. This alternative was evaluated to address the impacts identified for the originally proposed WSIP on the Tuolumne River, Alameda Creek, and Peninsula watersheds, including Pilarcitos Creek and Crystal Springs Reservoir, and related resources. (DEIR, pp. 9-78 to 9-84; C&R Section 14.10.)

Water supply sources in both the Modified WSIP Alternative and the Phased WSIP Variant are similar, but differ in a few respects. First, the Modified WSIP Alternative proposes to divert an additional annual average of 15 mgd from the upper Tuolumne River compared to existing conditions through 2030 and thus would result in diverting more water from the Tuolumne River than would occur under the Phased WSIP Variant through 2018. Under the Modified WSIP Alternative, water would be diverted at Hetch Hetchy Reservoir to meet 2030 demand. That diversion would result in reduced inflow to Don Pedro Reservoir, which, under this Alternative, would be offset by reduced outflow from Don Pedro because of conservation measures undertaken by MID or TID (and/or in the service area of another nearby water agency). Water releases from Don Pedro Reservoir to the lower Tuolumne River thus would be the similar to existing conditions under the Modified WSIP Alternative. The Phased WSIP Variant proposes long-term increases in diversions of about 2 mgd, average annual, from the Tuolumne River to meet the Program's reliability and drought rationing objectives and would maintain total deliveries to customers from the watersheds at 265 mgd, average annual. In the short term, the Phased WSIP Variant may result in the need to deliver more than a total of 265 mgd, average annual, to customers for a limited period while local conservation, recycling and groundwater programs are being implemented. Where the Phased WSIP Variant diverts more than an average annual of 265 mgd from the watersheds, mitigation measures will be implemented for the Lower Tuolumne River.

Second, the approach to the dry-year transfer is slightly different for the Modified WSIP Alternative and the Phased WSIP Variant. The Westside Groundwater Basin conjunctive use program would provide a supplemental dry-year water supply source for both the Phased WSIP Variant and the Modified WSIP Alternative. The dry-year water transfer from TID and MID under the Modified WSIP Alternative would be a transfer made only from conserved water (approximately 17.5 mgd average over the design drought). The Phased WSIP Variant does not rule out the possibility of using conserved water only, and includes preferred mitigation measure 5.3.6-4a to be implemented if average annual deliveries of water from the watersheds exceeds 265 mgd, but it does not require that dry-year transfers be conserved water only (approximately 2 mgd average over the design drought). Thus, the substantially reduced size of the dry-year transfer under the Phased WSIP Variant compared to the Modified WSIP Alternative combined with the urgency of undertaking the improvements and increasing reliability through implementation of the dry year supply measures make it difficult to require that no transfer occur without equal and balancing conservation measures in MID/TID service area at this time.

Third, the Phased WSIP Variant proposes more conservation, recycling and groundwater programs than the Modified WSIP Alternative. Both the Alternative and the Variant assume 10 mgd of conservation, recycling and groundwater programs in San Francisco. While the Modified WSIP Alternative commits to 5 – 10 mgd of additional conservation, recycling and groundwater programs in the wholesale customer area through 2030, the Phased WSIP Variant requires that a minimum of 10 mgd of additional conservation, recycling and groundwater programs be implemented in the wholesale customer area by 2018.

The Modified WSIP Alternative would result in more impacts on the upper Tuolumne River watershed than the Phased WSIP Alternative, but possibly fewer impacts on the lower Tuolumne River watershed if under the Phased WSIP Variant, average annual deliveries from the watersheds were to exceed 265 mgd in the short-term. The Modified WSIP Alternative would lessen but not entirely eliminate impacts on the lower Tuolumne River, but the impacts would be considered less than significant. (See C&R, Section 14.10, pages 14.10-2 – 14.10-26.) As long as average annual deliveries from the watersheds do not exceed 265 mgd under the Phased WSIP Variant, impacts on the lower Tuolumne River would be considered less than significant; mitigation measures will be implemented any time the SFPUC's average annual deliveries from the watersheds exceed an average annual total of 265 mgd.

In the Alameda Creek watershed, the impacts of the Phased WSIP Variant and the Modified WSIP Alternative are essentially the same. The SFPUC has already incorporated the Alameda Creek bypass flows between the Alameda Creek Diversion Dam and the confluence with Calaveras Creek as protective measures under the Calaveras Dam Replacement project (SV-2), and is adopting now the mitigation measures proposed for the Alameda Creek watershed, so the Modified WSIP Alternative and the Phased WSIP Variant result in similar impacts in the Alameda Creek watershed.

The Modified WSIP Alternative incorporated as part of its "project description" four mitigation measures proposed for operations at Pilarcitos Reservoir and Stone Dam to reduce identified significant impacts of the originally proposed WSIP in the Pilarcitos Creek watershed to a less than significant level. The Phased WSIP Variant would not have any significant impacts in the Pilarcitos watershed through 2018 because operations would be similar to existing conditions. The impacts of the Modified WSIP Alternative and the Phased WSIP Variant are fairly similar; the Phased WSIP Variant avoids the significant impacts, and the Modified WSIP Alternative incorporates mitigation measures to reduce the significant impacts to a less than significant level.

The Final PEIR concluded that impacts of the proposed Crystal Springs Reservoir operations would be potentially significant and unavoidable for both the Modified WSIP Alternative and the Phased WSIP Variant with respect to Impact 5.5.5-1, effects on trout spawning habitat along Laguna and San Mateo Creeks. The impacts would be reduced with implementation of mitigation measures, but impacts would remain potentially significant under both scenarios. Both scenarios assume that the impacts and mitigation measures will be re-evaluated in detail at the project level and refined as part of the environmental review of the Lower Crystal Springs Dam Improvements project (PN-4). Impacts on terrestrial biological resources in upper and lower Crystal Springs Reservoirs are significant and mitigable for both the Phased WSIP Variant and the Modified WSIP Alternative, although the impacts may be slightly less under the Modified WSIP Alternative.

The Modified WSIP Alternative includes implementation of potentially fewer long-term conservation, water recycling and local groundwater projects within the regional service area than under the Phased WSIP Variant. While construction of these facilities would cause temporary construction disruption and related environmental impacts, long-term implementation of these regional conservation, water recycling, and local groundwater projects would offset impacts of the operational modifications proposed under the Modified WSIP Alternative on the Tuolumne River. Compared to the Phased WSIP Variant, the Modified WSIP Alternative would result in approximately the same impacts on land use, air quality, noise, traffic, and energy in urban environments (expected to be largely mitigable). Both the Phased WSIP Variant and the Modified WSIP Alternative will result in fewer and significantly less severe impacts on biological and fishery resources in natural habitats than the originally proposed WSIP.

The Modified WSIP Alternative was identified as the environmentally superior alternative in the Draft PEIR for the 2030 planning horizon. It would reduce key impacts of the originally proposed WSIP on natural resources along the lower Tuolumne River, in Alameda and Pilarcitos Creeks, and in/around Crystal Springs and Pilarcitos Reservoirs, but it would continue to meet the WSIP's primary goals and objectives. Like the Phased WSIP Variant, this alternative would maximize the use of existing facilities and the largely gravity-driven system without also requiring the construction of additional major facilities called for under many other alternatives, or substantially increasing the energy demand of the system or need for pumping. This Alternative will have more impacts on the upper Tuolumne River, and possible less on the Lower Tuolumne River. It is not entirely clear that the Modified WSIP Alternative is substantially environmentally superior to the Phased WSIP Variant and does not provide a strong basis for selecting this Alternative.

This Commission finds that the Phased WSIP Variant is substantially similar to this Alternative in that it includes essentially the same elements relevant through 2018. The Commission rejects this Alternative insofar as it makes a decision through 2030; instead, the Phased WSIP Variant focuses the SFPUC and the customers on implementation of conservation, recycling and groundwater projects before 2018. The SFPUC will then re-evaluate the water supply decision in 2018. The Modified WSIP Alternative incorporates as part of the program most of the mitigation measures proposed for the original WSIP in the PEIR. Because this Commission is adopting all relevant mitigation measures as part of this Phased WSIP Variant approval, most of the impacts of the two approaches are similar.

The feasibility of this Alternative is not easily confirmed because of its reliance on MID and TID and/or another water supplier for conserved water of 15 mgd average annual, as well as the dry year transfer. If the SFPUC could not procure conserved water from the MID, TID or another water supplier, then no additional diversions from the Tuolumne River could occur under this Alternative. Such an outcome would push the Alternative in the direction of the No Purchase Request Increase Alternative, and the impacts of this Alternative would thus become similar to the No Purchase Request Increase Alternative.

After balancing competing policy considerations, including the extent to which those components of the Modified WSIP Alternative not included in the Phased WSIP Variant would delay resolution of key issues relating to the TID-MID dry-year "conserved water" transfer and operating criteria at Crystal Springs Reservoir, the Commission presently rejects as infeasible within the meaning of CEQA those components the Modified WSIP Alternative not included within the Phased WSIP Variant. In doing so, however, the SFPUC recognizes that mitigation measure 5.3.6-4a is the preferred mitigation measure and should be undertaken as part of the Phased WSIP Variant. The SFPUC is by no means closing the door on the possibility of an dry-year "conserved water" transfer from TID and MID. Whether the SFPUC will ultimately be able to implement the dry year transfer of conserved water will depend on complex negotiations, regulatory issues, cost considerations, and other issues that may or may not be possible for the various agencies involved to resolve within a reasonable time frame or during implementation of the Phased WSIP Variant.

VII. STATEMENT OF OVERRIDING CONSIDERATIONS

Pursuant to CEQA section 21081 and CEQA Guideline 15093, the Commission hereby finds, after consideration of the Final PEIR and the evidence in the record, that each of the specific overriding economic, legal, social, technological and other benefits of the Program as set forth below independently and collectively outweighs these significant and unavoidable impacts and is an overriding consideration warranting approval of the Program. Any one of the reasons for approval cited below is sufficient to justify approval of the Program. Thus, even if a court were to conclude that not every reason is supported by substantial evidence, the Commission will stand by its determination that each individual reason is sufficient. The substantial evidence supporting the various benefits can be found in the preceding findings, which are incorporated by reference into this Section, and in the documents found in the Record of Proceedings, as defined in Section I.

On the basis of the above findings and the substantial evidence in the whole record of this proceeding, the Commission specially finds that there are significant benefits of the proposed Program to support approval of the Phased WSIP Variant in spite of the unavoidable significant impacts, and therefore makes this Statement of Overriding Considerations. The Commission further finds that, as part of the process of obtaining Program approval, all significant effects on the environment from implementation of the Phased WSIP Variant have been eliminated or substantially lessened where feasible. All mitigation measures proposed in the PEIR for this Variant are adopted as part of this approval action. Furthermore, the Commission has determined that any remaining significant effects on the environment found to be unavoidable are acceptable due to the following specific overriding economic, technical, legal, social and other considerations.

The Phased WSIP Variant has the following benefits:

1. Implementation of facility improvement projects will reduce vulnerability to earthquakes. Improvements are designed to meet current seismic standards. The regional water system is a critical and vulnerable link in the City's and wholesale customer's ability to survive after a major earthquake and to maintain access to critically needed water supplies. Not only will water be

necessary for human consumption, but will provide emergency water supply after an earthquake to protect the public health and safety. The SFPUC will be able to meet the fundamental and most pressing needs of the water system – to improve the seismic safety and reliability of the water system as a means of saving human life and property under a catastrophic earthquake scenario or even a disaster scenario not rising to the level of catastrophic. As the system ages, its reliability decreases and the risk of failure increases. The 167-mile-long system crosses five active earthquake faults. Facilities located near these points of intersection are at risk of failure in the event of a major earthquake, an event considered likely in the next 30 years. Due to the age of the system, many facilities do not meet modern seismic standards. A failure of the water system could leave some customers without water for 10 – 30 days, and in some instances as long as 60 days. Alternative supplies will be limited. Many communities have only a few days of locally stored reserves in tanks and small reservoirs, most of which would be depleted within the first 48-72 hours of an emergency to meet the initial spike in demand for emergency services. Potential economic losses to the region from a water supply interruption as well as incremental damage from lack of adequate water supply to suppress post-quake fires would likely total tens of billions of dollars. The SFPUC system is a critical regional asset providing an essential service and commodity to the Bay Area economy. Its deteriorating condition places the regional economy and the welfare of millions of Bay Area residents at risk. Effecting the necessary repairs and improvements to assure the water system's continued reliability, and developing it as part of a larger, integrated water security strategy, is critical to the Bay Area's economic security, competitiveness and quality of life. (See "Hetch Hetchy Water and the Bay Area Economy", Bay Area Economic Forum 2002)

2. The SFPUC will be able to deliver basic service to the three regions in the service area (East/South Bay, Peninsula, and San Francisco) within 24 hours after a major earthquake.

3. The SFPUC will be able to restore facilities to meet projected average-day demand within 30 days after a major earthquake.

4. The Program reduces the physical, social, and economic impacts associated with the potential rupture of the existing system including, but not limited to, public health and safety, flooding, erosion, biological impacts, traffic interruption, and property damage.

5. The Program supports the economic vitality of the Region by fulfilling the water demands under emergency conditions.

6. The Water system will maintain high-quality water and a gravity-driven system, allowing the SFPUC to continue to provide clean, unfiltered water originating from Hetch Hetchy Reservoir and filter all other surface water sources.

7. Improvements are designed to meet current and foreseeable future federal and state water quality requirements.

8. The Phased WSIP Variant promotes on-going monitoring of watershed areas, limiting diversions while exploring all options and demand by 2018 – the dynamic nature of information and technology weighs in favor of making a decision on water supply only through 2018.

9. The Program will increase delivery reliability and improve the ability to maintain the water system, providing operational flexibility to allow planned maintenance shutdown of individual facilities without interrupting customer service, operational flexibility to minimize the risk of service interruption due to unplanned facility upsets or outages, and operational flexibility and system capacity to replenish local reservoirs as needed. In order to implement a feasible asset management program in the future that will provide continuous maintenance and repairs to facilities, the regional water system requires redundancy (i.e., backup) of some critical facilities necessary to meeting day-to-day customer water supply needs. Without adequate redundancy of critical facilities, the SFPUC has limited operational flexibility in the event of an emergency or a system failure, as well as constraints on conducting adequate system inspection and maintenance. Failure to implement the Program would place the water system at significant risk to seismic hazards, increased facility failures, and increased supply shortages on a day-to-day basis, as well as result in prolonged service disruptions to many customers in the event of an earthquake or other emergency due to inadequate facility redundancy and operational flexibility.

10. The SFPUC can meet the estimated average annual demand under the conditions of one planned shutdown of a major facility for maintenance concurrent with one unplanned facility outage.

11. The SFPUC can meet customer water supply needs; the Phased WSIP Variant would serve 265 mgd of retail and wholesale customer purchases from the SFPUC watersheds, and meet or offset the remaining 20 mgd through conservation, recycled water, and groundwater in the retail and wholesale service areas. Ten mgd of this would be met, as proposed under the WSIP, through conservation, recycled water, and groundwater projects in San Francisco, and 10 mgd would be met through local conservation, recycled water and groundwater in the wholesale service area.

12. The Phased WSIP Variant can meet dry-year delivery needs through 2018 while limiting rationing to a maximum 20 percent system-wide reduction in water service during extended droughts.

13. The Phased WSIP Variant diversifies water supply options during non-drought and drought periods.

14. The Phased WSIP Variant will substantially improve use of new water sources and drought management, including use of groundwater, recycled water, conservation, and transfers.

15. The Program will enhance sustainability in all system activities, including management of natural resources and physical systems to protect watershed ecosystems and to protect public health and safety.

16. The Phased WSIP Variant will achieve a cost-effective, fully operational system, ensuring cost-effective use of funds, and maintaining a gravity-driven system.

17. The water system will continue to provide a source of clean energy and require a low level of energy to run the system, both of which help maintain and minimize GHG emissions associated with water and power utility services.

18. The PEIR identified climate change as a factor that may affect regional water system operations due to potential changes in precipitation that originates as rainfall or snowmelt in the Tuolumne watershed, and the magnitude of rain events in the local system watersheds. Understanding and adapting to climate change as it affects watershed ecosystems will be an ongoing task for regional water system operators, but the science underlying the changes may be better known in 2018 than it is today. The Phased WSIP Variant will allow the SFPUC to benefit from a better understanding of the science and potential effects of climate change when it evaluates whether to increase water supply deliveries in 2018.

19. The PEIR identified at least three watersheds where increases in instream releases may be required by regulatory changes or in conformance with SFPUC stewardship goals, with corresponding reductions in regional water system yield. By 2018 most of these regulatory requirements or stewardship programs will have been implemented, thereby clarifying the reliability and yield of the regional water system. The Program gives the SFPUC the flexibility to take into consideration these issues when it evaluates whether to increase water supply deliveries in 2018.

To accomplish all of the SFPUC's objectives, it must move forward with the WSIP facility improvement projects as proposed, to improve seismic and water delivery reliability, to meet current and future water quality regulations, to provide for additional system conveyance for maintenance and delivery reliability, and to meet water supply reliability goals for 2018 and possibly beyond. Like all water utilities, the SFPUC must consider current needs as well as possible future changes and unplanned outages, and design a system that achieves a balance among the numerous objectives, functions and risks a water supplier must face. As prudent water managers, the SFPUC must make decisions about how to manage its water system effectively. Approval of the Phased WSIP Variant will allow the SFPUC to accomplish these many goals.

Having considered these benefits, including the benefits discussed in Section I above, the Commission finds that the benefits of the Program outweigh the unavoidable adverse environmental effects, and that the adverse environmental effects are therefore acceptable.

GLOSSARY AND ACRONYMS

Glossary

100-year flood – A flood that has a 1-percent chance of being equaled or exceeded in any given year.

A-weighted decibel (dBA) – Since the human ear is not equally sensitive to all sound frequencies within the entire spectrum, human response is factored into sound descriptions in a process called “A-weighting,” expressed as “dBA.” The dBA, or A-weighted decibel, refers to a scale of noise measurement that approximates the range of sensitivity of the human ear to sounds of different frequencies.

Accretion – An addition, such as an addition of water to a stream from groundwater or other sources.

Acre-foot – The quantity of water required to cover 1 acre to a depth of 1 foot. Equal to 1,233.5 cubic meters (43,560 cubic feet).

Aestivation habitat – Aestivation is a state of dormancy or inactivity during hot or dry months, typically characterized by a slower metabolism. For the California tiger salamander, aestivation habitat consists of shelter or protection from excess heat and aridity.

Alevins – A stage of development in young salmon and trout (salmonids). After hatching, developing salmonids remain in the gravel for four to six weeks while they grow and absorb their egg sac.

Alquist-Priolo Earthquake Fault Zone – The Alquist-Priolo Earthquake Fault Zoning Act was passed in 1972 to mitigate the hazard of surface faulting to structures for human occupancy. In accordance with this act, the state geologist established regulatory zones called “earthquake fault zones” around the surface traces of active faults and published maps showing these zones. Within these zones, buildings for human occupancy cannot be constructed across the surface trace of active faults. Each earthquake fault zone extends approximately 200 to 500 feet on either side of the mapped fault trace.

Alluvium – Consists of unconsolidated mixtures of gravel, sand, clay, and silt typically deposited by streams.

Anoxia – Generally refers to low-oxygen conditions within the hypolimnion (bottom) of a thermally stratified reservoir.

Aqueduct – A pipe or channel designed to transport water from a remote source, usually by gravity.

Aquifer – Permeable subsurface materials (soil, sediments, and rock) that contain groundwater. Aquifers may be large or small, local or regional, shallow or deep, and confined or unconfined, depending on the subsurface geologic conditions. The permeable materials that surround an unconfined aquifer allow the water table to fluctuate in response to recharge (precipitation in the wet season) and discharge (evapotranspiration in the dry season). A confined aquifer is contained within impermeable materials and, as a result, the water table does not fluctuate.

Aquitard – A semi-impermeable layer that confines an aquifer.

Amphibolite schists – Amphibolite is a metamorphic rock composed chiefly of amphibole with minor plagioclase and little quartz. In a schist, the minerals have been metamorphosed to the point that their crystals are foliated, or plated, and flaky.

Anadromous – Anadromous fish hatch (rear) in freshwater, migrate to the ocean (saltwater) to grow and mature, and migrate back to freshwater to spawn and reproduce.

Anaerobic – A condition where there is no air or free oxygen. An anaerobic organism is capable of living or growing in the absence of free oxygen.

Andesitic mudflow breccia – Breccia is a coarse-grained rock composed of angular broken rock fragments in a fine-grained matrix. Andesitic mudflow breccia is formed by a mudflow composed primarily of volcanic rock fragments of andesitic composition.

Andesitic tuffaceous sediments – Tuff is a rock consisting of consolidated volcanic ash. Andesitic tuffaceous sediments are sediments derived from a tuff of andesitic composition.

Asbestos – A term used for several types of naturally occurring fibrous materials found in many parts of California, some of which have been found to be cancer-causing agents.

Aversion – The act of pulling or tearing apart or off; forcible separation.

Bankfull channel – A channel that conveys commonly occurring flows, with larger flows spilling over the banks and onto the floodplain.

Barbel – A long, thin, fleshy growth projecting from the mouths or nostrils of some fishes.

Base flows – Flows in a river or stream that occur in the absence of any recent rainfall.

Bedload – Refers to the amount of sediment, gravel, cobbles, and rocks transported along the stream bottom (as opposed to suspended in the stream flow).

Beneficial use – Those uses of water as defined in the State of California Water Code (Chapter 10 of Part 2 of Division 2), including but not limited to agricultural, domestic, municipal, industrial, power generation, fish and wildlife habitat, recreation, and mining.

Biological monitoring – The periodic examination of biological specimens for the purposes of monitoring their exposure to or the effects of potentially toxic chemicals in the environment. Biological monitoring is typically performed by analyzing the amount of a toxic substance or its metabolites in body tissues and fluids. Also refers to assessing the biological status of populations and communities of organisms at risk in order to protect them and to gain an early warning of possible hazards to human health.

Biological Opinion – Document issued under the authority of the Federal Endangered Species Act stating the U.S. Fish and Wildlife Service and/or the National Marine Fisheries Service findings as to whether a federal action is likely to jeopardize the continued existence of a threatened or endangered species or result in the destruction or adverse modification of critical habitat.

Brackish water – Water that is saltier than freshwater, but not as salty as seawater. May result from the mixing of seawater with freshwater, as in estuaries.

Capacity – Engineering term which indicates the highest or maximum volume or flow of structures. There are multiple uses of the term, including hydraulic capacity, sustainable capacity, design capacity, and peak capacity which are defined as follows:

> *Hydraulic* – The maximum flow that can be accommodated through a treatment facility or transmission system component without consideration for regulatory, maintenance or engineering standards, or other system operational constraint.
>
> *Sustainable* – The highest flow rate at which a treatment facility (filtration plant) can be expected to operate, given normal/average source water conditions, while meeting regulatory water quality and routine maintenance requirements.
>
> *Design* – The maximum capacity or flow rate to which a treatment facility or transmission system component is designed to operate, under a specified set of regulatory criteria, engineering standards, or other engineering assumptions.
>
> *Peak* – The maximum capacity or flow rate to which a treatment facility or transmission system component is designed that will allow it to operate within regulatory or engineering standards.

Categorical Exemption – An exemption from CEQA for a class of projects based on a finding by the Secretary of Resources that the class of projects does not have a significant effect on the environment.

Channel – A natural or artificial watercourse, with a defined bed and banks to confine and convey continuously or periodically flowing water.

Chloramine/chloraminated – Chloramine is a chemical disinfecting agent comprised of a combination of chlorine and ammonia. Water that has been disinfected with chloramines is "chloraminated."

Chlorination – A disinfection process that involves the addition of free chlorine, whether as chlorine gas or liquid sodium hypochlorite.

Chute – An inclined trough, passage, or channel feature through or down which things may pass. A waterfall or rapid.

Colluvium – A loose deposit of rock debris accumulated through the action of gravity at the base of a cliff or slope.

Community Noise Equivalent Level (CNEL) – Because community receptors are more sensitive to unwanted noise intrusion during the evening and at night, state law requires that, for planning purposes, an artificial dBA increment be added to "quiet time" noise levels to form a 24-hour noise descriptor called the Community Noise Equivalent Level (CNEL). CNEL adds a 5-dBA "penalty" during the evening hours (7:00 p.m. to 10:00 p.m.) and a 10-dBA penalty during the night hours (10:00 p.m. to 7:00 a.m.).

Confined aquifer – See Aquifer.

Conjunctive-use program – The joint use of surface water and groundwater to meet water supply needs. Surface water is used when it is available rather than groundwater, and when there is a shortage of surface water, groundwater use is used. See also in-lieu recharge.

Cultural resource – A fragile and nonrenewable remain of human activity that is valued by or significantly representative of a culture or that contains significant information about a culture. Cultural resources encompass archaeological, traditional, and build environment resources, including landscapes or districts, sites, buildings, structures, objects, or cultural practices that are usually greater than 50 years of age and possess architectural, historic, scientific, or other technical value.

Cumulatively considerable – A CEQA term used to indicate whether or not a cumulative impact is significant.

Day-night noise level (Ldn) – Another 24-hour noise descriptor, called the day-night noise level (Ldn), is similar to CNEL. While both add a 10-dBA penalty to all nighttime noise events between 10:00 p.m. and 7:00 a.m., Ldn does not add the evening 5-dBA penalty. In practice, Ldn and CNEL usually differ by less than 1 dBA at any given location for transportation noise sources.

Dead pool – The depth beyond which the reservoir cannot be drained.

Deciduous trees – Trees that shed their leaves each year, typically in winter.

Delta – A low, nearly flat alluvial tract of land formed by deposits at or near the mouth of a river. In this report, "delta" refers to the delta formed by the Sacramento and San Joaquin Rivers.

Delta smelt – A small, slender-bodied fish with a typical adult size of 2 to 3 inches that is found only in the Sacramento–San Joaquin Delta Estuary.

Design capacity – The maximum size or capacity to which a facility or structure is designed, but which may or may not be realized during operation due to unforeseen conditions.

Design drought – A planning and operation tool water supply agencies use to define a reasonable worse-case drought scenario based on local hydrology in order to establish design and operating parameters for the water system. Droughts more severe than the design drought would cause failure of supply within the water system. The design drought developed by the SFPUC is based on a drought that is more severe than the worst historical drought. Studies suggest a 30 percent chance that the SFPUC system will experience a drought in the next 75 years equal to or more severe than the 1987–1992 drought, which was the most extreme recorded drought event to affect the regional system. The WSIP uses a design drought based on the hydrology of the six years of the worst historical drought (1987–1992) plus the 2.5 years of the 1976–1977 drought, for a combined total of an 8.5-year design drought sequence.

Discharge – The flow of surface water in a stream or canal or the outflow of groundwater from a flowing artesian well, ditch, or spring. Also refers to the discharge of liquid effluent from a facility, or to chemical emissions into the air through designated venting mechanisms.

Disinfection and Disinfection Byproducts – Disinfection is the treatment process used to inactivate and destroy disease-causing bacteria, viruses, and other waterborne microorganisms. Chlorine, a commonly and historically used disinfectant in drinking water, provides a high degree of public health protection from bacteria and viruses. However, in 1974 it was discovered that chlorine reacts with natural organic and inorganic matter in water to form disinfection byproducts. The major groups of disinfection byproducts produced by chlorination are trihalomethanes and haloacetic acids, and these byproducts have been shown to cause health effects in laboratory animals. Thus, based on numerous toxicological studies, the U.S. EPA adopted the Stage 1 and Stage 2 Disinfectants and Disinfection Byproducts Rules to lower the public health risk associated with potential exposure to disinfection byproducts.

Disinfectants and Disinfection Byproducts (D/DBPs) Rules – Federal drinking water regulations adopted by the U.S. EPA. The Stage 1 D/DBP Rule was adopted in December 1998 and became effective in February 1999. The Stage 1 D/DBP Rule reduces the maximum allowable levels of disinfectants and disinfection byproducts in drinking water supplies. The intent of the rule is to provide increased public health protection from exposure to potentially harmful disinfection byproducts. The Stage 2 DBP rule, adopted in December 2005, focuses on public health protection by limiting exposure to DBPs, specifically total trihalomethanes (TTHM) and five haloacetic acids (HAA5), which can form in water through disinfectants used to control microbial pathogens. This rule will apply to all community water systems and nontransient noncommunity water systems that add a primary or residual disinfectant other than ultraviolet (UV) light or deliver water that has been disinfected by a primary or residual disinfectant other than UV.

Dissolved oxygen (DO) – The oxygen freely available in water, which is vital to fish and other aquatic life and for the prevention of odors. DO levels are considered an important indicator of a water body's ability to support desirable aquatic life. Secondary and advanced waste treatment are generally designed to ensure adequate DO in waste-receiving waters.

Disturbance – Any event or series of events that disrupt ecosystem, community, or population structure and alter the physical environment.

Diversion – The use of part of a stream flow as water supply; a channel for diverting water to sites where it can be used and disposed of.

Don Pedro Reservoir/New Don Pedro Reservoir – The New Don Pedro Reservoir, owned and operated by the Turlock and Modesto Irrigation Districts, was constructed in 1971 along the Tuolumne River downstream of Hetch Hetchy and Early Intake to replace the original Don Pedro reservoir, which was constructed in 1923. The new reservoir has a capacity of 2,030,000 acre-feet and was constructed as part of the New Don Pedro Project. However, the new reservoir is now commonly referred to simply as Don Pedro Reservoir, and this terminology is used in this PEIR.

Drawdown – The lowering of the level of water body, such as a reservoir or a groundwater basin.

Early Intake – The weir, diversion tunnel, and hydropower house on the Tuolumne River upstream of Don Pedro Reservoir and downstream of Hetch Hetchy Reservoir.

Earthquake faults –

> *Reverse faults* involve predominantly vertical movement in which the upper block moves upward in relation to the lower block.
>
> *Thrust faults* are low-angle reverse faults.
>
> *Blind-thrust faults* are low-angled subterranean faults that have no surface expression.
>
> *Range-front faults* are faults along the front of mountain ranges responsible for the uplift of the mountains.

Ecosystem – A geographically identifiable area that encompasses unique physical and biological characteristics. It is the sum of the plant community, animal community, and environment in a particular region or habitat.

Endangered species – Any species or subspecies of bird, mammal, fish, amphibian, reptile, or plant that is in serious danger of becoming extinct throughout all or a significant portion of its range. Federally endangered species are officially designated by the U.S. Fish and Wildlife Service or the National Marine Fisheries Service and published in the Federal Register. Species may also be listed under the California Endangered Species Act by the Department of Fish and Game.

Endemism – Species that are geographically restricted.

Enhancement – Measures that develop or improve the quality or quantity of existing conditions or resources beyond a condition or level that would have occurred without an action (i.e., beyond compensation).

Entrainment – The incidental trapping of fish and other aquatic organisms in the water (for example, at water and/or irrigation diversions and power plant cooling water intakes).

Environmental cases – Sites suspected of releasing hazardous substances or that have had cause for hazardous materials investigations and are identified on regulatory agency lists. These are sites where soil and/or groundwater contamination is known or suspected to have occurred.

Ephemeral streams – Streams that flow briefly during and immediately following storm events.

Epilimnion – The uppermost portion of a thermally stratified reservoir; the epilimnion is generally the warmest part and is relatively well oxygenated.

Estuary – A transition zone between inland sources of freshwater and saltwater from the ocean.

Eutrophic – Indicates generally warm and shallow waters, with high nutrient levels and high microbiological activity.

Eutrophication – The over-enrichment of a water body with nutrients, resulting in the excessive growth of organisms and depletion of dissolved oxygen.

Evapotranspiration – The return of water from the soil and from plants to the atmosphere by evaporation and transpiration.

Expansive soils – These types of soils are characterized by their ability to undergo significant volume change (shrink and swell) due to variations in soil moisture content.

Farmland Security Zone – A contract between a private landowner and a county that restricts land to agricultural or open space uses for a minimum initial term of 20 years.

Fault creep – Movement along a fault that does not entail earthquake activity.

Filter feeders – Animals that feed by straining suspended matter and food particles from water.

Filtration avoidance or filtration exemption – Use of the terms "filtration avoidance" and "filtration exemption" is meant to convey the fact that water from the Hetch Hetchy reservoir may be consumed without the need for filtration, and does not imply that this water supply does not meet the full requirements of both state and federal Safe Drinking Water Acts. EPA and the California Department of Health Services have determined that Hetch Hetchy watershed fecal / total coliform and turbidity levels are consistently below specified threshold criteria, that the SFPUC's comprehensive watershed protection program meets specific pathogen barrier criteria, and that as a consequence this water source meets state and federal water quality requirements without the need to provide filtration. In addition, the Hetch Hetchy water supply is disinfected in accordance with Safe Drinking Water Act requirements.

Firm yield – see System Firm Yield

Fish screen – Barrier on the front face of a river intake to prevent the entrainment of fish and debris into the water supply.

Fishery enhancement – A term used to refer to protection and enhancement of fishery habitat, including augmentation of stream flows during certain times of the year.

Floodplain – Land adjacent to a watercourse over which water flows in times of flood. The limits of the flood plain are defined by the peak level of a 1 in 100 year return period flood.

Flow – The volume of water passing a given point per unit of time.

> *Instream flow requirements* – Amount of water flowing through a stream course as required under statutory, regulatory, or contractual authority.
>
> *Minimum flow* – Lowest flow in a specified period of time.
>
> *Peak flow* – Maximum instantaneous flow in a specified period of time.
>
> *Return flow* – Portion of water previously diverted from a stream and subsequently returned to that stream or to another body of water.

Fluvial – Of or found in a river.

Fluvial geomorphologic conditions – This term refers to the shape of the stream channels and associated erosional and depositional features (e.g., canyons, streambeds, stream banks, floodplains), resulting from flowing water.

Free chlorine – Free chlorine consists of a compound, hypochlorous acid, and the hypochlorite ion, both of which form when chlorine gas is added to water

Fry – A stage of development in young salmon or trout. During this stage the fry is usually less than one year old, has absorbed its yolk sac, is rearing in the stream, and is between the alevin and parr stage of development.

Fugitive dust – "Fugitive" emissions generally refer to those emissions that are released to the atmosphere by some means other than through a stack or tailpipe.

Gaining river – A gaining river receives water from the inflow of groundwater. The same river could be both gaining and losing, depending on the conditions.

Geomorphology – The study of the arrangement, origin, and changes of the earth's surface features.

Groundwater banking – A water management tool that uses available space in groundwater aquifers to store water during wet years (years when there is abundant rainfall and surplus water available), so that it can be pumped and used during dry years (years with little rainfall and no surplus water).

Groundwater recharge – Inflow to aquifers from precipitation, infiltration, through-flow, and/or other means that replaces groundwater lost through pumping or other forms of discharge. The process of water being added to the saturated zone *or* the volume of water added by this process.

Habitat – The specific area or environment in which a particular type of animal or plant lives.

Hazardous materials – Defined in Section 25501(h) of the California Health and Safety Code, are materials that, because of their quantity, concentration, or physical or chemical characteristics, pose a substantial present or potential hazard to human health and safety or to the environment if released to the workplace or environment. Hazardous materials have been and are commonly used in commercial, agricultural, and industrial applications as well as in residential areas to a limited extent.

Hazardous materials business plans – Businesses that handle specified quantities of chemicals are required to submit a hazardous materials business plan (HMBP) in accordance with community right-to-know laws. This plan allows local agencies to plan appropriately for a chemical release, fire, or other incident.

Hazardous waste – Any material that is relinquished, recycled, or inherently waste-like. Title 22 of the California Code of Regulations, Division 4.5, Chapter 11 contains regulations for the classification of hazardous wastes. A waste is considered a hazardous waste if it is toxic (causes human health effects), ignitable (has the ability to burn), corrosive (causes severe burns or damage to materials), or reactive (causes explosions or generates toxic gases) in accordance with the criteria established in Article 3. Article 4 lists specific hazardous wastes, and Article 5 identifies specific waste categories, including Resource Conservation and Recovery Act (RCRA) hazardous wastes, non-RCRA hazardous wastes, extremely hazardous wastes, and special wastes.

Headwaters – The point or area of origin for a river or stream.

Heritage trees – Large, old, or historically important trees that receive protection on a local basis.

Hetch Hetchy Aqueduct – The part of the regional water system consisting of the transmission facilities that convey water from Hetch Hetchy Reservoir, including pipelines and tunnels from the beginning of the Foothill Tunnel to the Alameda East Portal.

Hypolimnion – The bottom portion of a thermally stratified water body, such as a lake or reservoir; water in the hypolimnion is generally cool and has a low oxygen concentration.

Hydraulic head – The pressure of the water column and elevation difference. The force per unit area exerted by a column of liquid at a height above a depth (and pressure) of interest. Fluids flow down a hydraulic gradient, from points of higher to lower hydraulic head.

Hydrograph – A chart that illustrates the pattern of flow in a stream as a function of time.

Hydrology – The science that deals with the waters above and below land surfaces; their occurrence, circulation, and distribution, both in time and space; their biological, chemical, and physical properties; and their reaction with their environment, including their relation to living beings.

Hydrophytic vegetation – Plant life growing in water or on a substrate that is at least periodically deficient in oxygen as a result of excessive water content.

Hydrologic year types – The California Department of Water Resources uses the following classifications to define rainfall year types relative to average hydrologic conditions, including rainfall, runoff, and snowmelt conditions, in order of decreasing availability of water: wet year, above-normal year, normal year, below-normal year, dry year, and critically dry year. *Drought year* typically refers to one year during consecutive dry or critically dry years.

Hyporheic flow – Water that interchanges between the stream and subsurface media.

Important farmlands –

> *Prime Farmland* is land that has the best combination of physical and chemical characteristics for crop production. It has the soil quality, growing season, and moisture supply needed to produce sustained high yields of crops when treated and managed.
>
> *Farmland of Statewide Importance* is land other than Prime Farmland that has a good combination of physical and chemical characteristics for crop production.
>
> *Unique Farmland* does not meet the criteria for Prime Farmland or Farmland of Statewide Importance but has been used for the production of specific high-economic-value crops.
>
> *Farmland of Local Importance* is either currently producing crops or has the capability of production, but does not meet the criteria of the categories above.
>
> *Grazing Land* is land on which the vegetation is suited to the grazing of livestock.

In-lieu recharge – In-lieu recharge is the storage of water by utilizing surface water “in-lieu” of pumping groundwater, thereby storing an equal amount in the groundwater basin. See also conjunctive-use program.

Isothermal – Refers to constant temperature in the water column; this condition is present when the reservoir is not stratified, typically during the winter months.

Juvenile – A young or sexually immature animal.

Lateral spreading – A phenomenon where large blocks of intact, nonliquefied soil move downslope on a liquefied substrate of large aerial extent

Leq – Time variations in noise exposure are typically expressed in terms of a steady-state energy level (called Leq) that represents the acoustical energy of a given measurement. Leq (24) is the steady-state energy level measured over a 24-hour period.

Levee – An embankment raised to prevent a river from overflowing.

Liquefaction – A phenomenon in which saturated granular sediments temporarily lose their shear strength during periods of earthquake-induced, strong groundshaking. The susceptibility of a site to liquefaction is a function of the depth, density, and water content of the granular sediments and the magnitude of earthquakes likely to affect the site.

Long Term-2 Enhanced Surface Water Treatment Rule – A rule under the federal Safe Drinking Water Act that was adopted by the U.S. Environmental Protection Agency in January 2006. The purposes of this rule are to improve public health protection through the control of microbial contaminants by focusing on systems with elevated *Cryptosporidium* risk, and to prevent significant increases in microbial risk that might otherwise occur when systems implement the Stage 2 Disinfectants and Disinfection Byproducts Rule. Systems covered by this rule include water systems that use surface water or groundwater under the direct influence of surface water.

Level of service – As used in this PEIR, level of service is used as a tool to measure to operating condition and performance ability of water supply facilities and related infrastructure[1].

Losing river reach – A losing river reach loses water to the groundwater.

Mafic rocks – Igneous rocks containing a group of dark-colored minerals, composed chiefly of magnesium and iron.

Maximum contaminant level (MCL) **–** The MCL is the highest level of a contaminant that is allowed in drinking water. The MCL is set as close to the maximum contaminant level goal (MCLG – see below) as is economically or technically feasible. While the MCL is higher than the MCLG, it is considered protective of human health.

Maximum contaminant level goal – The MCLG is the level below which there is no known or expected health risk to human health.

Meander sequences – Sinuous sections of river channel.

[1] In many EIRs, level of service (abbreviated as LOS) is used in the traffic analysis as a qualitative description of transportation infrastructure's performance based on average delay per vehicle, vehicle density, or volume-to-capacity ratios. This type of analysis is not relevant to the WSIP PEIR traffic impacts.

Mélange – Generally a mixture of rock materials of differing sizes and types generally contained within a sheared matrix.

Mesotrophic – Indicates moderate nutrient levels and microbiological activity in a water body.

Metasedimentary – Rocks that were originally sedimentary, but have been metamorphosed.

Mitigation – One or all of the following: (1) Avoiding an impact altogether by not taking a certain action or parts of an action; (2) minimizing impacts by limiting the degree or magnitude of an action and its implementation; (3) rectifying an impact by repairing, rehabilitating, or restoring the affected environment; (4) reducing or eliminating an impact over time by preservation and maintenance operations during the life of an action; and (5) compensating for an impact by replacing or providing substitute resources or environments.

Modeling – A tool used to mathematically represent a process which could be based upon empirical or mathematical functions. Models can be computer programs, spreadsheets, or statistical analyses.

Montmorillonite clay – An expansive type of clay that undergoes large changes in volume with changes in water content.

Morphology – As used in this PEIR, the form and structure of a stream or river.

Negative declaration – A form of environmental review documentation of proposed projects subject to CEQA. It consists of a written statement and supporting documentation issued by the lead agency responsible for CEQA implementation that briefly describes the reasons that a proposed project will not have a significant effect on the environment and therefore does not require the preparation of an EIR.

New Don Pedro Project – See Don Pedro Reservoir

Nitrification – To oxidize (an ammonia compound) into nitric acid, nitrous acid, or any nitrate or nitrite, especially by the action of nitrobacteria.

Oscillation – The rate of oscillation of sound waves is the amount of fluctuation between two values.

Oxbows – River meanders cut off from the main channel.

Perched groundwater – A local saturated zone above the water table. It typically exists above an impervious layer (such as clay) with limited extent.

Permitted hazardous materials uses – Facilities that use hazardous materials or handle hazardous wastes but comply with current hazardous materials and hazardous waste regulations.

Pocket water – A water hole in the bed of an intermittent stream, especially the bowl at the foot of a cliff over which the stream passes when in the flood stage.

PPV – To assess the potential for structural damage associated with vibration, the vibratory ground motion in the vicinity of the affected structure is measured in terms of peak particle velocity (PPV) in the vertical and horizontal directions (vector sum), typically in units of inches per second (in/sec).

Propagation – To move or transmit something forward in space, especially as a light or sound wave.

Predation – The act of preying on another animal or animals.

Primary disinfection – Primary disinfection provides inactivation and/or reduction of microbial pathogens to meet specific regulatory requirements prior to water entering the distribution system. Primary disinfection may occur by one or more disinfecting agents.

Program Environmental Impact Report – One type of environmental review document identified under the California Environmental Quality Act that may be used to evaluate a plan or program that has multiple components (projects and actions) or to address a series of actions that are related.

Rearing – The amount of time that juvenile fish spend feeding in nursery areas of rivers, lakes, streams, and estuaries before migration, or the care and support for young fish.

Rearing habitat – Areas where larval and juvenile fish find food and shelter.

Regional water system – The entire SFPUC water system starting at Hetch Hetchy Reservoir and ending in San Francisco; the regional system includes all facilities serving the SFPUC wholesale and retail customers, except for the retail customers in San Francisco. The SFPUC regional water system consists of a complex network of facilities covering a geographic range of about 160 miles, from the Sierra Nevada on the east to San Francisco on the west. The regional water system crosses seven counties—Tuolumne, Stanislaus, San Joaquin, Alameda, Santa Clara, San Mateo, and San Francisco. The regional water system includes over 280 miles of pipelines, over 60 miles of tunnels, 11 reservoirs, 5 pump stations, and 2 water treatment plants.

Recapture – Returning released water to the system past the point of benefit.

Recruitment – The establishment of conditions that facilitate the growth of new vegetation; the entry of new individual organisms into a population of plants or animals.

Redd – A spawning nest made by a salmonid for laying eggs. The female salmonid creates the nest by undulating her tail and body against the substrate of a stream.

Reservoir – An artificially impounded body of water.

Riffles – A stretch of choppy water caused by stones or other objects in a river or stream.

Riparian – The land adjacent to a natural watercourse such as a river or stream. Riparian areas support vegetation that provides important wildlife habitat, as well as important fish habitat when sufficient to overhang the bank.

Rhyolitic tuff – Tuff is a rock composed of compacted volcanic ash varying in size from fine sand to coarse gravel. Rhyolitic tuff is comprised of ash similar in composition to granite.

Safe Drinking Water Act – The nation's major law regulating drinking water quality, implemented by the U.S. EPA. The Safe Drinking Water Act established primary and secondary drinking water regulations, and implementation and enforcement of this act has been delegated to the states. This act promulgates primary drinking water regulations that specify a maximum contaminant level for contaminants that "may have any adverse effect on the health of persons and which is known or anticipated to occur in public water systems."

Salmonid – Salmon or trout.

Salt marsh – An area where salt water from an ocean, bay, or gulf meets freshwater from a river.

Saltwater intrusion – The mixing of saltwater and groundwater in a groundwater aquifer resulting from overpumping of the aquifer.

Secondary disinfection –Secondary disinfection refers to the maintenance of a disinfectant residual in the distribution system necessary to meet regulatory requirements. The secondary disinfectant may be the same as or different from (one of) the agent(s) used for primary disinfection. Secondary disinfection of wastewater involves oxidation of organic matter using biological processes.

Secondary maximum contaminant level – Established to protect the esthetic quality of drinking water.

Sedimentation – The deposition of material suspended in a stream system, whether in suspension (suspended load) or on the bottom (bedload).

Seiche – Earthquake-induced oscillating waves in an enclosed water body.

Sensitive receptors – A land use that is sensitive or more vulnerable to (i.e., "receives") effects of noise, air quality, or a specified resource than the general population.

Serpentine – A naturally occurring group of minerals that can be formed when ultramafic rocks are metamorphosed during uplift to the earth's surface. Serpentinite is a rock consisting of one or more serpentine minerals. This rock type is commonly associated with ultramatic rock along earthquake faults. Small amounts of chrysotile asbestos, a fibrous form of serpentine minerals, are common in serpentinite.

Siltation – Sediment influx from either erosion or from sediment carried into a water body by inflowing rivers and tributaries.

Shear zones – A zone of rock fracturing consisting of many closely spaced, roughly parallel, discontinuous cracks. Shear zones typically occur along faults.

Sliplining – A method of lining the water mains to prevent corrosion and encrustation.

Smolts – Juvenile fish that have undergone the physiological changes necessary for them to migrate from freshwater streams to the ocean.

Spark arrestor – A device that prohibits exhaust gases from an internal combustion engine from passing through the impeller blades where they could cause a spark. A carbon trap is commonly used to retain carbon particles from the exhaust.

Spawning – Laying (and fertilizing) eggs in the process of reproduction.

Special-status species – Several species known to occur within the general region of the program area are accorded "special status" because of their recognized rarity or vulnerability to habitat loss or population decline. Some of these species receive specific protection in federal and/or state endangered species legislation. Others have been designated as "sensitive species" or "species of special concern" on the basis of adopted policies of federal, state, or local resource agencies. These species are referred to collectively as "special-status species."

Spill sites – Locations where a spill of hazardous materials has been reported to the state or federal regulatory agencies.

Squeezing ground – A time-dependent phenomenon usually associated with tunnel construction through a fault zone. Squeeze occurs when the in-situ stresses are high relative to the strength of the material. A high stress-to-strength ratio causes a slow creep of ground around the tunnel toward the excavated opening.

Subsidence – The lowering of the land surface in response to groundwater pumping.

Substrate – The materials found in streambeds or riverbeds (i.e., large and small boulders, stone, rubble, cobble, pebble, coarse and fine gravel, sand, silt, and clay). The surface upon which an organism grows or is attached.

Surface water – All water that is naturally open to the atmosphere (i.e., rivers, lakes, reservoirs, ponds, streams, impoundments, seas, estuaries, etc.).

Suspended particulates (PM_{10} and $PM_{2.5}$) – Particulate matter is a class of air pollutants that consists of solid and liquid airborne particles in an extremely small size range. Particulate matter is measured in two size ranges: PM_{10} for particles less than 10 microns in diameter, and $PM_{2.5}$ for particles less than 2.5 microns in diameter.

Sustainable capacity – The highest rate at which plant production can be expected to meet water quality requirements for a period of 60 days, given normal source water conditions.

Swales – Areas where winter rain collects but does not stand as long as in vernal pools.

System firm yield – The average annual water delivery that can be sustained by a water supply system throughout an extended drought.

Thermocline – The boundary between the warmer surface waters and cooler waters below.

Terrestrial species – Types of species of animals and plants that live on or grow from the land.

Threatened species – Legal status afforded to plant or animal species that are likely to become endangered within the foreseeable future throughout all or a significant portion of their range, as determined by the U.S. Fish and Wildlife Service or the National Marine Fisheries Service.

Threshold damage vibration – The highest vibration amplitude at which no cosmetic, minor, or major damage occurs, which includes "threshold cracks" or "hair-sized" cracks in room walls that occur at the lowest vibration amplitudes.

Through-flow – Water flowing through sediments.

Tunnel Safety Order – The California Tunnel Safety Orders (California Administrative Code, Title 8, Subchapter 20, Article 8) require the Division of Industrial Safety to classify all tunnels or portions of tunnels into one of the following classifications before a public works project can be put out to bid:

- *Nongassy*, the classification assigned when there is little likelihood of encountering gas during the construction of the tunnel.
- *Potentially gassy*, the classification assigned when there is a possibility that flammable gas or hydrocarbons will be encountered during construction of the tunnel.
- *Gassy*, the classification assigned when it is likely gas will be encountered, or if monitoring indicates the presence of hazardous gases at a concentration greater than 5 percent of the lower explosive limit.
- *Extrahazardous*, the classification assigned to tunnels when the Division finds that there is a serious danger to the safety of employees, flammable gas or petroleum vapors emanating from the strata have been ignited in the tunnel, or monitoring indicates the presence of hazardous gases at a concentration greater than 20 percent of the lower explosive limit.

Turnout – A water diversion point.

Ultramafic rocks – These rock units are formed in high-temperature environments well below the surface of the earth.

Unconfined aquifer – See Aquifer.

Unimpaired flow – The natural river flow that existed prior to the placement of upstream water diversions, storage reservoirs, or other impediments.

Valve lots/valve house – A structure that encloses electrical and mechanical equipment and other related facilities uses to regulate, direct, and control flow of water.

Vernal pools – Seasonal wetlands formed in gently undulating or rolling topography where the soil is underlain by a slowly permeable claypan or hardpan.

Water rights – In California, the legal right to the use of water.

Waters of the United States – A broad federal definition that describes Corps jurisdiction over deep-water habitats and special aquatic sites, including wetlands, as follows:

a. The territorial seas with respect to the discharge of fill material.
b. Coastal and inland waters, lakes, rivers, and streams that are navigable waters of the United States, including their adjacent wetlands.
c. Tributaries to navigable waters of the United States, including wetlands.
d. Interstate waters and their tributaries, including adjacent wetlands.

All other waters of the United States not identified above, such as isolated wetlands and lakes, intermittent streams, prairie potholes, and other waters that are not a part of a tributary system to interstate waters or navigable waters of the United States, the degradation or destruction of which could affect interstate commerce.

Watershed – A region or area bounded peripherally by a water parting and draining ultimately to a particular watercourse or body of water.

Watershed management – The net result of numerous and varied actions in a watershed that directly affect watershed function and productivity. Actions may include, but are not limited to, land use decision-making, restoration and enhancement projects, monitoring and assessment of watershed condition, natural resource allocation and use, parcel management techniques, and education programs. Watershed management includes protection of existing healthy conditions.

Weir – A small dam in a river used to divert or control water flow. When uncontrolled, the weir is termed a fixed-crest weir; other weir types include broad-crested, sharp-crested, drowned, and submerged.

Wetland – A zone periodically or continuously submerged or having high soil moisture, which has aquatic and/or riparian vegetation components, and is maintained by water supplies significantly in excess of those otherwise available through local precipitation.

Wild and Scenic River – A river that has been designated under the National Wild and Scenic Rivers Act as having distinctively unique or "outstanding remarkable values" that set it apart from all other rivers, making it worthy of special protection.

Williamson Act – Under a Williamson Act (Land Conservation Act of 1965) contract, the landowner agrees to limit the use of the land to agriculture and compatible uses for a period of at least 10 years. In return, the land is taxed at a rate based on the agricultural production of the land, rather than its real estate market value.

Conversion Factors

Volume

1 cubic foot (ft^3)	= 7.481 gallons
1 gallon (gal)	= 0.1337 ft^3
1 acre-foot	= 43,560 ft^3 = 325,872 gal = 0.325 million gallons
1 million gallons	= 3.068 acre-feet

Flow

1 cubic foot per second (cfs)	= 7.481 gal/sec = 448.8 gpm = 0.646 mgd = 723.941 afy
1 gallon per minute (gpm)	= 0.00223 cfs = 0.00144 mgd = 1.613 afy
1 million gallons per day (mgd)	= 1.547 cfs = 694.4 gpm = 1,120.55 afy
1 acre-foot per year (afy)	= 0.001381 cfs = 0.0008924 mgd

Temperature

Degrees Celsius (°C) = 5/9 x (°F – 32)

Degrees Fahrenheit (°F) = 9/5 x (°C) + 32

Summary

SUMMARY

S.1 Introduction and Purpose of the PEIR (Chapter 1)

The San Francisco Public Utilities Commission (SFPUC) proposes to adopt and implement the Water System Improvement Program (WSIP or proposed program) to increase the reliability of the regional water system that serves 2.4 million people in San Francisco and the San Francisco Bay Area. The WSIP would improve the regional system with respect to water quality, seismic response, water delivery, and water supply to meet water delivery needs in the service area through the year 2030 and would establish level of service goals and system performance objectives. The WSIP would implement a proposed water supply option, modify system operations, and construct a series of facility improvement projects. The proposed program area spans seven counties—Tuolumne, Stanislaus, San Joaquin, Alameda, Santa Clara, San Mateo, and San Francisco.

The San Francisco Planning Department, Major Environmental Analysis (MEA) Division, determined that implementation of the WSIP could have a significant effect on the environment and therefore required preparation of a Program Environmental Impact Report (PEIR) in compliance with the California Environmental Quality Act (CEQA). This PEIR is intended to provide the public and responsible and trustee agencies with information about the potentially significant environmental effects of the proposed program, to identify possible ways to minimize the potentially significant effects, and to describe and evaluate feasible alternatives to the proposed program.

S.2 Program Description (Chapter 3)

Need for and Objectives of the Program

The City and County of San Francisco (CCSF), through the SFPUC, owns and operates a regional water system that extends from the Sierra Nevada to San Francisco and serves retail and wholesale customers in San Francisco, San Mateo, Santa Clara, Alameda, and Tuolumne Counties. The existing regional system includes over 280 miles of pipelines, over 60 miles of tunnels, 11 reservoirs, 5 pump stations, and 2 water treatment plants. The SFPUC currently delivers an annual average of about 265 million gallons per day (mgd) of water to its customers. The source of the water supply is a combination of local supplies from streamflow and runoff in the Alameda Creek watershed and in the San Mateo and Pilarcitos Creeks watersheds (referred to together as the Peninsula watersheds), augmented with imported supplies from the Tuolumne River watershed. Local watersheds provide about 15 percent of total supplies and the Tuolumne River provides the remaining 85 percent. **Figure S.1** shows the general location of the SFPUC regional system and water supply watersheds.

The SFPUC serves about one-third of its water supplies directly to retail customers, primarily in San Francisco, and about two-thirds of its water supplies to wholesale customers by contractual agreement. The wholesale customers are largely represented by the Bay Area Water Supply and Conservation Agency (BAWSCA), which consists of 27 total customers, shown in **Figure S.2**. Some of these wholesale customers have other sources of water in addition to what they receive from the SFPUC regional system, while others rely completely on the SFPUC for supply.

While the SFPUC has historically met and is currently serving its customers' water demands, there are numerous factors contributing to the need for a comprehensive, systemwide program such as the WSIP. In order to continue to provide reliable water service to its customers, the SFPUC must plan for the future as well as address existing, known deficiencies, including the following:

- *Aging Infrastructure*. Many of the components of the SFPUC regional water system were built in the 1800s and early 1900s. As the system ages, its reliability decreases and the risk of failure increases.

SFPUC Water System Improvement Program . 203287

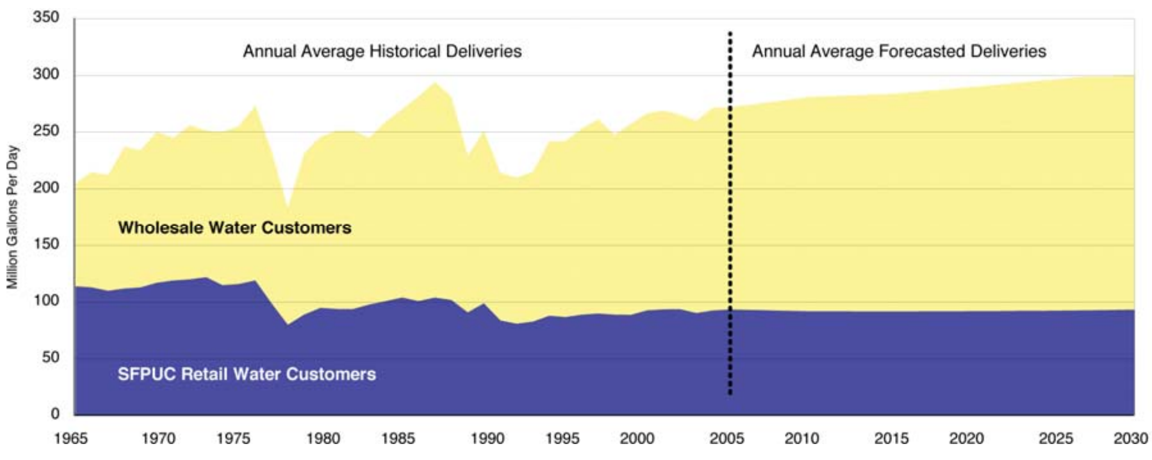
Figure S.2 (Revised)
SFPUC Water Service Area - San Francisco and SFPUC Wholesale Customers

- *Exposure to Seismic and Other Hazards*. The system crosses five active earthquake faults, and many of the existing facilities do not meet modern seismic standards. The California Division of Safety of Dams (DSOD) imposed operating restrictions on two of the system's reservoirs, Calaveras and Lower Crystal Springs Reservoirs, due to seismic and flood control safety hazards, respectively. The restricted operations at these reservoirs reduce local storage capacity and impair normal system operations.

- *Water Quality*. The regional system currently meets or exceeds existing water quality standards. However, system upgrades are needed to improve the SFPUC's ability to maintain compliance with current water quality standards and to meet anticipated future water quality standards.

- *Delivery Reliability*. The system requires additional redundancy (i.e., backup) of some critical facilities to ensure sufficient operational flexibility to carry out adequate system inspection and maintenance and to be adequately prepared in the event of an earthquake, system failure, or other emergency. These critical facilities are necessary to meeting day-to-day customer water supply needs, and increased operational flexibility is needed in order to maintain service to all customers during a full range of operating conditions.

- *Customer Water Demand*. The regional system currently has insufficient water supply to meet customer demand during a prolonged drought, and this situation will worsen in the future without the WSIP. Additional supplies are needed to satisfy current demand in drought years as well as to meet future demand. Water demand among SFPUC retail and wholesale customers is projected to increase over the next 25 years, from an average annual demand of about 366 mgd to 417 mgd in 2030. Of this total projected demand in the SFPUC service area, retail and wholesale customers would purchase an annual average of about 300 mgd from the SFPUC system in 2030, compared to 265 mgd in 2005, as shown in **Figure S.3**. Thus, the SFPUC would need to provide additional water supplies to serve a projected average annual increase in purchase requests of 35 mgd by 2030.



SFPUC Water System Improvement Program ■ 203287

SOURCE: SFPUC, 2007b

Figure S.3 (Revised)
Annual Average Historical and
Projected Future Customer Purchase Requests

To address these challenges, the SFPUC must replace or upgrade numerous system facilities, add some new facilities, and expand its water supply portfolio—thus the need for the WSIP. In 2005, the SFPUC developed goals and objectives for the WSIP based on a planning horizon through 2030. The goals and objectives are founded on two fundamental principles pertaining to the existing regional water system: (1) maintaining a clean, unfiltered water source from the Hetch Hetchy system, and (2) maintaining a gravity-driven system. The overall goals of the WSIP are to:

- Maintain high-quality water
- Reduce vulnerability to earthquakes
- Increase delivery reliability and improve the ability to maintain the system
- Meet customer water supply purchase requests in nondrought and drought periods
- Enhance sustainability in all system activities
- Achieve a cost-effective, fully operational system

To further these program goals, the WSIP includes objectives that address system performance in the areas of water quality, seismic reliability, delivery reliability, and water supply through the year 2030. **Table S.1** presents the WSIP goals and objectives. The WSIP also includes proposed levels of service for the regional water system, which are intended to further define the system performance objectives through 2030 and provide design guidelines for the facility improvement projects. The levels of service (shown in Table 3.5, in Chapter 3, Program Description) address water quality, seismic response after a major earthquake, delivery during system maintenance, average annual water supply, regional system firm yield, and drought-year rationing.

Key program elements are summarized below and described in more detail in Chapter 3 (also see the SFPUC's 2006 *Water System Improvement Program* and 2007 *Water Supply Options* reports).

- *Water Supply*. Proposed water supply option to meet customer purchase requests during both nondrought and drought years.

- *System Operations*. Proposed system operations strategy to achieve water quality, seismic response, and delivery reliability performance objectives under a range of operating conditions, including the following scenarios: day-to-day, maintenance, unplanned outage, earthquake or other emergencies, and drought.

- *Facilities*. Proposed facility improvement projects to repair, upgrade, and, in some cases, expand the regional system facilities to reliably meet level of service goals and system performance objectives and to provide a cost-effective, fully operational water system.

Proposed Water Supply

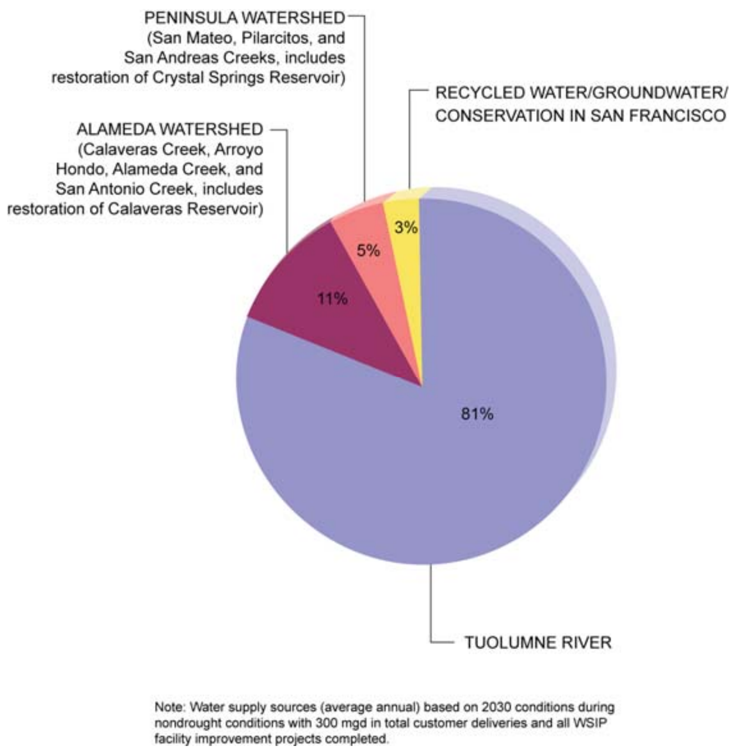
Under the WSIP, the SFPUC proposes to meet the increased 35 mgd in purchase requests by continuing to maximize use of local watershed supplies, increasing diversions from the Tuolumne River under its existing water rights, and developing new local resources consisting of a combination of additional conservation, water recycling, and groundwater supply programs in

TABLE S.1
WSIP GOALS AND OBJECTIVES

Program Goal	System Performance Objective
Water Quality – *maintain high water quality*	• Design improvements to meet current and foreseeable future federal and state water quality requirements. • Provide clean, unfiltered water originating from Hetch Hetchy Reservoir and filter all other surface water sources. • Continue to implement watershed protection measures.
Seismic Reliability – *reduce vulnerability to earthquakes*	• Design improvements to meet current seismic standards. • Deliver basic service to the three regions in the service area (East/South Bay, Peninsula, and San Francisco) within 24 hours after a major earthquake. Basic service is defined as average winter-month usage, and the performance objective for the regional system is 229 million gallons per day (mgd). The performance objective is to provide delivery to at least 70 percent of the turnouts (i.e., water diversion connecting points from the regional system to customers) in each region, with 104, 44, and 81 mgd delivered to the East/South Bay, Peninsula, and San Francisco regions, respectively. • Restore facilities to meet average-day demand of 300 mgd within 30 days after a major earthquake.
Delivery Reliability – *increase delivery reliability and improve the ability to maintain the system*	• Provide operational flexibility to allow planned maintenance shutdown of individual facilities without interrupting customer service. • Provide operational flexibility to minimize the risk of service interruption due to unplanned facility upsets or outages. • Provide operational flexibility and system capacity to replenish local reservoirs as needed. • Meet the estimated average annual demand of 300 mgd for 2030 under the conditions of one planned shutdown of a major facility for maintenance concurrent with one unplanned facility outage.
Water Supply – *meet customer water needs in nondrought and drought periods*	• Meet average annual water purchase requests of 300 mgd from retail and wholesale customers during nondrought years for system demands through 2030. • Meet dry-year delivery needs through 2030 while limiting rationing to a maximum 20 percent systemwide reduction in water service during extended droughts. • Diversify water supply options during nondrought and drought periods. • Improve use of new water sources and drought management, including use of groundwater, recycled water, conservation, and transfers.
Sustainability – *enhance sustainability in all system activities*	• Manage natural resources and physical systems to protect watershed ecosystems. • Meet, at a minimum, all current and anticipated legal requirements for protection of fish and other wildlife habitat. • Manage natural resources and physical systems to protect public health and safety.
Cost-effectiveness – *achieve a cost-effective, fully operational system*	• Ensure cost-effective use of funds. • Maintain gravity-driven system. • Implement regular inspection and` maintenance program for all facilities.

SOURCE: SFPUC, 2005.

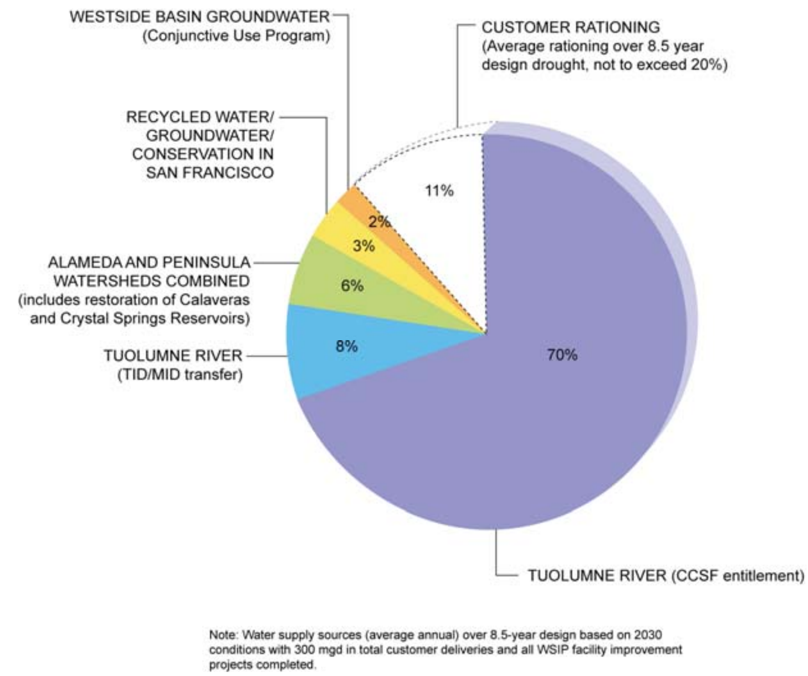
San Francisco, as shown in **Figure S.4**. The water recycling and groundwater supply programs would be developed as part of the proposed facility improvement projects. This combination of water supply sources is expected to fully meet customer purchase requests during nondrought years through 2030. However, based on recent experience, these water supply sources would not be adequate during drought periods. The WSIP level of service goals include a policy to limit customer rationing to a maximum of 20 percent systemwide in any one year of a drought.



SFPUC Water System Improvement Program . 203287

Figure S.4
WSIP Water Supply Sources, Nondrought Years

To provide adequate water supply to customers during a prolonged drought, the WSIP includes supplemental sources to augment the nondrought-year water supplies described above. The SFPUC proposes to secure a water transfer with the Turlock Irrigation District (TID) and/or Modesto Irrigation District (MID) to provide supplemental dry-year water from the Tuolumne River. Further, the SFPUC proposes to implement a groundwater banking program in the Westside Groundwater Basin in San Mateo County. Under this program, SFPUC wholesale customers that utilize the Westside Groundwater Basin would use supplemental surface water supplies in nondrought years to reduce their groundwater pumping and allow for in-lieu groundwater banking; these wholesale customers could then increase their groundwater pumping in drought years and reduce their demand for surface water supply in those years. In addition, two of the WSIP facility improvement projects involve the restoration of historical operating capacities at two of the system reservoirs, Calaveras and Lower Crystal Springs Reservoirs, which would further augment drought supplies for the regional system. As shown in **Figure S.5**, during drought years under the WSIP, the SFPUC would also include up to 20 percent systemwide rationing.



SFPUC Water System Improvement Program . 203287

Figure S.5
WSIP Water Supply Sources, Drought Years

Proposed System Operation Strategy

Operation of the regional water system is affected by numerous factors, including fluctuations in customer demand; meteorological and hydrologic conditions; physical facilities and infrastructure capacity and maintenance requirements; and multiple institutional parameters. The WSIP addresses the condition of the physical facilities and infrastructure while planning for and taking into account these various factors. The operating strategy addresses four components of system operation: water supply and storage, water quality, water delivery, and asset management.

Under the WSIP, general day-to-day operation of the regional water system would be similar to existing operations but would provide for additional facility maintenance activities and improved emergency preparedness. Implementation of the program would allow for a refinement of the operations strategy to meet the WSIP goals and objectives and would thereby increase system reliability and provide additional flexibility for scheduling repairs and maintenance. The proposed operations strategy would also include a multistage drought response program during an extended drought. Under the WSIP, regional system operations would continue to comply with all applicable institutional and planning requirements, including:

- Complying with all water quality, environmental, and public safety regulations
- Maximizing the use of water from local watersheds
- Assigning a higher priority to water delivery over hydropower generation
- Meeting all downstream flow requirements

Proposed Facility Improvement Projects

The WSIP includes 22 facility improvement projects along the regional system, from Oakdale Portal in Tuolumne County on the east end to San Francisco on the west. The projects, described in **Table S.2**, have been identified as necessary to achieve the level of service goals and system performance objectives of the WSIP. **Figure S.6** indicates the location of each facility improvement project.

Standard Construction Measures

The SFPUC has established standard construction measures that would be implemented as part of all WSIP projects. The main objective of these measures is to minimize potential disruption of surrounding neighborhoods during construction and to reduce impacts on environmental resources to the extent feasible. The construction measures would be implemented individually for the facility improvement projects; some measures might not be applicable to some projects, while some projects would require the development of more detailed construction measures and implementation steps as the individual projects are designed. The standard construction measures to be included in WSIP construction contracts address the following topics: neighborhood notice, seismic and geotechnical studies, onsite air and water quality measures during construction, groundwater, traffic, noise, hazardous materials, biological resources, cultural resources, and project site (i.e., the use of non-CCSF-owned land during construction).

Proposed Construction Schedule

Figure S.7 presents a preliminary master schedule of the construction phases for the facility improvement projects. The SFPUC developed the preliminary schedule to assure that water delivery service is maintained throughout construction of the numerous projects, but is preparing schedule refinements and adjustments as the projects are further developed and more information is known about construction requirements. All WSIP projects are scheduled to be completed by the end of 2014. The acquisition of supplemental water supplies during droughts would be implemented as needed to match the water supply needs of the retail and wholesale customers (see Chapter 5, Section 5.1) and is not included on the construction schedule.

TABLE S.2
WSIP FACILITY IMPROVEMENT PROJECTS

No.[a]	Project Title	Principal Type of Facility/ Objectives[b]	Location of Preferred Project[c]	Project Description
San Joaquin Region				
SJ-1	Advanced Disinfection	Treatment / Water Quality	Tesla Portal	This project would provide for the planning, design, and construction of a new advanced disinfection facility for the Hetch Hetchy water supply to comply with the new federal drinking water regulatory requirements contained in the Long Term 2 Enhanced Surface Water Treatment Rule. This regulation is designed to provide treatment for the parasite *Cryptosporidium*. The project is in the planning phase and the SFPUC is evaluating applicable technologies and possible locations to identify the most technologically sound and cost-effective alternative. In addition, the project includes planning and conceptual engineering for providing advanced disinfection facilities at the Sunol Valley and Harry Tracy Water Treatment Plants (WTPs). This project may be combined with the Tesla Portal Disinfection Station project along with portal modifications, and the need for the Lawrence Livermore Supply Improvements project may be affected by the location and technology selected for this project.
SJ-2	Lawrence Livermore Supply Improvements	Treatment / Water Quality	Thomas Shaft	This project includes design and construction of treatment upgrades for the water supplied to the Lawrence Livermore Laboratory. The project would construct water treatment facilities from the Thomas Shaft of the Coast Range Tunnel. An advanced disinfection facility planned at an upstream location under the Advanced Disinfection project could affect project design.
SJ-3	San Joaquin Pipeline System	Pipeline / Water Supply, Delivery Reliability	Isolated locations along the existing San Joaquin Pipeline corridor	The preferred project would generally be located within the existing San Joaquin Pipeline (SJPL) right-of-way and would include: • Construction of a new 6.4-mile-long, up to 86-inch-diameter fourth San Joaquin Pipeline parallel to the existing three pipelines at the east end of the pipelines, starting at Oakdale Portal, and associated portal modifications. • Construction of two additional crossover facilities between the San Joaquin Pipelines within the existing right-of-way, both located in Stanislaus County, with one about 20 miles east of Modesto and the other about 15 miles west of Modesto, and improvements at the existing Roselle Crossover. • Construction of a new 10-mile-long, up to 86-inch-diameter fourth San Joaquin Pipeline parallel to the existing three pipelines at the west end of the pipelines ending at Tesla Portal. This project would provide additional facilities to upgrade the hydraulic capacity of the San Joaquin Pipeline system to 314 mgd (and a 271-mgd average during system maintenance when a pipeline segment must be taken out of service) and to provide redundancy for prestressed concrete cylinder pipe for reliability. Note: While the current preferred alternative would construct 16 miles of pipeline, as much as 22 miles of pipeline could be constructed depending on the results of a conditions assessment of the existing pipelines.
SJ-4	Rehabilitation of Existing San Joaquin Pipelines	Pipeline / Water Supply, Delivery Reliability	Rehabilitation could occur anywhere along the pipeline corridor, which extends from Oakdale Portal to Tesla Portal	Reconditioning/rehabilitation of the existing San Joaquin Pipelines. There are three existing pipelines, each 47.7 miles long, extending from Oakdale Portal to Tesla Portal: • SJPL-1, riveted steel pipe, 56- to 72-inch internal diameter • SJPL-2, reinforced concrete pipe and welded steel pipe, 61- to 62-inch internal diameter • SJPL-3, prestressed concrete cylinder pipe and welded steel pipe, 78-inch internal diameter

TABLE S.2 (Continued)
WSIP FACILITY IMPROVEMENT PROJECTS

No.[a]	Project Title	Principal Type of Facility/ Objectives[b]	Location of Preferred Project[c]	Project Description
San Joaquin Region (cont.)				
SJ-5	Tesla Portal Disinfection Station	Treatment / Water Quality, Seismic Reliability	Tesla Portal	This project includes the planning, design, and construction of new disinfection facilities for the Hetch Hetchy water supply. The project would replace and upgrade the existing disinfection facilities at the Tesla Portal Disinfection Facility to meet current seismic, safety/fire, and building code standards. The preferred project would include construction of: • New control building and storage room • Pump houses • Chemical storage tanks and feed equipment and sampling systems • Emergency generator, including primary and standby power supplies • Access road It should be noted that the design and location of the Advanced Disinfection project would affect the design and location of this project.
Sunol Valley Region				
SV-1	Alameda Creek Fishery Enhancement	Other / Water Supply, Sustainability	Structural Alternatives: Alameda Creek in Sunol Valley, downstream of Calaveras Dam	This project would recapture the water released as part of the Calaveras Dam project and return it back to the regional system for use. A number of structural and non-structural recovery alternatives are under consideration for this project, including: a water recapture facility downstream of the Sunol Valley WTP, conjunctive groundwater use, horizontal collector wells, or other groundwater recovery systems yet to be defined. Other alternative designs for this project could be developed. If a structural alternative involving construction of a recapture facility is selected, the recapture facility would be located at the downstream end of the reach of Alameda Creek between the lower Sunol Valley and the confluence with Arroyo de la Laguna. As an alternative to the recapture facility, the SFPUC may coordinate with other water agencies to develop and implement other means of recapturing fishery enhancement flows consistent with the 1997 CDFG MOU.
SV-2	Calaveras Dam Replacement	Storage / Water Supply, Delivery and Seismic Reliability	Sunol Valley, immediately downstream of existing dam and at the Alameda Creek Diversion Dam	This project would provide for the planning, design, and construction of a replacement dam at Calaveras Reservoir to meet seismic safety requirements. The new dam would provide for a reservoir with the same storage capacity as the original reservoir (96,800 acre-feet), but the replacement dam would be designed to accommodate enlargement of the dam in the future. The preferred project would include construction of: • New earthfill dam • New intake tower and new outlet valve for water releases for instream flow requirements • New or rehabilitated outlet works for seismic safety and improved operations and maintenance • New bypass structure at the Alameda Creek Diversion Dam As part of this project, Calaveras Reservoir and the proposed bypass structure at the diversion dam would be operated to release up to 6,300 acre-feet per year (5.5 mgd) of water to Alameda Creek in support of fisheries in compliance with the 1997 CDFG MOU. When flow is available in Alameda Creek, releases would be made through the proposed bypass structure at the Alameda Creek Diversion Dam and would be supplemented as necessary with releases from Calaveras Dam.

TABLE S.2 (Continued)
WSIP FACILITY IMPROVEMENT PROJECTS

No.[a]	Project Title	Principal Type of Facility/ Objectives[b]	Location of Preferred Project[c]	Project Description
SV-3	Additional 40-mgd Treated Water Supply	Treatment / Water Quality, Delivery Reliability	Sunol Valley WTP and pipeline to connect to the Alameda Siphons or Irvington Tunnel	This project would provide for the planning, design, and construction of an additional 40 mgd of treatment capacity at the Sunol Valley WTP. The project would increase the sustainable capacity of the Sunol Valley WTP to 160 mgd. The planning-level study would evaluate treatment operations protocol and an alternative treatment process. The project would include either retrofitting the existing facilities with a membrane treatment process or expanding the existing facilities with: • New flocculation and sedimentation system • Upgrade of existing filters or addition of three new filters and a new flow distribution chamber

TABLE S.2 (Continued)
WSIP FACILITY IMPROVEMENT PROJECTS

No.[a]	Project Title	Principal Type of Facility/ Objectives[b]	Location of Preferred Project[c]	Project Description
Sunol Valley Region (cont.)				
SV-3 (cont.)				• New filtered water and backwash piping Additionally, the project would include: • New chemical feed and piping system • Upgrade of the electrical supply system • Miscellaneous piping, valves, and mechanical and electrical work • Approximately two miles of 78-inch-diameter pipe to connect to the Alameda Siphons or Irvington Tunnel
SV-4	New Irvington Tunnel	Tunnel / Delivery and Seismic Reliability	Sunol Valley to Fremont, parallel to and just south of the existing Irvington Tunnel	This project would construct a new tunnel parallel to and just south of the existing Irvington Tunnel to convey water from the Hetch Hetchy system and the Sunol Valley WTP to the Bay Area. The new tunnel would be a redundant water transmission facility to the existing Irvington Tunnel. The preferred project would include construction of: • New 18,200-foot-long, 10-foot-diameter tunnel • New portal at the east end adjacent to the existing Alameda West Portal in the Sunol Valley with connections to the existing Alameda Siphons and proposed new siphon • New portal at the west end adjacent to the existing Irvington Portal in Fremont with connections to the existing Bay Division Pipelines and proposed new pipeline (Bay Division Pipeline Reliability Upgrade) • Valves and equipment to control and monitor flows • Modifications to the existing Alameda West and Irvington Portals
SV-5	SVWTP – Treated Water Reservoirs	Storage and Treatment / Delivery Reliability	North of the Sunol Valley WTP	This project would provide for the planning, design, and construction of new treated water storage reservoirs at the Sunol Valley WTP to comply with requirements of the California Department of Health Services. The preferred project would include construction of: • One 5-million-gallon chlorine contact basin • Two 8.75-million-gallon storage basins • New inlet and outlet piping and reservoir drainage system • Pipe bridge over Alameda Creek • Chemical (ammonia and chlorine) storage and feed system • Backup filter washwater supply and filter washwater supply system • Instrumentation and controls and miscellaneous pumping appurtenances to integrate the reservoirs into the existing treatment plant • Expansion of the existing Sunol Valley WTP electrical substation • Two 750-kilowatt diesel-powered emergency generators

TABLE S.2 (Continued)
WSIP FACILITY IMPROVEMENT PROJECTS

No.[a]	Project Title	Principal Type of Facility/ Objectives[b]	Location of Preferred Project[c]	Project Description
Sunol Valley Region (cont.)				
SV-6	San Antonio Backup Pipeline	Pipeline / Delivery and Seismic Reliability	Sunol Valley between San Antonio Reservoir and San Antonio Pump Station	This project would consist of three proposed facilities: (1) San Antonio Backup Pipeline, a new pipeline (size undetermined) from San Antonio Reservoir to San Antonio Pump Station, about two miles long; (2) San Antonio Creek discharge facilities (improvements allowing for the discharge of Hetch Hetchy water and associated road improvements); and (3) Alameda East Portal vent overflow pipeline and portal modifications.
Bay Division Region				
BD-1	Bay Division Pipeline Reliability Upgrade	Pipeline and Tunnel / Water Supply, Delivery and Seismic Reliability	Along existing Bay Division Pipelines Nos. 1 and 2 easement from Fremont to Redwood City	This project would construct a new Bay Division Pipeline No. 5 (BDPL No. 5) from Irvington Tunnel Portal in Fremont to Pulgas Tunnel Portal near Redwood City, consisting of 16 miles of new pipeline and 5 miles of tunnel under San Francisco Bay. Portions of the section of BDPL No. 1 between Edgewood Valve Lot and Pulgas Valve Lot would be removed (approximately 1.4 miles), and existing aboveground and submarine sections of BDPL Nos. 1 and 2 over the five-mile-long section from Newark Valve House to Ravenswood Valve House would be decommissioned (decommissioning is not part of this project). The redundancy provided by the project would increase the overall transmission capacity of the Bay Division Pipeline system. The preferred project would include construction of: • New welded-steel pipeline, approximately 72 inches in diameter, extending along the seven-mile reach from Irvington Portal to Newark Valve Lot, located within the existing SFPUC right-of-way of BDPL Nos. 1 and 2 • New "Bay Tunnel" segment of BDPL No. 5, approximately 120 inches in diameter, extending five miles from Newark Valve Lot to Ravenswood Valve Lot, crossing under San Francisco Bay and adjacent marshlands; BDPL Nos. 1 and 2 would tie into the tunnel at both ends and would be decommissioned between Newark and Ravenswood Valve Lots • New welded-steel pipeline, approximately 60 inches in diameter extending along the nine-mile reach from Ravenswood Valve Lot to Pulgas Portal, located within the existing SFPUC right-of-way of BDPL Nos. 1 and 2 • New facilities at eight valve vault lots along the alignment, containing new concrete vaults and control structures that house electrical control panels, isolation valves, mechanical equipment, and cross-connections between BDPL No. 5 and the existing Bay Division Pipelines • Two flow metering vaults at or near Mission Boulevard (in Fremont) and Pulgas Portal areas • New Isolation valves and piping for connecting BDPL No. 5 to Irvington and Pulgas Portals

TABLE S.2 (Continued)
WSIP FACILITY IMPROVEMENT PROJECTS

No.[a]	Project Title	Principal Type of Facility/ Objectives[b]	Location of Preferred Project[c]	Project Description
Bay Division Region (cont.)				
BD-2	BDPL Nos. 3 and 4 Crossovers	Valve House / Delivery and Seismic Reliability	Three locations adjacent to where BDPL Nos. 3 and 4 traverse Guadalupe River, Barron Creek, Bear Gulch Reservoir	This project would construct three additional crossover facilities along BDPL Nos. 3 and 4 to provide operational flexibility for maintenance or during emergencies. The new crossover facilities would reduce the length of pipe to be removed from service, either for maintenance or for emergencies, and would reduce the duration of outages. Each crossover facility would include construction of: • Four mainline valves and one cross-connect valve • Automatic controlled actuators • Discharge facilities to enable release of water that meets water quality discharge requirements within discrete pipeline segments to surface waters, either for maintenance or emergencies
BD-3	Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault	Pipeline / Seismic Reliability	Along existing BDPL Nos. 3 and 4 in Fremont	This project would provide for the planning, design, and construction of upgraded, seismically resistant sections of the BDPL Nos. 3 and 4 where they cross the Hayward fault. The replacement pipelines would be located between the two new crossover/isolation valves that would be built as part of BDPL Nos. 3 and 4 Crossover/Isolation Valve at Hayward Fault project (a WSIP project determined to be independent of the PEIR). In addition to the replacement pipelines, a new bypass pipeline between the two new crossover/isolation valve vaults could also be built as part of one of the several alternatives being considered for this project.
Peninsula Region				
PN-1	Baden and San Pedro Valve Lots Improvements	Valve House / Delivery and Seismic Reliability	Baden Valve Lot, South San Francisco, San Pedro Valve Lot, Daly City	This project would upgrade valve vaults, valves, and piping at the existing Baden and San Pedro Valve Lots to meet current seismic standards. Work could also be performed at the Pulgas Pump Station and Pulgas Valve Lot as part of transmission reliability. The project would include a new pressure-reducing valve at one of the locations to allow transfer of water between high and low pressure zones from the Harry Tracy WTP to the Peninsula under an emergency scenario.
PN-2	Crystal Springs/ San Andreas Transmission Upgrade	Pipeline / Delivery and Seismic Reliability	Lower Crystal Springs Reservoir to San Andreas Reservoir, including Crystal Springs Pump Station	This project would consist of seismic improvements of facilities that convey water from Crystal Springs Reservoir to the Harry Tracy WTP. This project would increase the transmission capacity of the existing raw water pipeline from Crystal Springs Reservoir to San Andreas Reservoir in order to reliably supply 140 mgd of raw water for treatment at the Harry Tracy WTP. The project would include: • Repair of Upper Crystal Springs Dam discharge culverts • Upgrade and repair of Lower Crystal Springs Dam outlet structures and tunnels conveying water to Crystal Springs Pump Station • Replacement or refurbishment of Crystal Springs Pump Station • Upgrade and repair of the chemical system and Crystal Springs chlorine emergency feed • Improvements to the Crystal Springs/San Andreas Pipeline, including replacement of approximately 1,350 feet of 66-inch-diameter pipeline, general renewal of the remaining pipeline, and addition of new manholes, blowoff valves, and isolation valves; or construction of a new redundant pipeline along a new alignment.

TABLE S.2 (Continued)
WSIP FACILITY IMPROVEMENT PROJECTS

No.[a]	Project Title	Principal Type of Facility/ Objectives[b]	Location of Preferred Project[c]	Project Description
Peninsula Region (cont.)				
PN-2 (cont.)				• Seismic and hydraulic upgrade and repair of San Andreas outlet facilities • Addition of fish screens on the outlet structures for both Crystal Springs and San Andreas Reservoirs • Repair of two pipelines that convey raw water from San Andreas Reservoir to the Harry Tracy WTP raw water pump station
PN-3	HTWTP Long-Term Improvements	Treatment / Water Quality, Delivery and Seismic Reliability	Harry Tracy WTP	This project would be a seismic retrofit and rehabilitation of the existing building and facility to provide long-term reliability and process improvements. The project would increase the sustained treatment capacity of the plant from 120 to 140 mgd for 60 days. The proposed improvements would include: • Replacement and upgrade of the ozone generation system for primary disinfection • Replacement or upgrade of the existing sedimentation basins at the same location • Improvements to sludge handling facilities • New, redundant pipeline from the treatment works to the finished water storage reservoir • Raw water pump station improvements • Upgrade and replacement of electrical and instrumentation components, including improvements to process and plant security facilities
PN-4	Lower Crystal Springs Dam Improvements	Storage / Water Supply and Delivery Reliability	Lower Crystal Springs Dam	This project would consist of major repairs and improvements to Lower Crystal Springs Dam to provide adequate protection of the dam and downstream areas from the probable maximum flood, as defined by the DSOD. DSOD has placed operational restrictions on the dam, and the capacity of the reservoir is limited to 56,800 acre-feet. The project would restore the historical reservoir capacity of 68,000 acre-feet. The project would be coordinated with San Mateo County, which is concurrently planning the replacement of the existing county bridge built above the crest of the dam. Project elements would include: • Lowering the existing parapet wall on either side of the existing spillway to lengthen the overflow weir (central spillway) from the reservoir • Raising the remaining parapet walls and adding two new spillway bays, one on each side of the existing central spillway • Enlarging the spillway stilling basin to accommodated the probable maximum flood • Installing four gates (with control building) or installing a fixed weir within the spillway to restore the historical storage capacity

TABLE S.2 (Continued)
WSIP FACILITY IMPROVEMENT PROJECTS

No.[a]	Project Title	Principal Type of Facility/ Objectives[b]	Location of Preferred Project[c]	Project Description
Peninsula Region (cont.)				
PN-5	Pulgas Balancing Reservoir Rehabilitation	Storage / Water Quality, Delivery and Seismic Reliability	Pulgas Balancing Reservoir and mouth of Laguna Creek at south end of Upper Crystal Springs Reservoir	This project would provide for the planning, design, and construction of improvements to the existing Pulgas Balancing Reservoir and associated facilities. The project would include: • Modifications to the inlet/outlet piping (Phase 1, currently under construction) • Design and construction to rehabilitate and/or expand the discharge channel to Crystal Springs Reservoir (or to install a parallel channel) (Phase 2) • Geotechnical investigations, design, and construction of recommended seismic improvements, including repair/replacement of the reservoir walls, floor, and roof (Phase 3) • Restoration of a six- to eight-acre sediment catchment basin in Laguna Creek to also serve as sustainable habitat for San Francisco garter snake and California red-legged frog, including culvert replacement, sediment removal, revegetation, and protective measures to avoid impacts on sensitive species (Phase 4) • Modification of the existing dechlorination process, including modifications to the chemical feed system to enable pH adjustment and dechlorination system to operate reliably (Phase 5)
San Francisco Region				
SF-1	San Andreas Pipeline No. 3 Installation	Pipeline / Delivery and Seismic Reliability	Daly City to San Francisco	This project would replace the out-of-service Baden-Merced Pipeline, which is beyond repair, and would construct a new pipeline extension of the existing San Andreas Pipeline No. 3 from San Pedro Valve Lot in Daly City to Merced Manor Reservoir in San Francisco. It would also connect the existing San Andreas Pipeline No. 2 at Sloat Boulevard in San Francisco and install an additional pipeline to serve the water turnouts along San Andreas Pipeline No. 2. The project would provide seismic reliability and system redundancy for Peninsula and San Francisco customers. The project would include: • New 3.8-mile-long, 36-inch-diameter pipeline • Approximately 0.27 mile of 36-inchdiameter pipeline for three connections between San Andreas Pipelines Nos. 2 and 3 • Removal of the Baden-Merced Pipeline where the new San Andreas Pipeline No. 3 alignment matches the Baden-Merced alignment • Less than 0.1 mile of 12- to 16-inch-diameter new pipeline for five branch connections to user turnouts (three turnouts to Daly City, two turnouts to San Francisco distribution lines) • Installation of line valves and vaults, manholes, cathodic protection and monitoring stations, sample taps, air valves, blowoffs, and other pipeline appurtenances
SF-2	Groundwater Projects	Other / Water Supply	West side of San Francisco and northern San Mateo County	This project includes three groundwater projects: Lake Merced, Local Groundwater, and Regional Groundwater. • The Lake Merced project would address raising the level of Lake Merced in San Francisco using a supplemental source of water, such as treated stormwater, recycled water, groundwater, or SFPUC system water.

TABLE S.2 (Continued)
WSIP FACILITY IMPROVEMENT PROJECTS

No.[a]	Project Title	Principal Type of Facility/ Objectives[b]	Location of Preferred Project[c]	Project Description
San Francisco Region (cont.)				
SF-2 (cont.)				• The Local Groundwater Projects would include development of 2 mgd of new local groundwater for blending with water in the potable water system in San Francisco. An estimated four wells and well stations would be constructed to develop this new local groundwater. This project would also include the use of an additional 2 mgd of groundwater through replacement of existing irrigation wells at the San Francisco Zoo, Golden Gate Park, and/or other locations, once recycled water were available for irrigation (to be developed under the Recycled Water Projects). Two existing wells would be modified to enable emergency supply to local residents in the event of a major earthquake or other disaster. This project would include the pipelines, water treatment equipment, and controls needed to add the groundwater to the municipal supply. The additional water supply developed under this project would be used during both nondrought and drought years. • As part of a regional conjunctive-use project, the SFPUC would construct about 10 new groundwater production wells in San Mateo County to develop about 6 mgd of potable groundwater for use as a supplemental drought-year supply. In nondrought years under this project, the SFPUC would provide potable water from the regional system to customers in Daly City, San Bruno, and South San Francisco to substitute for groundwater currently used for municipal purposes, thereby reducing groundwater pumping and allowing the groundwater basin to recharge naturally. In drought years, the groundwater would be available for local use to supplement the regional system water. This project would require agreements with the affected agencies see (Section 3.13).
SF-3	Recycled Water Projects	Other / Water Supply, Sustainability	Various locations on west side of San Francisco	This project includes recycled water projects in San Francisco and other locations. Projects include Westside Baseline and Harding Park/Lake Merced. This project would provide treatment, storage, and distribution facilities for about 4 mgd of recycled water to users on the west side of San Francisco. Primary users would include Golden Gate Park, Lincoln Park, Lincoln Park Golf Course, Harding Park Golf Course, San Francisco Zoo, Sunset Boulevard medians, and San Francisco State University. As described under Groundwater Projects, the SFPUC is also investigating appropriate sources of supply for increasing and maintaining Lake Merced lake levels, including recycled water that has undergone advanced treatment.

[a] The numbering system is consistent, to the extent possible, with that presented in the Notice of Preparation (NOP) regarding preparation of an environmental impact report on the WSIP issued in September 2005. However, due to a regrouping of the projects after publication of the NOP, some projects have been renumbered.
[b] General types of facilities. Objectives refer to the WSIP objectives met by each project; see Table S.1 for a complete description of WSIP goals and objectives.
[c] See Figure S.6 for the approximate locations of preferred projects; many of the projects are still in development, and the SFPUC may ultimately consider other design options.

Figure S.7
Preliminary WSIP Construction Schedule

S.3 Environmental Effects (Chapters 4, 5, and 7)

Approach to Analyzing WSIP Facility Projects and Water Supply System Operations

The PEIR analysis of the environmental impacts of the WSIP is divided into three parts:

- Impacts Associated with Facility Improvement Projects (Chapter 4)
- Impacts Associated with Water Supply and System Operations (Chapter 5)
- Growth-Inducement Potential and Indirect Effects of Growth (Chapter 7)

Chapter 4 of this PEIR evaluates the major environmental effects of implementing proposed facility improvement projects from a broad perspective; this evaluation is a *program-level* analysis. While the SFPUC is aggressively developing the design, construction, and operation details of the projects included in the WSIP, these project details are not the focus of this PEIR. Instead, the PEIR frames the nature and magnitude of the expected environmental impacts associated with the proposed WSIP projects and identifies program mitigation measures to reduce the impacts of the projects as proposed. More detailed *project-level* analysis of individual facility improvement projects will be conducted separately, as required by CEQA.

In addition, Chapter 5 of this PEIR provides a *project-level* impact analysis of implementing the proposed water supply option through 2030. The chief environmental issues evaluated in the PEIR at a *project level* include:

- The effects of providing additional water to serve increasing customer purchase requests within the SFPUC service area (specifically, the effect of increasing the average annual water supply to serve customer purchase requests through 2030)
- The effects of using the proposed sources of water to serve the increased purchase requests through 2030 during both nondrought and drought periods
- The effects of proposed changes in system operations associated with implementing the proposed facility improvement projects and achieving the WSIP system performance objectives

The PEIR also evaluates the growth-inducement potential of the proposed WSIP—specifically, the proposal to serve increased customer purchase requests through 2030. The PEIR provides a comprehensive analysis of growth inducement for the WSIP as a whole and the secondary effects of growth; therefore, these issues do not need to be reevaluated during the environmental review of each individual WSIP facility improvement project.

Impact Significance Determinations

The level of significance of each impact was determined using significance criteria (thresholds) developed for each category of impacts. The following categories are used to describe impact significance:

Not Applicable (N/A). An impact is considered not applicable to a WSIP project if there is no potential for impacts or the environmental resource does not occur within the project area or the area of potential effect.

Beneficial (B). This determination applies to impacts that are beneficial for one or more environmental resource.

Less than Significant (LS). This determination applies if there is a potential for some limited impact, but not a substantial adverse effect that qualifies under the significance criteria as a significant impact.

Less than Significant with Program-Level Mitigation (LSM). This determination applies to the "collective" impact analysis only. The collective impact analysis is found in Chapter 4, Section 4.16, which presents the combined and overlapping effects of multiple WSIP facility projects.

Potentially Significant, Mitigatable (PSM). This determination applies if there is the potential for a substantial adverse effect that meets the significance criteria, but mitigation is available to reduce the impact to a less-than-significant level.

Potentially Significant, Unavoidable (PSU). This determination applies to impacts that are significant but for which there appears to be no feasible mitigation available to reduce the impacts to a less-than-significant level.

Significant Unavoidable (SU). This determination applies to impacts that are significant but for which there appears to be no feasible mitigation available to reduce the impact to a less-than-significant level.

Effects of the Facility Improvement Projects (Chapter 4)

Chapter 4 of this PEIR presents a program-level evaluation of the potential environmental impacts of constructing and operating each of the 22 regional WSIP facility improvement projects. It also evaluates the impacts associated with the combined and overlapping effects of multiple WSIP facility projects, referred to as "collective" impacts. In addition, Chapter 4 identifies the cumulative effects of implementing the WSIP facility improvement projects in combination with other past, present, and reasonably foreseeable future projects with similar impacts within the same regions. **Table S.3** lists the results of the impact assessment for each facility improvement project, by resource topic area. **Table S.4** summarizes the mitigation measures that will be implemented to avoid, minimize, or otherwise reduce significant impacts to a less-than-significant level for one or more of the facility improvement projects. The key impacts associated with implementation of the WSIP facility improvement projects are summarized below.

Facility Construction Effects

The major impacts associated with the facility improvement projects would occur primarily during the construction phase rather than during the operations phase. Although most construction impacts would be short term, they could pose significant effects. The construction of facility improvement projects could result in potential land use disruption, slope instability, water quality and flooding effects, disruption of sensitive habitats and impacts on special-status species, impacts on cultural resources, short-term traffic delays and impaired access along project roadways, local and regional degradation of air quality, short-term noise and vibration impacts, disruption of public utilities, effects on solid waste landfill capacity, temporary conflicts with recreational and agricultural uses, exposure to hazardous materials, and use of energy. These impacts would be mitigated to a less-than-significant level through implementation of the mitigation measures described in Chapter 6 of the PEIR, with the exception of the effects listed below. This PEIR makes a conservative determination that the effects listed below would be potentially significant and unavoidable. When more facility siting and construction information is available and MEA completes more detailed project-level CEQA review on the WSIP projects, it may be determined that these effects can be avoided or mitigated to a less-than-significant level.

- A ranch property in the Sunol Valley would be subject to 24-hour construction effects for the full duration of construction of the New Irvington Tunnel project, and such land use disruption is considered to be potentially significant and unavoidable even with implementation of traffic, noise, and air quality mitigation measures (Chapter 4, Section 4.3).
- Existing land uses could be displaced to accommodate proposed facilities at some locations under the following projects: San Joaquin Pipeline System, Additional 40-mgd Treated Water Supply, San Antonio Backup Pipeline, Bay Division Pipeline Reliability Upgrade, Crystal Springs/San Andreas Transmission Upgrade, Groundwater Projects, and Recycled Water Projects. Since final facility locations are undetermined, any possible permanent displacement of existing land uses is conservatively considered to be potentially significant and unavoidable in this PEIR (Chapter 4, Section 4.3).
- Removal of a large area of existing oak woodland cover as part of the Calaveras Dam Replacement project would permanently alter a scenic vista, a potentially significant and unavoidable impact (Chapter 4, Section 4.3).
- Alteration or demolition of existing facilities under the following projects could result in potentially significant and unavoidable impacts on the historical significance of individual facilities: Calaveras Dam Replacement, New Irvington Tunnel, Crystal Springs/San Andreas Transmission Upgrade, and Lower Crystal Springs Dam Improvements (Chapter 4, Section 4.7).
- The Calaveras Dam Replacement and Crystal Springs/San Andreas Transmission Upgrade projects would result in potentially significant and unavoidable impacts on historic districts, if historic districts are determined to be present (Chapter 4, Section 4.7).
- Temporary construction-related noise impacts could occur under all facility improvement projects analyzed in the PEIR and would be potentially significant and unavoidable if excessive construction noise occurred in close proximity to sensitive receptors or audible construction noise occurred during the more noise-sensitive nighttime hours (Chapter 4, Section 4.10).

TABLE S.4
SUMMARY OF FACILITY MITIGATION MEASURES BY IMPACT

Impact	Mitigation Measure(s)
Impact 4.3-1: Temporary disruption or displacement of existing land uses during construction.	Traffic, Transportation, and Circulation Measures (4.8-1a and 4.8-1b); Air Quality Measures (4.9-1a thru 4.9-1d, 4.9-2a and 4.9-2b); Noise Measures (4.10-1a, 4.10-1b, 4.10-2a thru 4.10-2c, 4.10-3a thru 4.10-3c); and Recreational Resources Measure (4.12-1), described below.
Impact 4.3-2: Permanent displacement or long-term disruption of existing land uses.	**Measure 4.3-2, Facility Siting Studies:** Conduct project-specific facility siting studies for non-SFPUC land and implement these studies' recommendations to avoid or minimize impacts on existing land uses.
Impact 4.3-3: Temporary construction impacts on scenic vistas or visual character.	None required.
Impact 4.3-4: Permanent adverse impacts on scenic vistas or visual character.	**Measure 4.3-4a, Architectural Design:** Design permanent new, aboveground facilities to be compatible with existing visual character of the site and surrounding area. **Measure 4.3-4b, Landscaping Plans:** Prepare and implement landscaping plans to restore (recontour, revegetate, landscape) sites to preconstruction conditions. Monitor landscape plantings. **Measure 4.3-4c, Landscape Screens:** Include new plantings and landscape berms to screen views of new structures and equipment from scenic roads. **Measure 4.3-4d, Minimize Tree Removal:** Minimize or avoid the removal of trees that screen existing and proposed WSIP facility sites; implement tree replacement plan.
Impact 4.3-5: New permanent sources of light and glare.	**Measure 4.3-5, Reduce Lighting Effects:** Use cut-off shields and nonglare fixture design, direct lighting onsite and downward, prevent use of highly reflective building materials or finishes.
Impact 4.4-1: Slope instability during construction.	**Measure 4.4-1, Quantified Landslide Analysis:** Avoid sites with landslide hazards; where they cannot be avoided, conduct site-specific slope stability analyses and implement recommendations.
Impact 4.4-2: Erosion during construction.	None required.
Impact 4.4-3: Substantial alteration of topography.	None required.
Impact 4.4-4: Squeezing ground and subsidence during tunneling.	**Measure 4.4-4, Subsidence Monitoring Program:** Monitor subsidence and implement corrective actions as warranted.
Impact 4.4-5: Surface fault rupture.	None required.
Impact 4.4-6: Seismically induced groundshaking.	None required.
Impact 4.4-7: Seismically induced ground failure, including liquefaction and settlement.	None required.
Impact 4.4-8: Seismically induced landslides or other slope failures.	None required.
Impact 4.4-9: Expansive or corrosive soils.	**Measure 4.4-9, Characterize Extent of Expansive and Corrosive Soil:** Characterize presence of expansive/corrosive soils; implement recommendations.

[a] Mitigation measure text is summarized; please see Chapter 6 for details.
[b] The City and County of San Francisco (including the SFPUC, the Planning Department, and other City agencies and departments) would be responsible for implementing all mitigation measures; please see Chapter 6 for details.

TABLE S.4 (Continued)
SUMMARY OF FACILITY MITIGATION MEASURES BY IMPACT

Impact	Mitigation Measure(s)
Impact 4.5-1: Degradation of water bodies as a result of erosion and sedimentation or a hazardous materials release during construction.	None required.
Impact 4.5-2: Depletion of groundwater resources.	**Measure 4.5-2, Site-Specific Groundwater Analysis and Identified Measures:** Conduct project-specific analysis of dewatering and implement measures to ensure that groundwater resources beneficial uses of groundwater not adversely affected.
Impact 4.5-3a: Degradation of water quality due to construction dewatering discharges.	None required.
Impact 4.5-3b: Degradation of water quality due to construction-related discharges of treated water.	None required.
Impact 4.5-4: Flooding and water quality impacts associated with impeding or redirecting flood flows.	**Measure 4.5-4a, Flood Flow Protection Measures:** Preclude exposure of stockpiled soils, hazardous materials, and construction materials to flood flows. **Measure 4.5-4b, Site-Specific Flooding Analysis and Identified Measures:** Implement design measures to preclude projects from causing flooding or damage from redirected flood flows.
Impact 4.5-5: Degradation of water quality and increased flows due to discharges to surface water during operation.	**Measure 4.5-5**, **Stormwater Treatment and Groundwater Monitoring:** If treated stormwater is used to maintain Lake Merced water levels, monitor surface water and groundwater quality in the vicinity of Lake Merced. Identify and implement corrective actions (e.g., treatment).
Impact 4.5-6: Degradation of water quality as a result of alteration of drainage patterns or an increase in impervious surfaces.	**Measure 4.5-6, Appropriate Source Controls and Site Design Measures:** If a WSIP project will affect jurisdictional wetlands, implement source control and site design measures to ensure compliance with applicable water quality criteria and goals and protect the beneficial uses of the receiving water.
Impact 4.6-1: Impacts on wetlands and aquatic resources.	**Measure 4.6-1a, Wetlands Assessment:** Wetland scientist will determine whether wetlands could be affected by the project, and if so, perform a wetland delineation and develop mitigation. **Measure 4.6-1b, Compensation for Wetlands and Other Biological Resources:** If a WSIP project will affect jurisdictional wetlands, implement avoidance measures, restoration procedures, and compensatory creation or enhancement to ensure no net loss of wetland extent or function. Compensate for sensitive riparian and upland habitats supporting key special-status species. Obtain permits for each project and comply with applicable regulations addressing sensitive habitats and species. The Habitat Reserve Program is an alternative for implementing offsite habitat compensation.
Impact 4.6-2: Impacts on sensitive habitats, common habitats, and heritage trees.	Biological Resources Measure 4.6-1b, described above. **Measure 4.6-2, Habitat Restoration/Tree Replacement:** Restore temporarily affected sensitive habitats. Replace trees designated as heritage trees (or similar local designation) consistent with requirements of local ordinances. Minimize loss of sensitive habitats by coordinating WSIP projects.

[a] Mitigation measure text is summarized; please see Chapter 6 for details.
[b] The City and County of San Francisco (including the SFPUC, the Planning Department, and other City agencies and departments) would be responsible for implementing all mitigation measures; please see Chapter 6 for details.

TABLE S.4 (Continued)
SUMMARY OF FACILITY MITIGATION MEASURES BY IMPACT

Impact	Mitigation Measure(s)
Impact 4.6-3: Impacts on key special-status species – direct mortality and/or habitat effects.	Biological Resources Measure 4.6-1b, described above. **Measure 4.6-3a, Protection Measures During Construction for Key Special-Status Species and Other Species of Concern:** Where key special-status species and other species of concern are potentially present, implement general practice measures (preconstruction surveys, worker awareness program, environmental inspector, minimization of habitat loss). **Measure 4.6-3b, Standard Mitigation Measures for Key Special-Status Plants and Animals:** Implement measures to reduce impacts on key special-status species.
Impact 4.6-4: Water discharge effects on riparian and/or aquatic resources.	**Measure 4.6-4, Pipeline and Water Treatment Plant Treated Water Discharge Restrictions:** Design planned discharges from the WSIP pipelines and water treatment plants to natural water bodies to minimize impacts on riparian and aquatic resources and to avoid or minimize temperature effects on aquatic resources.
Impact 4.6-5: Conflicts with adopted conservation plans or other approved biological resources plans.	Biological Resources Measures 4.6-1a, 4.6-1b, 4.6-2, 4.6-3a, and 4.6-3b, described above.
Impact 4.7-1: Impacts on paleontological resources.	**Measure 4.7-1, Suspend Construction Work if Paleontological Resource is Identified:** Suspend work and notify a qualified paleontologist when a paleontological resource is discovered at any of the project sites. The paleontologist will document the discovery as needed, evaluate the potential resource, and assess the significance of the find under CEQA criteria. Temporarily halt or divert excavation within 50 feet of a fossil find until the discovery is examined by a paleontologist. If avoidance is not feasible, the paleontologist will prepare an excavation plan.
Impact 4.7-2: Impacts on archaeological resources.	**Measure 4.7-2a, Archaeological Testing, Monitoring, and Treatment of Human Remains:** Determine if implementation of an archeological testing or archaeological monitoring program or both is the appropriate strategy for avoidance of potential adverse effects on significant archaeological resources. Review any requirements approved by the State Historic Preservation Officer. Prepare an archeological testing plan, an archeological monitoring plan, final archeological resources report and, if applicable, a archeological data recovery plan. The treatment of human remains and of associated or unassociated funerary objects discovered during any soil-disturbing activity will comply with applicable state laws. **Measure 4.7-2b, Accidental Discovery Measures:** Distribute archaeological resource "ALERT" to contractors. If an archeological resource may be present within the project site, an archeological consultant will evaluate it and make a recommendation as to what action (e.g., preservation in situ) is warranted. The project sponsor will implement appropriate measures.

[a] Mitigation measure text is summarized; please see Chapter 6 for details.
[b] The City and County of San Francisco (including the SFPUC, the Planning Department, and other City agencies and departments) would be responsible for implementing all mitigation measures; please see Chapter 6 for details.

TABLE S.4 (Continued)
SUMMARY OF FACILITY MITIGATION MEASURES BY IMPACT

Impact	Mitigation Measure(s)
Impact 4.7-3: Impacts on historical significance of a historic district or a contributor to a historic district.	Cultural Resources Measures 4.7-4a thru 4.7-4f, described below. **Measure 4.7-3, Protection of Historic Districts:** A qualified historian will assess the city's water system facilities affected by WSIP facility projects for their potential contribution to a historic district. If a historic district would be affected by one or more proposed WSIP facility projects, develop and implement mitigation measures for effects with attention to the potential district as a whole. Should a historic district be identified at the project level, it should be recorded as such, using National/California Register criteria of significance. Document the district by completing the State of California Department of Parks and Recreation 523 forms and submit to the State Historic Preservation Officer.
Impact 4.7-4: Impacts on the historical significance of individual facilities resulting from demolition or alteration.	**Measure 4.7-4a, Alternatives Identification and Resource Relocation:** Identify feasible project alternatives to eliminate or reduce the need for demolition or removal of a historic resource to the greatest extent possible. If preservation of the affected historical resource at the current site is determined to be infeasible, the structure will, if feasible, be stabilized and relocated to other appropriate nearby sites. After relocation, the resource will be treated according to the Secretary of the Interior's *Standards for the Treatment of Historic Properties.* If the affected historical resource is to be demolished, consult with local historical societies and governmental agencies regarding salvage of materials for public information or reuse in other locations. **Measure 4.7-4b, Historical Resources Documentation:** Prepare documentation of historical resources prior to any construction work associated with demolition or removal. The appropriate level of documentation will be selected by a qualified professional who meets the standards for history, architectural history, and/or architecture (as appropriate) set forth by the Secretary of the Interior's *Professional Qualification Standards* (36 CFR 61) in consultation with a preservation specialist assigned by the San Francisco Planning Department and the local jurisdiction, if deemed appropriate by the Planning Department. **Measure 4.7-4c, Secretary of the Interior's Standards for Treatment of Historic Properties:** Prepare materials describing and depicting the proposed project. Review the proposed project for compliance with the Secretary of the Interior's *Standards for the Treatment of Historic Properties*. If a project is determined to be inconsistent with the *Standards for the Treatment of Historic Properties*, pursue and implement redesign of the project such that consistency with the standards is achieved. **Measure 4.7-4d, Historic Resources Survey and Redesign:** Undertake a historic resources survey to identify and evaluate potential historical resources that may exist in the project's area of potential effect. If a survey identifies one or more historical resources, assess the impact the project may have on those historical

[a] Mitigation measure text is summarized; please see Chapter 6 for details.
[b] The City and County of San Francisco (including the SFPUC, the Planning Department, and other City agencies and departments) would be responsible for implementing all mitigation measures; please see Chapter 6 for details.

TABLE S.4 (Continued)
SUMMARY OF FACILITY MITIGATION MEASURES BY IMPACT

Impact	Mitigation Measure(s)
Impact 4.7-4 (cont.)	resources. If the project will cause a substantial adverse change to a historical resource, assign a preservation specialist to review the proposed project, for compliance with the Secretary of the Interior's *Standards for the Treatment of Historic Properties*. If the project is determined to be inconsistent with those standards, pursue and implement redesign of the project such that consistency with the standards is achieved. **Measure 4.7-4e, Historic Resources Protection Plan:** A qualified historian will prepare a plan that specifies procedures for protecting and monitoring historical resources during construction. **Measure 4.7-4f, Preconstruction Surveys and Vibration Monitoring:** Include geotechnical investigations if vibration-related impacts could affect historical resources. Follow recommendations of the final geotechnical reports. Conduct a preconstruction survey of existing conditions and monitor the adjacent buildings for damage during construction, if recommended.
Impact 4.7-5: Impacts on adjacent historic architectural resources.	Cultural Resources Measures 4.7-4a thru 4.7-4f, described above.
Impact 4.8-1: Temporary reduction in roadway capacity and increased traffic delays.	**Measure 4.8-1a, Traffic Control Plan Measures:** Elements of the traffic control plan could include: circulation and detour plans, designated truck routes, sufficient staging area, access to driveways, use of standard construction specifications for controlling construction vehicle movements, restrictions on truck trips during peak morning and evening commute hours, lane closure restrictions, maintenance of alternate one-way traffic flow, detour signing, pedestrian and bicycle access and circulation, equipment and materials storage, construction worker parking, roadside safety protocols, considerations for sensitive land uses, coordination with local transit service providers, roadway repair, conformance with the *California Manual on Uniform Traffic Control Devices for Streets and Highways: Part 6 Temporary Traffic Control and Caltrans' 2006 Standard Plans*. **Measure 4.8-1b, Coordination of Individual Traffic Control Plans:** In the event that more than one construction contract is issued for work along existing or new pipelines, and where construction could occur within and/or across multiple streets in the same vicinity, coordinate the traffic control plans in order to mitigate the impact of traffic disruption by including measures that address overlapping construction schedules and activities, truck arrivals and departures, lane closures and detours, and the adequacy of on-street staging requirements.
Impact 4.8-2: Short-term traffic increases on roadways.	Traffic, Transportation, and Circulation Measures 4.8-1a and 4.8-1b, described above.
Impact 4.8-3: Impaired access to adjacent roadways and land uses.	Traffic, Transportation, and Circulation Measure 4.8-1a, described above.

[a] Mitigation measure text is summarized; please see Chapter 6 for details.
[b] The City and County of San Francisco (including the SFPUC, the Planning Department, and other City agencies and departments) would be responsible for implementing all mitigation measures; please see Chapter 6 for details.

TABLE S.4 (Continued)
SUMMARY OF FACILITY MITIGATION MEASURES BY IMPACT

Impact	Mitigation Measure(s)
Impact 4.8-4: Temporary displacement of on-street parking.	Traffic, Transportation, and Circulation Measure 4.8-1a, described above. **Measure 4.8-4, Accommodation of Displaced Public Parking Supply for Recreational Visitors:** Include an additional measure in the traffic control plans to accommodate any anticipated visitor parking demand that would be displaced by proposed projects at public recreational facilities.
Impact 4.8-5: Increased traffic safety hazards during construction.	Traffic, Transportation, and Circulation Measure 4.8-1a, described above.
Impact 4:8-6: Long-term traffic increases during facility operation.	None required.
Impact 4.9-1: Construction emissions of criteria pollutants.	**Measure 4.9-1a, SJVAPCD Dust Control Measures:** Include San Joaquin Valley Air Pollution Control District (SJVAPCD) Basic Control Measures in contract specifications for all construction sites. Include SJVAPCD Enhanced Control Measures in contract specifications when required to mitigate significant PM_{10} impacts. Include SJVAPCD Additional Control Measures in contract specifications for construction sites that are large in area, located near sensitive receptors, or which for any other reason warrant additional emissions reductions. Include SJVAPCD Rule 9510, Indirect Source Review, Section 6.1, Construction Equipment Emissions in contract specifications for any project subject to discretionary approval by a public agency that ultimately results in the construction of a new building, facility, or structure or reconstruction of a building, facility, or structure for the purpose of increasing capacity or activity and also involving 9,000 square feet of space. **Measure 4.9-1b, SJVAPCD Exhaust Control Measures:** Include SJVAPCD Exhaust Control Measures in contract specifications, where applicable, for heavy-duty equipment to limit exhaust emissions within the San Joaquin Region. **Measure 4.9-1c, BAAQMD Dust Control Measures:** For projects in the Sunol Valley, Bay Division, Peninsula, and San Francisco Regions, include Bay Area Air Quality Management District (BAAQMD) Basic Control Measures in contract specifications for all construction sites. Include BAAQMD Enhanced Control Measures in contract specifications for sites over four acres. Include BAAQMD Optional Control Measures in contract specifications for sites that are large in area, located near sensitive receptors, or which for any other reason warrant additional emissions reductions. **Measure 4.9-1d, BAAQMD Exhaust Control Measures:** For projects in the Sunol Valley, Bay Division, Peninsula, and San Francisco Regions, include BAAQMD Exhaust Control Measures to limit exhaust emissions, where applicable.

[a] Mitigation measure text is summarized; please see Chapter 6 for details.
[b] The City and County of San Francisco (including the SFPUC, the Planning Department, and other City agencies and departments) would be responsible for implementing all mitigation measures; please see Chapter 6 for details.

TABLE S.4 (Continued)
SUMMARY OF FACILITY MITIGATION MEASURES BY IMPACT

Impact	Mitigation Measure(s)
Impact 4.9-2: Exposure to diesel particulate matter during construction.	**Measure 4.9-2a, Health Risk Screening or Use of Soot Filters:** Complete a health risk screening if truck volumes associated with a particular project along a particular haul route exceed 40,000 truck trips over the entire construction period. If a potentially significant impact is indicated, complete a site-specific health risk assessment. Consider diesel particulate matter (DPM) emission rates in separate project-level analysis at the time of construction. Develop a mitigation program based on the site-specific health risk assessment implementing methods of reducing DPM emission or exposure to a less-than-significant level. **Measure 4.9-2b, Vacate SFPUC Land Managers' Residences in Sunol Valley:** Vacate the two SFPUC Land Managers' residences in the Sunol Valley during construction of the Calaveras Dam or SVWTP – Treated Water Reservoirs projects or complete a health risk screening (and, if warranted, a health risk assessment) to determine health risks at these residences from either of these two projects.
Impact 4.9-3: Exposure to emissions (possibly including asbestos) from tunneling.	**Measure 4.9-3, Tunnel Gas Odor Control:** Add water scrubbers and appropriate chemicals to tunnel ventilation systems if odorous gases become a nuisance odor problem (i.e., odor complaints are received).
Impact 4.9-4: Air pollutant emissions during project operation.	None required.
Impact 4.9-5: Odors generated during project operation.	None required.
Impact 4.9-6: Secondary emissions at power plants.	None required.
Impact 4.9-7: Conflict with implementation of applicable regional air quality plans addressing criteria air pollutants and state goals for reducing greenhouse gas emissions.	None required.
Impact 4.10-1: Disturbance from temporary construction-related noise increases.	**Measure 4.10-1a, Noise Controls:** For all WSIP projects located within 500 feet of any noise-sensitive receptors, implement appropriate noise controls to reduce daytime construction noise levels to meet the 70-dBA daytime speech interference criterion to the extent feasible. For all WSIP projects involving nighttime construction and located within 3,000 feet of any noise-sensitive receptors, implement appropriate noise controls to maintain noise levels at or below any applicable ordinance nighttime noise limits or the 50-dBA nighttime sleep interference criterion to the extent feasible. **Measure 4.10-1b, Vacate SFPUC Caretaker's Residence at Tesla Portal:** Vacate caretaker's residence at Tesla Portal during construction of the Advanced Disinfection and Tesla Portal Disinfection Station projects as well as those portions of the San Joaquin Pipeline System and Rehabilitation of Existing San Joaquin Pipelines projects located at Tesla Portal.
Impact 4.10-2: Temporary noise disturbance along construction haul routes.	**Measure 4.10-2a, Limit Hourly Truck Volumes:** Haul and delivery truck routes for all WSIP projects will, to the extent feasible, avoid local residential streets and follow local designated truck routes. Total project-related haul and delivery truck volumes on any particular haul truck route will be limited to 80 trucks per hour.

[a] Mitigation measure text is summarized; please see Chapter 6 for details.
[b] The City and County of San Francisco (including the SFPUC, the Planning Department, and other City agencies and departments) would be responsible for implementing all mitigation measures; please see Chapter 6 for details.

TABLE S.4 (Continued)
SUMMARY OF FACILITY MITIGATION MEASURES BY IMPACT

Impact	Mitigation Measure(s)
Impact 4.10-2 (cont.)	**Measure 4.10-2b, Restrict Truck Operations:** Prohibit haul and delivery trucks from operating within 200 feet of any residential uses during the nighttime hours. For receptors beyond 200 feet from a haul route, limit noise levels to the 50-dBA sleep interference criterion at the closest receptor. **Measure 4.10-2c, Vacate SFPUC Land Manager's Residence:** Vacate Land Manager's residence adjacent to Alameda East Portal during offsite truck operations associated with the New Irvington Tunnel project, if truck operations occur during the nighttime hours (10 p.m. to 7 a.m.) and are estimated to exceed the 50-dBA sleep interference criterion at this residence.
Impact 4.10-3: Disturbance due to construction-related vibration.	**Measure 4.10-3a, Vibration Controls to Prevent Cosmetic or Structural Damage:** Incorporate restrictions into all contract specifications (primarily for sheetpile driving, pile driving, or tunnel construction activities), whereby surface vibration will be limited to 0.2 in/sec peak particle velocity (PPV) for continuous vibration (e.g., vibratory equipment and impact pile drivers) and 0.5 in/sec PPV for controlled detonations at the closest receptors to ensure that cosmetic or structural damage does not occur. **Measure 4.10-3b, Limit Vibration Levels at or Below Vibration Perception Threshold:** Maintain vibration levels at or below the vibration perception threshold at adjacent properties to the extent feasible during nighttime. If vibration complaints are received, operational adjustments will be made to reduce vibration annoyance effects. **Measure 4.10-3c, Limit Tunnel-Related Detonation to Daylight Hours:** Limit controlled detonation associated with tunnel construction to daylight hours, Monday through Saturday.
Impact 4.10-4: Disturbance due to long-term noise increases.	None required.
Impact 4.11-1: Potential temporary damage to or disruption of existing regional or local public utilities.	**Measure 4.11-1a, Notify Neighbors of Potential Utility Service Disruption:** Notify residents and businesses in project area of potential utility service disruption two to four days in advance of construction. **Measure 4.11-1b, Locate Utility Lines Prior to Excavation:** Locate overhead and underground utility lines prior to excavation work. **Measure 4.11-1c, Confirmation of Utility Line Information:** Find the exact location of underground utilities by safe and acceptable means. Confirm information regarding the size, color, and location of existing utilities before construction activities commence. **Measure 4.11-1d, Safeguard Employees from Potential Accidents Related to Underground Utilities:** While any excavation is open, protect, support, or remove underground utilities as necessary to safeguard employees.

[a] Mitigation measure text is summarized; please see Chapter 6 for details.
[b] The City and County of San Francisco (including the SFPUC, the Planning Department, and other City agencies and departments) would be responsible for implementing all mitigation measures; please see Chapter 6 for details.

TABLE S.4 (Continued)
SUMMARY OF FACILITY MITIGATION MEASURES BY IMPACT

Impact	Mitigation Measure(s)
Impact 4.11-1 (cont.)	**Measure 4.11-1e, Notify Local Fire Departments:** Notify local fire departments any time damage to a gas utility results in a leak or suspected leak, or whenever damage to any utility results in a threat to public safety. **Measure 4.11-1f, Emergency Response Plan:** Develop an emergency response plan in the event of a leak or explosion prior to commencing construction activities.
	Measure 4.11-1g, Prompt Reconnection of Utilities: Promptly reconnect any disconnected utility lines. **Measure 4.11-1h, Coordinate Final Construction Plans with Affected Utilities:** Coordinate final construction plans and specifications with affected utilities.
Impact 4.11-2: Temporary adverse effects on solid waste landfill capacity.	**Measure 4.11-2, Waste Reduction Measures:** Incorporate into contract specifications for each WSIP project the requirement to obtain any necessary waste management permits prior to construction and to comply with conditions of approval attached to project implementation.
Impact 4.11-3: Impacts related to compliance with statutes and regulations related to solid waste.	Public Services and Utilities Measure 4.11-2, described above.
Impact 4.11-4: Impacts related to the relocation of utilities.	Public Services and Utilities Measures 4.11-1a thru 4.11-1h, described above.
Impact 4.12-1: Temporary conflicts with established recreational uses during construction.	Traffic, Transportation, and Circulation Measures (4.8-1a and 4.8-1b); Air Quality Measures (4.9-1a, 4.9-1b, 4.9-2a, 4.9-2b); and Noise Measures (4.10-1a, 4.10-1b, 4.10-2a thru 4.10-2c, and 4.10-3a thru 4.10-3b), described above. **Measure 4.12-1, Coordination with Golf Course/Recreational Facility Managers:** Coordinate with managers of golf courses or other recreational facilities directly affected by pipeline construction to minimize adverse impacts on golfers and other recreational users.
Impact 4.12-2: Conflicts with established recreational uses due to facility siting and project operation.	Land Use and Visual Quality Measures 4.3-4a thru 4.3-4d, described above. **Measure 4.12-2, Appropriate Siting of Proposed Facilities:** Locate WSIP project facilities on park and recreation properties in consultation with park planning staff to minimize the direct loss of recreation and play space and to minimize inconvenience to park and recreation users.
Impact 4.13-1: Temporary conflicts with established agricultural resources.	Traffic, Transportation, and Circulation Measures (4.8-1a and 4.8-1b); Air Quality Measures (4.9-1a thru 4.9-1d, and 4.9-2a and 4.9-2b); and Noise Measures (4.10-1a, 4.10-b, 4.10-2a thru 4.10-2c, and 4.10-3a thru 4.10-3c), described above. **Measure 4.13-1a, Supplemental Noticing and Soil Stockpiling:** For the San Joaquin Pipeline projects (San Joaquin System and Rehabilitation of Existing San Joaquin Pipeline), stockpile and replace topsoil in mapped areas of Prime and Unique Farmland and Farmland of Statewide Importance that would be temporarily disturbed by pipeline construction, unless other actions are required under specific agreements with individual landowners.

[a] Mitigation measure text is summarized; please see Chapter 6 for details.
[b] The City and County of San Francisco (including the SFPUC, the Planning Department, and other City agencies and departments) would be responsible for implementing all mitigation measures; please see Chapter 6 for details.

TABLE S.4 (Continued)
SUMMARY OF FACILITY MITIGATION MEASURES BY IMPACT

Impact	Mitigation Measure(s)
Impact 4.13-1 (cont.)	**Measure 4.13-1b, Avoidance or Soil Stockpiling:** Minimize any potential impacts on agricultural lands in the Sunol Valley by avoiding these resources wherever possible. Where this is not possible, stockpile, replace, and hydroseed topsoil to prevent erosion, unless other actions are required as a result of contracts affecting use of the property or under specific agreements with individual landowners.
Impact 4.13-2: Conversion of farmlands to non-agricultural uses.	**Measure 4.13-2, Siting Facilities to Avoid Prime Farmland:** Avoid areas identified as Prime Farmland, Unique Farmland, or Farmland of Statewide Importance. If avoidance is not feasible, adopt a permanent set-aside for an equivalent acreage of similarly valued farmland in the area.
Impact 4.14-1: Potential to encounter hazardous materials in soil and groundwater.	**Measure 4.14-1a, Site Health and Safety Plan:** For all projects where the site assessment indicates the potential to encounter hazardous materials, prepare a site health and safety plan identifying the chemicals present, potential health and safety hazards, monitoring, soils-handling methods, appropriate personnel protective equipment, and emergency response procedures. **Measure 4.14-1b, Materials Disposal Plan:** For all projects where the site assessment indicates the potential to encounter hazardous materials in the soil, prepare a materials disposal plan that specifies the disposal method and approved disposal site for the soil. **Measure 4.14-1c, Coordination with Property Owners and Regulatory Agencies:** Based on regulatory agency file reviews, assess the potential to encounter unacceptable levels of hazardous materials at known environmental cases, for construction activities to cause groundwater plume migration or interfere with ongoing remediations at known environmental cases, and for increased water levels in reservoirs or lakes to inundate known environmental cases. Modify construction or remediation activities.
Impact 4.14-2: Exposure to naturally occurring asbestos.	**Measure 4.14-2, Health Risk Screening and Airborne Asbestos Monitoring Plan:** For tunneling projects where soil or rock may contain naturally occurring asbestos, conduct a health risk screening assessment to identify acceptable levels of asbestos in tunnel emissions. Prepare an airborne asbestos monitoring plan for approval by the BAAQMD.
Impact 4.14-3: Risk of fires during construction.	None required.
Impact 4.14-4: Gassy conditions in tunnels.	None required.
Impact 4.14-5: Exposure to hazardous building materials.	**Measure 4.14-5, Hazardous Building Materials Surveys and Abatement:** For all WSIP projects involving demolition or renovation of existing facilities, perform a hazardous building materials survey for each structure prior to demolition or renovation activities. If any friable asbestos-containing materials, lead-containing materials, or hazardous components of building materials are identified, implement adequate abatement practices prior to demolition or renovation.
Impact 4.14-6: Accidental hazardous materials release from construction equipment.	None required.

[a] Mitigation measure text is summarized; please see Chapter 6 for details.
[b] The City and County of San Francisco (including the SFPUC, the Planning Department, and other City agencies and departments) would be responsible for implementing all mitigation measures; please see Chapter 6 for details.

TABLE S.4 (Continued)
SUMMARY OF FACILITY MITIGATION MEASURES BY IMPACT

Impact	Mitigation Measure(s)
Impact 4.14-7: Increased use of hazardous materials during operation.	None required.
Impact 4.14-8: Emission or use of hazardous materials within 1/4 mile of a school.	None required.
Impact 4.15-1: Construction-related energy use.	Air Quality Measures 4.9-1b and 4.9-1d, described above.
Impact 4.15-2: Long-term energy use during operation.	**Measure 4.15-2, Incorporation of Energy Efficiency Measures:** Consistent with the Energy Action Plan II priorities for reducing energy usage, ensure that energy-efficient equipment is used in all WSIP projects. Prepare a repair and maintenance plan for each facility to minimize power use. Evaluate the potential for use of renewable energy resources.
Impact 4.16-1a: Collective temporary and permanent impacts on existing land uses in the vicinity of proposed facility sites.	None required.
Impact 4.16-1b: Collective temporary and permanent impacts on the visual character of the surrounding area.	None required.
Impact 4.16-2: Collective exposure of people or structures to geologic and seismic hazards.	None required.
Impact 4.16-3: Collective WSIP impacts related to the degradation of surface waters and flooding hazards.	None required.
Impact 4.16-4: Collective loss of sensitive biological resources.	**Measure 4.16-4a, Bioregional Habitat Restoration Measures:** Address the following bioregional effects and implement conservation principles when implementing habitat compensation mitigation required for individual WSIP facility projects: compound impacts on functional units of habitat as WSIP projects simplify vegetation structure and increase “edge” (the boundary between two different habitats); increased habitat impacts due to the spread of weedy, non-native plant species; genetic diversity impacts on small populations; impacts on wildlife movement due to habitat fragmentation; suppression of natural disturbance regimes; and reduced population recovery opportunities from stochastic events. **Measure 4.16-4b, Coordination of Construction Staging and Access:** Coordinate construction contractor(s) to minimize surface disturbance when construction schedules for WSIP projects affecting the same areas overlap.
Impact 4.16-5: Collective increase in impacts related to archaeological, paleontological, and historical resources.	None required.
Impact 4.16-6: Collective traffic increases on local and regional roads.	**Measure 4.16-6a, SFPUC WSIP Projects Construction Coordinator:** Identify a qualified construction coordinator to coordinate project-specific traffic control plans; develop a public information campaign to inform the public of construction activities, detour routes, and alternate routes; work with local and regional agencies to pursue additional traffic mitigation measures and incorporate such measures into the project-specific traffic control plans.

[a] Mitigation measure text is summarized; please see Chapter 6 for details.
[b] The City and County of San Francisco (including the SFPUC, the Planning Department, and other City agencies and departments) would be responsible for implementing all mitigation measures; please see Chapter 6 for details.

TABLE S.4 (Continued)
SUMMARY OF FACILITY MITIGATION MEASURES BY IMPACT

Impact	Mitigation Measure(s)
Impact 4.16-6 (cont.)	**Measure 4.16-6b, Combined San Joaquin Traffic Control Plan:** Develop a San Joaquin Traffic Control Plan that coordinates the project-specific traffic control plans and identifies additional measures (consistent with the standards of San Joaquin County, Stanislaus County, and Caltrans) to minimize the combined impacts of multiple WSIP project construction traffic on I-580, Chrisman Road, and Vernalis Road. **Measure 4.16-6c, Combined Sunol Valley Traffic Control Plan:** Develop a Sunol Valley Traffic Control Plan that coordinates the project-specific traffic control plans and identifies additional measures (consistent with the standards of Alameda County and Caltrans) to minimize the impacts of construction traffic on Calaveras Road and I-680.
Impact 4.16-7: Collective increases in construction and/or operational emissions in the region.	**Measure 4.16-7a, Dust and Exhaust Control Measures for All WSIP Projects:** Require implementation of Air Quality Measures 4.9-1a thru 4.9-1d for all WSIP projects to address collective construction-related air quality impacts. **Measure 4.16-7b, Health Risk Screening or Use of Soot Filters for All Projects in the San Joaquin and Sunol Valley Regions**: Require Measure 4.9-2a for all WSIP projects in the San Joaquin and Sunol Valley Regions to address collective DPM impacts. When this requirement is applied to the New Irvington Tunnel project, it will be applied to both the Sunol Valley and Fremont tunnel portals, taking into account truck traffic from other WSIP projects in the vicinity of both portals. **Measure 4.16-7c, Vacate SFPUC Land Managers' Residences for All Projects in the Sunol Valley Region:** Require Measure 4.9-2b for all WSIP projects in the Sunol Valley Region to address collective DPM impacts.
Impact 4.16-8: Collective increases in construction-related and operational noise.	**Measure 4.16-8a, Limiting Hourly Truck Volumes and Restricting Truck Operations on Haul Routes for Multiple WSIP Projects:** Apply Measures 4.10-2a and 4.10-2b to total haul and delivery truck volumes attributable to all WSIP projects on any particular haul truck route (including haul routes in the Tesla Portal, Irvington Portal, and Lower Crystal Springs Dam vicinities as well as haul routes in the San Francisco Region) to address collective truck-related noise impacts. **Measure 4.16-8b, Vacate Land Manager's Residence for All Projects in Sunol Valley Region:** To address collective noise impacts, vacate Land Manager's residence adjacent to Alameda East Portal during construction truck operations associated with all WSIP projects in this region if collective daytime truck volumes exceed the 70-dBA speech interference criterion or nighttime truck volumes exceed the 50-dBA sleep interference criterion.
Impact 4.16-9: Collective impacts on utilities and landfill capacity.	None required.
Impact 4.16-10: Collective effects on recreational resources during construction.	None required.

[a] Mitigation measure text is summarized; please see Chapter 6 for details.
[b] The City and County of San Francisco (including the SFPUC, the Planning Department, and other City agencies and departments) would be responsible for implementing all mitigation measures; please see Chapter 6 for details.

TABLE S.4 (Continued)
SUMMARY OF FACILITY MITIGATION MEASURES BY IMPACT

Impact	Mitigation Measure(s)
Impact 4.16-11: Collective conversion of farmland to nonagricultural uses.	None required.
Impact 4.16-12: Collective effects related to hazardous conditions and exposure to or release of hazardous materials.	None required.
Impact 4.16-13: Collective increases in the use of nonrenewable energy resources.	None required.
Impact 4.17-1: Cumulative disruption of established communities, changes in existing land use patterns, and impacts on the existing visual character.	None required.
Impact 4.17-2: Cumulative exposure of people or structures to geologic and seismic hazards.	None required.
Impact 4.17-3: Cumulative impacts related to the degradation of water quality, alteration of drainage patterns, increased surface runoff, and flooding hazards.	None required.
Impact 4.17-4: Cumulative loss of sensitive biological resources.	None required.
Impact 4.17-5: Cumulative increase in impacts on archaeological, paleontological, and historical resources.	None required.
Impact 4.17-6: Cumulative traffic increases on local and regional roads.	**Measure 4.17-6, SFPUC WSIP Projects Construction Coordinator – Other Agencies:** The SFPUC WSIP construction coordinator designated in accordance with Measure 4.16-6a will also consider the effects of any traffic generated by SFPUC maintenance activities and other SFPUC projects; and coordinate with Caltrans, other county agencies, and local jurisdictions regarding construction of other private and public development projects so as to minimize traffic impacts on local access roads.
Impact 4.17-7: Cumulative increases in construction and/or operational emissions in the region.	None required.
Impact 4.17-8: Cumulative increases in construction-related and operational noise.	**Measure 4.17-8, Coordination of Truck Traffic on Local Streets:** The SFPUC WSIP construction coordinator designated in Measure 4.17-6 will also be responsible for coordinating truck traffic generated on these same streets by SFPUC maintenance activities and other SFPUC projects so that SFPUC-related truck noise increases are maintained at or below threshold levels specified in Measures 4.10-2a and 4.10-2b to the extent feasible.
Impact 4.17-9: Cumulative impacts related to disruption of utility service or relocation of utilities.	None required.
Impact 4.17-10: Cumulative effects on recreational resources during construction.	None required.
Impact 4.17-11: Cumulative conversion of farmland to nonagricultural uses.	None required.
Impact 4.17-12: Cumulative effects related to hazardous conditions and exposure to or release of hazardous materials.	None required.
Impact 4.17-13: Cumulative increases in the use of nonrenewable energy resources.	None required.

[a] Mitigation measure text is summarized; please see Chapter 6 for details.
[b] The City and County of San Francisco (including the SFPUC, the Planning Department, and other City agencies and departments) would be responsible for implementing all mitigation measures; please see Chapter 6 for details.

- Temporary noise disturbance could occur along construction haul routes under the following projects: Advanced Disinfection, San Joaquin Pipeline System, Rehabilitation of Existing San Joaquin Pipelines, Tesla Portal Disinfection Station, Bay Division Pipeline Reliability Upgrade, BDPL Nos. 3 and 4 Crossovers, Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault, Baden and San Pedro Valve Lots Improvements, HTWTP Long-Term Improvements, San Andreas Pipeline No. 3 Installation, Groundwater Projects, and Recycled Water Projects. This impact is conservatively considered potentially significant and unavoidable because haul routes, truck volumes, and hours of truck operations have not yet been determined for these projects (Chapter 4, Section 4.10).

- If any construction activities were to generate vibration in proximity to sensitive receptors during the nighttime hours, potentially significant and unavoidable vibration impacts could occur under the following projects: San Joaquin Pipeline System, Rehabilitation of Existing San Joaquin Pipelines, Additional 40-mgd Treated Water Supply, Bay Division Pipeline Reliability Upgrade, BDPL Nos. 3 and 4 Crossovers, Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault, Baden and San Pedro Valve Lots Improvements, San Andreas Pipeline No. 3 Installation, Groundwater Projects, and Recycled Water Projects (Chapter 4, Section 4.10).

- Collective temporary impacts on residences near the Irvington Tunnel portal in Fremont (Bay Division Region) could result during construction because staging and access for both the New Irvington Tunnel and Bay Division Pipeline Reliability Upgrade projects would overlap in this vicinity. Since the feasibility of coordinating construction activities for these projects cannot be determined at this stage of project planning, such an effect is conservatively considered to be potentially significant and unavoidable (Chapter 4, Section 4.16).

- WSIP projects in the Sunol Valley Region would have a potentially significant and unavoidable collective impact on biological resources because of the number of WSIP projects in this region and the extent of overlap in terms of construction activity timing and location (Chapter 4, Section 4.16).

- Potentially significant and unavoidable collective impacts on special-status plant species could occur during construction of the Crystal Springs/San Andreas Transmission Upgrade and Lower Crystal Springs Dam projects in the Peninsula Region; incidental disturbance of plants along the road shoulder would be difficult to completely avoid, even with proposed mitigation measures (Chapter 4, Section 4.16).

- WSIP projects within the Sunol Valley and Peninsula Regions could collectively cause substantial adverse changes to historic districts, but until more detailed assessments are completed to determine if any historic districts exist, this potential collective impact is conservatively considered to be potentially significant and unavoidable (Chapter 4, Section 4.16).

- Even with proposed control measures, construction-related criteria air pollutant emissions associated with all of the WSIP projects would have a potentially significant and unavoidable collective impact on air quality, since the projects would contribute to the nonattainment status for ozone and particulate matter in both the San Francisco Bay Area and San Joaquin Valley Air Basins (Chapter 4, Section 4.16).

- Since the hours of construction as well as haul routes, truck volumes, and hours of truck operations have not yet been determined for all of WSIP facility projects within the San Joaquin, Bay Division, Peninsula, and San Francisco Regions, there is the potential that collective noise impacts could result from construction of multiple WSIP projects near Tesla Portal, Irvington Tunnel portal in Fremont, and Lower Crystal Springs Dam. Also, there could be collective truck traffic increases along any overlapping haul routes in these regions. Given these unknowns, such collective effects are conservatively considered to be potentially significant and unavoidable (Chapter 4, Section 4.16).

- Several WSIP projects and several other SFPUC projects could cumulatively affect individual historical resources or potential historic districts (if historic districts are determined to be present), and until project-level analysis is completed, this cumulative effect is conservatively considered to be potentially significant and unavoidable (Chapter 4, Section 4.17).

- Construction-related traffic generated by the WSIP projects would contribute to potentially significant and unavoidable cumulative traffic impacts (e.g., increased travel times), particularly if the travel routes of individual drivers coincided with the construction routes for the WSIP projects, other SFPUC projects, and/or other public and private projects within one or more regions, and/or when construction vehicles associated with the cumulative projects utilize regional facilities (Chapter 4, Section 4.17).

- Construction emissions associated with the WSIP projects, other SFPUC projects, and other public and private projects would cumulatively contribute to the nonattainment status for ozone and particulate matter, a potentially significant and unavoidable cumulative impact (Chapter 4, Section 4.17).

- Potential overlap of the WSIP's construction truck traffic with construction truck traffic of other public and private projects could result in cumulative increases in diesel particulate matter (DPM) and noise on local roadways. Since the SFPUC would have no control over the construction schedules or traffic routes for other projects outside its jurisdiction, potential DPM and noise impacts are considered to be potentially significant and unavoidable (Chapter 4, Section 4.17).

Facility Operations Effects

Implementation of WSIP facility improvement projects would also result in long-term effects associated with facility operations. Effects associated with long-term maintenance and operations activities would occur, such as new permanent sources of light and glare, effects on scenic vistas, effects of treated water discharge on water quality and aquatic resources, and long-term energy use. These impacts would be mitigated to a less-than-significant level through implementation of the mitigation measures described in Chapter 6.

Effects of Water Supply and System Operations (Chapter 5)

Chapter 5 of this PEIR addresses the effects of the proposed water supply and system operations on the Tuolumne River system, Alameda Creek system, Peninsula system, and Westside Basin groundwater resources. In addition, Chapter 5 identifies the cumulative effects of implementing the WSIP water supply option and system operations in combination with other past, present, and reasonably foreseeable future projects within each of these watersheds; it also discusses the potential effects of climate change and global warming on the regional water system. **Tables S.5** through **S.8** summarize the water supply and system operations effects associated with the WSIP and the mitigation measures proposed to address the effects found to be potentially significant.

TABLE S.5
SUMMARY OF WATER SUPPLY IMPACTS AND MITIGATION MEASURES – TUOLUMNE RIVER SYSTEM AND DOWNSTREAM WATER BODIES

Impact	Significance Determination					Mitigation Measures
		Biological Resource Impacts				
	All Impacts (except Biological Resources)	Sensitive Habitats	Key Special-Status Species	Other Species of Concern	Common Habitats and Species	
STREAM FLOW						
Impact 5.3.1-1: Effects on flow along the Tuolumne River below O'Shaughnessy Dam.	LS					None required.
Impact 5.3.1-2: Effects on flow along Cherry Creek below Cherry Dam.	LS					None required.
Impact 5.3.1-3: Effects on flow along Eleanor Creek below Eleanor Dam.	LS					None required.
Impact 5.3.1-4: Effects on flow along the Tuolumne River below La Grange Dam.	LS					None required.
Impact 5.3.1-5: Effects on flow along the San Joaquin River and the Sacramento–San Joaquin Delta.	LS					None required.
GEOMORPHOLOGY						
Impact 5.3.2-1: Effects on sediment transport and channel characteristics between O'Shaughnessy Dam and Don Pedro Reservoir.	LS					None required.
Impact 5.3.2-2: Effects on sediment transport and channel characteristics below La Grange Dam.	LS					None required.
SURFACE WATER QUALITY						
Impact 5.3.3-1: Effects on water quality in Hetch Hetchy Reservoir and along the Tuolumne River below O'Shaughnessy Dam.	LS					None required.
Impact 5.3.3-2: Effects on water quality in Don Pedro Reservoir and along the Tuolumne River below La Grange Dam.	LS					None required.
Impact 5.3.3-3: Effects on water quality along the San Joaquin River and the Sacramento–San Joaquin Delta.	LS					None required.

[a] Mitigation measure text is summarized; please see Chapter 6 for details.

(shaded) Not applicable

TABLE S.5 (Continued)
SUMMARY OF WATER SUPPLY IMPACTS AND MITIGATION MEASURES – TUOLUMNE RIVER SYSTEM AND DOWNSTREAM WATER BODIES

Impact	Significance Determination					Mitigation Measures
	All Impacts (except Biological Resources)	Biological Resource Impacts				
		Sensitive Habitats	Key Special-Status Species	Other Species of Concern	Common Habitats and Species	
SURFACE WATER SUPPLIES						
Impact 5.3.4-1: Effects on Tuolumne River, San Joaquin River, and Stanislaus River water users.	LS					None required.
Impact 5.3.4-2: Effects on Delta water users.	LS					None required.
GROUNDWATER						
Impact 5.3.5-1: Alteration of stream flows along the Tuolumne River, which could affect local groundwater recharge and groundwater levels.	LS					None required.
Impact 5.3.5-2: Alteration of stream flows along the Tuolumne River, which could affect local groundwater quality.	LS					None required.
FISHERIES						
Impact 5.3.6-1: Effects on fishery resources in Hetch Hetchy Reservoir.	LS					None required.
Impact 5.3.6-2: Effects on fishery resources along the Tuolumne River between Hetch Hetchy Reservoir and Don Pedro Reservoir.	LS					None required.
Impact 5.3.6-3: Effects on fishery resources in Don Pedro Reservoir.	LS					None required.
Impact 5.3.6-4: Effects on fishery resources along the Tuolumne River below La Grange Dam.	PSM					**Measure 5.3.6-4a, Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water:** The SFPUC will pursue a water transfer arrangement with MID/TID and/or other water agencies which would offset the WSIP's effects on water storage in Don Pedro Reservoir and minimize WSIP-induced changes in releases from La Grange Dam. **If Measure 5.3.6-4a proves to be infeasible, the SFPUC will implement Measure 5.3.6-4b.

[shaded] Not applicable

TABLE S.5 (Continued)
SUMMARY OF WATER SUPPLY IMPACTS AND MITIGATION MEASURES – TUOLUMNE RIVER SYSTEM AND DOWNSTREAM WATER BODIES

Impact	Significance Determination					Mitigation Measures
	All Impacts (except Biological Resources)	Biological Resource Impacts: Sensitive Habitats	Biological Resource Impacts: Key Special-Status Species	Biological Resource Impacts: Other Species of Concern	Biological Resource Impacts: Common Habitats and Species	
FISHERIES (cont.)						
Impact 5.3.6-4 (cont.)						**Measure 5.3.6-4b, Fishery Habitat Enhancement:** The SFPUC will implement or fund one of two fishery habitat enhancement projects that are consistent with the Lower Tuolumne River Restoration Plan; augmentation of spawning gravel at three selected sites or the filling or isolation from the river of one of the existing inactive quarry pits.
Impact 5.3.6-5: Effects on fishery resources along the San Joaquin River.	LS					None required.
TERRESTRIAL BIOLOGY						
Impact 5.3.7-1: Impacts on riparian habitat and related biological resources in Hetch Hetchy Reservoir and along the bedrock channel portions of the Tuolumne River from O'Shaughnessy Dam to Don Pedro Reservoir.		LS	LS	LS	LS	None required.
Impact 5.3.7-2: Impacts on alluvial features that support meadow and riparian habitat along the Tuolumne River from O'Shaughnessy Dam to Don Pedro Reservoir.		PSM	PSM	PSM	PSM	The SFPUC will implement Measure 5.3.7-2 to reduce adverse impacts on sensitive habitats, key special-status species, other species of concern, and common habitats and species to a less-than-significant level. **Measure 5.3.7-2, Controlled Releases to Recharge Groundwater in Streamside Meadows and Other Alluvial Deposits:** The SPPUC will manage releases to the Tuolumne River from Hetch Hetchy Reservoir during the spring with the goal of recharging groundwater that supports meadow and riparian habitat. The SFPUC will periodically survey meadow habitat to determine the efficacy of release management and will modify releases as necessary to sustain meadow habitat.
Impact 5.3.7-3: Impacts on biological resources in Lake Eleanor and along Eleanor Creek.		LS	LS	LS	LS	None required.
Impact 5.3.7-4: Impacts on biological resources in Lake Lloyd and along Cherry Creek.		LS	LS	LS	LS	None required.

GEOMORPHOLOGY						
Impact 5.5.2-1: Changes in sediment transport and channel morphology in the Peninsula watershed.	LS					None required.
WATER QUALITY						
Impact 5.5.3-1: Effects on water quality in Crystal Springs Reservoir, San Andreas Reservoir, and San Mateo Creek.	LS					None required.
Impact 5.5.3-2: Effects on water quality in Pilarcitos Reservoir and along Pilarcitos Creek.	PSM					**Measure 5.5.3-2a, Low-head Pumping Station at Pilarcitos Reservoir:** The SFPUC will install a permanent low-head pumping station at Pilarcitos Reservoir which would enable the SFPUC to access and use an additional 350 acre-feet of water from Pilarcitos Reservoir. In years when the WSIP would cause releases from Pilarcitos Reservoir to Pilarcitos Creek to be reduced to reservoir inflow earlier in the summer than under the existing condition (about 25 percent of years in the hydrologic record), the SFPUC will use the pumping station to augment flow in Pilarcitos Creek with water from the reservoir. The pumping station will draw water from the cool pool of water below the thermocline during times when the reservoir is stratified. The pumping station outlet will be designed to ensure that water discharged to the creek is adequately aerated. **Measure 5.5.3-2b, Aeration System at Pilarcitos Reservoir:** The SFPUC will install a permanent aeration system at Pilarcitos Reservoir. The SFPUC will operate the aeration system as necessary to avoid anoxic conditions and maintain good water quality conditions at the reservoir.

Impact 5.7.5-1: North Westside Groundwater Basin.	LS							None required.
Impact 5.7.5-2: South Westside Groundwater Basin.	LS							None required.

NOTE: Significance determinations presented in this table assume implementation of all mitigation measures as they are presented in Chapter 5, Section 5.6, and described in Chapter 6.

Due to the proposed increase in diversions from the Tuolumne River and changes in system operations, implementation of the WSIP would result in changes in reservoir levels and associated changes in downstream flows in rivers or creeks in the three affected watersheds. In all three watersheds, these hydrologic changes could in turn result in impacts on geomorphology of the water body, groundwater, water quality, fisheries, terrestrial biological resources, and recreational and visual resources. In the Tuolumne River watershed, changes in stream flow could also affect downstream water supplies and hydropower generation. In the Alameda Creek and Peninsula watersheds, implementation of the WSIP would include restoration of the historical storage capacities of Calaveras and Lower Crystal Springs Reservoirs, respectively, resulting in impacts on reservoir levels, downstream flows, fisheries, terrestrial biological resources, and visual resources. In addition, implementation of the WSIP would include development of groundwater supplies in the North Westside Groundwater Basin as well as a conjunctive-use program in the South Westside Groundwater Basin. Identified impacts on these resources were determined to be less than significant with implementation of the mitigation measures described in Chapter 6, with the exception of the following:

- The WSIP would result in a significant and unavoidable impact in the Alameda Creek watershed on the flow along Alameda Creek below the Alameda Creek Diversion Dam (Chapter 4, Section 5.4.1).
- The WSIP would result in a potentially significant and unavoidable impact in the San Mateo Creek watershed on fishery resources in Crystal Springs Reservoir (Chapter 4, Section 5.5.5).

Growth Inducement (Chapter 7)

The WSIP would support planned growth in the existing SFPUC service area, although some growth associated with the availability of water would occur irrespective of the WSIP due to already planned increases in water delivery efficiencies throughout the service area (e.g., plumbing code changes), conservation, and other water supply sources. Some customers have multiple sources of supply and do not rely on the SFPUC system to meet all of their existing or future water demands; in these areas, other sources of supply may also support additional growth in the service area. In some areas, the WSIP could support a degree of population and/or employment above that planned for in jurisdictions' adopted general plans, as indicated by a comparison of the levels of growth assumed in WSIP demand studies and general plan documents. In some jurisdictions (Foster City, Half Moon Bay, Milpitas, and Burlingame), the WSIP could support more population growth than is forecasted in adopted general plans. In other jurisdictions (East Palo Alto, Foster City, San Bruno, Fremont, Newark, and Union City), the WSIP could support more employment growth than is forecasted in the adopted general plans of the respective jurisdictions.

The existing service area includes areas in four counties (San Francisco, San Mateo, Santa Clara, and Alameda) that are within the core of the nine-county Bay Area. Growth in the communities served by the SFPUC regional system would primarily be infill development within already developed Bay Area communities. This growth is representative of the "smart growth" principles promoted by the Association of Bay Area Governments (ABAG) to minimize urban and suburban sprawl and concentrate additional development in the existing core areas.

Indirect Effects of Growth Supported by the WSIP

As identified in Impact 7-1, the WSIP would indirectly contribute to environmental impacts caused by growth; some of these impacts would be unavoidable. The WSIP would support some of the growth that is reflected in the adopted land use plans of jurisdictions in the SFPUC service area. The EIRs prepared for general plans and related land use plans in the service area identified impacts of planned growth and mitigation measures to reduce the impacts. Some of the impacts of planned growth cannot be reduced to a less-than-significant level. In these cases, the respective decision-making body (e.g., city council) identified overriding considerations that justified adoption of the general plan despite its adverse impacts. Due to the longer planning horizon of the WSIP and relative age of some of the adopted general plans, as well as differing expectations about the level of job growth that will occur in the coming decades, in some jurisdictions not all of the growth that the WSIP would in part support has been addressed in adopted land use plans or evaluated in the plans' CEQA documents. Therefore, growth supported by the WSIP could result in impacts that are somewhat more severe than those identified in the general plan EIRs, although it is likely that the impacts would be similar in kind to those previously identified.

Potential impacts beyond those previously identified would generally be related either to increased density of development or to the conversion of less developed areas to urban uses. The measures specified in adopted general plans and related land use plans and their CEQA documents to mitigate the impacts of growth should also serve to reduce the impacts of growth supported by the WSIP. In addition, although the EIRs reviewed for this PEIR were prepared prior to the passage of the California Global Warming Solutions Act of 2006 and do not include assessments of impacts from greenhouse gas emissions, it is expected that planned growth in the area could result in a significant and unavoidable contribution to greenhouse gas emissions resulting from increased fossil fuel use for transportation, increased industrial and commercial activities, domestic fuel combustion, operation of power plants, and oil refining. The key regional effects of planned growth relate to air quality, traffic congestion, and water quality. Regional agencies, including the Metropolitan Transportation Commission, Bay Area Air Quality Management District, and Regional Water Quality Control Board, and the jurisdictions in the service area, are working both regionally and locally to address these impacts.

By providing water to support planned growth, the WSIP would help to mitigate the impact of insufficient water supply that was identified in the general plans EIRs of some jurisdictions in the service area.

Significant, Irreversible Environmental Changes

Construction and operational impacts associated with implementation of the WSIP projects would result in an irretrievable and irreversible commitment of natural resources through the use of fossil fuels and construction materials. Operation of project facilities would incrementally increase power consumption associated with water facilities, even though operation of SFPUC facilities would predominantly use hydropower. The program's incremental increased use of these resources, however, would not significantly increase the overall commitment of resources associated with water treatment and distribution. The program would involve only minor incremental use of nonrenewable resources and would locate facilities primarily on lands already committed to water treatment and supply purposes. Furthermore, since the SFPUC would implement the mitigation measures identified in this PEIR in concert with other ongoing stewardship and watershed protection activities, implementation of the WSIP would not result in significant irreversible environmental changes. When completed, the program would provide a high level of public health protection against potential seismic hazards as well as increase the long-term reliability of the drinking water throughout the SFPUC service area.

S.4 Areas of Controversy and Issues to be Resolved

Areas of Controversy

The San Francisco Planning Department circulated a Notice of Preparation (NOP) to prepare an EIR on the WSIP on September 6, 2005. Comments submitted during the NOP review period and scoping meetings raised issues regarding the scope and content of the Draft PEIR as well as the WSIP. Appendix A further describes the scoping process and summarizes the public comments received. Areas of controversy highlighted in this section include select items of particular public concern (as evidenced by the number of comments received during scoping on a topic and/or by a divergence of opinion on an issue) as well as topics identified during preparation of the Draft PEIR. These topics are organized into the following categories: Proposed Program; Impact Analysis – Assumptions and Methods; Environmental Impacts; and Alternatives.

Proposed Program

Comments received during the scoping process raised questions about the level of service objectives established by the SFPUC for the regional system and reflected in the WSIP, as follows:

- *Demand Estimates / Customer Purchase Request Increase*. Comments were received on the methods used for estimating future water needs, and whether and how the SFPUC's customers incorporated conservation and local water recycling projects into their future purchase request estimates. The approach to developing the customer purchase requests for 2030 is explained in detail in the 2004 San Francisco Public Utilities Commission Purchase Estimates Technical Memorandum. This approach is summarized in Chapter 3, Program Description, and Chapter 7, Growth-Inducement Potential.

  Comments were received on the ability to accurately project growth and associated water supply requirements through 2030. Water agencies must routinely develop relatively long-range projections (e.g., 15 to 25 years) regarding water supply and reliability service needs within their service areas in order to guide water system improvement and supply planning efforts. The SFPUC worked closely with its wholesale customers to support the development of future purchase estimates for their communities. Many customers, in turn, used growth projections prepared by ABAG. ABAG is the agency responsible for providing regional growth projections for the Bay Area and issues revised projections every five years. Chapter 7 includes an evaluation of the consistency between customers' demand projections and the corresponding future purchase requests using ABAG projections. Finally, while implementation of the WSIP would prepare the SFPUC to meet the projected 2030 customer purchase requests, customers would only purchase and receive additional water as needed when additional demand for water actually occurs.

- *Unfiltered Water Goal / Filtration Avoidance.* The SFPUC considers maintaining a system that can deliver high-quality water that does not require filtration to be an overarching principle to be used in developing the WSIP. Some commentors raised concerns that this objective limits the potential to consider other water supply alternatives, since few supply sources can meet this goal. The discussion and analysis in Chapter 9, Alternatives, considers the filtration avoidance principle along with other program objectives and factors in the evaluation of alternatives to the proposed program.

- *Drought Planning Assumptions – Design Drought*. Comments were provided during scoping on the drought assumptions used by the SFPUC to develop the WSIP. A necessary aspect of future water supply planning includes drought planning. Water agencies typically consider one or more potential drought scenario(s), or "design drought," in developing their drought response plans. The SFPUC developed and used an 8.5-year design drought for its planning purposes. The most recent drought experienced in the Bay Area was 6.5 years (1986 through 1992). The 8.5-year design drought represents a reasonable, worst-case scenario for planning purposes. Some commentors expressed concern that this planning assumption was too conservative and that the SFPUC should lower its objective for drought planning. Since the PEIR analysis assumes the SFPUC's 8.5-year design drought, the analysis considers the effect of actions needed in the event such a drought occurred. If this assumed drought scenario does not occur in the future, some impacts identified in the PEIR would be less severe than assumed, particularly those associated with actions taken to recover from such a severe drought.

- *Rationing Objective*. As part of its drought response planning for service through 2030, the SFPUC established a goal of limiting rationing to a maximum of 20 percent systemwide and used this level of service objective in developing the WSIP. Under the WSIP, the SFPUC could impose systemwide rationing of up to 20 percent in any one year of a drought. Commentors have argued that this planned maximum level of rationing is both too high and too low. Specifically, the BAWSCA expressed concern on behalf of its member agencies (the SFPUC wholesale customers) that this level of rationing would result in substantial hardship and economic impact on customers in the regional system service area. Other commentors suggested that system customers could implement higher levels of rationing and water conservation to reduce the need for additional water supplies during a drought. Chapter 8, WSIP Variants, analyzes a variation of the proposed WSIP that includes a 10 percent maximum systemwide rationing goal rather than the 20 percent goal. Chapter 9, Alternatives, further discusses the potential for additional conservation by the system customers and the potential effects of rationing that is greater than 20 percent.

- *San Joaquin Pipelines*. Many commentors raised concerns during scoping about an initial proposal to include a San Joaquin Pipeline No. 4 project in the WSIP to construct a new, fourth pipeline across the San Joaquin Valley, and that the PEIR needed to fully analyze the effects of such a pipeline project on the SFPUC's ability to expand the capacity of the water system in the future. This project was subsequently removed from the program and replaced with a modified version of the original proposal. The modified proposal does not include construction of a completely new fourth pipeline extending across the valley, but instead adds segments of new pipeline in select reaches along with two crossover facilities between the existing pipelines. A description of the modified project (San Joaquin Pipeline System) is included in Chapter 3, Program Description.

Impact Analysis – Assumptions and Methods

- *Environmental Baseline*. The CEQA Guidelines indicate that, in most cases, the potential environmental impacts of a project should be determined relative to the existing conditions that occur at the time the environmental process is initiated. In accordance with CEQA, mitigation measures are required, if feasible, when a project would have a significant effect on the existing environmental conditions. A project sponsor is not required to implement mitigation measures to remedy the environmental impacts caused by past actions. The effects of past actions are taken into consideration in the impact analysis insofar as the existing environmental conditions reflect the effects of such past actions. For example, the existing condition of riparian habitat along a creek may be degraded today because of a past action, such as the previous construction of a dam that altered downstream flows; or conversely, a particular fishery population may have been enhanced as a result of a past action, such as construction of a reservoir. The environmental conditions that currently exist reflect the effects of past actions and ongoing activities and operations.

  For the WSIP, the environmental conditions as they existed in the year 2005, when the PEIR process began, represent the environmental baseline for the purpose of determining the impacts of the WSIP. As discussed above, while these existing baseline conditions reflect the effects of past actions, the EIR does not analyze the impacts of past actions on those existing conditions, nor does it require mitigation for past environmental impacts.

- *Evaluation of Water Resource Impacts and Use of Modeling Tools*. Comments were received about the approach to evaluation of potential water resource impacts and, with respect to the Tuolumne River, about the need for environmental baseline studies prior to PEIR preparation. Concerns were raised about the use of computer models as part of the impact analysis, and whether the models would be accurate enough to adequately identify impacts.

  The PEIR makes use of the best available information regarding the environmental setting in areas potentially affected by the WSIP and also employed computer modeling tools to aid in the impact analysis. The SFPUC has developed a computerized mathematical model to assist in the evaluation of its water system operations: the Hetch Hetchy/Local Simulation Model (HH/LSM). This water supply planning model represents the best available tool for assessing the effects on water resources resulting from changes in regional system operations. Section 5.1 provides a summary description of the model; additional detail is provided in Appendix H.

The model includes information about key aspects of the SFPUC regional system and provides the most comprehensive approach to evaluating changes throughout the system. The model makes use of 82 years of historical hydrologic data (actual past precipitation data) and simulates system operations over the course of this 82-year sequential hydrologic period, from July 1920 through September 2002. This 82-year period includes many different types and sequences of actual hydrologic events ranging from floods to droughts of different magnitude and duration. Because natural river systems are dynamic and runoff and flow vary each year, and as it is not possible to predict future precipitation, it is a necessary and standard industry practice to use a long-term historical record to represent the range of hydrologic conditions that can be expected in the future. The model is used to assess both how the regional water system would perform in terms of meeting the system objectives established for the WSIP and what types of impacts the program might have under a broad range of hydrologic conditions.

The model does have limitations in terms of its ability to reflect the changing day-to-day operations of the system. The model uses a monthly time step, reporting changes on a monthly basis in such factors as reservoir storage levels or the volume of water released from a reservoir. This monthly timeframe is adequate for the assessment of most impact issues. However, the system operators can and do make changes in system operations on a weekly or even daily basis in some instances. To address those instances where monthly information is not sufficient for the analysis of a particular impact, the PEIR also makes use of information from the actual regional system operators rather than the model.

Environmental Impacts

- *Alameda Creek – Potential Steelhead Restoration in Alameda Creek*. Commentors raised concerns about potential effects of the program on steelhead and the potential for steelhead restoration in Alameda Creek. For the purposes of full disclosure, the PEIR provides a discussion of steelhead in lower Alameda Creek and the potential for steelhead to be restored to the upper reaches of Alameda Creek (above the BART weir). In addition to migration barriers, reduced winter and spring flows in Alameda Creek above the BART weir would limit migration and spawning if steelhead were to gain access upstream. The Alameda Creek Fisheries Restoration Workgroup (Workgroup), formed for the purpose of restoring steelhead to Alameda Creek, will be undertaking a series of flow studies to determine the flows necessary to support steelhead in the watershed. The Workgroup includes the SFPUC, Alameda County Flood Control and Water Conservation District, Alameda County Resource Conservation District, Alameda County Water District, Alameda Creek Alliance, California State Coastal Conservancy, California Department of Fish and Game, East Bay Regional Park District, National Marine Fisheries Service, Natural Resources Defense Council, Pacific Gas and Electric Company, and the Zone 7 Water Agency.

  While this restoration planning is in progress, because steelhead access does not currently exist and there is no current steelhead migration above the BART weir, there would be no impact on steelhead migration, spawning, or juvenile rearing upstream of the BART weir as a direct result of WSIP implementation compared to the existing condition. However, to address the potential that steelhead could regain access to the upper Alameda Creek watershed in the event that planned and proposed projects and actions designed to restore steelhead in Alameda Creek are successfully implemented, a cumulative impact assessment for potential future-occurring steelhead was conducted.

- *Economic Impacts.* Comments were raised about potential economic impacts associated with proposed rationing during a drought. CEQA requires analysis of physical changes in the environment and does not require analysis of potential economic effects, unless an economic effect would, in turn, indirectly result in a physical environmental effect. Chapter 5, Water Supply and Systems Operations, evaluates the environmental effects of the proposed water supply option, and Chapter 9, Alternatives, discusses the potential environmental effects of alternatives to the program, including increased levels of conservation and increased rationing requirements. The discussion in Chapter 9 acknowledges that increased rationing and/or aggressive conservation could result in economic impacts within the SFPUC service area, but these effects would not be expected to result in significant, physical environmental effects.

  With respect to potential economic effects due to increased Tuolumne River diversions, as discussed in Chapter 5, Section 5.3, the WSIP's impact on hydrology and related effects on recreational resources would be less than significant or could be mitigated to a less-than-significant level; consequently, there are no expected economic effects from the WSIP on Tuolumne River recreational users.

- *Growth-Inducement Potential and Secondary Effects.* Comments on growth inducement primarily concerned whether the 2030 customer purchase requests for water supply associated with the WSIP would provide for growth beyond the SFPUC's existing service area. The proposed program would not expand the existing service area to support 2030 customer purchase requests, but would support urban infill development. The existing service area includes four counties (San Francisco, San Mateo, Santa Clara, and Alameda) and areas within those counties that are within the core of the nine-county Bay Area. Growth in the communities served by the SFPUC regional system would primarily be infill development within already developed Bay Area communities. This growth is representative of the "smart growth" principles promoted by ABAG to minimize urban and suburban sprawl and concentrate additional development in the existing core areas.

Alternatives

- *Restore Hetch Hetchy Valley / Remove O'Shaughnessy Dam.* Construction of Hetch Hetchy Reservoir was controversial when it was approved by Congress in 1913 and remains so today. Commentors requested analysis of a proposal to remove O'Shaughnessy Dam and to restore Hetch Hetchy Valley. Doing so would require developing a replacement water supply for the SFPUC regional system. In 2004, the Environmental Defense Fund prepared a planning-level analysis for replacing the water and hydropower benefits provided by the Hetch Hetchy Reservoir and O'Shaughnessy Dam. The suggested supply alternatives included expansion of New Melones Reservoir on the Stanislaus River, expansion of Don Pedro Reservoir downstream on the Tuolumne River, and/or diversion from the Delta.

  Regardless of the merits of removing O'Shaughnessy Dam under this proposal, as explained in Chapter 9, Alternatives, the dam removal proposal does not satisfy the CEQA requirements for an alternative to the WSIP. The CEQA Guidelines state that an EIR must describe and evaluate a reasonable range of alternatives to the proposed project that would feasibly attain most of the project's basic objectives and avoid or substantially lessen any significant adverse environmental effects. This proposed alternative is a different project proposal in its own right, with a completely different set of goals and objectives from the WSIP; water supply replacement is required by this proposal, but upgrading the regional system facilities and improving the system's water quality, seismic, delivery, and supply reliability are not central objectives of this proposal. Further, this alternative proposal is not reasonably related to the reduction or elimination of the significant impacts that could occur with implementation of the proposed program, but suggests far greater changes than would be necessary to address any impacts that the WSIP would cause on the Tuolumne River and related resources. To the extent that Tuolumne River water would continue to be diverted under this alternative proposal, it would be likely to result in similar impacts as the WSIP. Further, the proposal itself is likely to result in numerous, significant environmental impacts associated with construction and operation of unknown new storage, conveyance, and treatment facilities at unknown locations and would require increased long-term energy requirements compared to the Hetch Hetchy system, which is gravity-driven and not subject to water filtration requirements. In addition, there would likely be significant impacts related to the diversion of Tuolumne River water elsewhere, as well as impacts on any other surface water bodies developed to replace Tuolumne River supply and their associated resources. For these reasons, this alternative is not evaluated in detail in this PEIR.

- *Alternative Water Supply Sources Other than the Tuolumne River*. Increasing diversions from the Tuolumne River is controversial. Many commentors requested evaluation of alternatives to this element of the WSIP, including increasing demand management efforts (conservation and water recycling) and other alternative supply sources. Further, the San Francisco Board of Supervisors has called for the PEIR to evaluate an alternative that involves no increase in Tuolumne River diversions. These alternative supply proposals are controversial for the SFPUC's water customers, since the Tuolumne River is a high-quality, secure source of supply to which the CCSF already has rights, and the use of additional Tuolumne River water would maximize the use of existing facilities and require few additional facility projects in contrast to other alternatives. In Chapter 9, the PEIR discusses the following alternatives to address these requests for program alternatives: Aggressive Conservation/Water Recycling and Local Groundwater (with and without supplemental Tuolumne River diversions), Year-round Desalination at Oceanside, and Regional Desalination for Drought.

Issues to Be Resolved

Section S.5, below, identifies the actions necessary for the overall adoption and approval of the WSIP. Following certification of the PEIR by the San Francisco Planning Commission, in order to adopt the WSIP, the SFPUC must make findings for each significant effect identified in the PEIR and determine whether it will adopt each mitigation measure (and if not, why).

As further project details are known about the facility improvement projects and site-specific information is gathered, it is possible that individual project effects identified in this document might not occur or that additional project effects not identified in this document would occur. Such changes in project details will be addressed during project-specific environmental review.

In considering approval of the WSIP as proposed, the SFPUC would be considering a commitment to: (a) meet the 2030 customer purchase request increase, (b) secure and develop the proposed water supply portfolio for long-term supply to the regional service area,

(c) establish a 20 percent maximum system rationing limit during a drought, (d) implement the 22 facility improvement projects evaluated in the PEIR to improve the regional water system, and (e) operate the system in accordance with the level of service goals and system performance objectives established for the WSIP. The proposed water supply option adds recycled water, local groundwater, conservation, water transfers, and regional groundwater conjunctive use to the SFPUC's water supply portfolio for the system, while continuing to rely predominantly on Hetch Hetchy system water and local watershed supply captured in local reservoirs.

S.5 Required Actions and Approvals (Chapter 3)

The following list identifies the approvals necessary for overall adoption and approval of the WSIP, including adoption of the proposed levels of service and water supply option, and general approval of the facility improvement projects. The approval and adoption of the overall WSIP as a program and policy are distinct actions from the approvals for individual facility improvement projects.

Approvals and actions applicable to the overall WSIP include:

- *San Francisco Planning Commission*
  - Certifies Final PEIR on the WSIP
- *San Francisco Public Utilities Commission*
  - Reviews Final PEIR and adopts CEQA findings and mitigation monitoring and reporting program
  - Approves and adopts the WSIP
- *San Francisco Board of Supervisors*
  - Hears and decides any appeals of the Planning Commission's certification of the Final PEIR

Implementation of the WSIP could involve the following additional discussion and actions by the agencies listed below:

- *San Francisco Public Utilities Commission*
  - Approves any water transfer agreements with TID, MID, or other agencies
  - Approves contracts for the construction of WSIP facility improvement projects
  - Approves operating agreements for the Westside Basin conjunction-use program
  - Annually reviews its cost of utility service and revises the rate schedules applicable to retail water sales as required[1]

[1] Retail water sales include sales to Lawrence Livermore National Laboratory, the Town of Sunol, and approximately 190 other retail customers (see list of major water customers in Table 3.1). The SFPUC sells water to Groveland Community Services District under the terms of a 1984 contract that allows the water rate to be adjusted every four years.

   - Approves any water sales agreements with SFPUC wholesale and retail customers

- *San Francisco Planning Department/Planning Commission*
   - Conducts ongoing environmental review of individual facility improvement projects as well as compliance with mitigation and monitoring reporting program during WSIP implementation
   - Makes determinations of consistency with the San Francisco General Plan, if needed, for projects requiring certain approvals by the Board of Supervisors

- *San Francisco Board of Supervisors*
   - Appropriates funding for implementation of the WSIP projects, including general obligation bond monies and annual budget appropriations
   - May reject rates and charges that the SFPUC establishes for water customers by resolution within 30 days of adoption by the SFPUC
   - Considers appeals of EIR certifications and negative declaration approvals by the San Francisco Planning Department

- *State Water Resources Control Board*
   - Reviews and authorizes any transfer under a post-1914 water right that may be necessary to implement long-term water transfers with TID or MID

- *Turlock and Modesto Irrigation Districts*
   - Review and approve water transfer agreements with the SFPUC and/or amendments to the SFPUC's water bank account in Don Pedro Reservoir

- *SFPUC wholesale and retail water customers*
   - Approves any agreements between SFPUC and individual wholesale and retail customers

- *Daly City, California Water Service Company's South San Francisco service area, and San Bruno*
   - Approve operating agreement(s) for the Westside Basin conjunctive-use program (Regional Groundwater Projects), including approval of new system wells

S.6 WSIP Variants (Chapter 8)

The SFPUC requested that the PEIR also include environmental assessment of four variants to the WSIP. The WSIP variants are essentially the same as the proposed program except for minor differences in water supply sources or rationing limits. The variants are not intended to serve as CEQA alternatives, which are discussed separately in the PEIR. This evaluation of the variants is provided to allow decision-makers to compare the environmental impacts of the variants to those of the WSIP.

Variant 1 – All Tuolumne

Variant 1 – All Tuolumne is the same as the proposed program in all respects except for one. Instead of developing 10 mgd of additional supply sources through recycled water, groundwater, and conservation projects in San Francisco, the SFPUC would rely exclusively on increased diversions from the Tuolumne River to serve the 2030 increase in purchase requests of 35 mgd during most (nondrought) years. All other aspects of the proposed water supply option would be the same, and all of the same facility improvement projects would be implemented, with the exception of the recycled water and groundwater projects in San Francisco. The environmental analysis determined that Variant 1 would result in slightly more severe impacts on the Tuolumne River resources compared to the WSIP, although it would avoid potential impacts on the North Westside Groundwater Basin. However, all other water supply and system operations impacts and mitigation measures would be the same as under the WSIP. There would be no additional impacts, and no additional mitigation measures would be required. Facilities-related impacts under Variant 1 would be slightly less than those of the WSIP, since construction and operational impacts associated with the recycled water and groundwater projects in San Francisco would not occur.

Variant 2 – Regional Desalination for Drought

Variant 2 – Regional Desalination for Drought would be identical to the WSIP except that, instead of relying on water transfers with TID and MID as a supplemental dry-year supply, the SFPUC would receive water from a regional desalination plant during droughts. All other aspects of the proposed water supply option would be the same, and all of the same facility improvement projects would be implemented. The SFPUC is currently participating with the East Bay Municipal Utility District, Contra Costa Water District, and Santa Clara Valley Water District in studying the feasibility of developing a Bay Area Regional Desalination Plant (BARDP). Depending on the location of BARDP, the SFPUC would either receive desalinated water directly from the plant for blending in the regional system or arrange for an exchange with other water agencies through existing interties connected to the regional system. The environmental impacts of Variant 2 would be essentially the same as those of the WSIP, with a very slight reduction in impacts on Tuolumne River resources, since water transfers from TID and MID during dry years would not occur. However, due to the extent of additional facilities required for the BARDP and associated conveyance facilities, this variant would have substantially greater facilities-related impacts than the WSIP, most notably the increased energy impacts and water quality/biological resources impacts associated with seawater intake structures and brine disposal.

Variant 3 – 10% Rationing

Variant 3 – 10% Rationing would be the same as the WSIP in all respects, except that the maximum systemwide rationing limit during droughts would be reduced from 20 to 10 percent. To achieve this reduction in the rationing limit, the SFPUC would increase the amount of water transfers with TID and MID during dry years, increasing average annual diversions from the Tuolumne River. Variant 3 would otherwise include the same water supply options and facility improvement projects as the WSIP. Variant 3 would result in all the same impacts as the WSIP, except for somewhat more severe impacts on Tuolumne River resources. However, all impacts would be the same as under the WSIP, and no additional mitigation measures would be required.

Variant 4 – Phased WSIP

Variant 4 – Phased WSIP would generally be the same as the WSIP, except that an interim mid-term planning horizon of 2018 would be used instead of the WSIP 2030 planning horizon. Under this variant, all facility improvement projects would be implemented, and the SFPUC would make a decision about future water supply to its customers through 2018 only and defer a decision regarding long-term water supply until after 2018. Variant 4 would limit deliveries from SFPUC watersheds to an annual average of 265 mgd through 2018 and would promote development and implementation of 10 to 20 mgd of additional local conservation, water recycling, and groundwater projects. The environmental impacts of Variant 4 would be essentially the same as those for the WSIP or Modified WSIP Alternative, except for a reduction in impacts on Tuolumne River resources. However, it would result in additional impacts associated with construction and operation of recycled water and groundwater facilities similar to those of the Modified WSIP Alternative.

S.7 Alternatives to the Proposed Program (Chapter 9)

Based on a review of the environmental impacts identified in the PEIR for the WSIP and on input received during the public scoping period, numerous alternative concepts were screened to assess their ability both to meet most of the program objectives established by the SFPUC for the WSIP and to avoid or minimize the significant environmental effects of the proposed program. A range of program alternatives was selected for more detailed review in comparison to the WSIP, as required by CEQA. The alternatives analyzed in the PEIR are summarized below.

With the exception of the No Program Alternative, these alternatives were included in the PEIR because of their apparent ability to meet most of the program's basic objectives, their ability to reduce one or more of the significant impacts associated with program implementation, their potential feasibility, and their collective ability to provide a reasonable range of alternatives to foster informed decision-making and public participation. Analysis of the No Program Alternative is included as required by CEQA.

No Program Alternative

Under the No Program Alternative, the SFPUC would implement only those facility improvement projects driven by regulatory requirements or existing agreements with regulatory agencies. The system would meet the water quality goals of the WSIP, but it would fail to meet the seismic and delivery reliability goals and would have limited ability to serve the increase in customer purchase requests through 2030, particularly during drought periods. The SFPUC would endeavor to meet increasing customer purchase requests through 2030 by diverting additional Tuolumne River water only when available. It would not secure an additional dry-year supply transfer of Tuolumne River water, implement the Westside Basin groundwater conjunctive-use program, or develop the proposed recycled water and groundwater projects in San Francisco. The wholesale customers may decide to pursue supplemental supply sources and/or conservation measures to make up for the reduced reliability and the supply shortfall under this alternative. Compared to the WSIP, this alternative would develop less in terms of new water supplies for the regional system and would implement far fewer of the proposed facility improvement projects.

No Purchase Request Increase Alternative

The No Purchase Request Increase Alternative is designed to serve wholesale customers only the amount of water required under the existing Master Water Sales Agreement between CCSF and each of the wholesale customers; therefore, this alternative would not fully meet the purchase request increase by the SFPUC wholesale customers for additional supply through

2030. Under the No Purchase Request Increase Alternative, the SFPUC would implement all of the proposed WSIP facility improvement projects. It is expected the wholesale customers would pursue supplemental supply sources and/or conservation measures to make up the supply shortfall under this alternative. This alternative was included in the alternatives analysis in an effort to avoid or minimize the potential growth-inducing effects and secondary effects of growth associated with providing more water to the regional customers, and it evaluates the consequences of the SFPUC not meeting the full future purchase request increase.

Aggressive Conservation/Water Recycling and Local Groundwater Alternative

Under this alternative, the SFPUC would implement all of the proposed WSIP facility improvement projects, but would endeavor to serve the projected increase in customer purchase requests through 2030 only through additional conservation, water recycling, and local groundwater projects. It does not appear feasible to fully meet the 2030 purchase requests with reasonably foreseeable conservation, recycled water, and groundwater projects within the service area. Therefore, under the Aggressive Conservation/Water Recycling and Local Groundwater Alternative, the SFPUC would have to either: (a) limit future customer purchase deliveries to the level that can be met, short of the 2030 requests (approximately 294 mgd instead of 300 mgd average annual) and increase the level of rationing to 25 percent or more during droughts, or (b) provide a supplemental supply to make up the delivery shortfall to meet the 300 mgd. As a result, two scenarios are discussed in the PEIR:

> **No Supplemental Tuolumne River Supply** – The SFPUC would not provide a supplemental supply of water from the Tuolumne River to augment this alternative to meet the 2030 customer purchase requests of 300 mgd.
>
> **With Supplemental Tuolumne River Supply** – The SFPUC would supplement this alternative with additional Tuolumne River diversions under its existing water rights.

These two alternatives represent alternative sources of supply and different demand delivery levels for the regional system compared to the WSIP. They are evaluated to address the impacts on resources in the Tuolumne River, Alameda Creek, and Peninsula watersheds, including Pilarcitos Creek.

Lower Tuolumne River Diversion Alternative

Under the Lower Tuolumne River Diversion Alternative, the SFPUC would implement all of the proposed facility improvement projects and would serve the projected increase in customer purchase requests through 2030 through diversions from the lower Tuolumne River near its confluence with the San Joaquin River, assuming it could reach agreement with TID and MID. This alternative would include construction and operation of additional conveyance and treatment facilities to divert, transport, treat, and blend the new supply into the regional system. Compared to the WSIP, this alternative represents an alternative source of supply and is evaluated to address impacts on the Tuolumne River and related resources.

Year-round Desalination at Oceanside Alternative

Under the Year-round Desalination at Oceanside Alternative, the SFPUC would implement all of the proposed WSIP facility improvement projects and would construct a 25-mgd desalination plant in San Francisco to serve the projected increase in customer purchase requests through 2030. This alternative would not involve increased levels of diversions from the Tuolumne River. The desalination plant would provide year-round supplies during all hydrologic year types to blend into the regional system at the Sunset Reservoir in San Francisco. Compared to the WSIP, this alternative represents an alternative source of supply and is evaluated to address the impacts on the Tuolumne River, Alameda Creek, and Peninsula watersheds, including Pilarcitos Creek, and related resources.

Regional Desalination for Drought Alternative

Under the Regional Desalination for Drought Alternative, the SFPUC would implement all of the proposed WSIP facility improvement projects and would partner with other Bay Area water agencies to construct and operate a regional desalination plant that would provide the SFPUC with supplemental supply during drought years. Compared to the WSIP, this alternative represents an alternative source of supply and is evaluated to address the impacts on the Tuolumne River, Alameda Creek, and Peninsula watersheds, including Pilarcitos Creek, and related resources.

Modified WSIP Alternative

Under the Modified WSIP Alternative, the SFPUC would implement all of the proposed facility improvement projects, but would modify proposed system operations to minimize environmental effects. This alternative would include the implementation of key mitigation measures identified in this PEIR, including acquiring a water transfer of conserved water as a supplemental dry-year source, implementing a minimum instream flow requirement for resident fish in a portion of Alameda Creek, modifying operations to accommodate increased demands from the Coastside County Water District, managing the inundation levels at Crystal Springs Reservoir to preserve upland habitat to the extent possible, and increasing recycled water, conservation, and local groundwater in partnership with wholesale customers. This alternative is similar to the WSIP but includes alternate supply sources and system operations. It is evaluated to address the impacts on the Tuolumne River, Alameda Creek, and Peninsula watersheds, including Pilarcitos Creek and Crystal Springs Reservoir, and related resources.

Comparison of Alternatives to the Proposed WSIP

The eight alternatives analyzed in the PEIR would have varying abilities to meet the goals and objectives established by the SFPUC for the WSIP and would have a wide range of additional environmental effects. The No Program, No Purchase Request Increase, and Aggressive Conservation/Water Recycling and Local Groundwater Alternatives would fail to meet one or more key program objectives, while the Lower Tuolumne River Diversion, Year-round Desalination at Oceanside, Regional Desalination for Drought, and Modified WSIP Alternatives appear to meet most of the basic project objectives.

Two alternatives—the Aggressive Conservation/Water Recycling and Local Groundwater Alternative (Without Supplemental Tuolumne River Water) and the Year-round Desalination at Oceanside Alternative—do not involve increases in Tuolumne River diversion over existing average annual levels. Impacts on the Tuolumne River and related resources would be reduced under these alternatives compared to the WSIP, but would not be completely avoided due to changes in the regional system operations that could affect the Tuolumne River in some years under all alternatives, regardless of whether there are additional average annual diversion increases. Other alternatives would also reduce impacts on the Tuolumne River compared to the WSIP, but impacts would remain potentially significant and require mitigation, similar to the WSIP. Most alternatives would result in similar impacts on Alameda Creek, Crystal Springs Reservoir and Pilarcitos Creek and related resources; impacts on these water bodies and their associated resources are primarily the result of specific facility improvement projects that must be implemented under all alternatives to meet regulatory requirements, and are not affected by which sources of supply are selected to augment the regional system supply portfolio.

All alternatives could also affect other water bodies not affected by the WSIP. The Lower Tuolumne River Diversion Alternative would result in direct impacts on the lower Tuolumne River due to construction and operation of a new intake structure on the river that would not occur under the WSIP. The Year-round Desalination at Oceanside Alternative and the Regional Desalination for Drought Alternative would affect the offshore waters of the Pacific Ocean and the upper San Francisco Bay, respectively, due to water intake for desalination treatment and discharge of the concentrated brine following treatment. The WSIP would not affect these water bodies. Under the other alternatives that require additional conservation, water recycling and local groundwater use and/or those alternatives that result in a supply or reliability shortfall for the wholesale customers, supplemental water supply projects could affect other surface water bodies, including rivers north or south of the Delta and the Delta as well as local groundwater aquifers.

All alternatives, except for the No Program Alternative, would include implementation of the 22 facility improvement projects within the regional system proposed under the WSIP. However, all alternatives would also require the construction and operation of additional major facility projects. These other facility projects would be required as part of securing alternative water supply sources and/or supplemental water supplies that the SFPUC or BAWSCA (and the wholesale customers) would need to pursue to insure the program objectives are met. The other facilities that would be required in addition to the facility improvement projects for the SFPUC regional system vary by alternative, but include new recycled water treatment, storage and transmission facilities; new groundwater wells a desalination plant and associated storage and transmission facilities and/or a new water treatment plant and associated new river intake and transmission facilities. Consequently, each alternative would result in greater impacts from facility construction and operation than the WSIP because additional new or expanded facilities would be required.

All alternatives are expected to have growth inducement potential and associated secondary effects of growth similar to those of the WSIP. The No Purchase Request Increase Alternative evaluates an option in which the SFPUC would not to fully serve its customers' purchase request through 2030, even under this alternative, BAWSCA and the wholesale customers are expected to pursue supplemental supply sources to make up for any supply delivery or drought reliability shortfall from the regional system such that the communities in the service area could implement their planned growth. Thus, withholding additional supply from the regional system to the wholesale customers would not necessarily reduce the growth in the communities within the service area.

Environmentally Superior Alternative

CEQA requires the identification of an environmentally superior alternative from among the proposed project and the set of alternatives evaluated. The CEQA Guidelines further state that if the No Program Alternative is the environmentally superior alternative, then the EIR must also identify which of the action alternatives is the environmentally superior alternative. In this case, the No Program Alternative is not the environmentally superior alternative. As summarized above, under the No Program Alternative, the SFPUC would be unable to meet most of the program objectives. The No Program Alternative would leave the SFPUC and its customers at significant risk of supply reduction or disruption during an earthquake or other emergency, or during a drought. This is not a feasible or acceptable alternative for the SFPUC.

Although it appears that fewer facility improvement projects would be implemented under the No Program Alternative and that, as a result, there would be fewer facility and construction impacts, it is expected that there would be much more emergency facility repair and replacement projects under this alternative as the system continues to age without proactive improvement. Ultimately, through required repair and replacement efforts, a similar level of facility improvement projects as that proposed under the WSIP might have to be conducted under the No Program Alternative, resulting in much of the same facility impacts as the WSIP; however, these repair and replacement projects would likely occur over a longer period of time and in a less coordinated and comprehensive manner. In addition, implementing system improvements through a piecemeal and largely emergency response approach could result in greater environmental impacts and less mitigation for such impacts; when projects are implemented under emergency conditions, they often require little or no environmental review and thus could be implemented without the same level of mitigation and mitigation compliance monitoring that would be required for the WSIP. Furthermore, piecemeal implementation could also increase the cumulative effects of multiple, sequential facility repair and replacement projects throughout the system.

With respect to impacts on water resources, the No Program Alternative's effects on the Tuolumne River would be similar to but less than those of the WSIP because river diversions would not increase quite as much as with the WSIP; however, the No Program Alternative would result in the same significant impacts on the Tuolumne River as the WSIP and would require the same mitigation. As summarized above, the No Program Alternative would also have the same impacts as the WSIP on the Alameda Creek / Alameda watershed resources and on the Peninsula watersheds (including Pilarcitos Creek) resources. The No Program Alternative would have the same growth-inducement potential and associated secondary effects of growth as the WSIP because BAWSCA and the wholesale customers would be expected to secure supplemental supplies to meet any supply delivery and reliability shortfall from the regional system that would result under the No Program Alternative.

Finally, under this alternative, BAWSCA and/or the wholesale customers might have to construct and operate additional facilities in order to develop supplemental surface water supplies, recycled water, or groundwater. Required facilities could include new treatment plants, storage and transmission facilities, and groundwater wells. The impacts of constructing and operating these facilities would be in addition to those resulting from improvement and repair of the regional system. Thus, the No Program Alternative could result in greater facility impacts than the WSIP. Because the No Program Alternative would not appreciably lessen the environmental impacts of the WSIP, might result in additional impacts due to the need for supplemental supply development and associated facility construction, and would not meet most of the basic program objectives, it is not considered the environmentally superior alternative.

The Modified WSIP Alternative is considered to be the environmentally superior alternative. It would reduce key impacts of the proposed WSIP on natural resources along the lower Tuolumne River, along Alameda Creek below the diversion dam, at Pilarcitos Reservoir and along Pilarcitos Creek, and in Crystal Springs Reservoir, but it would continue to meet the WSIP's primary goals and objectives. Like the WSIP, this alternative would maximize the use of existing facilities and the largely gravity-driven system without also requiring the construction of additional major facilities called for under many other alternatives, or substantially increasing the energy demand of the system or need for pumping. While some of the other alternatives would avoid or lessen certain WSIP impacts, they would also result in substantial additional impacts that the WSIP would not generate, because these alternatives would require substantial additional major facilities and affect other environmental resources in different geographic locations in addition to those affected by the WSIP.

The Modified WSIP Alternative includes implementation of more conservation, water recycling and local groundwater projects within the regional service area than under the WSIP, which would also require construction of some additional facilities in some areas not affected by the WSIP but not to the same extent as other alternatives. However, while construction of these facilities would cause temporary construction disruption and related environmental impacts, long-term implementation of these regional conservation, water recycling, and local groundwater projects would offset impacts of the operational modifications proposed under the Modified WSIP Alternative on the Tuolumne River. Depending on the extent of these projects implemented by wholesale customers in collaboration with the SFPUC, they could also help reduce the amount of additional diversion required from the Tuolumne River to serve the 2030 customer purchase requests. Compared to the WSIP, the Modified WSIP Alternative would result in slightly greater impacts on land use, air quality, noise, traffic, and energy in urban environments (expected to be largely mitigable), but fewer and significantly less severe impacts on biological and fishery resources in natural habitats.

1 Introduction

CHAPTER 1
Introduction

1.1 Introduction

The City and County of San Francisco (CCSF), through the San Francisco Public Utilities Commission (SFPUC), owns and operates a regional water system that extends from the Sierra Nevada to San Francisco and serves 2.4 million people in San Francisco, San Mateo, Santa Clara, Alameda, and Tuolumne Counties. The SFPUC proposes to adopt and implement the Water System Improvement Program (WSIP or proposed program) to increase the reliability of the regional system with respect to water quality, seismic response, water delivery, and water supply to meet water delivery needs in the service area through the year 2030. The WSIP would implement the SFPUC's service goals and system performance objectives for the regional system. These goals and objectives provide the basis for the facility improvement projects included in the WSIP and for the proposed water supply option to meet water delivery needs through 2030.

1.2 Purpose of the Program EIR

The San Francisco Planning Department, Major Environmental Analysis (MEA) Division, determined that implementation of the WSIP could have a significant effect on the environment and therefore required preparation of an Environmental Impact Report (EIR). The Planning Department prepared this Program Environmental Impact Report (PEIR) to provide the public and responsible and trustee agencies with information about the potentially significant environmental effects of the proposed program, to identify possible ways to minimize the potentially significant effects, and to describe and evaluate feasible alternatives to the proposed program.

This PEIR has been prepared in compliance with the California Environmental Quality Act (CEQA) of 1970 (as amended), codified in California Public Resources Code Sections 21000 et seq., and the CEQA Guidelines, codified in the California Code of Regulations, Title 14, Division 6, Chapter 3. This document has been prepared as a program EIR. According to the CEQA Guidelines, Section 15168(a), a program EIR is one type of environmental review document that may be used to evaluate a plan or program that has multiple components (projects and actions) or to address a series of actions that are related:

- Geographically
- As logical parts in the chain of contemplated actions

- In connection with the issuance of rules, regulations, plans, or other general criteria to govern the conduct of a continuing program, or
- As individual activities carried out under the same authorizing statutory or regulatory authority and having generally similar environmental effects that can be mitigated in similar ways

The proposed WSIP includes multiple projects and actions that cover a broad geographic scale. This PEIR provides a foundation for any necessary future environmental review documents that focus on individual projects of the WSIP. A program EIR can provide the following additional advantages (CEQA Guidelines, Section 15168[b]):

- Provide for a more exhaustive consideration of effects and alternatives than would be practical in an EIR on an individual action
- Ensure consideration of cumulative impacts that might not be evident in a case-by-case or project-by-project analysis
- Avoid duplicative consideration of basic policy issues
- Allow the lead agency to consider broad policy alternatives and program-wide mitigation measures early in the process when the agency has greater flexibility to deal with basic problems of cumulative impacts
- Allow a reduction in paperwork

A program EIR may be prepared on a plan or program before the details of every project included in the program have been developed, as is the case for the WSIP. Therefore, this PEIR addresses the environmental effects of the program as a whole. The analyses focus on the environmental effects of implementing the overall WSIP as a plan to improve and expand the ability of the regional water system to deliver water to the SFPUC service area through the year 2030 and increase the overall reliability of the system. To accomplish this, the PEIR includes a combination of *program-level* and *project-level* analyses.

This PEIR evaluates the major environmental effects of implementing proposed facility improvement projects from a broad perspective; this evaluation is a *program-level* analysis. While the SFPUC is aggressively developing the design, construction, and operation details of the projects included in the WSIP, these project details are not the focus of this PEIR. Instead, the PEIR frames the nature and magnitude of the expected environmental impacts associated with these proposed WSIP projects and identifies program mitigation measures to reduce the impacts of the projects as proposed. As discussed further below, more detailed *project-level* analysis of individual facility improvement projects will be conducted separately as required by CEQA.

In addition to the program-level analysis of proposed facility improvements, this PEIR also includes a *project-level* impact analysis of implementing the proposed WSIP water supply option through the 2030. The chief environmental issues evaluated in the PEIR at a *project-level* include:

- The effects of providing additional water to serve increasing purchase requests within the service area (specifically, the effect of increasing average annual water supply to serve customer needs through 2030)
- The effects of using the proposed sources of water to serve the increasing purchase requests through 2030 during both nondrought and drought periods
- The effects of proposed changes in system operations associated with implementing the proposed facility improvements and achieving the WSIP system performance objectives

For these water supply and system operations impacts, the PEIR also identifies mitigation measures when appropriate to address significant effects. This project-level analysis is intended to address these issues without the need for additional environmental review.

This PEIR can be used to simplify the task of preparing project-specific environmental review documents that evaluate the effects of implementing the individual WSIP facility improvement projects at a more detailed, *project-level* of analysis. As required by CEQA and where necessary, project-level CEQA review will be conducted separately for individual facility improvement projects proposed under the WSIP. The separate environmental review of individual projects will evaluate site-specific impacts and incorporate feasible mitigation measures and alternatives developed in the PEIR as appropriate (CEQA Guidelines, Section 15168[c]). In addition, this PEIR can be incorporated by reference into project-level CEQA analyses to deal with water supply effects, regional influences, secondary effects of growth, and other factors that apply to the program as a whole (CEQA Guidelines, Section 15168[d]).

1.3 CEQA Process

1.3.1 Notice of Preparation

In accordance with Sections 15063 and 15082 of the CEQA Guidelines, the San Francisco Planning Department, as lead agency, prepared a Notice of Preparation (NOP) of an EIR and conducted scoping meetings (see **Appendix A**). The NOP was circulated to local, state, and federal agencies and to other interested parties on September 6, 2005, initiating a public comment period that extended through October 24, 2005. An Initial Study was not prepared because the lead agency decided in advance that a PEIR would be required for this program.

As indicated in the NOP, the PEIR addresses the full range of environmental impacts of the WSIP. The NOP included a preliminary list of the potential environmental impacts related to the following resource topics: surface water resources; groundwater resources; fisheries and aquatic resources; terrestrial vegetation and wildlife; geology, soils, and seismicity; cultural resources; land use, plans, and policies; recreation; agricultural resources; traffic, transportation, and circulation; air quality; noise and vibration; public services, utilities, and energy; hazards and public safety; visual quality; socioeconomics; growth-inducement potential and secondary effects of growth; and cumulative effects. The NOP provided a general description of the proposed action, the need for the program and program benefits, the proposed facilities, and the program location.

1.3.2 Public Scoping Meetings

Pursuant to CEQA Guidelines Section 15083, the San Francisco Planning Department held five public scoping meetings as follows:

- Wednesday, October 5, 2005 – Sonora Opera House, Sonora, CA
- Thursday, October 6, 2005 – Thomas Downey High School Cafeteria, Modesto, CA
- Tuesday, October 11, 2005 – Fremont Main Library, Fremont, CA
- Tuesday, October 18, 2005 – Palo Alto Arts Center, Palo Alto, CA
- Wednesday, October 19, 2005 – Tenderloin Community School, San Francisco, CA

Public notices were placed in local newspapers informing the general public of the scoping meetings. The purpose of the meetings was to present the proposed WSIP to the public and receive public input regarding the proposed scope of the PEIR analysis. Attendees were provided an opportunity to voice comments or concerns regarding potential effects of the program.

A scoping report was prepared to summarize the public scoping process and the comments received in response to the NOP, and the report is included in Appendix A of this PEIR. Based on sign-in sheets at each of the meetings, 260 participants attended the scoping meetings, with 75 of those participants providing oral comments. Transcripts of the each scoping meeting are included in the scoping report.

The San Francisco Planning Department held a scoping meeting for resource agencies on Thursday, November 3, 2005 in San Francisco. Representatives from the following agencies attended: U.S. Army Corps of Engineers, San Francisco Bay Regional Water Quality Control Board, California Department of Fish and Game, and U.S. Fish and Wildlife Service. Representatives of the U.S. Environmental Protection Agency and the National Marine Fisheries Service were invited but were unable to attend. Additional coordination with public agencies was provided through informal consultation and telephone interviews conducted throughout the PEIR process.

1.3.3 Public and Agency Comments on the NOP

The comment period on the NOP extended from September 6 through October 24, 2005. In response to the NOP, comments were received by letter sent via mail, email, or fax (104, including 5 form letters counted once each but submitted multiple times), orally by speakers at the scoping meetings (79), and by phone (187 voicemail messages left with the San Francisco Planning Department). The comments addressed concerns regarding the full range of potential environmental issues as well as program alternatives and the CEQA process. As described in the previous section, a scoping report was prepared to compile and summarize comments received on the NOP and is included in Appendix A.

1.3.4 PEIR – Impact Determination

This document constitutes the PEIR. It describes the WSIP and the environmental setting for the proposed program, identifies potential impacts, presents mitigation measures for impacts found to be significant or potentially significant, and evaluates program alternatives. It also includes an analysis of three variants to the proposed WSIP, as requested by the SFPUC.

The analysis of environmental impacts in this PEIR is divided into three main groups: (1) construction and operational impact of the WSIP facility improvement projects are analyzed in Chapter 4; (2) water supply and system operational impacts of the WSIP are analyzed in Chapter 5; and (3) growth-inducing impacts Chapter 7. In assessing construction and operational impacts of the facility improvement projects, Chapter 4 considers impacts of individual projects, the "collective" construction and operational impacts from multiple WSIP facility improvement projects, and cumulative impacts associated with construction and operation of WSIP projects in combination with other past, present, and future actions with potential for similar impacts on the same resources as those affected by the WSIP. Similarly, in assessing water supply and system operations impacts, Chapter 5 includes analysis of cumulative impacts associated with the WSIP water supply and system operations in combination with other past, present, and future actions with potential for impacts on the same resources as those affected by the WSIP.

Each environmental issue presented in this PEIR is analyzed with respect to significance criteria that are based on MEA guidance regarding the environmental effects to be considered significant. MEA guidance is, in turn, based on CEQA Guidelines Appendix G with some modifications. In cases where potential environmental issues associated with the WSIP are identified but are not clearly addressed by MEA's standard Initial Study checklist, additional impact significance criteria are presented. Appendix B of this PEIR presents the MEA Initial Study checklist as applied to the WSIP, and indicates the criteria applicable to the WSIP and discussed in the PEIR.

For the impact analyses, the following categories are used to describe impact significance:

Not Applicable (N/A). An impact is considered not applicable if there is no potential for impacts or if the environmental resource does not occur within the study area or the area of potential effect.

Beneficial (B). An impact is considered beneficial if it is determined that WSIP water supply or system operations would improve an environmental resource or result in a beneficial effect on the environment.

Less than Significant (LS). This determination applies if there is a potential for some limited impact, but not a substantial adverse effect that qualifies under the significance criteria as a significant impact. LS impacts do not require mitigation.

Less than Significant with Program-Level Mitigation (LSM). This determination applies to the collective impact analysis and is used only in Chapter 4. It indicates a potential for some limited impact after implementation of program-level mitigation measures, but not a substantial adverse effect that qualifies under the significance criteria as a significant impact. LSM impacts for a collective impact do not require additional mitigation beyond program-level mitigation (see Chapter 4 for further explanation).

Potentially Significant, Mitigatable (PSM) / Significant Mitigable (SM). This determination applies if there is the potential for a substantial adverse effect that meets the significance criteria, but mitigation is available to reduce the impact to a less-than-significant level. In Chapter 4, an impact is labeled “potentially” significant when there is not enough site-specific information at the program level of analysis to determine definitively that it is significant; separate, project-level CEQA evaluation of the WSIP projects could confirm that the impact is significant for that project or document that the impact is less than significant. In Chapter 5, an impact is labeled “potentially” significant in the cases where the analysis cannot conclusively determine the extent of adverse effects and the PEIR errs on the conservative side.

The impacts identified as “potentially significant” are treated as significant impacts in this PEIR. In both Chapters 4 and 5, “significant, mitigable” applies if there is certainty that a substantial adverse effect that meets the significance criteria would occur, but implementation of mitigation measures would reduce the impact to less than significant. For both PSM and SM impacts, mitigation would reduce or lessen the severity of the impact to a less-than-significant level.

Potentially Significant, Unavoidable (PSU). This determination applies if there is a potential for a substantial adverse effect that meets the significance criteria but for which there appears to be no feasible mitigation available to reduce the impacts to a less-than-significant level. Mitigation might be available to lessen the severity of the impact, but the residual effect remains significant and therefore unavoidable. The impacts identified as potentially significant are treated as significant impacts in this PEIR.

In Chapter 4, an impact is labeled “potentially” significant and unavoidable when there is not enough site-specific information at the program level of analysis to determine definitively that the impact is significant or that recommended mitigation could sufficiently reduce the severity of the impact; in these cases, the PEIR errs on the conservative side and applies this determination. However, project-level CEQA evaluation could confirm that the impact is in fact significant and unavoidable for a specific WSIP project or could provide additional detail to determine the impact is significant but can be mitigated to a less-than-significant level.

In Chapter 5, an impact is labeled “potentially” significant and unavoidable when the mitigation measure could lessen the effect of the impact, but it is not certain that if it could reduce the impact to less than significant.

In both Chapter 4 and 5, this determination is also applied if the feasibility of the mitigation is contingent on review and approval by other jurisdictional agencies (i.e., mitigation feasibility is outside SFPUC control). For PSU impacts, mitigation would be required to the extent feasible even if the severity of the impact with mitigation would not be reduced to a less-than-significant level.

Significant Unavoidable (SU). This determination applies if there is certainty for a substantial adverse effect that meets the significance criteria but for which there appears to be no feasible mitigation available to reduce the impact to a less-than-significant level. The word “potentially” is not used for impacts where it can be determined during this PEIR process that: (1) the impact would occur and (2) the impact could not be mitigated to a less-than-significant level. For SU impacts, mitigation would be required to the extent feasible even if the severity of the impact with mitigation would not be reduced to a less-than-significant level.

1.3.5 PEIR—Documents Incorporated by Reference

The following documents are incorporated by reference in this PEIR. See Section 1.3.6 for locations where these documents were available for review during the public review period.

- City of Belmont, *San Juan Hills Area Plan Environmental Impact Report*, State Clearinghouse #86122320, adopted March 22, 1988.
- City of Belmont, *Western Hills Area Plan Environmental Impact Report,* State Clearinghouse #89051615, adopted June 12, 1990.
- City of Brisbane, *City of Brisbane 1993 General Plan Environmental Impact Report, Volume I: Environmental Setting* (1993) and *Volume II: Draft EIR*, State Clearinghouse #93071072, January, 1994a.
- City of Brisbane, Resolution No. 94-23: A Resolution of the City Council of the City of Brisbane, State of California, Making Certain Findings Regarding the Environmental Impact Report for the 1994 General Plan and Adopting a Mitigation Monitoring Program, June 1994b.
- City of East Palo Alto, *General Plan Final Program Environmental Impact Report*, State Clearinghouse #98051028, November 23, 1999a.
- City of East Palo Alto, Final Environmental Impact Report CEQA Findings: City of East Palo Alto General Plan Final Program EIR, November 23, 1999b.
- City of Foster City, *Final Environmental Impact Report on the General Plan Revision for the City of Foster City*, State Clearinghouse #92073017, April 1993.
- City of Fremont, *Fremont 1990 General Plan Final Program Environmental Impact Report*, State Clearinghouse #90030675, March, 1991a.
- City of Fremont, Resolution No. 8080: Resolution of the City of Fremont Adopting an Updated General Plan, Certifying a Project EIR, and Adopting Findings of Fact and a Statement of Overriding Considerations, May 7, 1991b.
- City of Hayward, *General Plan Final Environmental Impact Report*, State Clearinghouse #2001072069, January 2002a.
- City of Hayward, City of Hayward Resolution 02-025 Certifying the Program Environmental Impact Report and Adopting the Mitigation Monitoring and Reporting Program, Statement of Overriding Considerations and General Plan, March, 12, 2002b.
- City of Menlo Park, *Final Environmental Impact Report: Amendments to the City of Menlo Park General Plan and to the City of Menlo Park Zoning Ordinance including Policy Document, Background Report, and Land Use and Circulation Elements*, State

Clearinghouse #890 124 20, October 19, 1994 (includes November 15, 1994 Findings for Project and Final EIR).

- City of Millbrae, *Final Environmental Impact Report for the City of Millbrae General Plan Revision*, State Clearinghouse #98041090, October 1998a.

- City of Millbrae, *Draft Finalized with Addition of Comments and Responses as Adopted by City Council November 24, 1998: Millbrae Station Area Specific Plan Draft Environmental Impact Report*, State Clearinghouse #98041091, 1998b.

- City of Milpitas, Resolution No. 7150: A Resolution of the City Council of the City of Milpitas Certifying an Environmental Impact Report for the Milpitas Midtown General Plan Amendment and Specific Plan Project and Adopting Related Mitigation Findings, Findings Regarding Alternatives, A Statement of Overriding Considerations and a Mitigation Monitoring and Reporting Plan Pursuant to the California Environmental Quality Act, March 19, 2002b.

- City of Mountain View, *Final Environmental Impact Report: City of Mountain View 1992-2005 General Plan*, State Clearinghouse #91083044, November 1992a.

- City of Mountain View, Resolution 15481 series 1992, A Resolution Certifying the Final EIR for the 1992 General Plan, Adopting the 1992 General Plan Land Use Map and Adopting the City of Mountain View 1992-2005 General Plan, October 29, 1992b.

- City of Newark, *General Plan Update Project 2007 Draft Environmental Impact Report* (March 1992) and *Final Environmental Impact Report*, State Clearinghouse #91093071, June 1992a.

- City of Newark, Resolution No. 1241: Resolution Recommending to the City Council Approval and Certification of the Final Environmental Impact Report for the Newark General Plan Update, Including a Statement of Overriding Considerations and Mitigation Monitoring Program, passed May 26, 1992b.

- City of Palo Alto, *City of Palo Alto Comprehensive Plan Update Draft Environmental Impact Report* (December 1996) and *Final Environmental Impact Repor*t (September 1997), State Clearinghouse #96052043, certified July 1998a.

- City of Palo Alto, Resolution 7780 Certifying the Adequacy of the 1998-2010 Comprehensive Plan Final EIR and Making Findings Thereon Pursuant to the CEQA and Adopting the 1998-2010 City of Palo Alto Comprehensive Plan and Land Use and Circulation Map, July 20, 1998b.

- City of Redwood City, *Downtown Precise Plan Draft Environmental Impact Report* (October 2006) and *Final Environmental Impact Report*, State Clearinghouse #2006052027 certified March 2007a.

- City of Redwood City, Resolution No. 14769: A Resolution of the City Council of the City of Redwood City Making Certain Findings Concerning Mitigation Measures, Adopting a Mitigation Monitoring and Reporting Program, Making Findings Concerning Alternatives, and Adopting a Statement of Overriding Considerations in Accordance with the California Environmental Quality Act for the Redwood City Downtown Precise Plan, adopted March 26, 2007b.

- City of Redwood City, Ordinance No. 2308: An Ordinance of the City Council of the City of Redwood City Adopting the Redwood City Downtown Precise Plan and the Moderate Intensity Alternative as the Most Appropriate Maximum Alternative Development Limitation for the Downtown Precise Plan, approved April 24, 2007c.

- City of San Bruno, *City of San Bruno 1984 General Plan and Environmental Impact Report*, adopted June 25, 1984a.

- City of San Bruno, Resolution No. 1984-37 A Resolution of the City Council of the City of San Bruno Adopting a Modification to the General Plan of the City Including the Following Elements: Noise, Seismic Safety/Safety, Housing, Open Space, Conservation, Scenic Corridors, Circulation, and Land Use, and the Certification of an Environmental Impact Report Pertinent Thereto, June 25, 1984b.

- City of San Jose, *San Jose 2020 General Plan Final Environmental Impact Report*, State Clearinghouse #94023031, 1994.

- City of San Mateo, Final Environmental Impact Report: Proposed General Plan Revisions, State Clearinghouse #89100308, June 1990a.

- City of San Mateo, Resolution #77 (1990) Certifying the Final Environmental Impact Report Pertaining to the General Plan Revision, and Adopting the Revised City of San Mateo General Plan, July 16, 1990b.

- City of Santa Clara, Resolution No. 5728: A Resolution and Related Findings Certifying a Final Environmental Impact Report and Directing the Filing of a Notice of Determination, General Plan Amendment #32, State Clearinghouse #8908017, July 1992.

- City of Union City, *Draft Environmental Impact Report* (September 2001) and *Final Environmental Impact Report for the City of Union City General Plan Update*, State Clearinghouse #2000112009, January 2002a.

- City of Union City, Resolution 2109-02 A Resolution of the City Council of the City of Union City Adopting the 2002 General Plan Update Making Mitigations and Alternatives Finding and Adopting a Statement of Overriding Considerations and Adopting a Mitigation Monitoring Plan, February 12, 2002b.

- County of San Mateo, San Mateo County, Board of Supervisors Resolution 48639 Adopting Findings Pursuant to Certification of the Final Environmental Impact Report for the San Mateo County General Plan, State Clearinghouse #84042404, November 18, 1986.

- County of Santa Clara, *Santa Clara County General Plan Draft Environmental Report* (September 1994) and *Final Environmental Impact Report Addendum,* State Clearinghouse #94023004, November 1994a.

- County of Santa Clara, Resolution of the Board of Supervisors of the County of Santa Clara Recommending Certification of Final Impact Report, Adopting Related Overriding

Considerations and Monitoring Program, and Adoption of the County General Plan, December 20, 1994b.

- County of Santa Clara, *2000 Stanford University Draft Community Plan and General Use Permit Application Final Environmental Impact Report,* State Clearinghouse #1999112107, December 2000a.

- County of Santa Clara, Resolution of the Board of Supervisors or the County of Santa Clara Certifying the Environmental Impact Report, Making Related Findings, and Adopting a Mitigation Monitoring and Reporting Program for the Stanford University Community Plan and 2000 General Use Permit, December 12, 2000b.

1.3.6 Draft PEIR—Public Review

The Draft PEIR was circulated to local, state, and federal agencies and to interested organizations and individuals to allow them to review and comment on the report. Publication of this Draft PEIR marked the beginning of a 108-day public review period, which extended from June 29, 2007 to October 15, 2007 and during which written comments were directed to the following address:

San Francisco Planning Department
Attn: Paul Maltzer, Environmental Review Officer
WSIP PEIR
1650 Mission Street, Suite 400
San Francisco, CA 94103

Or by email to: wsip.peir.comments@gmail.com

Copies of the Draft PEIR and related key documents, as well as documents incorporated be reference, were available for review at the following public locations in the seven counties affected by construction and/or operation of the WSIP:

- San Francisco County:
  San Francisco Planning Department
  1660 Mission Street, 1st Floor
  Planning Information Counter
  San Francisco, CA

  San Francisco Main Library
  100 Larkin Street
  San Francisco, CA

  San Francisco Public Utilities Commission
  1145 Market Street, 1st Floor
  San Francisco, CA

- San Mateo County:
  City of San Mateo Main Library
  55 West 3rd Avenue
  San Mateo, CA

- Santa Clara County:
  Dr. Martin Luther King, Jr. Library
  150 E. San Fernando
  San Jose, CA

- Alameda County: Alameda County/City of Fremont Library
  2400 Stevenson Blvd.
  Fremont, CA

- San Joaquin County: Stockton-San Joaquin County Public Library
  605 N. El Dorado Street
  Stockton, CA

- Stanislaus County: Modesto Library
  1500 I Street
  Modesto, CA

- Tuolumne County: Tuolumne County Library
  480 Greenley Road
  Sonora, CA

The PEIR can also be accessed through the internet at: www.sfgov.org/site/planning/mea.

Public Hearings

Public comments on the Draft PEIR were accepted from June 29, 2007 to October 15, 2007. Public hearings on the Draft PEIR to accept written or oral comments were scheduled and held as follows:

- Sonora, CA: Sonora Opera House
  250 S. Washington St.
  Sonora, CA

  September 5, 2007, 6:30 pm

- Modesto, CA: Thomas Downey High School Cafeteria
  1000 Coffee Road
  Modesto, CA

  September 6, 2007, 6:30 pm

- Fremont, CA: Fremont Main Library, Fukaya Room
  2400 Stevenson Blvd
  Fremont, CA

  September 18, 2007, 6:30 pm

- Palo Alto, CA: Avenidas Senior Center
  450 Bryant Street
  Palo Alto, CA

  September 19, 2007, 6:30 pm

- San Francisco, CA: San Francisco Planning Commission
  City Hall, 1 Dr. Carleton B. Goodlet Place
  Commission Chambers, Room 400

  September 20, 2007, 1:30 pm

- San Francisco, CA: San Francisco Planning Commission
  City Hall, 1 Dr. Carleton B. Goodlet Place
  Commission Chambers, Room 400

  October 11, 2007, 3:30 pm

1.3.7 Comments and Responses Document and Final Program EIR

Written and oral comments received in response to the Draft PEIR were addressed in the Comments and Responses document. The Comments and Responses document was released for public review on September 30, 2008. The Draft PEIR and the Comments and Responses document together constitute the Final PEIR. On October 30, 2008, the Final PEIR was certified by the San Francisco Planning Commission, and the program was subsequently approved and adopted by the SFPUC.

CEQA requires the adoption of findings prior to approval of a project where a certified EIR identifies significant environmental effects (CEQA Guidelines, Sections 15091 and 15092). As part of the WSIP approval process on October 30, 2008, the SFPUC adopted the CEQA Findings, which describe the findings of fact and decisions regarding mitigation measures and alternatives, and provides a statement of overriding considerations for significant impacts identified by the PEIR that cannot be mitigated to less-than-significant levels (CEQA Guidelines, Section 15093[b]).

1.3.8 Mitigation Monitoring and Reporting

At the time of project approval, CEQA requires lead agencies to "adopt a reporting and mitigation monitoring program for the changes to the project which it has adopted or made a condition of project approval in order to mitigate or avoid significant effects on the environment" (CEQA, Section 21081.6; CEQA Guidelines, Section 15097). The mitigation measures identified and presented in this PEIR form the basis of the WSIP Mitigation Monitoring and Reporting Program (MMRP). All measures adopted by the SFPUC as conditions for approval of the program were included in the WSIP MMRP to ensure compliance. The SFPUC adopted the WSIP MMRP as part of the CEQA Findings. Project-level CEQA review for individual WSIP facility improvement projects will include mitigation measures adopted under the PEIR as appropriate based on project-specific analyses.

[Additional discussion of the CEQA process for the PEIR is provided in the Comments and Responses document. Please refer to Section 11.2, Environmental Review Process (Vol. 7, Chapter 11).]

2 Existing Regional Water System

CHAPTER 2
Existing Regional Water System

2.1 System Overview

The City and County of San Francisco (CCSF), through the San Francisco Public Utilities Commission (SFPUC), owns and operates a regional water system that serves 2.4 million people, primarily in San Francisco and the south San Francisco Bay region. The system extends about 167 miles, from Yosemite National Park to San Francisco, and develops water supply from three principal watersheds: the Tuolumne River, Alameda, and Peninsula watersheds. This water is conveyed to retail and wholesale customers in San Francisco, San Mateo, Santa Clara, Alameda, and Tuolumne Counties. The system currently delivers an annual average of about 265 million gallons per day (mgd), of which about 85 percent is from the Tuolumne River watershed and about 15 percent is from the combined Alameda and Peninsula watersheds (referred to collectively as the “local” watersheds). The regional water system includes over 280 miles of pipeline, over 60 miles of tunnels, 11 reservoirs, 5 pump stations, and 2 water treatment plants (filtration). The history of the system dates back to the 1860s, and many parts of it are over 100 years old.

This chapter provides a summary description and background of the existing regional water system, with emphasis on those components of the system that would be modified or otherwise affected by the proposed Water System Improvement Program (WSIP or program). This chapter also describes the sources and quantity of water used and how the water is generally conveyed, stored, treated, and delivered to system customers. Laws, regulations, and other institutional factors relevant to the water system are also described. Information on the system related to the proposed program, including more detail on the system customers and service area, is presented in Chapter 3, Program Description.

2.2 Regional Water System Facilities

The regional water system is primarily a linear system; it transports water across the state, from the Sierra Nevada to the Bay Area, almost entirely by gravity. Major facilities in the regional water system are shown in **Figure 2.1**. For the organizational purposes of this Program Environmental Impact Report (PEIR), the regional water system can be divided geographically into six smaller regions, which are, from east to west, the Hetch Hetchy, San Joaquin, Sunol Valley, Bay Division, Peninsula, and San Francisco Regions. The Hetch Hetchy Region covers the east end of the system in Tuolumne County and continues west to the east side of the San Joaquin Valley, almost to the western boundary of Tuolumne County; the San Joaquin Region covers facilities in the San Joaquin Valley, from the western boundary of Tuolumne County through Stanislaus and San Joaquin Counties, almost to the east boundary of Alameda County; the Sunol Valley Region includes facilities in the Sunol Valley within Alameda and Santa Clara Counties and west to the city of Fremont; the Bay Division Region starts in Fremont and covers the general South Bay area, including parts of Alameda, Santa Clara, and San Mateo Counties, continuing west to the south end of the San Francisco Peninsula; the Peninsula Region is entirely on the Peninsula within San Mateo County, from about San Mateo to Daly City; and the San Francisco Region, which geographically overlaps with the Peninsula Region, covers facilities in northern San Mateo County and within San Francisco. **Table 2.1** lists major facilities in the regional water system by their primary function—storage, transmission, or treatment—as well as by their geographic region. **Table 2.2** shows the capacity of the major facilities in the regional water system.

2.2.1 Hetch Hetchy Facilities

The regional water system begins with Hetch Hetchy Reservoir and O'Shaughnessy Dam, which are located in Yosemite National Park on the main stem of the Tuolumne River in the Sierra Nevada. Hetch Hetchy Reservoir was constructed between 1912 and 1923 and was raised in height in 1938. It collects drainage primarily in the form of snowmelt from the surrounding 459 square miles of the Tuolumne River watershed, which is located entirely within Yosemite National Park. The water from Hetch Hetchy Reservoir is used to supply system customers as well as to generate hydroelectric power; the reservoir is also operated to provide instream flows to benefit fisheries and other wildlife.

Two additional reservoirs in the Hetch Hetchy Region—Lake Eleanor and Lake Lloyd (also called Cherry Reservoir)—collect water from the Tuolumne River basin. Lake Eleanor (completed in 1918) is located within Yosemite National Park, and Lake Lloyd (completed in 1955) is located west of Yosemite National Park in Stanislaus National Forest; both reservoirs are

TABLE 2.2
EXISTING CAPACITY OF MAJOR FACILITIES IN THE REGIONAL WATER SYSTEM

Facility	Capacity	Notes
Major Storage Facilities		
Hetch Hetchy Reservoir	360,400 acre-feet (with drum gates raised) 340,000 acre-feet (with drum gates lowered)	117.4 billion gallons 110.8 billion gallons
Lake Eleanor	27,100 acre-feet (with flashboards installed) 21,500 acre-feet (without flashboards)	8.8 billion gallons 7.0 billion gallons
Lake Lloyd (Cherry Reservoir)	273,300 acre-feet (with flashboards installed) 268,800 acre-feet (without flashboards)	89.1 billion gallons 87.6 billion gallons
Calaveras Reservoir[a]	96,800 acre-feet (normal conditions) 37,800 acre-feet (interim conditions as required by the Division of Safety of Dams)	31.5 billion gallons 12.4 billion gallons
San Antonio Reservoir	50,300 acre-feet	16.4 billion gallons
Crystal Springs Reservoir[b]	56,800 acre-feet (interim conditions as required by the Division of Safety of Dams) 68,000 acre-feet (normal conditions)	18.5 billion gallons 22.2 billion gallons
Pilarcitos Reservoir	2,900 acre-feet	0.97 billion gallons
San Andreas Reservoir	19,000 acre-feet	6.2 billion gallons
Sunset Reservoir (north and south)	540 acre-feet	174.8 million gallon
University Mound Reservoir (north and south)	430 acre-feet	140.9 million gallons
Merced Manor Reservoir	30 acre-feet	9.5 million gallons
Major Transmission Facilities		
Canyon Tunnel	873 mgd	1,350 cfs
Mountain Tunnel	433 mgd	670 cfs
Foothill Tunnel	450 mgd	700 cfs
San Joaquin Pipelines Nos. 1, 2, 3	290–300 mgd (total, 3 pipelines)	Physical design capacity approximately 300 mgd
Coast Range Tunnel	345 mgd	541 cfs
Irvington Tunnel	300–340 mgd	300 mgd in winter, 340 mgd in summer
Bay Division Pipelines Nos. 1, 2, 3, 4	290–340 mgd (total, 4 pipelines)	
Major Treatment Facilities		
Sunol Valley Water Treatment Plant	120 mgd (sustainable capacity) 160 mgd (peak capacity)	Sustainable capacity is the highest flow rate at which a treatment plant can be expected to operate, given normal source water conditions, while meeting regulatory water quality and routine maintenance requirements. Peak capacity is the maximum flow rate to which a treatment plant is designed that will allow it to operate within regulatory or engineering standards.
Harry Tracy Water Treatment Plant	120 mgd (sustainable capacity) 140 mgd (peak capacity) 180 mgd (hydraulic capacity)	Plant capacity depends on the quality of raw water. During most winters, the raw water source often contains algae that can limit plant capacity to 90–100 mgd for several weeks.

[a] As designed and constructed, Calaveras Reservoir has a normal capacity of 96,800 acre-feet. However, the California Division of Safety of Dams (DSOD) has placed interim operational restrictions on the reservoir due to concerns regarding seismic stability of the dam. See Section 2.2.3 for further discussion.

[b] Since 1983, the DSOD has placed operational restrictions on Lower Crystal Springs Dam due to concerns regarding the stability of the dam during major flood events. Over the past 23 years, the SFPUC has adjusted its operating procedures to comply with the DSOD restrictions and, with the exception of the 1987 to 1992 drought period, has been able to accommodate customer water demands with this reduced level of storage in Crystal Springs Reservoir. However, it should be noted that the DSOD restriction on Crystal Springs Reservoir operations has reduced storage capacity in the Peninsula watershed by 17 percent, a critical concern from the perspective of emergency preparedness.

SOURCES: SFPUC, 2004; Olivia Chen Consultants, 2005; CDM, 2005; URS, 2006.

northwest of Hetch Hetchy Reservoir on tributaries to the Tuolumne River. The Eleanor-Cherry Diversion Tunnel and Pump Station link the two reservoirs, allowing them to be operated as a single unit.

Under normal operating conditions, Hetch Hetchy Reservoir is the only reservoir in this region that directly supplies water to the Bay Area; as discussed in Section 2.4, Hetch Hetchy water is delivered to customers without filtration, since the quality of this water supply has warranted a filtration exemption[1] from the U.S. Environmental Protection Agency (U.S. EPA) and California Department of Health Services (DHS). Water from Lake Eleanor and Lake Lloyd is used primarily to meet minimum instream flow requirements to benefit fish and other wildlife, satisfy downstream water rights of the Turlock and Modesto Irrigation Districts (TID and MID) (discussed in Section 2.5, below), produce hydroelectric power, and provide flows to support recreational use including whitewater recreation. However, if necessary during emergency or drought conditions, water from Lake Lloyd or Lake Eleanor can be released to Cherry Creek and then diverted to Mountain Tunnel for transport to the Bay Area, which occurred once during the early 1990s. In the event that water from Cherry and Eleanor Creeks is diverted to the regional water system, filtration of all water delivered from the Hetch Hetchy system would be necessary prior to delivery to customers, in accordance with requirements of the U.S. EPA and DHS.

From Hetch Hetchy Reservoir, water diverted at O'Shaughnessy Dam flows by gravity through the 10-mile-long Canyon Power Tunnel to Kirkwood Powerhouse to generate power. From Kirkwood Powerhouse, depending on flows from Canyon Tunnel, water is either returned to the river or diverted into the Early Intake Bypass and then to Mountain Tunnel. When Hetch Hetchy Reservoir was originally constructed, water from the face of the dam flowed down the river to Early Intake Reservoir (built in 1924), and from there was diverted to Mountain Tunnel; with the construction of Canyon Power Tunnel and the Early Intake Bypass in the 1960s, the Early Intake Reservoir and Diversion Dam lost much of their functional role in the regional system, and Tuolumne River water flows relatively unimpeded through the spillway adjacent to the diversion dam. Early Intake Reservoir and Diversion Dam, however, continue to serve important functions because they permit the SFPUC to divert water into the Mountain Tunnel from Cherry or Eleanor Creeks in emergencies or extended drought, and from the Tuolumne River in the event of loss of Canyon Tunnel or the Kirkwood Penstocks.

The 19-mile-long Mountain Tunnel, completed in 1925, allows the SFPUC to deliver raw water to the Groveland Community Services District, a retail customer. From Mountain Tunnel, the water is conveyed by gravity through Priest Reservoir, Moccasin Powerhouse, and Moccasin Reservoir. These two reservoirs regulate flows between facilities and can facilitate power peaking operations. If turbidity becomes a concern in these reservoirs, water is bypassed through pipelines. After Moccasin Reservoir, water travels through the Moccasin Gate Tower to the 16-mile-long Foothill Tunnel (completed in 1928), which passes beneath Don Pedro Reservoir

[1] As described in Section 2.4, the U.S. Environmental Protection Agency and the California Department of Health Services have determined that Hetch Hetchy water supply meets all state and federal water quality requirements without the need to provide filtration. In addition, the Hetch Hetchy water supply is disinfected in accordance with Safe Drinking Water Act requirements.

(owned by TID and MID) and ends at Oakdale Portal (where the San Joaquin Pipelines begin). Approximately three miles upstream from Oakdale Portal is the Rock River Lime Facility, where chemicals are added to water in Foothill Tunnel for corrosion control (SFPUC, 2004). The station is located above a shaft that accesses Foothill Tunnel. Water deliveries from the Hetch Hetchy system are transported entirely by gravity to the San Joaquin Region.

2.2.2 San Joaquin Facilities

Oakdale Portal is the connection between the western end of Foothill Tunnel and the San Joaquin Pipelines. From Oakdale Portal, water from the Hetch Hetchy facilities is conveyed 47 miles west across the San Joaquin Valley by gravity in three parallel pipelines known as San Joaquin Pipelines Nos. 1, 2, and 3 (built in 1932, 1953, and 1968, respectively). The three pipelines are buried for most of their full length. The pipelines pass through Modesto, under the San Joaquin River, and past Tracy to Tesla Portal on the west side of the San Joaquin Valley. The current capacity of the three pipelines is approximately 290 mgd; however, when originally planned in 1912, the San Joaquin Pipeline system was envisioned with an ultimate nominal capacity of 400 mgd.

The San Joaquin Pipelines end at Tesla Portal and connect to the Coast Range Tunnel (built from 1927 to 1934). Tesla Portal, which is located on the east side of the Coast Ranges, is also the location of the Tesla Disinfection Facility, where Hetch Hetchy water is disinfected with chlorine and monitored for water quality. From Tesla Portal, the chlorinated Hetch Hetchy water is transported 25 miles through the Coast Range Tunnel to system facilities in the Sunol Valley. Water delivery to Lawrence Livermore Laboratory, a retail customer, occurs from the Coast Range Tunnel via two access shafts from the tunnel, Thomas and Mocho Shafts. At Thomas Shaft, a standby/backup chlorination facility provides disinfection in the event of operational difficulty at Tesla Portal. The 25-mile-long Coast Range Tunnel ends at the Alameda East Portal in the Sunol Valley (SFPUC, 2004). Again, water deliveries are transported entirely by gravity across the San Joaquin Region to the Sunol Valley.

2.2.3 Sunol Valley Facilities

Local water supplies from the Alameda watershed enter the regional system in the Sunol Valley and are blended with the Hetch Hetchy water supply. The Alameda watershed generally refers to CCSF-owned lands that are located within the much larger hydrologic boundaries of the southern Alameda Creek watershed. Local water supply sources contributing to the regional water system include Arroyo Hondo and Alameda and Calaveras Creeks, which provide inflow to Calaveras Reservoir, and San Antonio Creek, which flows to San Antonio Reservoir. **Figure 2.2** shows a schematic of the SFPUC’s Alameda watershed facilities.

The Alameda East Portal is the connection between the Coast Range Tunnel and the Alameda Siphons. The Alameda Siphons are three pipelines (built in 1934, 1953, and 1967) that cross the Sunol Valley and beneath Alameda Creek. The roughly 3,000-foot-long Alameda Siphons connect the Coast Range Tunnel at the Alameda East Portal to the Irvington Tunnel at the Alameda West Portal. At the Alameda Siphons, Hetch Hetchy water is blended with water from Calaveras

SFPUC Water System Improvement Program . 203287

Figure 2.2
Alameda Watershed Facilities

and San Antonio Reservoirs that has been treated at the Sunol Valley Water Treatment Plant (WTP). Directly adjacent to the Alameda Siphons, the Sunol Valley Chloramination Facility provides secondary disinfection with chloramine, along with fluoride addition and pH adjustment for corrosion control, for both Hetch Hetchy water and treated water from the Sunol Valley WTP prior to transmission to the Bay Area. Water deliveries to the General Electric pumping facility and individual accounts in the town of Sunol, both retail customers, occur from two of the siphons at a location downstream of the blending point for treated water with Hetch Hetchy water.

Calaveras Reservoir, located at the south end of the Alameda watershed, collects and stores water from the local watershed, including drainage from Calaveras Creek and Arroyo Hondo. The reservoir was originally constructed in 1913 and was completed in 1925. The Alameda Creek Diversion Dam and Tunnel, constructed from 1925 to 1931 following completion of Calaveras Dam, divert flows and drainage from the southern Alameda Creek watershed into Calaveras Reservoir. Water from Calaveras Reservoir flows by gravity through the Calaveras Pipeline to the Sunol Valley WTP for treatment, and then flows to the Alameda Siphons, where it is blended with the Hetch Hetchy water supply. Water from Calaveras Reservoir can also be transferred for storage to San Antonio Reservoir and later for treatment at the Sunol Valley WTP.

In 2001, the California Department of Water Resources, Division of Safety of Dams (DSOD) performed an evaluation of Calaveras Dam and concluded that the dam does not meet current seismic stability criteria at normal operating levels due to properties of the soil material used in dam construction (DSOD, 2003; Olivia Chen Consultants, 2003). As a result, the DSOD placed interim operational restrictions on Calaveras Reservoir, lowering the level at which the reservoir can be safely operated and restricting the maximum water elevation to 705 feet. These restrictions reduced the total storage capacity of the reservoir by 60 percent (see Table 2.2 for normal and restricted reservoir capacities) and the total working storage capacity of the SFPUC's local reservoirs by over 30 percent. Due to the DSOD restrictions, the Calaveras system is currently diverting less flow from Alameda Creek via the Alameda Creek Diversion Dam and utilizes less water from Calaveras Reservoir. In addition, in 1991 the SFPUC and California Department of Fish and Game (CDFG) agreed on a minimum operating level for Calaveras Dam of 690 feet to protect juvenile fish populations (described below in Section 2.5.3). Therefore, under DSOD and CDFG restrictions, the SFPUC currently operates Calaveras Reservoir at water level elevations ranging between 690 and 705 feet to the extent feasible.[2]

These interim operating procedures allow the SFPUC to continue meeting water needs from local sources to a limited extent; however, the DSOD restrictions were placed "with the understanding that the SFPUC will continue to pursue an aggressive schedule for the remediation of Calaveras Dam" (DSOD, 2003). The SFPUC has adjusted its system operations to meet these restrictions, but considers this an impaired operating mode that puts the system at risk of being unable to adequately meet customer water demands in the event of an emergency or a prolonged drought. From the perspective of emergency preparedness, the DSOD restriction has reduced the SFPUC's total

2 Since December 2001 following periods of heavy inflow, reservoir storage levels have risen temporarily beyond the restricted levels. At such times, the SFPUC employs best efforts to lower the reservoir level by releasing water to the regional system, and if necessary, discharging excess inflow to Calaveras Creek below Calaveras Dam.

reservoir storage, including its emergency storage capacity, by over 58,000 acre-feet. The SFPUC is complying with the DSOD requirements by actively pursuing remediation of Calaveras Dam. The Calaveras Dam Replacement project is in development as part of the WSIP, and the San Francisco Planning Department initiated environmental review of this project in October 2005.

San Antonio Reservoir and Turner Dam, completed in 1965, impound water from San Antonio Creek. This reservoir can also receive and store water from the Hetch Hetchy water supply or from Calaveras Reservoir. Water stored in San Antonio Reservoir must be conveyed in the San Antonio Pipeline to the Sunol Valley WTP for treatment before it can be added to the regional distribution system at the Alameda Siphons.

The Sunol Valley WTP was constructed in 1966 and upgraded in 2003 to a peak capacity of 160 mgd (with a sustained capacity of 120 mgd); it can treat water from the local Alameda watershed drainages, including waters stored in both the Calaveras and San Antonio Reservoirs. Water from the Hetch Hetchy system can also be treated at the Sunol Valley WTP, which is necessary when the water does not meet DHS permit conditions as it enters the Sunol Valley (which occurs on rare occasions due to storm events in the Sierra causing high turbidity levels, or to conditions in the San Joaquin Pipelines) and when Hetch Hetchy water is used to maintain water treatment operations at the plant.

Hetch Hetchy water from the Coast Range Tunnel that is blended with treated water from the Alameda watershed in the Alameda Siphons then exits the Sunol Valley at the Alameda West Portal, located at the west end of the Alameda Siphons, where it enters the 3.5-mile-long Irvington Tunnel and flows by gravity to the city of Fremont in the East Bay. Irvington Tunnel was constructed in the 1930s and has a maximum capacity of 340 mgd (CDM, 2005). It is the only operating facility that conveys Hetch Hetchy and treated Alameda watershed water supplies to the Bay Area; since it must operate year-round to meet Bay Area customer demands, maintenance and inspection of Irvington Tunnel has not occurred for over 40 years (SFPUC, 2004).

2.2.4 Bay Division Facilities

The Irvington Portal in Fremont, at the west end of Irvington Tunnel, is where the tunnel connects to the four Bay Division Pipelines (Nos. 1, 2, 3, and 4), which consist of two sets of two parallel pipelines constructed in 1925, 1936, 1952, and 1973, respectively. The Bay Division Pipelines serve multiple purposes: providing water to customers in the East Bay, South Bay, and Peninsula through turnouts along the pipelines; conveying water to users in the northern Peninsula and in San Francisco; and transmitting water to Crystal Springs Reservoir to supplement local storage in the Bay Area. Numerous valve lots along the pipelines allow for flow control.

The Bay Division Pipelines Nos. 1 and 2 are 22 miles long and pass through the cities of Fremont and Newark, cross San Francisco Bay at the Dumbarton Strait, and continue through East Palo Alto, Redwood City, Menlo Park, and Atherton; they include about 3,000 feet of submarine pipeline that passes under the bay, as well as aboveground pipeline supported on a pipe bridge over water or on a trestle over the land and marsh along the bay margin. Within the urban areas, the Bay Division Pipelines Nos. 1 and 2 are buried pipelines. These two pipelines feed the SFPUC's Palo Alto Pipeline.

The Bay Division Pipelines Nos. 3 and 4 extend 34 miles around the south end of San Francisco Bay, almost entirely as buried underground pipeline. These two pipelines pass through the cities of Fremont, Milpitas, San Jose, Santa Clara, Sunnyvale, Mountain View, Los Altos, Palo Alto, Menlo Park, Atherton, Woodside, and Redwood City. Pipelines Nos. 3 and 4 converge for approximately 1,360 feet of tunnel at the Stanford Tunnel in Palo Alto. Pipelines Nos. 3 and 4 reconnect with Pipelines Nos. 1 and 2 at the Pulgas Portal entrance to Pulgas Tunnel just west of Redwood City (SFPUC, 2004).

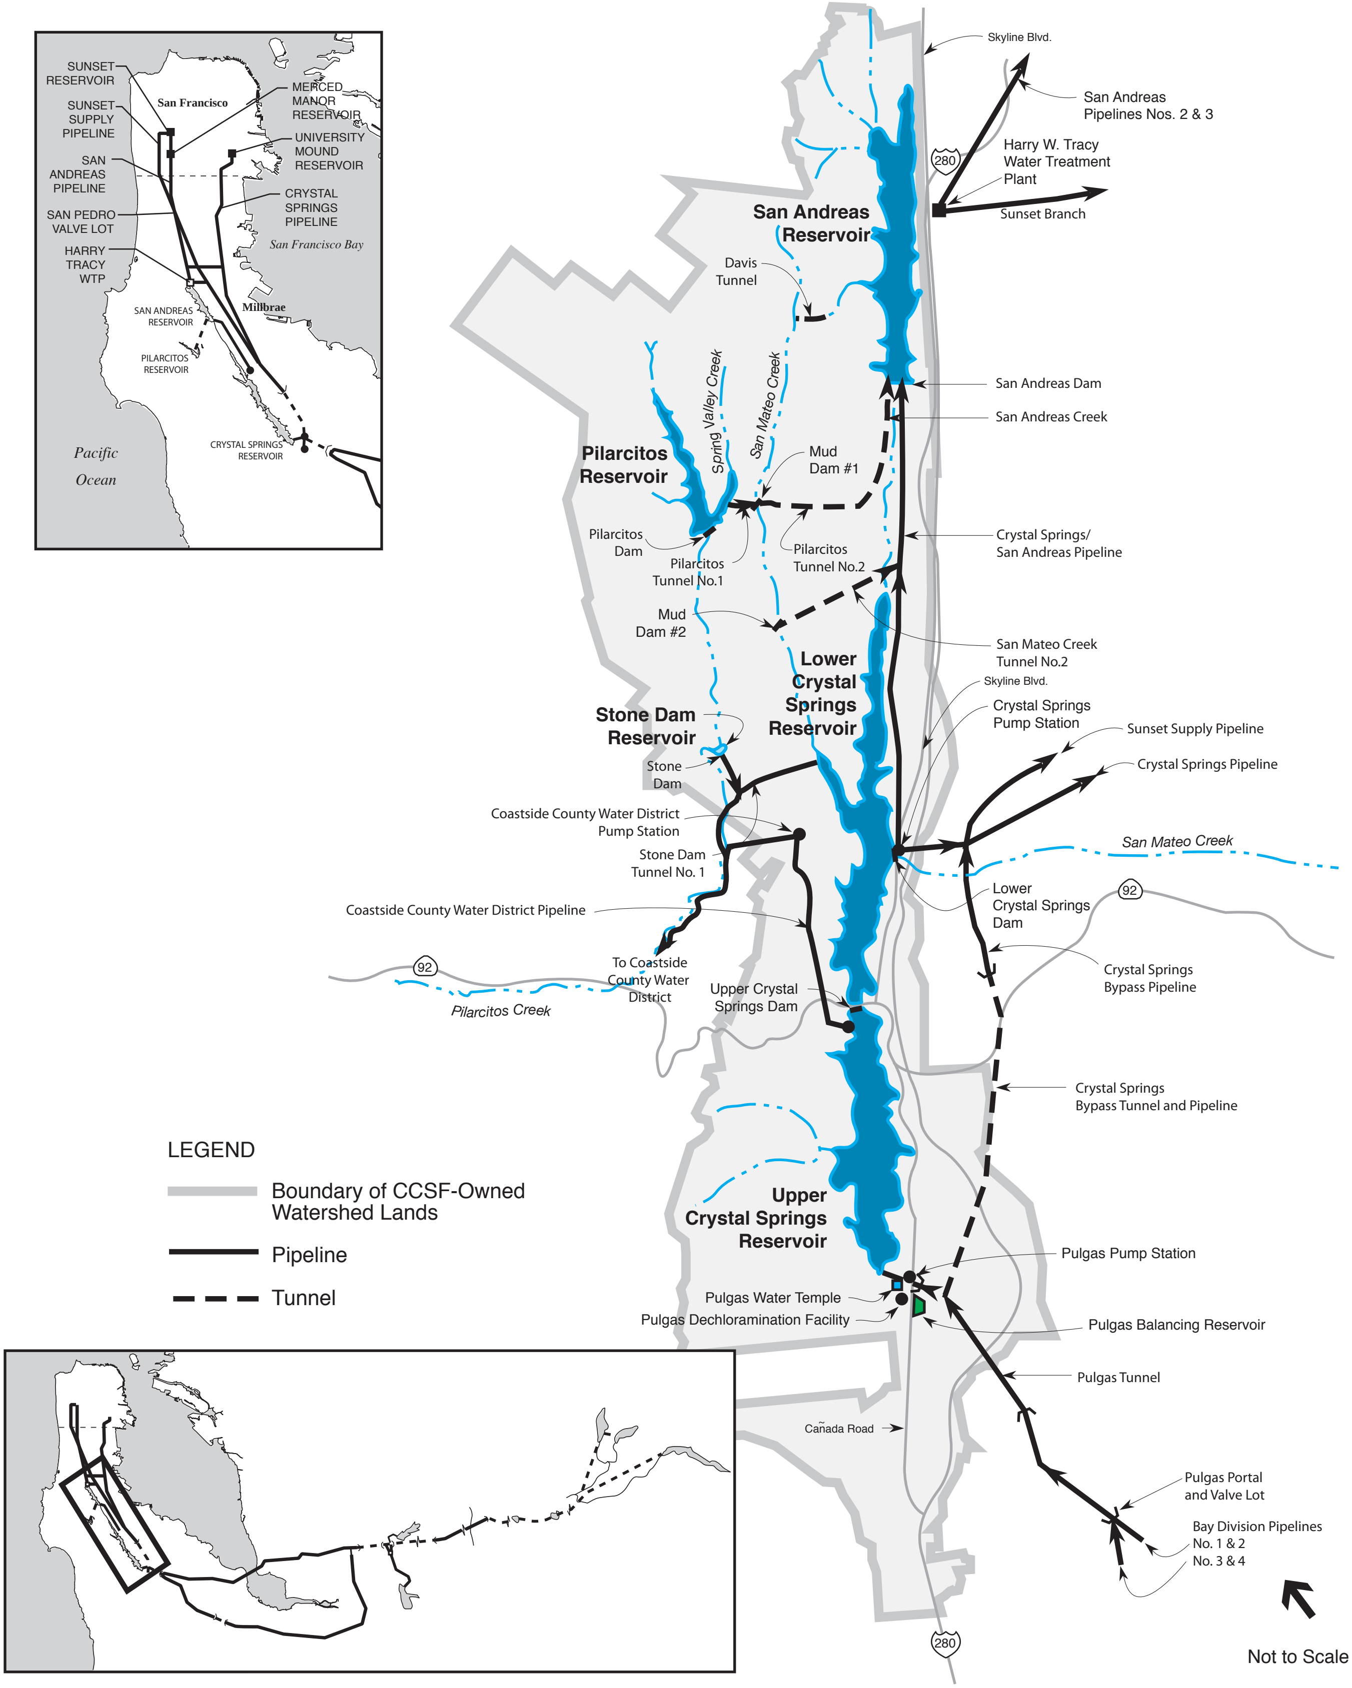
The existing SFPUC intertie with the Santa Clara Valley Water District (SCVWD) is also part of the Bay Division facilities and serves as a means to transfer water between the SFPUC and SCVWD during an emergency or during periods of planned maintenance work on critical facilities. The SFPUC intertie with the East Bay Municipal Utility District (EBMUD), which is currently under construction, will also be part of the Bay Division facilities and will serve as a means to transfer water between the SFPUC and EBMUD during an emergency or during periods of planned maintenance work on critical facilities. The actual water to flow through either intertie is not implicitly part of the operating agreements for the interties, and any exchange must occur under separate agreement by the SFPUC and the SCVWD or EBMUD.

The SCVWD intertie is located near Milpitas Boulevard in Milpitas. This intertie has a capacity of 40 mgd and has been used twice in the past to transfer a total of approximately 2 billion gallons of water from the SFPUC to SCVWD when the latter experienced shutdown of its Penitencia plant. The SCVWD is currently returning supplies to the SFPUC at an average rate of 5 mgd through the intertie.

The EBMUD intertie project includes a pump station at the Hayward Executive Airport, 1.5 miles of new pipeline, improvements to the City of Hayward's pipelines, and other modifications to the existing system that allow for the flow of up to 30 mgd. The project is scheduled for completion in June 2007.

2.2.5 Peninsula Facilities

At the Pulgas Portal and Valve Lot, Hetch Hetchy water supplies combined with treated Alameda watershed supplies enter the Peninsula system through the two-mile-long Pulgas Tunnel (built in 1926). The Peninsula system contains some of the oldest facilities in the regional system and includes three reservoirs—Crystal Springs (comprising the upper and lower reservoirs), Pilarcitos, and San Andreas Reservoirs—as well as the Harry Tracy WTP and extensive transmission facilities. The Peninsula watershed refers to the CCSF-owned lands and includes large portions of the natural drainage area of San Mateo, Pilarcitos, and San Andreas Creeks. **Figure 2.3** shows a schematic of the Peninsula watershed facilities.



SOURCE: San Francisco Planning Department, 2001

SFPUC Water System Improvement Program . 203287

Figure 2.3
Peninsula Watershed Facilities

From Pulgas Tunnel, the Peninsula system splits into two flow streams: one flow stream goes north along the east side of the Peninsula to the Crystal Springs Bypass system and the other west to Crystal Springs Reservoir. Generally, the bulk of the flow from Pulgas Tunnel goes directly into the 3.4-mile-long Crystal Springs Bypass Tunnel (constructed in 1969). The water flows to the 4,500-foot-long Crystal Springs Bypass Pipeline (also constructed in 1969). The Crystal Springs Bypass Pipeline connects to either the Crystal Springs Pipeline or Sunset Supply Pipeline, which convey water to users in northern San Mateo County and San Francisco. Up to this point, the water from Hetch Hetchy Reservoir is delivered entirely by gravity for over 120 miles; water conveyed through the Sunset Supply Pipeline and Crystal Springs Pipeline continues to flow by gravity north up the Peninsula, eventually ending at University Mound Reservoir in San Francisco.

A portion of water from the Pulgas Tunnel flows into Crystal Springs Reservoir, with flows regulated as necessary to meet customer demand through use of the Pulgas Balancing Reservoir and Pulgas Pump Station. Prior to discharge to Crystal Springs Reservoir, chloramine is removed from the combined Hetch Hetchy and Alameda watershed flows and the pH is adjusted at the Pulgas Dechloramination Facility in order to meet regulatory discharge requirements and to protect the water quality in the reservoir (SFPUC, 2004).

Crystal Springs Reservoir is where Hetch Hetchy and Alameda watershed water supplies blend with local water sources from the Peninsula watershed. Originally constructed as two separate reservoirs for the Spring Valley Water Company, Crystal Springs Reservoir is composed of Upper and Lower Crystal Springs Reservoirs. As constructed, Upper Crystal Springs Dam, built in 1877, divided the two reservoirs; however, since 1924, two large culverts through the dam enable unregulated flow between the reservoirs. Upper Crystal Springs Dam also forms the roadbed for State Highway 92, which crosses Crystal Springs Reservoir. Lower Crystal Springs Dam, originally built in 1888 and raised in 1891 and 1911, is located on San Mateo Creek; San Mateo County subsequently built a bridge over the crest of the dam.

Since 1983, the DSOD has placed operational restrictions on Lower Crystal Springs Dam due to concerns regarding the ability of the dam to retain water during major flood events. The DSOD operating restrictions have reduced the historical capacity of the combined Crystal Springs Reservoir by about 15 percent (see Table 2.2 for historical and restricted reservoir capacities). For the past 23 years, the SFPUC has adjusted its operating procedures to comply with the DSOD restrictions.

Crystal Springs Reservoir impounds local drainage from the surrounding lands, including the upper San Mateo Creek drainage northwest of the reservoir, as well as inflow from Pulgas Tunnel, which delivers water from the Hetch Hetchy and Alameda watersheds to the reservoir. In addition, local water supplies from Stone Dam Reservoir on Pilarcitos Creek (discussed below) are conveyed to and stored in Crystal Springs Reservoir. The Crystal Springs Pump Station (built in 1933) pumps water stored in Crystal Springs Reservoir through the Crystal Springs/San Andreas Pipeline to San Andreas Reservoir. This pipeline was originally built between 1898 and 1932, then largely rebuilt in 1968, although it still retains elements from the 1898 to 1932 era.

San Andreas Reservoir also receives water from Pilarcitos Reservoir (described below), but its primary source of water is Crystal Springs Reservoir. Water in San Andreas Reservoir is treated at the Harry Tracy WTP (also discussed below) before transmission to the regional system and delivery to customers.

Pilarcitos Dam was built in 1866 and raised in 1874; it collects local drainage and water from the Pilarcitos Creek watershed, forming Pilarcitos Reservoir. Stone Dam was built in 1871, two miles downstream of Pilarcitos Dam, capturing drainage along Pilarcitos Creek below the dam. Water from Pilarcitos Reservoir can be diverted to San Andreas and Crystal Springs Reservoirs through a system of tunnels originally built at the end of the 19th century. Almost half of Pilarcitos Reservoir supply is used to serve the Half Moon Bay area through wholesale service to the Coastside County Water District (Coastside CWD).

San Andreas Reservoir was originally constructed in 1870 to collect drainage from the San Andreas Creek watershed. Today, San Andreas Reservoir serves as the terminus for the multiple water sources collected in the Peninsula storage reservoirs. It receives inflow from Pilarcitos Reservoir, San Mateo Creek drainage, and Crystal Springs Reservoir (including Hetch Hetchy and Alameda watershed water stored in Crystal Springs Reservoir, which is conveyed through the Pulgas Tunnel). San Andreas Reservoir is the source of raw water inflow to the Harry Tracy WTP.

The Harry Tracy WTP, formerly known as the San Andreas Filter Plant, was built in 1971 and expanded in 1988 and 1990. It provides filtration, fluoridation, and disinfection for water collected in all of the Peninsula reservoirs. The plant has a hydraulic capacity of 180 mgd; however, in recent years the SFPUC has come to consider its sustainable capacity to be 120 mgd. Additionally, during most winters, San Andreas Reservoir experiences blooms of filter-clogging algae that can limit plant production to 90 to 100 mgd for several weeks.

Treated water from the Harry Tracy WTP is delivered to customers in northern San Mateo County and San Francisco through turnouts along the system. Several valve lots used to regulate flow and provide operational flexibility are located along the pipeline alignment between the Harry Tracy WTP and San Francisco, including the Capuchino, Baden, and San Pedro Valve Lots. Water from the Harry Tracy WTP is eventually delivered via the San Andreas Pipelines Nos. 2 and 3 or the Sunset Branch Pipeline to the Sunset or Merced Manor Reservoir in San Francisco, the final destination of this portion of the regional water system (SFPUC, 2004).

2.2.6 San Francisco Regional Facilities

The regional water system ends in San Francisco, where it connects to the city's local distribution system. There are three pipeline systems and three terminal reservoirs in this part of the regional system.

The three regional pipeline systems transporting water from the Peninsula to San Francisco are the Sunset Supply Pipeline, Crystal Springs Pipelines, and San Andreas Pipelines. The Sunset Supply and Crystal Springs Pipelines both extend about 20 miles from the Crystal Springs Bypass

Pipeline near Hillsborough to the Sunset and University Mound Reservoirs in San Francisco, respectively. The Crystal Springs and Sunset Supply Pipelines lines are referred to as "low zone" facilities, meaning that they operate on the Hetch Hetchy gradient, flowing by gravity from the Sierra all the way to San Francisco. Portions of these pipelines were built over 100 years ago and are still in service. The San Andreas Pipeline Nos. 2 and 3 start at the Harry Tracy WTP and deliver water to the Sunset and Merced Manor Reservoirs. These pipelines were designed to transmit water from San Andreas Reservoir to San Francisco; they are referred to as the "high zone" pipelines because the elevation of this part of the system on the Peninsula is about 150 feet higher than the low zone facilities. Water can be transferred between pressure zones at the Baden Pump Station (from low to high) and at the Capuchino Valve Lot (from high to low). Water is distributed to wholesale and a few retail customers in San Francisco and San Mateo Counties through turnouts along all three regional pipeline systems.

The three terminal reservoirs of the regional system are the Merced Manor, Sunset, and University Mound Reservoirs. Merced Manor and Sunset Reservoirs are on the west side of San Francisco. Merced Manor Reservoir, built in 1936, has a capacity of 9.5 million gallons. Sunset Reservoir–North Basin (built in 1938) and Sunset Reservoir–South Basin (built in 1960) have a combined capacity of about 177 million gallons. On the east side of San Francisco, University Mound–North Basin (built in 1924) and University Mound–South Basin (built in 1937) have a combined capacity of about 140 million gallons. The three terminal reservoirs in the regional system provide water for retail customers in San Francisco and regional system storage for wholesale customers on the Peninsula (SFPUC, 2004).

2.3 Water System Operations and Maintenance

System operations involve a complex interaction of numerous factors, including the capacity and operating conditions of physical facilities, customer needs, meteorological and hydrologic conditions, regulatory requirements, and institutional constraints. This section briefly discusses system customers, water supply sources, water quality, operational requirements, normal system operations for water deliveries, operations during drought periods, system maintenance, hydropower operations, and watershed management.

2.3.1 System Customers

The SFPUC provides water delivery services to retail and wholesale customers in San Francisco, San Mateo, Santa Clara, Alameda, and Tuolumne Counties that serve a total of about 2.4 million people. The SFPUC serves about one-third of its water supplies directly to retail customers located primarily in San Francisco, and about two-thirds of its water supplies to wholesale customers, primarily in the South Bay and Peninsula, by contractual agreement. Chapter 3 provides more detailed information on system customers, including a map of the service area (Figure 3.2), a list of retail and wholesale customers (Table 3.1), and a summary of current customer purchases from the regional system (Table 3.4).

2.3.2 Water Supply Sources

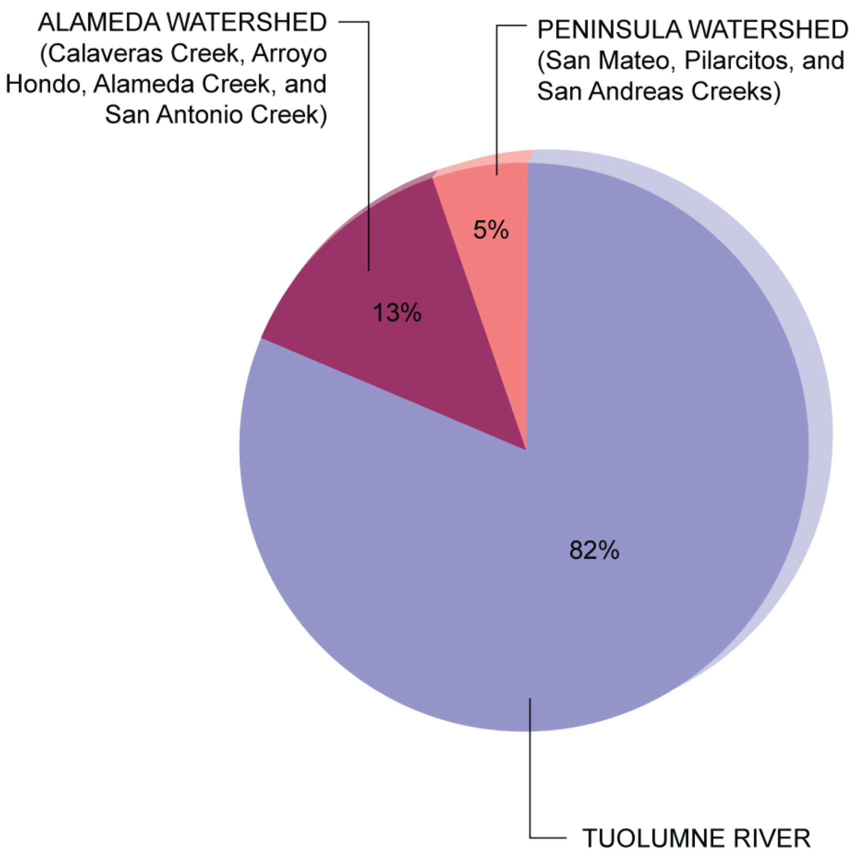
The SFPUC currently delivers an annual average of about 265 mgd through the regional water system. As described above, a majority of the water for the regional system comes from the Tuolumne River; this water is used to augment water supplies from local creeks and runoff in the Alameda and Peninsula watersheds. Local creeks and runoff in the local Alameda and Peninsula watersheds provide an average of about 15 percent of the total water supply. The Tuolumne River provides an average of about 85 percent to make up the remainder of the total water supply needed by customers.

In the Alameda watershed, the creeks feeding the local reservoirs include Arroyo Hondo and Alameda, Calaveras, and San Antonio Creeks; on the Peninsula, the major local water sources are San Mateo, Pilarcitos, and San Andreas Creeks. **Figure 2.4** illustrates the general breakdown of current water sources for the regional water system to meet all customer purchase requests for a typical year with adequate rainfall and snowmelt conditions. However, during extended dry periods, the regional system currently does not have a sufficient water supply, stored water, or supplemental water sources to fully meet customer purchase requests. Depending on the severity and duration of the drought condition, the SFPUC implements customer rationing (see the detailed discussion in Section 2.3.5), as occurred during the 1987–1992 drought. **Figure 2.5** depicts the breakdown of water sources and customer rationing that could occur under existing conditions during an extended drought sequence (see Chapter 3, Sections 3.4.1 and 3.5.4 for discussion of assumptions and planning tools, such as design drought and system firm yield, used in determining drought-year water supply needs).

2.3.3 Water Quality

The SFPUC regional water system delivers extremely high-quality water. As shown in Figure 2.4, the majority of the water is from the Tuolumne River, which originates in the upper Tuolumne River watershed high in the Sierra Nevada, remote from human development and pollution. This pristine water, referred to as Hetch Hetchy water, is delivered through pipelines and tunnels to the Bay Area and requires only minimal treatment (disinfection and pH adjustment) before it is served to customers. The U.S. EPA and DHS have approved the use of this drinking water source without requiring filtration at a treatment plant, as is generally required by the Surface Water Treatment Rule. However, in the event that water originating from Cherry and Eleanor Creeks is diverted to the regional water system, filtration of all water delivered from the Hetch Hetchy system would be required.

Local water supplies from the Alameda and Peninsula watersheds are subject to the Surface Water Treatment Rule, which specifies filtration requirements to meet drinking water quality standards. Filtration of Alameda and Peninsula water supply sources occurs at the Sunol Valley and Harry Tracy WTPs, respectively. Filtered and treated water from local watersheds is blended with Hetch Hetchy water, and all customers west of Sunol receive blended water. System water quality, including both raw and treated water quality, is continuously monitored and tested to assure that water delivered to customers meets or exceeds federal and state drinking water and public health requirements.



Note: Water supply sources (average annual) based on 2005 conditions during nondrought years, with Calaveras Reservoir operating at restricted levels and with 265 mgd in total systemwide deliveries.

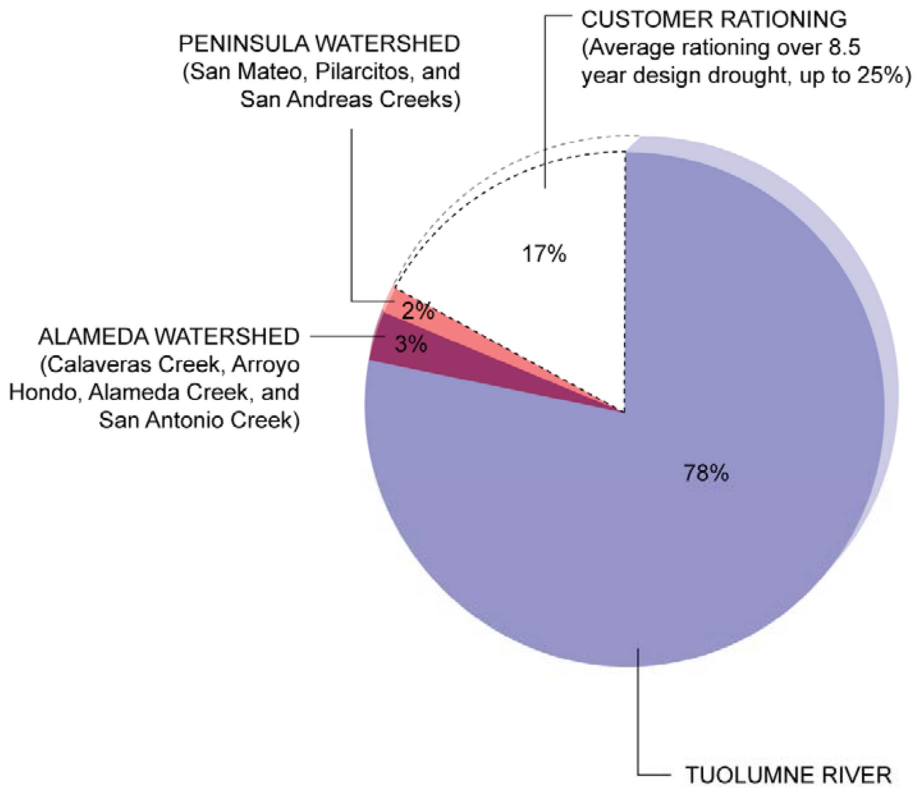
2.3.4 Normal System Operations for Water Deliveries

The SFPUC's Water First Policy gives priority to the production and protection of water supply over the production of hydropower generation in the operation of the Hetch Hetchy system. The Water First Policy was adopted in California in 2002 as part of the Wholesale Regional Water System Security and Reliability Act (Assembly Bill No. 1823), but has been the operational practice of the SFPUC since 1993 (Moran, 1994). Water quality is also a priority over hydropower operations that originate out of Hetch Hetchy Reservoir because of the need to meet drinking water permit requirements. The Water First Policy is further discussed in Section 2.4.3, below.



Note: Water supply sources (average annual) over 8.5-year design drought based on 2005 conditions, with Calaveras Reservoir operating at restricted levels and with 265 mgd in total systemwide deliveries. The chart depicts the expected level of water supply and rationing that could occur under these conditions.

SFPUC Water System Improvement Program . 203287

Figure 2.5
Existing Water Supply Sources, Dry Periods

Operation of the regional water system can be generally delineated between rules and strategies affecting the operation of the local system of reservoirs (in the Alameda and Peninsula watersheds) and rules and strategies affecting the operation of the Hetch Hetchy system. Although generally discussed separately, the two systems are interdependent, and operations of the systems are integrally linked in order to maximize water availability and quality. Schematic diagrams showing the linkage of system facilities that determine system operations are presented in **Figure 2.6**.

SFPUC customer purchase requests are met through a combination of flows from the Hetch Hetchy system and local reservoirs. The SFPUC operates the local reservoirs to conserve local watershed runoff and diverts water from the Hetch Hetchy system to supplement the supply developed by the local reservoirs. The overriding operating goal of meeting system demand is to ensure that sufficient water is available year-round regardless of hydrologic conditions (drought or nondrought).

System operations and the amount of water delivered to customers vary throughout the year based on seasonal demand and the availability of water. The availability of water for delivery to customers is affected by numerous factors, including meteorological and hydrologic conditions; the capacity and operating condition of physical facilities and infrastructure; and regulatory/institutional parameters that regulate and allocate the distribution of water from the various sources. Regulatory requirements applicable to the regional system are described in Section 2.4, and institutional parameters, including system operations required to meet downstream obligations, are discussed in Section 2.5. This section describes system operations to meet customer water demand under normal conditions (i.e., in years when water supplies from rainfall, snowmelt, and storage are sufficient to fulfill customer purchase requests without rationing).

Water in the Hetch Hetchy system (which includes Hetch Hetchy Reservoir, Lake Lloyd and Lake Eleanor) comes from a combination of rainfall and inflow from the melting snowpack in the Tuolumne River watershed. The majority (approximately 80 percent) of the inflow to the reservoirs occurs during the snowmelt period from April through July. The SFPUC integrates the operation of its three Tuolumne River reservoirs with the operation of the water bank account in Don Pedro Reservoir (for an explanation of the water bank account, see Sections 2.4 and 2.5, below, regarding the Raker Act and New Don Pedro Project). The operation of these reservoirs and the water bank account is guided by two primary objectives: (1) conserve Hetch Hetchy Reservoir storage for diversion to meet the water purchase needs of SFPUC customers, and (2) fulfill the SFPUC's obligations to TID and MID under the Raker Act. There are also minimum downstream release requirements prescribed by the resource agencies (described in Section 2.5.3, below) for Hetch Hetchy Reservoir, Lake Lloyd, and Lake Eleanor.

The primary objective of Hetch Hetchy Reservoir operation is to maximize the volume of water stored in the reservoir by July 1 of every year (referred to as "carryover storage"[3]). After July 1, typically the end of snowmelt season, Hetch Hetchy Reservoir levels decline as diversions to the Bay Area exceed inflow to the reservoir.

Diversions from the Tuolumne River primarily originate from Hetch Hetchy Reservoir and incidentally provide hydroelectric generation at Kirkwood and Moccasin Powerhouses, in keeping with the SFPUC's Water First Policy. In general, the SFPUC avoids large downstream releases immediately below Hetch Hetchy Reservoir by regulating inflow and making smaller controlled releases from the reservoir. In anticipation of snowmelt runoff, the SFPUC releases water from Hetch Hetchy Reservoir by sending water through Kirkwood Powerhouse, thus lowering the level of the reservoir and reducing the storage volume to allow room for inflow from snowmelt runoff. This reduction in storage normally begins in winter as forecasts of snowmelt runoff become available. Drawdown of reservoir storage is determined first by the releases needed to meet water demand and second by the capacity of Kirkwood Powerhouse. If

3 Carryover storage is storage in a reservoir that is available for use in a succeeding period. For the SFPUC system, it is normally defined as the reservoir storage on July 1 of a given year. Carryover storage is a measurement of excess water captured when water is available, such as during the rainy season or during wet years, which is then available for later use during the dry season and/or during dry years.

determined necessary due to hydrologic conditions and reservoir storage capacity, additional controlled releases are made to the river.

Similar to Hetch Hetchy Reservoir operations, the Lake Lloyd and Lake Eleanor system is operated to conserve reservoir inflow for both water supply and hydroelectric generation (see Section 2.5). Winter and spring operations rely on the occurrence and forecast of runoff, which at times allows the SFPUC to drawdown reservoir storage in Lake Lloyd and Lake Eleanor and to utilize Holm Powerhouse for hydropower generation. The water transfer capability from Lake Eleanor to Lake Lloyd through the Eleanor-Cherry Diversion Tunnel, which links the two watersheds, allows for the utilization of runoff from the Eleanor Creek watershed through Holm Powerhouse. Like Hetch Hetchy Reservoir, maximum carryover storage into the summer season is the primary objective for reservoir operations.

As previously stated, the primary operating strategy is to fill all Hetch Hetchy system reservoirs on or about July 1 of each year. Historically, this occurs in about 75 percent of years, and generally by April 15 of each year the SFPUC can project the amount of water that will be stored in the system by July 1 of that year.

Operation of the Hetch Hetchy system is integrally linked with and dependent on the local system in the Alameda and Peninsula watersheds, as the Hetch Hetchy supply is used to supplement local supplies. While the Hetch Hetchy system provides the majority of the water (about 85 percent on average), the local reservoirs are operated to maximize use of annual yield for water deliveries and to provide critical backup or redundancy in the event of water quality problems, transmission disruptions in the Hetch Hetchy system, emergencies, critical maintenance, and droughts. Local water supplies stored in Calaveras Reservoir are the system's primary backup to the Hetch Hetchy supply. San Antonio and Crystal Springs Reservoirs supplement the storage capacity of Hetch Hetchy Reservoir, since the regional system conveys water from Hetch Hetchy Reservoir for storage in these local reservoirs; Calaveras Reservoir, however, stores only local watershed supplies and does not supplement the storage capacity of Hetch Hetchy Reservoir. The system is operated to maximize use of local resources for annual water deliveries, drought supply, and emergencies. Carryover storage in local reservoirs is critical to support system maintenance and emergency and drought preparedness of the regional water system (SFPUC, 2005a).

When water in excess of customer demand is available from Hetch Hetchy Reservoir and there is available capacity in the transmission system and local reservoirs, the SFPUC diverts water from the Hetch Hetchy system for storage in local reservoirs, namely San Antonio Reservoir in the Sunol Valley and Crystal Springs Reservoir on the Peninsula;[4] this "topping off" or replenishment operation also develops carryover storage in the regional system. Replenishment of local reservoirs is part of the overall strategy for maximizing the locally available water supply. The operational goal is to replenish storage in local reservoirs following the end of the rainy season, if necessary to supplement inflow from the local watershed, with water conveyed from the Hetch Hetchy system.

4 The regional system is designed so that Calaveras and Pilarcitos Reservoirs are used exclusively to store water from local drainages; they are not used to store water from the Hetch Hetchy system.

The SFPUC operates the local reservoir system to manage water needed for customer deliveries, water captured from local watershed runoff, and water conveyed from the Hetch Hetchy system. A primary objective of the local reservoir system is to conserve local watershed runoff for delivery. The local reservoir system's operation is seasonally driven. During the winter, when rainfall and local watershed runoff occurs, the local reservoirs are managed to maintain sufficient available storage and to minimize uncontrolled spills. In anticipation of or subsequent to storm events, runoff is conveyed to the Harry Tracy and Sunol Valley WTPs to maintain reservoir storage at winter storage objective levels. Towards the end of the winter as the likelihood of rain decreases, the reservoirs are operated to capture local watershed runoff with a goal of maximizing carryover storage in combination with Hetch Hetchy system storage.

During the summer, the amount of water drawn from the local reservoirs is minimized to preserve storage so that water is available in the event of a disruption of flow from Hetch Hetchy Reservoir or unplanned outages within the system. As the system demand increases beyond the capacity of flow from the Hetch Hetchy system, water is drawn from the local reservoirs to serve demand.

While the local watershed systems all have a common overall operating strategy, aspects of the Calaveras and Pilarcitos Reservoirs in the local system have a component of unique operation. As previously stated, Calaveras Reservoir's inflow is supplemented by diversions from Alameda Creek through the Alameda Creek Diversion Tunnel. Typically, the tunnel diverts flow from upper Alameda Creek when it is available up to the capacity of the tunnel. Flow at the diversion site that exceeds the diversion capacity spills over the dam and into the reach of the creek downstream of the diversion dam. Prior to 2002, the tunnel was kept open throughout the entire rainy season except when Calaveras Reservoir was full. Since 2002 with the DSOD restriction in place, the SFPUC has closed the tunnel more often, since Calaveras Reservoir is operated at reduced storage capacity. In addition, the SFPUC recently installed a low-flow valve at Calaveras Dam to allow for future low-flow releases.

Pilarcitos Reservoir stores runoff from the Pilarcitos Creek watershed for transfer to the SFPUC's reservoir in the San Mateo Creek watershed and for use by Coastside CWD. Water for Coastside CWD is released from Pilarcitos Reservoir to Pilarcitos Creek and then diverted by Coastside CWD at Stone Dam. Pilarcitos Reservoir is filled during the rainy season. Water not needed to fill the reservoir and meet Coastside CWD's needs is transferred from Pilarcitos Reservoir to San Andreas Reservoir and from Stone Dam to Crystal Springs Reservoir. Occasionally during wet months of wet years, runoff exceeds Coastside CWD's needs and the ability of the SFPUC to store water in Pilarcitos Reservoir or convey it to San Andreas and Crystal Springs Reservoirs. At such times, water spills over Stone Dam and flows down Pilarcitos Creek. In the summer months, when Coastside CWD's water demand is at its seasonal maximum, its water supply from Pilarcitos Creek becomes insufficient to meet its needs. At that point, Coastside CWD ceases diversions from Pilarcitos Creek and obtains its water by pumping from Crystal Springs Reservoir. The SFPUC is currently making experimental releases from Stone Dam to support ongoing studies of aquatic resources in Pilarcitos Creek below Stone Dam.

None of the Peninsula system reservoirs currently have regulatory agreement for an instream release immediately below their dams (see Section 2.5 for further discussion). Both San Mateo Creek downstream of Crystal Springs Reservoir, and Pilarcitos Creek below Stone Dam, have limited channel capacity due to urban (San Mateo Creek) and agricultural (Pilarcitos Creek) encroachments. Therefore, both reservoirs are operated to minimize uncontrolled reservoir spills. Calaveras Reservoir is the only reservoir in the Alameda system that has an instream release agreement; this agreement is pursuant to a 1997 Memorandum of Understanding (MOU) with the CDFG (see Section 2.5 for further discussion) (CDFG, 1997).

As described above, the regional system is highly dependent on storage, both in the Sierra Nevada and locally in the Bay Area, to be able to serve water under a wide variety of meteorological/ hydrological and operating conditions. During system upsets or when unusual water quality conditions occur in any of the reservoirs, the system provides a number of operational bypasses (see Figure 2.6) and backup facilities that allow the SFPUC to modify normal operations and continue to meet water quality standards without interrupting service to its customers.

2.3.5 Operations During Drought Periods

System operations during drought periods require more complex planning and system management than during nondrought years. Drought planning relies on two key concepts: “system firm yield” and “design drought.” System firm yield is the average annual water delivery that can be sustained throughout an extended drought. Design drought is a planning and operation tool that water supply agencies use to define a reasonable worst-case drought scenario based on local hydrology in order to establish design and operating parameters for the water system. Droughts more severe than the design drought would cause failure of supply within the water system. For the purposes of regional water system planning, the SFPUC uses a design drought that anticipates and plans for a more severe drought than historical events and evaluates the system firm yield assuming the system is experiencing the design drought. Studies suggest a 30 percent chance that the SFPUC system will experience a drought in the next 75 years equal to or more severe than the 1987–1992 drought, which was the most extreme recorded drought event to affect the regional system. The WSIP uses a design drought based on the hydrology of the six years of the worst historical drought (1987–1992) plus the 2.5 years of the 1976–1977 drought, for a combined total of an 8.5-year design drought sequence (SFPUC, 2007a).

With the DSOD restriction on Lower Crystal Springs Dam but no restriction on Calaveras Dam, the system firm yield is 226 mgd; this represented system conditions prior to December 2001. However, currently, due to the existing DSOD operating restriction on Calaveras Dam since December 2001, the system firm yield is reduced to about 219 mgd. The regional system currently provides an annual average of about 265 mgd of water to customers. Since the current deliveries (265 mgd) are greater than the system firm yield (226 mgd under normal conditions or 219 mgd under restricted conditions), the regional system cannot fully meet water deliveries to current customers during a prolonged drought. Reductions in deliveries (i.e., customer rationing) are required during drought periods (SFPUC, 2007a), as indicated in Figure 2.5.

The regional system has experienced drought periods in the last 30 years: most notable are the droughts that occurred from 1976 to 1977 and from 1987 to 1992. During the 1987–1992 drought, even with the implementation of customer rationing, the amount of carryover storage in the regional system was more severely depleted than during any previous time, and the SFPUC had to adjust its normal operating procedures to avoid running out of water (SFPUC, 2007a).

The 1987–1992 drought began at the end of the 1986 rainy season. Subsequent annual flows in the Tuolumne River were about 50 percent of average, CCSF entitlements were reduced to about 16 percent of the total river flow, and less than 50 percent of the normal amount of water delivered to customers was available from the river. As the drought progressed, the SFPUC developed and implemented short-term procedures to impose rationing on customers that resulted in a near 25 percent annual systemwide[5] reduction in water deliveries. The extended drought forced the SFPUC to adopt a mandatory rationing program from 1988 to 1989 and again from 1990 to 1993. The rationing program was based on an allocation method that reduced indoor water uses by 10 percent and outdoor water uses by 60 percent. However, due to the wide variation in types of water users in the regional service area, this program resulted in a wide variation in the cutbacks experienced by different customers, ranging from about 20 percent in areas with cooler climates and denser land use patterns to over 40 percent in areas with warmer climates and more landscaping. In the later stage of the six-year drought, the SFPUC was initiating programs to achieve a 45 percent reduction in systemwide water deliveries to balance water supplies with deliveries, but a series of storms in March 1991 provided relief from the anticipated water shortage, and the 45 percent rationing program was averted. However, based on the experience of the 1987–1992 drought, the SFPUC modified its operational procedures with regard to drought planning (SFPUC, 1993).

In 2000, the SFPUC adopted the *Interim Water Shortage Allocation Plan* (SFPUC, 2000a) in collaboration with the Bay Area Water Users Association (the organization representing wholesale customers, which has since been reorganized as the Bay Area Water Supply and Conservation Agency, or BAWSCA). This plan identified a water allocation method to be used to determine the share of water for wholesale customers during shortages caused by drought. The allocation method is effective for systemwide shortages of up to 20 percent during droughts. Following the adoption of the *Interim Water Shortage Allocation Plan* by all of the wholesale customers, the SFPUC adopted the *Retail Water Shortage Allocation Plan* consistent with the plan for wholesale customers (SFPUC, 2001b), which applies to all retail customers, including the residents and businesses in San Francisco.

Based on the two water allocation plans, the SFPUC system operations currently include a process for declaring a water shortage and a method for allocating reductions. The general protocol links total and anticipated reservoir storage conditions to suggested delivery reductions. Each year, during the spring snowmelt period, the SFPUC evaluates the amount of total water storage expected to occur throughout the regional system. If this evaluation finds the projected

5 For the purposes of this PEIR, "systemwide" refers to the entire regional water system and includes both retail and wholesale customers.

total water storage to be less than an identified level sufficient to provide sustained deliveries during drought, the SFPUC may impose delivery reductions or rationing. With existing purchase requests, there are currently three stages of delivery reduction: Stage 1 involves up to a 10 percent systemwide delivery reduction and is achieved by voluntary rationing; Stage 2 imposes up to a 20 percent systemwide delivery reduction and requires mandatory rationing; and, at Stage 3, a 20 percent or greater systemwide delivery reduction would result in mandatory rationing with further reduced allocations. As drought conditions continue and reservoir storage becomes further depleted, the SFPUC may need to impose an increasing level of delivery reductions. Prior to the initiation of any water delivery reductions, the SFPUC would hold a public meeting, open for public comment, to outline the water supply situation, the proposed water use reduction objectives, alternatives to water use reduction, and compliance methods (SFPUC, 2001b).

2.3.6 System Maintenance

The SFPUC performs maintenance of the regional system facilities as a fundamental part of operations so that it can continue to serve customers with reliable, high-quality water. Maintenance can include inspections and minor repairs/upkeep as well as major repairs, replacement, or rehabilitation. One of the inherent difficulties with performing maintenance on existing system facilities is that the most important facilities to maintain are also the most critical for system operation and, therefore, the most difficult to take out of service for inspection or repair. Planned outages for system inspections and repair must be scheduled in the context of the ongoing need to meet customer demand and maintain storage levels in local reservoirs. Pipelines, tunnels, treatment and pumping facilities, and other related facilities all require maintenance. Pipelines and tunnels have the greatest operational constraints with respect to maintenance because they need to be shut down during maintenance. Treatment and pumping facilities have more flexibility, since maintenance can generally be performed on these facilities without completely shutting them down.

Within the regional system, the current goal is to inspect all tunnels, except for the Irvington Tunnel, and all San Joaquin Pipelines on a 10-year cycle. Additionally, certain segments of the San Joaquin transmission system are inspected more frequently based on their age, leak history, condition, etc. Approximately four inspections per year are performed on the Bay Division and Peninsula pipeline sections. Following inspections, minor repairs may require outages of 45 days to two months, while major repairs may require shutdowns of 90 days or more.

The SFPUC attempts to meet the maintenance goals to the extent possible, given the capacity restrictions and limited redundancy (i.e., backup facilities) of the current system. Many of the tunnels in the system are important for water delivery to customers and lack redundancy, so it is difficult to shut them down for inspections. These include the Irvington, Pulgas, Crystal Springs Bypass, and Stanford Tunnels. Some of these tunnels have not been inspected for 20 to 30 years. As described previously, maintenance and inspection of Irvington Tunnel has not occurred for over 40 years.

Despite ongoing maintenance, unplanned outages occur periodically throughout the regional system for various reasons, including power outages and system failures. Major facility failures or outages that have recently occurred include:

- In August 1996, a rupture in SJPL No.3 occurred about 2 miles west of Oakdale Portal due to failure of the pipe material. The pipeline break resulted in reduction of water delivered from the Hetch Hetchy system to the Bay Area from 230 mgd to 150 mgd for a period of three weeks. The pipeline failure caused an unplanned discharge of over 10 million gallons of water at a rate of 200 to 400 cubic feet per second, flooded the surrounding cattle range land, and created a 1,000-foot long erosion gully. The SFPUC issued an emergency repair contract to replace the faulty pipe section and to restore water deliveries, and the surrounding lands were restored to their previous conditions.

- During the 1996/1997 rainy season, a landslide occurred on the hillside above the Crystal Springs Bypass Pipeline, burying a 350-foot segment of the roadway in which the pipeline is aligned. This landslide subjected the pipeline to excessive soil pressure and slight displacement. Although inspections of the pipeline found minor and repairable damage, corrective actions were necessary to stabilize the slope above the pipeline. The incident revealed how vulnerable the Crystal Springs Bypass Pipeline is to seismically induced landslides.

- During the 1996/1997 rainy season, concurrent with the unplanned outage of the Crystal Springs Bypass Pipeline, water in Crystal Springs Reservoir exhibited excessive levels of turbidity that limited the availability of water that could be treated at the Harry Tracy WTP. This condition lasted for about four weeks.

Pipeline leakage or failure is particularly susceptible where there are prestressed concrete cylinder pipe (PCCP) segments. PCCP breaks have occurred in recent years on parts of the San Joaquin No. 3, San Antonio, Bay Division No. 4, and San Andreas Pipelines, and repairs for these pipelines have taken from several days to several months. Seismic safety and flooding issues with Calaveras Dam and Lower Crystal Springs Dam, as described above, have restricted the normal operating capacity of the system. However, the SFPUC has generally been able to continue full water service during these outages and restricted conditions. Nevertheless, the deferred maintenance of major facilities within the system, including critical facilities, has reduced the overall system reliability and capacity over time.

2.3.7 Hetch Hetchy Hydropower Operations

Under the Raker Act of 1913 (discussed in Section 2.4.2, below), the CCSF was required to develop hydroelectric power, since such power was considered a natural byproduct of developing the Hetch Hetchy water supply. The Raker Act requires the CCSF to sell excess Hetch Hetchy power at cost, when available above the city’s own municipal needs, to TID and MID for agricultural pumping and municipal needs. After satisfying its own municipal load and Raker Act obligations to TID and MID, the Raker Act allows the CCSF to sell any remaining Hetch Hetchy power to public agencies for resale and/or directly to end-users. The Raker Act prohibits the CCSF from selling Hetch Hetchy power to private entities for resale.

The major portion of Hetch Hetchy power goes to satisfy San Francisco's own municipal needs, and the balance is sold to TID and MID, industrial customers (such as San Francisco International Airport tenants), and public entities. Municipal agencies (including the CCSF), departments, and enterprises consume slightly more than half of the electricity produced by the Hetch Hetchy power system. Among the city agencies that receive electricity from the SFPUC are the San Francisco Municipal Railway, San Francisco General Hospital, Laguna Honda Hospital, and the SFPUC's regional water, local water, and wastewater facilities. Regional water system facilities that use Hetch Hetchy power include the Sunol Valley WTP and San Antonio Pump Station. These electricity demands are expected to increase over the next decade (SFPUC, 2007b).

The hydropower system, known as the Hetch Hetchy Project, is comprised of 400 megawatts of hydroelectric power generation plants located on the Tuolumne River and 150 miles of high-voltage transmission lines delivering Hetch Hetchy power to the San Francisco Bay Area. Energy production varies by season and by year, depending on hydrologic conditions. The long-term annual average production is approximately 1.7 billion kilowatt-hours. Historical production has ranged from a low of 0.71 billion kilowatt-hours per year to a high of 2.2 billion kilowatt-hours per year (SFPUC, 2002).

There are three major hydropower facilities: the Holm, Kirkwood, and Moccasin Powerhouses. Holm Powerhouse, located on Cherry Creek, generates power from water released from Lake Lloyd/Lake Eleanor; after passing through the hydropower facilities, water is returned to Cherry Creek and ultimately flows in the Tuolumne River into Don Pedro Reservoir. Kirkwood Powerhouse, located along the Tuolumne River below O'Shaughnessy Dam, generates power from water released from Hetch Hetchy Reservoir; after passing through the hydropower facilities, this water is diverted first to Mountain Tunnel and then to the regional water system as part of the Tuolumne River water supply source. Moccasin Powerhouse, located downstream of Priest Reservoir, discharges to Moccasin Reservoir and uses Tuolumne River water to generate power before it flows to the Foothill Tunnel and then to the regional system. Water in excess of that diverted into Mountain Tunnel below Kirkwood Powerhouse and into Foothill Tunnel below Moccasin Powerhouse is released into the Tuolumne River and Moccasin Creek, respectively, and ultimately flows into Don Pedro Reservoir.

The Hetch Hetchy transmission system is comprised of eight transmission lines of varying lengths that interconnect to other power systems and the power grid; the system delivers Hetch Hetchy power to San Francisco's municipal load, TID, MID, several retail customers (including San Francisco International Airport), and to public entity customers. The Hetch Hetchy transmission system connects to MID's system at the Standiford and Warnerville substations, and to TID's system at the Oakdale substation. The Hetch Hetchy transmission system terminates in Newark, where it interconnects to the Pacific Gas and Electric Company (PG&E) power grid; PG&E facilities are used to convey Hetch Hetchy power from Newark to the San Francisco's municipal load and certain retail customers.

As described above, the SFPUC operates its facilities in accordance the Water First Policy. Under this policy, the production of hydropower is considered significant but secondary to water supply and water quality considerations (SFPUC, 2005a). The Water First Policy is also required by Assembly Bill 1823 (Water Code Section 73504[b]) and is further described under Section 2.4, below. For example, both Priest and Moccasin Reservoirs have bypass pipelines that can be put into service when warranted by water quality conditions; use of these pipelines limits peaking power generation, but assures that drinking water quality is preserved and regulatory requirements are met. As discussed in Section 2.5, hydropower operations during certain times of the year are coordinated with releases for whitewater rafting.

2.3.8 Watershed Management

Preservation and protection of watershed lands are an important aspect of SFPUC system operations. By actively managing activities within its watershed boundaries, the SFPUC can protect and maintain the water quality of the source waters for the regional system.

Tuolumne River Watershed

The 459-square-mile portion of the Tuolumne River watershed that flows into Hetch Hetchy Reservoir (Hetch Hetchy watershed) is entirely within Yosemite National Park; approximately 95 percent of this watershed is congressionally designated as wilderness area. This federal designation provides unique measures of protection to the watershed. The National Park Service (NPS) manages Yosemite National Park to preserve the resources that contribute to Yosemite's uniqueness and attractiveness, and to make the varied resources of the park available to people for enjoyment, education, and recreation. The NPS manages the Yosemite wilderness areas to meet the goals and principles of the 1964 Wilderness Act. In wilderness areas, human activities are limited to those that leave no long-term impact on the land or that have little or no effect on the natural resources of the area. People can enter wilderness areas by foot or on horseback, but mechanized access is not allowed.

The SFPUC and NPS negotiated a Watershed Protection Agreement that provides supplemental funding to the NPS to provide extra protection in the watershed (U.S. Department of Interior and SFPUC, 2005). The NPS has many regulations in place to protect water quality in Yosemite. SFPUC funding allows the NPS to employ additional rangers to enforce these regulations. The Watershed Protection Agreement also provides for additional onsite and offsite visitor education and information programs to inform park visitors to the watershed about water quality regulations and wilderness use techniques that protect water quality. Visitors are informed that the watershed is a source of drinking water for the San Francisco Bay Area and of their role in protecting the quality of the drinking water supply. The agreement also provides funding to the NPS so that it can operate and maintain facilities within the watershed to prevent source water contamination.

As part of the requirements for maintaining filtration avoidance (discussed in Section 2.4.1, below), the SFPUC conducts regular inspections of the protected Hetch Hetchy watershed and reservoirs. These inspections are collaborative efforts between the NPS and SFPUC to identify potential sources of drinking water contamination and identify actions to prevent contamination.

Alameda and Peninsula Watersheds

In the Alameda watershed, the CCSF owns about one-third of the lands comprising the southern Alameda Creek drainage area. Portions of the land have been leased for grazing, nursery, and quarry operations, although the watershed lands remain predominantly open space. In the Peninsula watershed, the CCSF owns the majority of the lands draining to the three Peninsula reservoirs (Crystal Springs, San Andreas, and Pilarcitos). In 1969, the CCSF, San Mateo County, and the state and federal governments made easement agreements to preserve the Peninsula watershed for water supply and open space purposes (Hanson, 1994, 2005).

In the 1990s, the SFPUC conducted planning and public outreach for the development of watershed management plans for the Alameda and Peninsula watersheds. Draft plans were published in 1998, followed by environmental review (San Francisco Planning Department, 2000 and 2001). The SFPUC adopted the Alameda and Peninsula Watershed Management Plans (WMPs) in 2000 and 2001, respectively (SFPUC, 2000b, 2001a). The adopted plans provide goals and polices aimed at improving water quality as well as creating a balance between the need for high-quality water and ecological resource protection, and the desire for public access and use of the watershed. The Alameda WMP includes specific elements for grazing and other Sunol Valley resources (including mining, recreation, and creek enhancements), and the Peninsula WMP includes an element for recreational access. Both plans contain specific elements to address fire management.

As part of implementation of the WMPs, the SFPUC is developing habitat conservation plans (HCPs) for both watersheds, in compliance with federal and state regulations for endangered species protection. The objective of these plans is to enable the SFPUC to implement watershed operations and maintenance activities while conserving and enhancing native species, habitats, and ecosystems. The HCPs will provide comprehensive, long-term conservation measures for species listed as threatened or endangered under the Endangered Species Acts or species that could be listed in the future. Other management actions that the SFPUC has implemented include restoration, training, and fire hazard management activities. The HCPs are further described in Chapter 4, Section 4.6, Biological Resources, under Regulatory and Conservation Planning Framework.

2.4 Regulatory Requirements

2.4.1 Safe Drinking Water Act

The basic regulations governing the regional water system are associated with the federal and California Safe Drinking Water Acts. The federal Safe Drinking Water Act, passed in 1974 and amended in 1986 and 1996, is the nation's primary law regulating drinking water quality and is implemented by the U.S. EPA. The act authorizes the U.S. EPA to set national health-based standards for drinking water and requires many actions to protect drinking water and its sources, including rivers, lakes, reservoirs, springs, and groundwater wells. In addition to source water protection, the act also provides for treatment, monitoring, sampling, analytical methods, reporting, and public information requirements. Implementation and enforcement of both the federal and California Safe Drinking Water Acts are under the jurisdiction of the California Department of Health Services (DHS), Division of Drinking Water and Environmental Management. Drinking water regulations are set forth in the California Code of Regulations, Titles 17 and 22.

The amended federal Safe Drinking Water Act established phases of regulation and a number of regulatory deadlines to address drinking water requirements. This amended act is implemented through subsidiary rules for regulation of specific contaminants or for monitoring or treatment requirements (U.S. EPA, 2007). The major U.S. EPA drinking water regulations are listed below:

- Surface Water Treatment Rule
- Interim Enhanced Surface Water Treatment Rule
- Total Coliform Rule
- Stage 1 Disinfectants and Disinfection Byproducts Rule
- Stage 2 Disinfectants and Disinfection Byproducts Rule
- Long Term 1 Enhanced Surface Water Treatment Rule
- Long Term 2 Enhanced Surface Water Treatment Rule
- Variances and Exemptions Rule
- Lead and Copper Rule
- Radionuclides Rule
- Filter Backwash Recycling Rule
- Arsenic Rule
- Public Notification Rule

Surface Water Treatment Rule and Hetch Hetchy Reservoir

In 1991, the U.S. EPA adopted the Surface Water Treatment Rule, which included water quality provisions for unfiltered systems, referred to as "filtration avoidance." In 1993, the SFPUC applied for the ability to comply with federal filtration avoidance regulations; the DHS reviewed and approved this application, and forwarded its recommendation to the U.S. EPA that the Hetch Hetchy supply be approved as an unfiltered source that meets all criteria in the federal statute for filtration avoidance. The U.S. EPA also approved this application in 1993. In 1998, the state added filtration avoidance provisions to Title 22 of the California Code of Regulations, under which the Hetch Hetchy supply is currently regulated. In 2000, the SFPUC adopted resolution number 00-0277, reaffirming its policy "to maintain the 'filtration avoidance' status for Hetch Hetchy water" and directing its staff "to prepare and submit operating fund and capital project budget requests which are consistent with proactive maintenance of 'filtration avoidance'" (SFPUC, 2000d).

Water from Hetch Hetchy Reservoir can be delivered to SFPUC customers without filtration, provided that it meets the filtration avoidance requirements outlined in the Surface Water Treatment Rule. These requirements include meeting source water quality standards, disinfection criteria, and site-specific criteria. In the Hetch Hetchy system, source water quality standards are measured for compliance at Tesla Portal, where disinfection also occurs. The SFPUC conducts extensive routine water quality monitoring and watershed protection activities and submits a monthly report to the DHS to fulfill filtration avoidance requirements. The report indicates coliform and turbidity levels, compliance with disinfection requirements, compliance with the Total Coliform Rule, quarterly disinfection byproduct levels, operability of disinfection equipment, watershed control activities, and any detected outbreaks of waterborne disease. In addition, the SFPUC submits an Annual Watershed Sanitary Survey Report summarizing compliance with watershed control program requirements, and the SFPUC's comprehensive watershed protection program has been shown to meet specific pathogen barrier criteria. Since 1993, these activities have demonstrated that, without filtration, the water from Hetch Hetchy Reservoir consistently meets or exceeds all water quality standards, indicating a high level of public health protection for regional system customers.

Water from Lake Eleanor, Lake Lloyd, and reservoirs in the Alameda and Peninsula watersheds does not meet filtration avoidance criteria and requires filtration at either the Sunol Valley or Harry Tracy WTPs before it can be delivered to customers.

2.4.2 Raker Act of 1913

In 1913, the federal government passed the Raker Act (Public Law No. 3-41, 38 Stat. 242), which states the following:

> An Act granting to the city and county of San Francisco certain rights of way in, over and through certain public lands, the Yosemite National Park, and Stanislaus National Forest, and certain lands in the Yosemite National Park, the Stanislaus National Forest, and the public lands in the State of California, and for other purposes.
>
> That there is hereby granted to the city and county of San Francisco … all necessary rights of way along such locations for the purpose of constructing, operating, and maintaining aqueducts, canals, ditches, pipes, pipe lines, flumes, tunnels, and conduits for conveying water for domestic purposes and uses to the city and county of San Francisco and such other municipalities and water districts as, with the consent of the city and county of San Francisco, or in accordance with the laws of the State of California in force at the time application is made.

The Raker Act granted to the CCSF rights-of-way and use of public lands in the affected areas to construct, operate, and maintain reservoirs, dams, conduits, and other structures necessary or incidental to developing and using water and power. However, the act imposed many conditions and obligations, stipulating, among others, that the CCSF was required to:

- Recognize the prior rights of TID and MID to receive water the districts could beneficially use, up to specified amounts of the natural daily flow, for direct use and storage
- Construct miles of scenic roads and trails in Yosemite National Park and donate them to the United States
- Started building the dam at Hetch Hetchy and complete it as rapidly as possible

- Enforce specific sanitary regulations within the watershed area
- Develop electric power for municipal and commercial use
- Not divert beyond the limits of the San Joaquin Valley any more of the waters from the Tuolumne watershed than shall be necessary for its beneficial use for domestic or other municipal purposes
- Pay an annual rental starting at $15,000 and rising to $30,000 after 20 years
- Not sell or give Hetch Hetchy water or power to a private person or corporation for resale

The CCSF ratified the Raker Act in the spring of 1914, and the Hetch Hetchy construction program started immediately. Since that time, the CCSF has developed and continues to develop the Hetch Hetchy water and power system and to use Tuolumne River water for municipal, industrial, and hydroelectric power purposes consistent with the provisions of this act.

2.4.3 Assembly Bill 1823

Adopted in 2002, California Assembly Bill 1823, known as the Wholesale Regional Water System Security and Reliability Act, is an act to add and repeal Division 20.5 of the California Water Code, which governs regional water systems. It imposes various requirements on wholesale regional water systems and applies directly to the CCSF and the SFPUC's regional water system. The bill includes numerous stipulations, including the following requirements for the CCSF: to adopt a capital improvement program by February 1, 2003; to adopt an emergency response plan by September 1, 2003; to distribute available water during any interruption to customers on an equitable basis; to continue operating reservoirs in Tuolumne County in a manner that ensures that the generation of hydroelectric power will not cause any reasonably anticipated adverse impact on water service; and to assign higher priority to water delivery to the Bay Area than to hydroelectric power generation.[6]

The act includes the Water First Policy (Water Code Section 73504[b]), which states:

> In order to supply adequately, dependably, and safely the requirements of all users of water, the city shall continue its practice of operating the reservoirs in the Counties of Tuolumne and Stanislaus in a manner that ensures the generation of hydroelectric power will not cause any reasonably anticipated adverse impact on water service. The city shall assign higher priority to delivery of water to the Bay Area than to the generation of electric power, unless the Secretary of the Interior, in writing, notifies the city that doing so would violate the Raker Act (63 Public Law 41).

The act identified specific projects to be included in the program, along with a requirement that a schedule be submitted to the DHS by March 2003 showing that projects representing 50 percent of the costs would be completed on or before 2010, and 100 percent of the projects would be completed on or before 2015. The SFPUC met this requirement and has submitted subsequent

6 The act allows the SFPUC to add or delete projects from the original capital improvement program, including the list of specific projects that was to be included in the original program.

revisions to the original capital improvement program, which has now been renamed the Water System Improvement Program (SFPUC, 2005b; SFPUC, 2006a).

2.4.4 Dam Safety Program

The California Water Code designates the regulatory Dam Safety Program to the Department of Water Resources, Division of Safety of Dams (DSOD). The principal goal of this program is to avoid dam failure and thus prevent loss of life and destruction of property. The DSOD reviews plans and specifications for the construction of new dams and for the enlargement, alteration, repair, or removal of existing dams, and must grant written approval before the owner can proceed with construction. Professional engineers and geologists from the DSOD evaluate each project, investigate proposed sites, and check available construction materials. Dams under DSOD jurisdiction include artificial barriers (together with appurtenant works) that are 25 feet or more in height or have an impounding capacity of 50 acre-feet or more. Any artificial barrier not in excess of 6 feet in height, regardless of storage capacity, or that has a storage capacity not in excess of 15 acre-feet, regardless of height, is not considered jurisdictional (DSOD, 2007).

In addition to Calaveras and Lower Crystal Springs Dams (which are currently operating under DSOD restrictions), other SFPUC regional system infrastructure under DSOD jurisdiction includes the following: Balboa Reservoir, University Mound Reservoirs (North and South), Sunset Reservoirs (North and South), Stanford Heights Reservoir, Sutro Reservoir, Calaveras Reservoir, Turner Dam, Crystal Springs Reservoir, Pilarcitos Reservoir, San Andreas Reservoir, O'Shaughnessy Dam, Lake Lloyd, Lake Eleanor, Priest Reservoir, Early Intake Reservoir, and Moccasin Reservoir.

2.5 Institutional Considerations

In additional to the regulatory requirements described above, the regional system is subject to a number of institutional agreements and other planning requirements, including those described below.

2.5.1 Existing Water Rights and Entitlements

The CCSF water rights and entitlements for the existing water supply sources of the regional water system have been obtained or granted pursuant to California law. With the exception of San Antonio Reservoir in the Alameda Creek watershed, all water diverted and stored in and through the regional system reservoirs and facilities in the Tuolumne River, Alameda, and Peninsula watersheds is done pursuant to pre-1914 appropriative water rights (see the description of appropriative rights in the following paragraphs). Water is diverted and stored in San Antonio Reservoir pursuant to a license granting an appropriative water right that was issued by the State Water Resources Control Board (SWRCB) in 1959.

Description of California Water Rights

California recognizes both appropriative and riparian water rights. An appropriative water right allows the holder to divert from a water source to a place of use not connected to the water source. The appropriative water right is based on a place of use, a purpose of use, and a method of diversion. Riparian rights holders, on the other hand, only have the right to divert from a water source to adjacent land for use on such land. Appropriative rights are based on seniority—that is, first in time, first in right—with those having the most senior water rights enjoying the most security in the use of water. In times of shortage, junior water-rights holders must cease diversions until all water rights that are senior to them have been satisfied. Use of water under an appropriative water right must be reasonable, beneficial, and not wasteful.

Originally, physical diversion was evidence of the right of use in California, but in 1872 California formally enacted Civil Code provisions (Civil Code Sections 1410–1422) recognizing appropriative water rights. After 1872, an appropriator simply had to post a notice of water right in a conspicuous place at the proposed point of diversion and then record the notice with the county recorder. Water rights noticed under the Civil Code were perfected through diligence in the construction of water diversion works that put the water to the beneficial uses in the places identified in the notice. If the appropriator followed the provisions of the Civil Code within the prescribed timeframes, the appropriator obtained a priority date as of the posting date of the notice, even though completion of the appropriation was substantially later. In recognition of the special needs of municipalities to make the best use of limited funds and to increase use as population grows, California law allows municipalities that hold pre-1914 water rights to increase the use of their water rights over time as the need for water increases (Civil Code Section 1416).

In 1914 California established a formal water rights permit system to create a more orderly method of appropriating unappropriated waters. The State Water Resources Control Board (SWRCB) now administers the water-rights permit system. While the SWRCB has sole authority to issue new appropriative water rights, it does not have authority to define the property rights created under a pre-1914 appropriative water right. The courts are charged with defining the validity and scope of water rights of pre-1914 appropriators when the extent of such rights or claims is in dispute.

San Francisco's Water Rights

The CCSF has sufficient pre-1914 and post-1914 water rights for existing operations and facilities as well as proposed operations and facilities under the WSIP. This is true for both the Hetch Hetchy and local portions of the regional water system, including the proposed Calaveras Dam Replacement project and the proposed Lower Crystal Springs Dam Improvement project (described in Chapter 3), neither of which would expand the capacity of these reservoirs beyond historical levels under CCSF water rights.

As to the Tuolumne River supply, the CCSF made numerous water-rights filings on the Tuolumne River between 1901 and 1911. The Tuolumne River water-rights filings support a *prima facie* diversion rate well over 400 mgd. The 1912 Freeman Report, which provided the basis for the CCSF's proposals to Congress to develop the Hetch Hetchy Project, identified 400 mgd as the ultimate diversion from the Tuolumne River.

The operation of the SFPUC water supply system is a matter of historical record. Since the third San Joaquin Pipeline was put into service in 1968, the historical annual diversions to the Bay Area from the Tuolumne River through the San Joaquin Pipelines (Tuolumne River diversions) have varied widely, depending on the time of year and year type. Since 1968, Tuolumne River diversions have averaged about 197 mgd (fiscal year [FY] 1968/2004), with a maximum annual diversion of 295 mgd (FY 1987/1988). The average diversion of 197 mgd is about 12 percent of the total average natural flow of the Tuolumne River at La Grange Dam. For that same period, FY 1968/2004, annual deliveries to SFPUC customers averaged about 248 mgd, with an annual average maximum purchase of 293 mgd (FY 1987/1988). Monthly Tuolumne River diversions have been as high as 305 mgd (January 1977), with daily sustained diversions as high as 310 mgd (August 1984).

As noted above, the Raker Act requires San Francisco to recognize the senior water rights of TID and MID to divert water from the Tuolumne River. Specifically, the Raker Act requires the CCSF to bypass certain flows through its Tuolumne River reservoirs to TID and MID for beneficial use. By agreement, the CCSF, TID, and MID, have supplemented these Raker Act obligations to increase the TID and MID entitlements to account for other senior Tuolumne River water rights and to allow the CCSF to "pre-pay" TID and MID their entitlement by storing water in the Don Pedro water bank (see the Don Pedro water bank discussion below). The CCSF is required to bypass inflow to TID and MID sufficient to allow them to divert 2,416 cfs or natural daily flow, whichever is less, at all times (as measured at La Grange), except for April 15 to June 13, when the requirement is 4,066 cfs or natural daily flow as measured at La Grange, whichever is less.

2.5.2 New Don Pedro Project

In 1964, the Federal Energy Regulatory Commission (FERC) issued a license to TID and MID to construct the New Don Pedro Dam and Reservoir on the lower Tuolumne River, about 50 miles downstream from O'Shaughnessy Dam and Hetch Hetchy Reservoir, as shown in **Figure 2.7**. Construction of the New Don Pedro Reservoir (referred to hereafter in this PEIR as Don Pedro Reservoir) was completed and operation began in 1971; it has a gross capacity of 2,030,000 acre-feet and a net usable capacity for irrigation, flood control, and hydropower generation of 1,721,000 acre-feet (FERC, 1996a).

As part of the development of the New Don Pedro Project, the CCSF, TID, and MID entered into agreements to specify the rights and entitlements of each party and their respective responsibilities for the New Don Pedro Project (CCSF/TID/MID, 1966). One of the agreements allocates storage space in Don Pedro Reservoir for a specified volume of water within the CCSF entitlement. This storage space is referred to as the "water bank account" and provides the SFPUC flexibility in the operation of Hetch Hetchy Reservoir. The water bank account allows the CCSF to meet the entitlements and prior rights of TID and MID under the Raker Act and subsequent agreement, while maximizing the use of water from Hetch Hetchy Reservoir to supply

Figure 2.7
Tuolumne River Features Below Hetch Hetchy Reservoir

water to SFPUC customers. As described above, TID and MID have senior water rights to the CCSF for Tuolumne River water and are entitled to the first increment of flow in the basin.

San Francisco's allocation of storage space in Don Pedro Reservoir varies from 570,000 to 740,000 acre-feet, depending on whether flood control restrictions on the reservoir are in effect. Basically, the SFPUC adds water to its water bank account whenever the inflow to Don Pedro Reservoir exceeds the TID and MID entitlements; conversely, the SFPUC debits from the water bank account whenever it diverts or stores Tuolumne River water that would otherwise be within the entitlements of TID and MID.

As described in Section 2.2.1, water from Lake Eleanor and Lake Lloyd that is used to produce hydroelectric power and provide flows for recreational and fishery (i.e., nonconsumptive) uses is returned to Cherry Creek and the Tuolumne River and ultimately flows downstream to Don Pedro Reservoir. The releases from Lake Eleanor and Lake Lloyd can be used to meet the TID and MID entitlements. When in excess of TID and MID entitlements, these flows to Don Pedro Reservoir can be credited to the SFPUC water bank account, thus allowing the SFPUC more flexibility during different times of the year to deliver water from Hetch Hetchy Reservoir to its customers.

2.5.3 Instream Flow Releases

Hetch Hetchy Facilities

The Raker Act gave the CCSF the right to develop a municipal water and power system subject to conditions and regulations of the Department of the Interior (DOI) and the Department of Agriculture (DOA) for the protection of public lands. In exercising their authority, the DOI and DOA have imposed conditions on the CCSF's rights-of-way to conform with federal policies, and, in the 1950s, the DOI and DOA began requiring water releases from Hetch Hetchy facilities to maintain minimum stream flows to benefit instream fisheries and other wildlife[7] (CCSF, 1961).

Lake Lloyd (Cherry Reservoir)

In 1949, the CCSF filed an amended application to change the boundaries for rights-of-way for the then-proposed Cherry Reservoir. The CCSF entered into stipulations with the DOA, which were executed on February 28, 1950, to release specified flows from Cherry Reservoir (now known as Lake Lloyd) "for the protection and maintenance of fish, wildlife and recreation in the Cherry River below the Dam." The Cherry stipulations require the CCSF to release 5 cfs from October 1 through June 30, and 15 cfs from July 1 through September 30 (CCSF, 1956).

[7] Hetch Hetchy Project facilities, with the exception of the Moccasin low-head hydroelectric facility, are exempt from FERC jurisdiction for the licensing of hydroelectric facilities. Most hydropower facilities in the United States are regulated by FERC, and many are required by FERC to make releases for instream fisheries.

Lake Eleanor

In the mid-1950s, the CCSF applied for permission from the DOI to relocate tunnel aqueducts, steel penstock, and the power plant site of the Cherry River Project. In granting the changes in rights-of-way, the DOI conditioned its approval on the CCSF agreeing to instream releases into Eleanor Creek to support fisheries. These flows were increased in 1982 when the CCSF sought changes in rights-of-way to build the Cherry-Eleanor Pump Station. The fishery releases were based on an evaluation performed by the U.S. Forest Service fisheries biologist, and evaluations and recommendations made by the U.S. Fish and Wildlife Service (USFWS) and the CDFG. The Eleanor stipulations require the CCSF to release 5 cfs from October 1 through June 30, and 15.5 cfs from July 1 through September 30 in years when no pumping occurs between Lake Lloyd and Lake Eleanor. In years when pumping occurs, the Eleanor stipulations require the CCSF to release 5 cfs from November 1 through February 28, 10 cfs from March 1 through April 14, 20 cfs from April 15 through September 15, and 10 cfs from September 16 through October 31 (CCSF, 1982).

Hetch Hetchy Reservoir

There were no instream flow requirements when O’Shaughnessy Dam was originally constructed. However, when the Canyon Power Project and Kirkwood Powerhouse were proposed in the 1950s, it became necessary to modify right-of-way conditions specified in the Raker Act, which led to a series of conditions for fishery releases from Hetch Hetchy Reservoir. In 1958, the CCSF agreed to make interim releases from Hetch Hetchy Reservoir until the NPS, U.S. Forest Service, and USFWS completed a fishery study. The study was completed in August 1976, but the CCSF contested the study. In 1984, the CCSF, federal agencies, and interested parties reached an agreement for fishery releases, which was approved by the DOI in 1985. The 1985 stipulations established three different minimum flow release schedules based on hydrologic year type. Shortly thereafter, the CCSF began building a third generating unit at Kirkwood Powerhouse, and the DOI determined that additional conditions for fishery releases were required. These stipulations, which were signed in 1987, modified and increased the flow schedules. This last set of stipulated fishery release schedules—based on the 1976 fish study and continued discussions and negotiations between federal agencies, the CCSF, and other interested parties—currently dictates the CCSF instream flow releases at O’Shaughnessy Dam (CCSF, 1987).

The Hetch Hetchy stipulations set forth basic flow schedules and amounts for discretionary releases. The flow schedules, defined for three hydrologic year types, are triggered by the amount of cumulative precipitation and runoff at Hetch Hetchy Reservoir over a specified period of time. The schedule for a given month is determined on the first day of the month. From January through June, a schedule for a given month is determined by the cumulative precipitation in the Hetch Hetchy watershed since October 1 of the preceding year. During July and August, the cumulative runoff into Hetch Hetchy Reservoir since October 1 of the preceding year determines which schedule will be used. The schedule for the balance of the year after August is the schedule in effect on August 1. The minimum amount of water to be released annually is 59,235 acre-feet for Schedule A, 50,019 acre-feet for Schedule B, and 35,215 acre-feet for Schedule C. The SFPUC must release an additional 64 cfs into the river below Hetch Hetchy Reservoir when the diversion through Canyon Tunnel exceeds 920 cfs. Finally, the stipulations provide for an additional supplemental release depending on water-year type, subject to completion of a habitat study and a corresponding determination of the timing of such releases. Chapter 5 of this PEIR presents more information on the triggers and the minimum release schedules for Hetch Hetchy Reservoir (CCSF, 1987).

Moccasin Fish Hatchery

The SFPUC releases water for the Moccasin Fish Hatchery under a 20-year lease agreement (1992–2012) between the CCSF and the State of California. Under the lease, the state has the right to take up to 30 cfs from Moccasin Reservoir for hatchery needs. After use in the hatchery, the water is released into Moccasin Creek, where it flows into Don Pedro Reservoir (CCSF, 1992).

Peninsula and Alameda Watershed Facilities

There are currently no release agreements to support fisheries in the regional system reservoirs or dams on the Peninsula, which includes Pilarcitos, Stone, San Andreas, and Crystal Springs Dams and Reservoirs. However, as described above, the SFPUC is currently making experimental releases from Stone Dam to support ongoing studies of aquatic resources in Pilarcitos Creek below Stone Dam. The SFPUC intends to develop a final release schedule from Stone Dam in coordination with the state and federal regulatory agencies as part of the Peninsula HCP.

In the Alameda watershed, Calaveras Dam and Reservoir is the only facility operating under an agreement to make releases in support of fisheries.[8] In 1997, the SFPUC and CDFG entered into an MOU regarding the magnitude and timing of flows to be released from Calaveras Reservoir for the improvement of habitat conditions for fisheries on Alameda and Calaveras Creeks (CDFG, 1997). The MOU specifies that the maximum quantity of water the SFPUC may be required to release will not exceed 6,300 acre-feet per year, and that the SFPUC will conform with flow schedules for water releases, varying between 7 cfs during late spring and summer and up to 20 cfs during the two-month winter trout-spawning period. The MOU also states that a suitable point exists for the recapture of water released, and a recapture facility may be constructed in the vicinity of the Sunol Valley WTP so that the SFPUC can recapture this water for consumptive use in the SFPUC service area. The recapture project is one of the WSIP facility improvement projects evaluated in this PEIR.

In addition, in October 1991 the SFPUC issued an MOU with the CDFG regarding the Calaveras Reservoir intake screen design and operating procedures (SFPUC, 1991). The agreement specifies that “Calaveras Reservoir will be operated to minimize the potential hazard to juvenile fish populations by recognition of critical season periods, operating levels and screen approach velocities.” In effect, the agreement restricts Calaveras Reservoir from being operated at an elevation greater than 690 feet (CDM, 2005).

8 The other SFPUC dams in the Alameda watershed include Turner Dam (on San Antonio Reservoir). The Sunol and Niles Dams—two inactive dams on Alameda Creek below San Antonio Reservoir in Niles Canyon—were removed in the fall of 2006 to help restore fish passage.

As previously described in Section 2.3.4, the SFPUC recently installed a low-flow valve at Calaveras Dam to allow for future lower volume releases.

Other Tuolumne River Fishery Release Requirements

As described above, TID and MID own and operate the New Don Pedro Project and make fishery releases below Don Pedro Reservoir at La Grange Dam consistent with a FERC license. In general, TID and MID are required to conform releases to one of seven basic flow schedules based on hydrologic year type. The total volume of release ranges from 94,000 acre-feet to 300,923 acre-feet, depending on the wetness of the San Joaquin River basin, with a summer flow ranging from 50 cfs to 250 cfs. Annual minimum flow schedules vary by three periods, defined as October 1 to October 15, October 16 to May 31, and June 1 to September 30, with additional fall and spring pulse flows for salmon adult attraction and smolt out-migration, respectively (FERC, 1996a).

In conjunction with the 1966 FERC license to TID and MID for the New Don Pedro Project, the CCSF, TID, and MID executed the Fourth Agreement to finance construction and establish operations for the project (CCSF/TID/MID, 1966). The three parties agreed to allocate the potential water supply risk that might result from a change in the interim flow schedules as follows:

> The Districts [TID and MID] and City [CCSF] recognize that Districts, as licensees under the [FERC] license for the New Don Pedro project, have certain responsibilities regarding the water release conditions contained in said license, and that such responsibilities may be changed pursuant to further proceedings before the [FERC]. As to these responsibilities, as they exist under the terms of the proposed license or as they may be changed pursuant to further proceedings before the [FERC], Districts and City agree:
>
> > … (b) That at any time Districts demonstrate that their water entitlements, as they are presently recognized by the parties, are being adversely affected by making water releases that are made to comply with [FERC] license requirements, and that the [FERC] has not relieved them of such burdens, City and Districts agree that there will be a re-allocation of storage credits so as to apportion such burdens on the following basis: 51.7121% to City and 48.2879% to Districts. (CCSF/TID/MID, 1966)

In 1994, FERC initiated mediation among 12 parties, including the CCSF, TID, and MID, on flow schedules and other matters related to releases in support of fisheries in the lower Tuolumne River. In February 1996, TID and MID filed with FERC an uncontested settlement agreement that included minimum flow schedules that are greater than the previous flow schedules. In July 1996, FERC amended the New Don Pedro Project license to incorporate the settlement agreement flow schedules (FERC, 1996b).

The CCSF, TID, and MID entered into a settlement agreement regarding the FERC flow schedules. Under this agreement, the CCSF makes annual payments to TID and MID, and TID and MID meet all flow requirements of the minimum flow schedules. The 1996 settlement agreement extends through the remainder of the FERC license (i.e., 2016) and any annual licenses. FERC may modify the fishery release requirements for the New Don Pedro Project in 2016 when TID and MID apply for a new license for hydroelectric operations (CCSF/TID/MID, 1995).

2.5.4 Rafting Flows

There are two whitewater runs in the Tuolumne River watershed above Don Pedro Reservoir: an 18-mile run on the Main Fork from Lumsden Campground to Ward's Ferry Bridge, known as the Lumsden Run, and a 9-mile run that begins at Holm Powerhouse on Cherry Creek and ends at Lumsden Campground, known as the Cherry Creek Run (refer to Chapter 5, Figure 5.3.8-1). Commercial companies operate under special-use permits issued by the U.S. Forest Service, Stanislaus National Forest. Private whitewater boaters must obtain permits from the Forest Service to boat the Tuolumne River between April 1 and September 30. Over the last 10 years, an average of 6,000 people per year participated in whitewater rafting on the river (see Chapter 5, Section 5.3.8, for more description of whitewater recreational use).

The flow schedules for Hetch Hetchy projects were intended to benefit fish and recreational fishing, not whitewater recreation. Neither the Raker Act nor the existing stipulations require the CCSF to make instream flow releases to maintain or enhance whitewater recreation. However, as described above, the 1996 FERC Settlement Agreement for the New Don Pedro Project requires the CCSF to consult, cooperate, and communicate with whitewater recreational interests with respect to SFPUC flow releases.

Subject to the availability of water and the CCSF's need for energy, the SFPUC attempts to accommodate whitewater recreation in the Tuolumne River by adjusting the day and hour of releases (i.e., "shaping" releases) from Holm Powerhouse to meet the needs of whitewater rafters. For rafting flows, the SFPUC attempts to meet up to 1,100 cfs on the Tuolumne River at Lumsden Campground. SFPUC staff meets annually with stakeholders representing the whitewater recreational community to develop, to the degree practicable, schedules of releases for whitewater recreation.

2.5.5 Customer Agreements – Master Water Sales Contracts

The SFPUC currently holds individual agreements with its wholesale customers, who are represented by the Bay Area Water Supply and Conservation Agency (BAWSCA) (formerly the Bay Area Water Users Association, or BAWUA). A list of the current BAWSCA members is provided in Chapter 3, Table 3.1, and their locations are shown on Figure 3.2. Wholesale water rates are set in accordance with the 1984 Settlement Agreement and Master Sales Water Contract (Master Water Sales Agreement) between the CCSF and each of the wholesale customers (CCSF, 1984). The current master contract expires in June 2009.

In addition to providing terms for the rate schedule and allocation of operating and capital costs, the Master Water Sales Agreement also addresses water supply and use of local water. Under the Master Water Sales Agreement, the CCSF has agreed that the wholesale customers may collectively purchase up to 184 mgd on an average annual basis through June 2009 subject to reductions in the event of a drought, water shortage, earthquake, other natural disaster, or rehabilitation and maintenance of the system; this amount is referred to as “the supply assurance.” The supply assurance remains effective following termination of the Master Water Sales Agreement and includes the corresponding individual contracts with the wholesale customers. The Master Water Sales Agreement requires that wholesale customers employ best efforts to use all sources of water owned or controlled by them, including groundwater (SFPUC and BAWUA, 2000).

Terms of the individual agreements vary among the wholesale customers. The City of Hayward and Estero Municipal Improvement District have “all requirements” agreements; that is, the SFPUC has agreed to meet all of these two customers’ water needs in excess of other water sources owned or controlled by them. The SFPUC’s agreement with the Estero Municipal Improvement District terminates in 2011, while the agreement with the City of Hayward has no termination date. These agreements imply that as Hayward and Estero’s water usage grows, the residual water of the supply assurance is shared among the other wholesale customers. Under the Master Water Sales Agreement, the SFPUC also sells water to the Cities of San Jose and Santa Clara on a temporary, interruptible basis.

The Master Water Sales Agreement does not address the issues of whether the CCSF is obligated under federal or state law to (1) supply the wholesale customers with water beyond the supply assurance of 184 mgd, or (2) expand the regional water system in order to provide additional water. However, the SFPUC works cooperatively with the BAWSCA and the individual wholesale customers to provide reliable, high quality and affordable water to meet customers’ needs.

2.5.6 SFPUC Water Resources Policies

The SFPUC has adopted numerous resolutions related to water resources, including policies fundamental in the development of the WSIP. These resolutions and policies were used as the basis of many of the program objectives for the WSIP, including policies related to protecting and maintaining the Tuolumne River water supply source; maximizing the use of conservation, recycled water, and groundwater; augmenting dry-year water supplies; coordinating water supply planning efforts with wholesale customers; protecting the environment; and filtration avoidance for Hetch Hetchy water. These resolutions are summarized in **Table 2.3**.

TABLE 2.3
SFPUC WATER RESOURCES POLICIES RELATED TO THE WSIP

Date	Resolution Number	Description
March 1993	93-0083 to 93-0088	This series of six resolutions addresses a water resource policy aimed at preserving and enhancing San Francisco's high-quality water supply and preparing for future water needs by pursuing the beneficial use of alternate resources.
	93-0083	The SFPUC directs staff and management to work with city leaders to develop funding and to provide necessary staffing and programs to accomplish the goals and objectives of this policy statement.
	93-0084	*Defense of Water Rights.* Due to the extraordinarily high quality of the Sierra water supply and the high degree of watershed protection it receives, it is important that San Francisco's share of the waters of the Tuolumne River be preserved for the beneficial municipal and industrial use of San Francisco and its customers. The SFPUC does and will continue to vigorously protect its Sierra water rights, facilities, and method of diversion against all challenges.
	93-0085	*Conservation, Recycled Water, and Groundwater.* Conservation, recycled water, and groundwater usage will extend the time before which maximum diversions from the Hetch Hetchy system will be required, may offset some required deliveries from the Hetch Hetchy system, and will provide greater reliability of supply during times of water shortage. It is the policy of the SFPUC to maximize the use of conservation, recycled water, and groundwater to the extent economically, technically, and environmentally reasonable to do so.
	93-0086	*Dry-Year Options and Supply Augmentation.* Because of San Francisco's junior rights to the waters of the Tuolumne River and the entitlement structure embodied in the Raker Act, San Francisco's Sierra supplies are vulnerable to prolonged periods of drought. There is growing interest and opportunity within the California water community in making water transfers on a long-term, planned basis. The SFPUC directs staff to pursue contractual arrangements that will augment its Sierra supplies. Priority will be given to transfers or exchanges that increase Tuolumne River supplies available to San Francisco, or conservation projects within the Tuolumne River basin that increase supplies available to San Francisco.
	93-0087	*Bay Area Water Supply Planning.* San Francisco supplies water to itself and 33 suburban customers in the Bay Area. Some of the suburban customers have access to other supplies such as the State Water Project, Santa Clara Valley Water District, groundwater, and local surface supplies. It is not possible to plan for the needs of San Francisco's suburban customers for water supplied from San Francisco's system without also projecting the availability of their alternate water sources. The SFPUC directs staff to engage with its suburban customers, the Santa Clara Valley Water District, and other interconnected suppliers in a comprehensive and coordinated water supply planning effort.
	93-0088	*Environmental Improvements.* The SFPUC, Mayor, Board of Supervisors, and the people of San Francisco share a concern for the protection of the environment. The SFPUC directs staff to seek opportunities to contribute to the improvement of the state's aquatic environment through design and operation of its conservation, recycled water, or groundwater projects; water purchase, transfer, and exchange agreements; and future water supply development. Further, the SFPUC will not object to a statewide financial assessment on the use of water so long as it is equitable and the funds are used to purchase water for environmental uses.

TABLE 2.3 (Continued)
SFPUC WATER RESOURCES POLICIES RELATED TO THE WSIP

Date	Resolution Number	Description
April 2000	00-0110	*Water Resource Policies* • To encourage the wise use of all water resources by the City of San Francisco and SFPUC suburban customers, including conservation, water recycling, and groundwater development • To fairly allocate water shortages among the City of San Francisco and SFPUC suburban customers • To fully recover the costs of capital improvements and water purchases • To fairly share the costs of financing capital improvements as they are implemented among the City of San Francisco and SFPUC suburban customers • To aggressively preserve and protect SFPUC water rights to the Tuolumne River supply • To retain full and absolute control of SFPUC water supplies, lands, and capital assets
September 2000	00-0277	*Filtration Avoidance* • The SFPUC reaffirms its policy to maintain the filtration avoidance status for Hetch Hetchy water. • The SFPUC directs staff to prepare and submit Operating Fund and capital project budget requests that are consistent with proactive maintenance of filtration avoidance.
June 2006	06-0105	*Water Enterprise Environmental Stewardship Policy* The Environmental Stewardship Policy will be integrated into SFPUC Water Enterprise planning and decision-making processes and also directly implemented through a number of efforts, including: • Implementation and updating of the existing Alameda and Peninsula Watershed Management Plans • Development of Habitat Conservation Plans for the Alameda and Peninsula Watersheds • Development and implementation of the Watershed and Environmental Improvement Program, which will cover the Tuolumne River, Alameda Creek, and Peninsula watersheds • Development of the Lake Merced Watershed Plan • Active participation in local forums, including coordination with Yosemite National Park Service and Stanislaus National Forest in the Tuolumne River watershed, the Tuolumne River Technical Advisory Committee, the Alameda Creek Fisheries Restoration Workgroup, the Pilarcitos Creek Restoration Workgroup, and the Lake Merced Task Force • Integration of the policy into the WSIP and individual infrastructure projects (i.e., repair and replacement programs) • Reliance on the policy to guide the development of project descriptions, alternatives and mitigation for all SFPUC projects during the environmental review process under CEQA and/or NEPA • Providing support for and encouragement to all employees to integrate environmental stewardship into daily operations through communication and training

3 Program Description

CHAPTER 3
Program Description

3.1 Introduction

The San Francisco Public Utilities Commission (SFPUC) proposes to adopt and implement a Water System Improvement Program (WSIP or proposed program) to increase the reliability of the regional water system. The WSIP would establish program goals for improvements to the regional water system and level of service objectives for system performance in the areas of water quality, seismic reliability, delivery reliability, and water supply through the year 2030. These goals and objectives provide the basis for a proposed water supply option to serve increased water demand, proposed operations during drought and nondrought periods, and a series of facility improvement projects to be constructed and implemented under the WSIP.

The facility improvement projects and the proposed water supply option included in the WSIP are designed to: (1) ensure compliance with existing and anticipated future water quality standards under all operating conditions; (2) upgrade the seismic standards of critical facilities to improve seismic reliability and to reduce the system's vulnerability to earthquakes; (3) improve water delivery reliability under a variety of operating conditions by improving overall operations of the system; and (4) assure that the SFPUC has an adequate supply of water available to deliver to customers during both nondrought and drought periods through 2030.

As described below in Section 3.4, the SFPUC initially proposed the draft WSIP in early 2006 as the result of long-term planning and in response to legislative mandates, including a 2002 voter-approved bond measure (see discussion of Assembly Bill No. 1823 in Section 3.4, below). However, for budgeting and management purposes, the SFPUC categorizes as part of the WSIP all capital improvements and projects that will receive financing from the 2002 voter-approved bond measure. Some, but not all, of the activities and projects that the SFPUC has identified for financing purposes as part of the WSIP are analyzed as a program in this Program Environmental Impact Report (PEIR), as defined under the California Environmental Quality Act (CEQA). Other proposed WSIP activities that are not evaluated in this PEIR as part of the proposed program are undergoing CEQA review independent of the PEIR. For the purposes of this PEIR, the WSIP or proposed program refers only to the key regional program elements of the WSIP, essentially consisting of the proposed water supply option, key regional facility improvement projects, and the associated modified operations strategy.

This chapter describes the proposed program and is organized as follows: Section 3.2 presents the regional location of the SFPUC water system (the reader is referred to Chapter 2 for additional details regarding the facilities and operations of the existing system). Section 3.3 describes the need for the program and outlines the WSIP goals and objectives, and Section 3.4 provides information on the background and development of the WSIP. Section 3.5 expands on the WSIP goals and describes the proposed levels of service and system performance objectives. Sections 3.6 and 3.7 outline the proposed water supply and the proposed system operations strategy, respectively. Section 3.8 summarizes the key regional WSIP facility improvement projects analyzed in this PEIR, and Sections 3.9, 3.10, and 3.11 describe the general construction assumptions for these projects. Section 3.12 presents related WSIP activities and their relationship to program components addressed in this PEIR. Section 3.13 outlines actions and approvals that could be required for the WSIP and the relationship to required actions and approvals for individual facility improvement projects.

[Since publication of the Draft PEIR, the SFPUC determined that it would like the option to consider approval and implementation of a variation of the WSIP called the "Phased WSIP Variant," which the SFPUC ultimately adopted. Please refer to Section 13.4, Phased WSIP Variant (Vol. 7, Chapter 13), for a description of this variation compared to the proposed program described in this chapter.]

3.2 Regional Location

3.2.1 Facilities

The SFPUC regional water system consists of a complex network of facilities covering a geographic range of about 167 miles across Central California, from the Sierra Nevada on the east to San Francisco on the west, as shown in **Figure 3.1**. The regional water system crosses seven counties—Tuolumne, Stanislaus, San Joaquin, Alameda, Santa Clara, San Mateo, and San Francisco. The existing facilities, location, and operations of the regional system are described in more detail in Chapter 2. The general location of the regional water system facilities, from east to west, is described below. A more detailed description of jurisdictions affected by proposed facility improvement projects is provided in Section 3.8, below.

The regional water system starts with three reservoirs and dams in Tuolumne County: Hetch Hetchy Reservoir/O'Shaughnessy Dam, Lake Eleanor/Eleanor Dam, and Lake Lloyd/Cherry Dam. Hetch Hetchy Reservoir and Lake Eleanor are located within Yosemite National Park. The system crosses into Stanislaus National Forest through about 30 miles of tunnels, regulating reservoirs, and hydropower facilities, passing south of the town of Groveland and through the town of Moccasin. The Hetch Hetchy Aqueduct continues in Foothill Tunnel to the San Joaquin Valley. At the western border of Tuolumne County, the 16-mile Foothill Tunnel connects to the three San Joaquin Pipelines at Oakdale Portal.

Starting in Tuolumne County for about the first mile, the San Joaquin Pipelines extend across Stanislaus County and end 47 miles later in San Joaquin County. These pipelines are almost entirely buried as they cross the San Joaquin Valley, passing south of the towns of Oakdale and Riverbank, through the city of Modesto, and under State Highway 99 and the San Joaquin River. South of the city of Tracy, the system crosses into San Joaquin County, over the Delta-Mendota Canal and California Aqueduct, and under Interstates 5 and 580. The San Joaquin Pipelines end at Tesla Portal, located just west of Interstate 580 in San Joaquin County. At Tesla Portal, the Hetch Hetchy system continues for 25 miles in the Coast Range Tunnel through the Diablo Range and crosses into Alameda County. The Coast Range Tunnel ends at Alameda East Portal in the Sunol Valley, where the Hetch Hetchy system connects to the Sunol Valley facilities.

The Sunol Valley facilities are located in Alameda and Santa Clara Counties. The Alameda East Portal connects the western end of the Coast Range Tunnel directly to the three buried Alameda Siphons. The Alameda Siphons traverse the valley about one-half mile, extending from the Alameda East Portal to the Alameda West Portal. In this valley, the Alameda Siphons also connect to pipelines that travel south to the Sunol Valley Water Treatment Plant (WTP) in Alameda County and continue south to Calaveras Reservoir, which lies in both Alameda and Santa Clara Counties. There are also pipelines traveling north from the Alameda Siphons to San Antonio Reservoir in Alameda County. The SFPUC has maintenance facilities farther north, just west of the town of Sunol, and isolated facilities serving customers in the Pleasanton and Niles Canyon areas. From the Alameda West Portal, the system connects to the 3.5-mile-long Irvington Tunnel, which passes through the Fremont Hills and ends at Irvington Portal in the city of Fremont in Alameda County, where it connects to the four Bay Division Pipelines.

SFPUC Water System Improvement Program . 203287

Figure 3.1
SFPUC Water System, Regional Location Map

The Bay Division Pipelines Nos. 1 and 2 extend about 22 miles through Fremont and Newark, continue across San Francisco Bay to San Mateo County, and pass through the cities of East Palo Alto, Redwood City, Menlo Park, and Atherton. Starting in Fremont, the Bay Division Pipelines Nos. 3 and 4 extend 34 miles around the bay, passing into Santa Clara County and through the cities of Milpitas, San Jose, Santa Clara, Sunnyvale, Mountain View, Los Altos, and Palo Alto; these two pipelines continue into San Mateo County and through the cities of Menlo Park, Atherton, Woodside, and Redwood City. With the exception of aboveground segments on the east and west side of the bay shoreline and on trestle bridges across the bay, the Bay Division Pipelines are almost entirely underground. The four Bay Division Pipelines connect again at the Pulgas Portal just west of Redwood City. From there, the system continues north up the Peninsula through San Mateo County via a network of tunnels, pipelines, pump stations, valve lots, reservoirs, and one treatment plant. The system crosses through the Peninsula towns of Belmont, San Mateo, Hillsborough, Burlingame, Millbrae, San Bruno, South San Francisco, Brisbane, and Daly City until it reaches San Francisco. The terminal reservoirs in the regional water system are located in San Francisco (SFPUC, 2004a).

3.2.2 Water Service Area

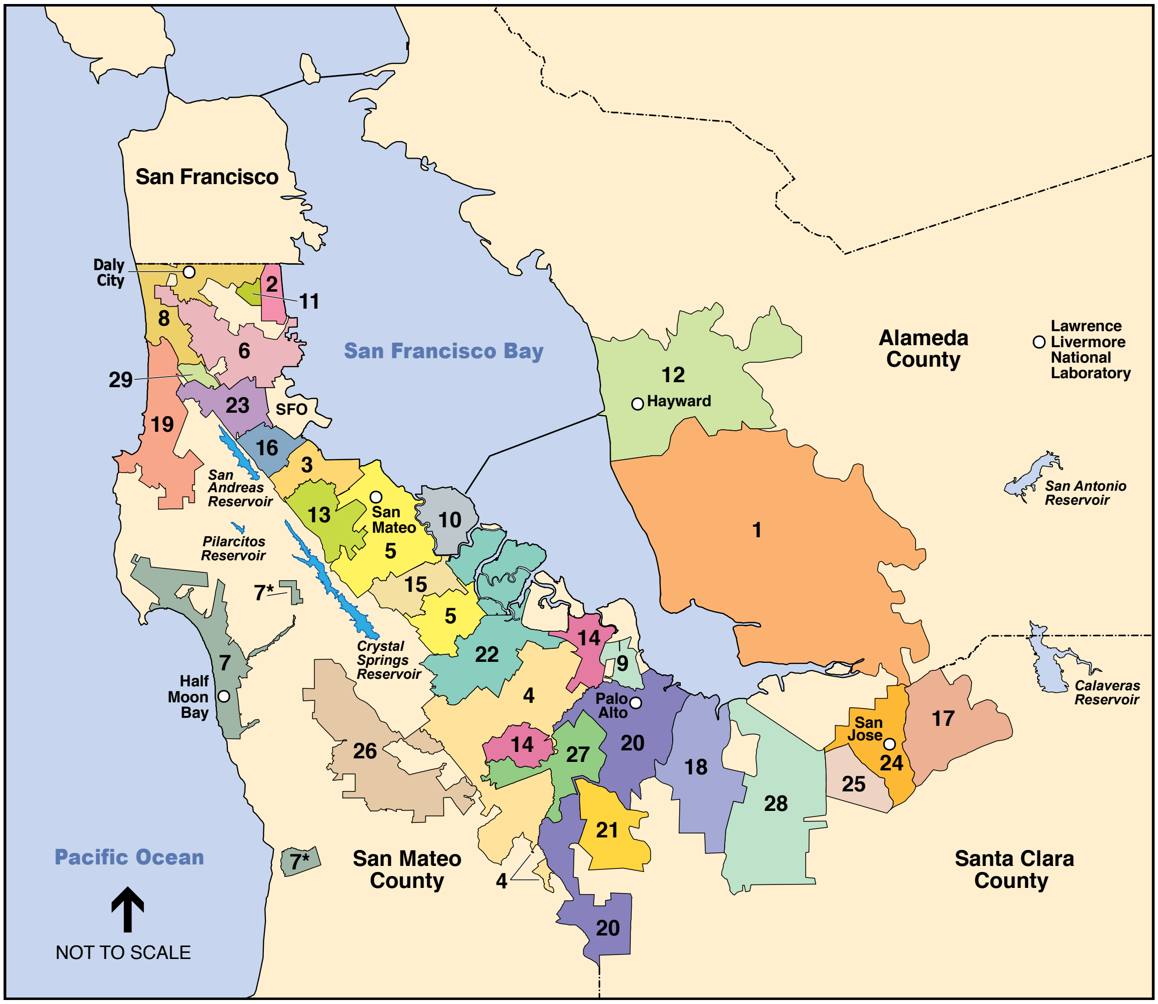
The SFPUC provides water delivery services to retail and wholesale customers, primarily in San Francisco, San Mateo, Santa Clara, and Alameda Counties, as shown in **Figure 3.2**. The SFPUC serves about one-third of its water supplies directly to retail customers in San Francisco, and about two-thirds of its water supplies to wholesale customers by contractual agreement. The wholesale customers are represented by the Bay Area Water Supply and Conservation Agency (BAWSCA) and consist of 27 total customers[11]: 25 cities and water districts plus Stanford University and one private utility. Some of these wholesale customers have other sources of water in addition to what they receive from the SFPUC regional system. The SFPUC also provides service to some isolated regional wholesale and retail customers along the water system, including customers in Tuolumne County. **Table 3.1** lists the major regional system customers and indicates the customers that receive water supplies from sources other than the SFPUC.

3.3 Need for and Objectives of the Program

The need for the WSIP is predicated on the basic mission of the SFPUC, which is in part:

> To serve San Francisco and its Bay Area customers with reliable, high-quality and affordable water, while maximizing benefits from power operations and responsibly managing the resources entrusted to its care (SFPUC, 2002)

[11] There are 28 wholesale customers identified in the 2004 SFPUC studies. Since the time of those studies, one of the wholesale customers, Los Trancos County Water District, was purchased by California Water Service Company, reducing the SFPUC wholesale customer count to 27.



Legend

(Wholesale customers and members of Bay Area Water Supply and Conservation Agency)

1 Alameda County Water District
2 City of Brisbane
3 City of Burlingame
4 CWS – Bear Gulch
5 CWS – Mid-Peninsula
6 CWS – South San Francisco
7 Coastside County Water District
8 City of Daly City
9 City of East Palo Alto
10 Estero Municipal Improvement District
11 Guadalupe Valley Municipal Improvement District
12 City of Hayward
13 Town of Hillsborough
14 City of Menlo Park
15 Mid-Peninsula Water District
16 City of Millbrae
17 City of Milpitas
18 City of Mountain View
19 North Coast County Water District
20 City of Palo Alto
21 Purissima Hills Water District
22 City of Redwood City
23 City of San Bruno
24 City of San Jose (North)
25 City of Santa Clara
26 Skyline County Water District
27 Stanford University
28 City of Sunnyvale
29 Westborough Water District

* Portions of Coastside County Water District not served by the SFPUC regional water system.

NOTE: For the purposes of this PEIR, the California Water Service (CWS) Company is a single wholesale customer with three different water service districts.

City of San Bruno*	City of Mountain View*	Town of Sunol (Alameda County)
Coastside County Water District*	City of Palo Alto*	Groveland Community Services District (Tuolumne County)
Estero Municipal Improvement District (Foster City)	City Redwood City*	
North Coast County Water District	City of San Jose (North San Jose Service Area)*	
Town of Hillsborough	City of Sunnyvale*	
Westborough County Water District	City of Santa Clara*	
	City of East Palo Alto	
	Purissima Hills Water District	
	Skyline County Water District	
	Stanford University*	

* Indicates customers that currently receive additional water supplies from sources other than the SFPUC.

a Not shown on the table because they are not a BAWSCA member, the Cordilleras Mutual Water Association is also a wholesale customer receiving water from the SFPUC. It is a small water association serving 18 single-family homes located in San Mateo County.

b Menlo Park receives all of its water supply from the SFPUC; however, a portion of the supply is obtained indirectly from the SFPUC through purchases from East Palo Alto (BAWSCA, 2006).

SOURCES: CDM, 2005; URS, 2004a.

While the SFPUC has historically met and is currently achieving its mission, there are numerous factors contributing to the need for a comprehensive, systemwide program such as the WSIP. In order to continue to reliably meet this mission in the future, the SFPUC must plan for future needs as well as address existing, known deficiencies. The proposed program would address these needs and deficiencies, including:

- *Aging Infrastructure*. The SFPUC regional water system is old. Many of its components were built in the 1800s and early 1900s; parts of the system were built using now-outdated construction materials and/or methods and are currently in need of major repair. As the system ages, its reliability decreases and the risk of failure increases.

- *Exposure to Seismic and Other Hazards*. The 167-mile-long system crosses five active earthquake faults. Many of the SFPUC system components are located on or in the immediate vicinity of major earthquake faults. Due to the age of the system, many facilities do not meet modern seismic standards. To protect public safety, the California Department of Water Resources, Division of Safety of Dams (DSOD) has imposed operating restrictions on Calaveras and Crystal Springs Reservoirs, reducing the local storage capacity and impairing normal system operations; this storage capacity needs to be restored (see Section 2.2 for discussion of the current operating restrictions on these dams).

- *Maintain Water Quality*. The regional system currently meets or exceeds existing water quality standards. However, system upgrades are needed to improve the SFPUC's ability to continue to maintain compliance with current water quality standards and to meet anticipated future water quality standards under a range of operating conditions, including such events as a major earthquake, without reducing system reliability (see Chapter 2, Section 2.4, for a discussion of water quality regulations that apply to the system).

- *Improve Asset Management and Delivery Reliability*. In order to implement a feasible asset management program in the future that will provide continuous maintenance and repairs to facilities, the system requires redundancy (i.e., backup) of some critical facilities necessary to meeting day-to-day customer water supply needs. Without adequate redundancy of critical facilities, the SFPUC has limited operational flexibility in the event of an emergency or a system failure, as well as constraints on conducting adequate system inspection and maintenance.

- *Meet Customer Water Demands*. Water demand among SFPUC customers is predicted to increase over the next 25 years. Additional supplies are needed to satisfy current demand in drought years and projected 2030 demand in all years. The experience of the last 150 years of record as well as recent studies on California's climate show the region is susceptible to droughts. Two of the biggest droughts occurred during the past 30 years. The regional system currently has insufficient water supply to meet customer demand during a prolonged drought, and this situation will worsen in the future.

To address these challenges to the reliability of the water system, the SFPUC must replace or upgrade numerous components of the system and add some new components—thus the need for the WSIP and its associated facility improvement projects.

[Additional discussion on the need for the program was prepared in response to comments on the Draft PEIR. Please refer to Section 14.1, Master Response on WSIP Purpose and Need (Vol. 7, Chapter 14).]

3.3.1 Program Goals and Objectives

The WSIP goals and objectives were developed based on a planning horizon through 2030. The SFPUC selected the year 2030 because published population projections generally do not extend beyond 20 to 25 years, and the agency determined the 2030 forecasts to be the most reasonably foreseeable future condition. The goals and objectives are founded on two fundamental principles pertaining to the existing regional system: (1) maintaining a clean, unfiltered water source from the Hetch Hetchy system, and (2) maintaining a gravity-driven system.

The overall goals of the WSIP for the regional water system are to:

- Maintain high-quality water and a gravity-driven system
- Reduce vulnerability to earthquakes

- Increase delivery reliability
- Meet customer water supply needs
- Enhance sustainability
- Achieve a cost-effective, fully operational system

To further these program goals, the WSIP includes objectives that address system performance. **Table 3.2** presents these objectives as they relate to the WSIP goals. The system performance objectives describe and, in many cases, more specifically quantify, what the regional water system proposes to achieve under the WSIP, and thereby guide the water supply actions, facility improvements, operations, and maintenance requirements included in the WSIP.

TABLE 3.2
WSIP GOALS AND OBJECTIVES

Program Goal	System Performance Objective
Water Quality – *maintain high water quality*	• Design improvements to meet current and foreseeable future federal and state water quality requirements. • Provide clean, unfiltered water originating from Hetch Hetchy Reservoir and filter all other surface water sources. • Continue to implement watershed protection measures.
Seismic Reliability – *reduce vulnerability to earthquakes*	• Design improvements to meet current seismic standards. • Deliver basic service to the three regions in the service area (East/South Bay, Peninsula, and San Francisco) within 24 hours after a major earthquake. Basic service is defined as average winter-month usage, and the performance objective for the regional system is 229 million gallons per day (mgd). The performance objective is to provide delivery to at least 70 percent of the turnouts (i.e., water diversion connecting points from the regional system to customers) in each region, with 104, 44, and 81 mgd delivered to the East/South Bay, Peninsula, and San Francisco regions, respectively. • Restore facilities to meet average-day demand of 300 mgd within 30 days after a major earthquake.
Delivery Reliability – *increase delivery reliability and improve the ability to maintain the system*	• Provide operational flexibility to allow planned maintenance shutdown of individual facilities without interrupting customer service. • Provide operational flexibility to minimize the risk of service interruption due to unplanned facility upsets or outages. • Provide operational flexibility and system capacity to replenish local reservoirs as needed. • Meet the estimated average annual demand of 300 mgd for 2030 under the conditions of one planned shutdown of a major facility for maintenance concurrent with one unplanned facility outage.
Water Supply – *meet customer water needs in nondrought and drought periods*	• Meet average annual water purchase requests of 300 mgd from retail and wholesale customers during nondrought years for system demands through 2030. • Meet dry-year delivery needs through 2030 while limiting rationing to a maximum 20 percent systemwide reduction in water service during extended droughts. • Diversify water supply options during nondrought and drought periods. • Improve use of new water sources and drought management, including use of groundwater, recycled water, conservation, and transfers.
Sustainability – *enhance sustainability in all system activities*	• Manage natural resources and physical systems to protect watershed ecosystems. • Meet, at a minimum, all current and anticipated legal requirements for protection of fish and other wildlife habitat. • Manage natural resources and physical systems to protect public health and safety.
Cost-effectiveness – *achieve a cost-effective, fully operational system*	• Ensure cost-effective use of funds. • Maintain gravity-driven system. • Implement regular inspection and maintenance program for all facilities.

SOURCE: SFPUC, 2006a.

Therefore, as described in detail below, the SFPUC conducted extensive studies leading to the development of the proposed program to increase the reliability of the regional water system. For the purposes of this PEIR, the term “reliability” is used to encompass a host of system parameters affecting water delivery, including those related to both physical facilities and water supply sources. System parameters related to the reliability of physical facilities could include physical or hydraulic capacity, physical or operational redundancy (i.e., backup systems), operational flexibility, facility vulnerability, and likelihood of failure. System parameters related to the reliability of water supply sources could include water quality considerations, vulnerability to hydrologic and meteorological conditions, and regulatory/institutional considerations. While the numerous system parameters affecting reliability are not interchangeable, they are all interrelated, and an improvement in any of the parameters affecting reliability would result in an improvement in the overall reliability of the system. The SFPUC developed the WSIP to address the need to provide comprehensive improvements to all aspects of system reliability.

3.4 Background and Development of the WSIP

Public awareness of the need for major capital improvements became evident in 2002 with the passage of three related legislative actions. Propositions A and E, passed in November 2002 by San Francisco voters, approved financing for San Francisco’s portion of the multi-billion-dollar water system improvements. Assembly Bill No. 1823 (AB 1823), the Wholesale Regional Water System Security and Reliability Act, also approved in 2002, required the City and County of San Francisco (CCSF) to adopt a capital improvement program designed to restore and improve the regional water system and to review and update the program as necessary (see Chapter 2, Section 2.4, for further description of this act). The SFPUC developed the Long-Term Strategic Plan for Capital Improvements in May 2002 (SFPUC, 2002) to address these requirements and then proceeded with a series of planning and engineering studies that form the foundation of the WSIP as currently proposed.

The SFPUC began planning for major system improvements over a decade ago and has conducted numerous planning and engineering studies of the regional system with respect to its vulnerability, reliability, performance, operations, water supply, watershed management, and water quality. The SFPUC primarily used three models in the development of the scope of the WSIP facility improvement projects, including determining the appropriate performance objectives and level of service goals. The three models—reliability, hydraulic, and hydrologic models—are described below, followed by descriptions of the major planning studies utilizing these models in the development of the WSIP.

- *Reliability Model*. The SFPUC used this statistical model to evaluate the ability of the system to meet identified targets when subjected separately to earthquakes on the San Andreas, Hayward, and Calaveras faults, as well as to quantify system risk. The model is comprised of two parts: a probabilistic model used to assess the baseline conditions for the existing and improved systems, and a deterministic model used to evaluate system recovery. For the deterministic model, the following events were used: (1) magnitude 7.9 earthquake on the San Andreas fault, (2) magnitude 7.3 earthquake on the Hayward fault, and (3) magnitude 6.9 earthquake on the Calaveras fault. The model employs the most likely value for failure of system components when subjected to the earthquake hazard for the selected scenario. The SFPUC used this model to compare system facilities under both existing and improved conditions, each under a range of operating scenarios (Parsons-CH2MHILL, 2005; Parsons, 2006). Depending on the model run, the "improved conditions" represented various conceptual stages of improvement projects included in the WSIP.

- *Hydraulic Model*. The SFPUC used this model to determine transmission pipeline and tunnel capacities, which were then used as input to the hydrologic model (see description below) to analyze system operations under existing and potential alternative future conditions. This model uses a simulation software package to simulate and analyze water distribution systems, and has been refined, enhanced, calibrated, and validated on many parts of the regional system. The SFPUC used it to analyze the hydraulic characteristics of the existing water system and to assist in determining facility sizing, given assumptions about requirements for operations and maintenance (Parsons-CH2MHILL, 2005).

- *Hydrologic Model*. The SFPUC used this model (also referred to as the Hetch Hetchy/Local Simulation Model, HH/LSM, or the water supply model) to simulate the monthly operation of all major water transmission and storage facilities in the regional water system. It was used to depict system operation under existing conditions and predict various alternative future conditions using historical hydrology for the 82-year period from July 1920 to September 2002. The model was also used to evaluate drought periods to establish system firm yield[12] capabilities, levels of rationing required, water transfer needs, and reservoir storage requirements. The model can also be used to assess the effects on system reliability under different conditions, including water supply sources, levels of conservation, operational criteria, transmission and storage facilities, and hydrologic conditions (Parsons-CH2MHILL, 2005).

3.4.1 Water Supply Studies

In 2000, the SFPUC prepared the *Water Supply Master Plan* (SFPUC, 2000) as a guidance document to address the future water supply needs for the SFPUC service area. This study recommended a water resource strategy of demand management, facilities improvements, and development of additional water supplies. Building on the analysis conducted for the *Water Supply Master Plan*, the SFPUC expanded and updated the evaluation of water supply sources as part of development of the WSIP, including review of additional water supply opportunities that had developed since preparation of the master plan. The *Water Supply Options* report (SFPUC, 2007a) presents the most current evaluation of water supply options and describes the SFPUC's proposed water supply option for the WSIP, as described in Section 3.6.

Using information developed in the *Water Supply Master Plan*, the *Water Supply Options* report reviewed seven categories of potential sources of supply for addressing SFPUC system needs through 2030. The SFPUC evaluated various water supply alternatives formulated from these categories based on facilities requirements, costs, environmental effects, water quality impacts, and institutional and regulatory issues. The evaluation determined that system capacity improvements were required regardless of the alternative. The *Water Supply Master Plan* evaluated the following seven categories of potential sources:

---

[12] System firm yield is the average annual water delivery that can be sustained throughout an extended drought.

- *Tuolumne River opportunities*—potential opportunities to increase the amount of Tuolumne River water diverted under existing water rights as well as through transfers from senior water-rights holders or increased storage under existing water rights.

- *Delta opportunities*—potential to acquire water from willing sellers located south of the Delta who possess water rights or contractual entitlements, including State Water Project contractors and Central Valley Project contractors. Alternatively, water could be purchased from willing sellers upstream of the Delta on the Sacramento, Feather, or Yuba Rivers, which would require an increase in Delta export pumping. However, this category of sources had many regulatory constraints.

- *Neighboring non-Delta, non-Tuolumne River opportunities*—potential to acquire water supplies through arrangements with neighboring agencies that are either near or adjacent to the SFPUC service areas or near major SFPUC storage or conveyance facilities. However, this category of sources had limited availability, since most of these agencies are projecting dry-year shortages similar to those expected for the SFPUC system.

- *Local opportunities*—potential to increase the yield of the Alameda and Peninsula system, including expansion of existing reservoirs, construction of new reservoirs, and implementation of groundwater banking programs.

- *Desalination opportunities*—potential to develop desalination facilities using San Francisco Bay water to produce potable water and connecting these facilities to the SFPUC system.

- *Recycled water opportunities*—potential to use recycled water for nonpotable uses to reduce SFPUC customer demands for deliveries from the SFPUC system.

- *Demand management*[13] *opportunities*—potential to reduce existing and future customer demand through conservation measures.

Additional water supply option analysis conducted by the SFPUC, and documented in the *Water Supply Options* report, confirmed the conclusion of the *Water Supply Master Plan* that the preferred strategy for meeting future SFPUC regional water system demand in normal and wet years is to implement additional Tuolumne River diversions under its existing water rights augmented by demand management activities, and to pursue water transfers on the Tuolumne River for meeting dry-year needs. However, the SFPUC determined that additional evaluation was required to identify the proposed water supply option for the WSIP. In particular, the SFPUC identified other options requiring further study to determine their feasibility to meet dry-year demand. These additional dry-year options included:

- Various regional water supply options through the Bay Area Blending Evaluation / Bay Area Water Quality and Supply Reliability Program (a program funded by CALFED that examined multiple regional water supply options involving seven Bay Area water agencies, including the SFPUC). The concepts that were considered to have potential dry-year benefits for the SFPUC system included: an enlarged Los Vaqueros Reservoir; an enlarged Calaveras Reservoir; a desalination plant in the East Bay that would produce potable water

[13] Demand management is the management of water supplies through activities that reduce the demand for water by altering water use practices, improving efficiency in water use, reducing losses of water, reducing waste of water, altering land management practices, and/or altering land uses. Demand management programs include water conservation, drought rationing and rate incentive programs.

from saline groundwater in the Newark Aquifer; a desalination project in Santa Clara County proposing up to three desalination plants to treat brackish groundwater for either potable or nonpotable uses; enhanced conservation implemented by individual agencies combined with additional regional conservation activities; and various recycled water projects and concepts.

- Storage in the Semitropic Water Storage District's groundwater bank near Bakersfield. Under this option, during wet years, the SFPUC would deliver Tuolumne River water to the Semitropic Groundwater Bank using the California Aqueduct, and in dry years, the SFPUC would receive water through the Semitropic Water Storage District's allocations of water from the State Water Project via the Delta and South Bay Aqueduct. The SFPUC also considered indirect participation in this program through current Bay Area partners, including the Santa Clara Valley Water District, Alameda County Flood Control and Water Conservation District Zone 7, and Alameda County Water District via Delta exchange.

- Westside Groundwater Basin conjunctive use, in which, during wet years, the SFPUC would provide regional system water to wholesale customers who would otherwise obtain water from the Westside Groundwater Basin in northern San Mateo County. This would allow the basin to naturally recharge during wet years, and, during dry years, those users would rely on groundwater and reduce their use of regional system water.

- Bay Area Regional Desalination Project involving four Bay area water agencies, including Contra Costa Water District, East Bay Municipal Utility District, Santa Clara Valley Water District, and the SFPUC, to explore the feasibility of developing a regional desalination plant to produce potable water for both drought and nondrought years.

The SFPUC analyzed and screened the above water supply options based on a combination of institutional, legal, technical, operational, environmental, and cost criteria. The screening analysis resulted in the retention of some options for further analysis and the elimination of others from further study. The following dry-year options were retained for further analysis: additional Tuolumne River supplies through transfers from the Turlock Irrigation District (TID) and/or Modesto Irrigation District (MID), demand management, recycled water and local groundwater programs, Westside Basin conjunctive use, and regional desalination(SFPUC, 2007a). These options are included either as part of the preferred WSIP water supply option described in this chapter or as part of the variants or alternatives discussed in Chapters 8 and 9 of this PEIR. The SFPUC eliminated the remaining options from further consideration due to institutional and technical feasibility issues. Further review of these options is provided in Chapter 9 of this PEIR to consider their potential as CEQA alternatives.

In addition to water supply sources, the water supply studies also examined drought-related strategies for meeting customer demand during extended periods of below-normal rainfall/snowmelt. As described in Chapter 2, Section 2.3.5, the regional system has experienced drought periods in the last 30 years, most notably the droughts from 1976 to 1977 and from 1987 to 1992. After the 1987–1992 drought, the SFPUC reevaluated and modified its operating procedures. As part of these modifications, the SFPUC developed a "design drought" to use in its system planning and adopted a Water First Policy to guide regional system operations (see Chapter 2, Section 2.3.4).

"Design drought" is a planning and operation tool that water supply agencies use to define a reasonable worst-case drought scenario based on known hydrology in order to establish design and operating parameters for the water system. Droughts more severe than the design drought would cause failure of supply within the water system. For purposes of regional water system planning, the SFPUC uses a design drought that anticipates and plans for a more severe drought than historical events and evaluates the system firm yield assuming the system is experiencing the design drought. Studies suggest a 30 percent chance that the SFPUC system will experience a drought in the next 75 years equal to or more severe than the 1987–1992 drought, which was the most extreme recorded drought event to affect the regional system. The WSIP uses a design drought based on the hydrology of the six years of the worst historical drought (1987–1992) plus the 2.5 years of the 1976–1977 drought, for a combined total of an 8.5-year design drought sequence (SFPUC, 2007a).

During a dry period, there is reduced inflow to the regional system's reservoirs, and maintaining water deliveries to customers is highly dependent on the amount water utilized from storage in the reservoirs. During a prolonged drought, the water delivered to customers exceeds inflow to the reservoirs, and the volume of water held in storage is continually depleted. In developing the water supply and drought-related goals for the WSIP, the SFPUC used the design drought along with customer demand projections to develop system firm yield requirements for 2030. (System firm yield is the average annual water delivery that can be sustained throughout an extended drought.) In addition to identifying options for acquiring additional water supply in dry years, the SFPUC also examined demand management and rationing as part of its drought planning strategy.

Current plans for drought response include a 20 percent rationing allocation, as established in the *Interim Water Shortage Allocation Plan* and the *Retail Water Shortage Allocation Plan* (described in Chapter 2, Section 2.3.5). In January 2005, the SFPUC staff presented two system rationing scenarios to the SFPUC commissioners for consideration: 10 and 20 percent maximum rationing during any given year of a drought. As described below, the Commission selected the 20 percent maximum systemwide[14] reduction in water service during drought periods for further study.

This systemwide level of 20 percent rationing translates into different percentages of allocation adjustments for each individual SFPUC customer. These percentages are dependent on the allocation plans mentioned above as well as further agreements among the wholesale customers. SFPUC wholesale customer allocation adjustments for a 20 percent systemwide rationing scenario could range from 12 to 40 percent for individual customers.

14 This rationing objective applies to the regional system as a whole, meaning overall system deliveries could be reduced by a maximum of 20 percent in any one year; this systemwide level of rationing could affect deliveries to specific sectors (turnouts) of the regional system differently, and individual customers could experience delivery reductions of more or less than 20 percent during a 20 percent systemwide reduction.

3.4.2 System Performance Studies

The SFPUC conducted extensive engineering analyses and studies regarding individual facilities and overall system performance to guide development of the facilities improvement program. A detailed assessment of regional system facilities was conducted from 1995 to 2006 to evaluate the vulnerability and reliability of the system. Using a statistical risk-based approach, the studies examined hazards and deficiencies at existing facilities, assessed their reliability, and determined the risk to the overall system (SFPUC, 1995; SFPUC, 2004b). The studies identified a range of conditions and deficiencies that could affect the reliability of critical system facilities, including hazards such as earthquakes, landslides, flood, fire, and general wear and tear. The SFPUC determined that the primary risks to its facilities are associated with seismic hazards as well as normal operating wear and tear. During this time, the SFPUC used the results of these studies to develop the capital improvement program in response to the AB 1823 requirements described above. The capital improvement program included numerous facility improvement projects that address the identified system deficiencies, particularly with respect to aging infrastructure and seismic hazards.

From 2004 through 2006, the SFPUC conducted system assessment and performance analyses of the WSIP (formerly known as the capital improvement program) with respect to the seismic and delivery reliability of the system over a range of operating conditions (SFPUC, 2004c; SFPUC, 2004d; Parsons, 2006). Using guidance from the SFPUC commissioners in January 2005, the system assessment developed level of service objectives for seismic and delivery reliability of the regional system on the basis of the following criteria:

- *Seismic Reliability*
  - Delivery after a major earthquake—how much can the system deliver after a major earthquake?
  - Percentage of turnouts that receive water—what percentage of the turnouts in each customer group will receive water after an earthquake?
  - Post-earthquake recovery—how much will the system be able to deliver 30 days after an earthquake?
- *Delivery Reliability*
  - Maintenance conditions—when key facilities are shut down for planned maintenance, how much can the system deliver without interrupting customer service?
  - Delivery during a Hetch Hetchy water quality event—how much can the system deliver when the quality of Hetch Hetchy water does not meet the requirements for unfiltered water sources[15] and filtration of all water sources is required prior to delivery to customers?
  - Delivery impacts due to unplanned outages—does the system have enough redundancy to allow for unplanned facility outages?

15 Water from Hetch Hetchy Reservoir can sometimes fail to meet the requirements for filtration avoidance, such as during storm events in the Sierra Nevada, which can lead to turbidity levels exceeding standards.

The seismic analyses were based on three earthquake scenarios: magnitude 7.9, 7.3, and 6.9 events on the San Andreas, Hayward, and Calaveras faults, respectively. For the seismic reliability assessment, delivery was evaluated on a customer group basis, and delivery to individual turnouts within a customer group could vary. The three customer groups in the service area consisted of the South Bay (Alameda/Santa Clara/southern San Mateo County), Peninsula (northern San Mateo County), and San Francisco.

The delivery analysis was used to evaluate the operational flexibility and redundancy within the system under reasonably foreseeable conditions, and evaluated three types of plausible scenarios. The planned maintenance scenarios assumed one planned shutdown of any one facility combined with an unplanned pipeline leak or break on either the San Joaquin or Bay Division Pipelines. Delivery during a Hetch Hetchy water quality event assumed that average-day demand could be met without the Hetch Hetchy source, or by treating part of the Hetch Hetchy source in addition to other supplies. In order to minimize risk of delivery due to unplanned outages under day-to-day conditions, the analysis evaluated the delivery capability with one source—Hetch Hetchy, Sunol Valley WTP, or Harry Tracy WTP—out of service.

Preliminary results indicated that the existing system would fail to meet seismic and delivery level of service objectives under most operating conditions, and that the performance of the system would decline in the future if no improvements were made. The studies also modeled how the regional system would perform with implementation of a program of facility improvement projects, and results demonstrated significant improvement in system performance under all operating conditions. The studies identified specific improvement projects and helped shape the scope of the facility improvement projects that are now proposed as part of the WSIP. Final results of the system assessment studies showing system performance with implementation of the proposed program are presented below in Section 3.5.

3.4.3 Operations Studies

Concurrent with the system performance studies, the SFPUC developed regional water system operations plans (CDM, 2005; URS, 2006a). These documents address operating goals, strategies, and constraints with respect to water supply and storage, water quality, and water delivery. Information from these studies was largely incorporated into the WSIP and is described further below in Section 3.7.

3.4.4 Water Demand Studies

From 2002 to 2006, the SFPUC, in collaboration with its wholesale customers and BAWSCA, conducted comprehensive planning studies to assess future water demands as well as the potential for water conservation programs and the use of recycled water to offset demand for potable water supplies in its retail and wholesale customer service areas. These studies, which provided a basis for 2030 water purchase estimates from the SFPUC regional water system, include the following:

- SFPUC Wholesale Customer Water Demand Projections (URS, 2004a)
- SFPUC Wholesale Customer Water Conservation Potential (URS, 2004b)

- SFPUC Wholesale Customer Recycled Water Potential (RMC, 2004)
- City and County of San Francisco Retail Water Demands and Conservation Potential (Hannaford and Hydroconsult, 2004)
- City and County of San Francisco Recycled Water Master Plan (RMC, 2006)
- SFPUC 2030 Purchase Estimates Technical Memorandum (URS, 2004c)

The studies indicate that total demand in 2000/2001 in the entire SFPUC service area from all water sources was about 366 million gallons per day (mgd). Of that total demand, about 261 mgd was purchased from the SFPUC regional water system. SFPUC wholesale customers met the balance of their supply needs from other water sources and conservation. The projected total service area demand in 2030 is approximately 417 mgd,[16] of which approximately 300 mgd would be purchased from the SFPUC system. The remaining 117 mgd would be met through other supply sources available to customers, primarily water purchases from other agencies, customers' local groundwater sources, additional water recycling, and conservation. Each customers' estimates of conservation savings and the use of recycled water, groundwater, and other supply sources as well as its 2030 purchase estimate is shown in **Table 3.3**. **Table 3.4** compares the 2030 estimated purchases to actual 2001 purchases of the wholesale and retail customers.

Demand Projection Methodology

This section summarizes the key steps involved in projecting 2030 water demand, upon which the estimates of 2030 purchases from the SFPUC regional water system are based. Following completion of the above studies, each wholesale customer submitted its estimate of 2030 purchases from the SFPUC regional system, taking into account water savings from ongoing and planned conservation programs and planned use of other water supply sources. The SFPUC also developed its estimate for the retail service area. These 2030 purchase estimates provide the basis for the WSIP water supply and delivery reliability objectives. A full description of the methodology used to forecast future water demand and assess conservation and recycled water potential is provided in the reports referenced above. Appendix E, Section E.2, of this PEIR also provides a detailed summary of the water demand forecasting methodology and results.

End-Use Demand Model

Future water demand projections for both retail and wholesale customers were developed using end-use demand models that break down total water use, by water service account, to specific end uses such as toilets, faucets, and irrigation. Projections for the wholesale service area were developed in close consultation with the wholesale customers, who provided critical inputs to the demand models and subsequently submitted statements concurring with the demand projections.

[16] Total 2030 demand (417 mgd) includes expected savings due to compliance with existing plumbing codes, which contain efficiency requirements. Total SFPUC service area demand without plumbing code savings is estimated at 453 mgd.

TABLE 3.3
SUMMARY OF WATER SUPPLY ASSUMPTIONS AND 2030 DEMAND PROJECTIONS

	A	B	C	D	E	TOTAL	
Customer	2030 Purchase Estimates (mgd[a])	2030 Projected Conservation Savings (mgd[a])	2030 Projected Use of Groundwater Sources (mgd[a])	2030 Projected Use of Other Surface Water Sources (mgd[a])	2030 Projected Use of Recycled Water (mgd[a])	Total 2030 Supply (mgd[a])[b]	2030 Projected Demand (with Plumbing Code Savings) (mgd[a])

Total, Wholesale Service Area[l]	**204 – 209**	**13 – 15**	**39 – 42**	**53**	**9 – 10**	**323 – 325**	**324**
SFPUC Retail Service Area[l,m]	**80 – 91**	**0 – 4**	**3 – 5**	**0**	**0 – 4**	**93 – 94**	**93**
TOTAL[l,n]	**284 – 300**	**13 – 19**	**42 – 47**	**53**	**9 – 14**	**417**	**417**

NOTES: 1. Numbers may not sum due to rounding.
2. The SFPUC serves one additional Bay Area wholesale customer, Cordilleras Mutual Water Users Association, which did not participate in the study because it is a finite group (18 single-family homes) with minimal usage (4,600 gallons per day, or 0.0046 mgd). As indicated in Table 3.1, Cordilleras Mutual Water Users Association is not a member of BAWSCA.

a mgd = million gallons per day.
b Total assumes low-range purchase estimate plus high-range value of other supply sources, and high-range purchase estimate plus low-range value of other sources, where a range was provided.
c CWS = California Water Service Company.
d CWS–Bear Gulch District includes the former Los Trancos County Water District.
e The upper range purchase estimate assumes loss of all local water sources (surface water and groundwater) and the lower range estimate assumes continuation of local sources; both estimates assume Level B water conservation.
f The purchase estimate range reflects a range of potential groundwater usage, established under a pilot project, from the sustainable yield (3.76 mgd) to the lowest annual production yield (1.34 mgd) according to Daly City's best estimate of 2030 water purchases (SFPUC, 2004e).
g 2030 conservation savings is based on URS 2004b and the City's UWMP as confirmed by the City (Popp, 2007).
h 2030 demand and conservation savings are based on information provided by the City of Palo Alto to the SFPUC (City of Palo Alto, 2005).
i In November 2005, Redwood City informed the SFPUC that it would be purchasing its low-range estimate of 11.6 mgd due to anticipated implementation of 1 mgd of recycled water in 2030(City of Redwood City, 2005). The high-range purchase estimate total of 300 mgd published in URS 2004c remains the SFPUC 2030 purchase estimate total for planning purposes, to be consistent with the previous and ongoing WSIP studies. The purchase estimate range originally submitted apparently reflects the average of the City's estimated conservation range plus the originally estimated range of recycled water use.
j Portion of north San Jose only.
k Demand and purchase estimates are based on Westborough Water District's 2005 UWMP, as requested by the district in a letter to the SFPUC (Westborough Water District, 2007). The UWMP discusses ongoing and planned future demand management programs but does not quantify conservation savings in relation to the demand and purchase estimate. The District's original estimate of water purchases indicated conservation savings of 0.020 mgd (SFPUC, 2004e).
l All totals have been rounded to the nearest 1 mgd.
m The low range of the SFPUC retail customer purchase estimate reflects the identified groundwater, recycled water, and conservation programs totaling 10 mgd in San Francisco that are included as part of the WSIP proposed water supply option.
n The single value for total supply assumes the low-range purchase estimate plus high-range value of other sources, and the high-range purchase estimate plus low-range value of other sources (i.e., both approaches round to 417 mgd).

Subtotal, Wholesale Customers	171	204 – 209	34 – 38
Retail Customers	90	80 – 91	-10 – 1
Total, SFPUC Regional Water System Customers	**261**	**284 – 300**	**24 – 39**

NOTES: 1. Numbers may not sum due to rounding.
2. One additional wholesale customer, Cordilleras Mutual Water Users Association, did not participate in the study because they are a finite group (18 single-family homes) with minimal usage (4,600 gallons per day).

a Wholesale customer that currently receives water supplies from sources other than the SFPUC, including local groundwater, local surface water, recycled water, and other sources of supply.
b CWS = California Water Service Company
c Wholesale customer that currently receive water supplies from other sources but projects receiving only SFPUC water by 2030 (assuming the high-range purchase estimate where a range is given).
d The former Los Trancos County Water District is now part of CWS–Bear Gulch District; information presented here reflects information in background reports (URS, 2004a; URS, 2004c).
e In November 2005, Redwood City informed the SFPUC that it would be purchasing its low-range estimate of 11.60 mgd due to anticipated implementation of 1 mgd of recycled water in 2030. The high-range purchase estimate total of 300 mgd published in URS 2004b remains the SFPUC 2030 purchase estimate total for planning purposes, to be consistent with the previous and ongoing WSIP studies.
f Portion of north San Jose only.
g Menlo Park purchased 96 percent of its 2001/2002 supply directly from the SFPUC; the balance of its 2001/2002 purchases also came from the SFPUC regional system, but was purchased from East Palo Alto. Menlo Park projects that it will purchase all of its 2030 supply directly from the SFPUC.

SOURCES: URS, 2004c; City of Redwood City, 2005; Westborough Water District, 2007.

To develop projections of future water demand in the wholesale customer service area, the SFPUC employed a model called the Decision Support System (DSS) model. The DSS model involves breaking down existing water use by customer type (residential or nonresidential) into detailed water end uses,[17] and then uses population and employment projections to develop residential and nonresidential account growth rates for projecting future water demand by end use. Water demand projections for the SFPUC retail service area were developed using a similar end-use model. The retail model, however, used composite employee water use rates (gallons per employee per day) with Association of Bay Area Governments (ABAG) industry-specific employment projections to project nonresidential water demand (rather than using employment forecasts to develop nonresidential account growth rates). The SFPUC selected the end-use models over other forecasting methods (e.g., forecasting water use by land use type in gallons per acre per day or on a simple per capita basis) because they allow for a more accurate representation of changing conditions, such as the future impact of plumbing and appliance codes and the effects of additional specific-use planned conservation (URS, 2004a).

Existing Water Demand

A key first step in water demand forecasting is developing accurate estimates of existing water demand (i.e., base-year conditions). Establishing base-year conditions for the end-use models entailed the following steps:

- Selecting the appropriate base year
- Developing water-use data
- Calibrating end uses for that year

The demand projection studies were initiated in the fall of 2002. The year 2001 was selected as a representative base year for the wholesale customer service area because water use data in 2001 showed less influence of the recession than did 2002 data, and because 2001 was a typical year in terms of rainfall. (Complete data were not available for 2003 since the wholesale customer demand study was undertaken that year.) The year 2000 was used as the base year for the SFPUC retail service area demand study because this year provided the best available data.

Customer billing data, along with published information on demographics and housing stock from sources such as the California Department of Finance and U.S. Census Bureau, were used to develop base-year water use, by end use, and plumbing fixture conditions. Base-year parameters, such as the average number of water users per household and per nonresidential account and the percentage of non-water-efficient toilets, were estimated for each service area.

[17] For example, for single-family and multifamily residential customers, water use was subdivided into indoor and outdoor use and then estimated for up to eight indoor end uses (e.g., toilets, showers, faucets, baths, clothes washers, etc.) and up to five outdoor end uses (e.g., irrigation, pools, etc.).

Projecting Future Demands

Once base-year conditions were estimated, the models were set up to project future water use through 2030. Account growth rates were developed for residential and nonresidential accounts using published population and employment projections, respectively. Each wholesale customer was asked to select the published population projection source to be used for its service area, and was asked to ensure that the employment and population projections were based on land use plans relevant to its service area. Most (19 of 30 wholesale customer entities[18]) selected *Projections 2002*, ABAG's current projections series at the time. Other wholesale customers selected from among the following sources: Annual Survey conducted by BAWSCA (known as the Bay Area Water Users Association [BAWUA] when the surveys cited were conducted) (3 customers); urban water management plans (3 customers); selected city planning sources (2 customers); another service area planning study (1 customer); a draft general plan (1 customer), and a water master plan (1 customer). Citywide planning estimates were used for the SFPUC retail service area population projections. *Projections 2002* was used as the source of employment projections for most of the SFPUC wholesale customers and was used in developing nonresidential demand for the retail service area.

Conservation Potential

As part of the modeling effort, the SFPUC also evaluated future water conservation potential in the wholesale and retail service areas (Hannaford and Hydroconsult, 2004; URS, 2004b). The evaluation considered the effects of implementation of existing plumbing code requirements for conservation practices on existing and future water users and continuation of existing conservation practices, as well as additional indoor and outdoor conservation measures for residential and non-residential customers that could feasibly be implemented. In the wholesale service area, the total water savings potential ranged from about 7.7 mgd to 19.6 mgd in 2030, not including the 25.4-mgd savings from effects of the plumbing codes. In the SFPUC retail service area, the total water savings potential ranged from about 0.64 mgd to 4.45 mgd in 2030, not including the 10.3-mgd savings from effects of the plumbing codes.

Although it is difficult to quantify water savings resulting from existing or historical conservation programs, substantial and sustained decreases in per-capita water demands were observed following the 1976–1977 and 1987–1992 droughts (of approximately 26 percent in the wholesale customer service area and over 22 percent in the retail service area) (RMC, 2003). The low range of conservation potential noted above represents the forecasted 2030 water savings associated with a continuation of the conservation measures currently being implemented. The high range of conservation potential presented above represents the outer range of feasible and cost-effective conservation programs.

[18] There are 27 wholesale customers that are members of BAWSCA; however, the background studies consider the three California Water Service Company districts and the former Los Trancos County Water District (now part of CWS–Bear Gulch District) as distinct entities.

Recycled Water Potential

The SFPUC evaluated recycled water potential by considering existing recycled water programs, plans to expand uses in the future, and the amount of potable water that could potentially be offset by future recycled water uses. The studies indicated that there is a range of about 47 to 53 mgd in potential for recycled water use in the wholesale and retail service areas, including current plus additional uses through 2020 (RMC, 2004). The *Recycled Water Master Plan* (RMC, 2006) assesses the technical feasibility of recycled water projects in the westside area of San Francisco; it identifies projects with the potential to provide approximately 6.2 mgd of recycled water to irrigate Golden Gate Park, Lincoln Park, Harding Park, the San Francisco Zoo, San Francisco State University, and other locations, as well as provide a supplemental water supply for Lake Merced. The first phase of projects identified in the report would provide 4.1 mgd of recycled water to this area (RMC, 2006). These San Francisco projects are included in the total SFPUC service area recycled water potential of 47 to 53 mgd in 2020 (RMC, 2004). It should be noted, however, that during the project planning and design phase of recycled water projects, the recycled water potential of specific users will be refined and could potentially be reduced. As such, it is assumed that 100 percent of these specific users' demand represents an offset in potable surface water supplies and that could be met by other appropriate sources of alternative water supply such as groundwater and/or stormwater if recycled water is deemed inappropriate for the specified use (SFPUC, 2008a).

[Additional discussion on the demand projections, conservation, and recycling assumptions was prepared in response to comments on the Draft PEIR. Please, refer to Section 14.2, Master Response on Demand Projections, Conservation, and Recycling (Vol. 7, Chapter 14) and to Section 15.4, Response SI_PacInst, responses to the letter from Pacific Institute (Vol. 7, Chapter 15).]

Purchase Estimates

Upon completion of the demand, conservation, and recycled water studies, the wholesale customers and the SFPUC (for the retail service area) submitted their best estimates of purchases from the SFPUC regional system in 2030. The purchase estimates incorporate the customers' expected 2030 conservation savings (shown in Table 3.3). As the table indicates, some customers provided an estimated range of purchases. The high-range estimate of 300 mgd was used for planning purposes to establish the delivery reliability and water supply objectives for the proposed program, as described below.

3.4.5 Draft Water System Improvement Program

From October 2004 to January 2005, the SFPUC held a series of public workshops to present the results of the planning and engineering studies conducted for the development of the proposed program. At the final workshop, the SFPUC Commission established guidance on the proposed performance standards and levels of service to serve as the basis for WSIP (described in Section 3.3). The SFPUC staff incorporated the performance standards and levels of service selected by the Commission into the proposed program and completed the *Water System*

Improvement Program in February 2005 (SFPUC, 2005a). This document was submitted to the San Francisco Planning Department for preparation of this PEIR, and a follow-up report documenting the proposed program in response to AB 1823 legislation was completed in March 2005 (SFPUC, 2005b). Following development of the level of service objectives published in the February 2005 report, the SFPUC continued to conduct technical and engineering assessments to evaluate and refine the program as needed. The Commission adopted refinements to the WSIP in November 2005, and the SFPUC completed a revised WSIP program description (SFPUC, 2006a) along with the required AB 1823 report (SFPUC, 2006b) in January 2006. These program description documents, together with supplemental information on the facility improvement projects and the proposed water supply option developed by the SFPUC (SFPUC, 2007a), provide the basis for the proposed program analyzed in this PEIR.

3.4.6 WSIP Project Refinement and Other WSIP Components

In addition to presenting the WSIP goals and objectives (described in Section 3.3), the draft WSIP program description issued in January 2006 included 34 facility improvement projects in five regions plus two systemwide projects; it focused on regional projects and did not include the San Francisco (local) projects to be funded through the WSIP bond measure. Since that time, the SFPUC has continued to develop and refine the WSIP projects identified in 2006. This refinement has resulted in the minor reclassification of some proposed facility improvement projects as well as identification by the San Francisco Planning Department of some regional projects that could proceed independently of projects and actions included in the PEIR. As explained earlier, for budgeting purposes, the SFPUC classifies as part of the WSIP all projects and actions that are or will be funded through the 2002 voter-approved bond measure, including projects analyzed in this PEIR as well as other projects and activities.

The SFPUC has identified the following projects for funding through the WSIP bond measure; these projects are listed below in six categories:

A. **Key Regional Projects** considered as part of a program pursuant to CEQA requirements and authorizations and analyzed as a program in this PEIR (the reference to WSIP and WSIP project or facilities in the PEIR refers to these projects and activities).

1. Advanced Disinfection
2. Tesla Portal Disinfection Station
3. Lawrence Livermore Supply Improvements
4. San Joaquin Pipeline System
5. Rehabilitation of Existing San Joaquin Pipelines
6. Alameda Creek Fishery Enhancement
7. Calaveras Dam Replacement
8. Additional 40-mgd Treated Water Supply
9. New Irvington Tunnel
10. Sunol Valley Water Treatment Plant (SVWTP) – Treated Water Reservoirs
11. San Antonio Backup Pipeline
12. Bay Division Pipeline Reliability Upgrade
13. Bay Division Pipelines Nos. 3 and 4 Crossovers
14. Seismic Upgrade of Bay Division Pipelines Nos. 3 and 4 at Hayward Fault
15. Baden and San Pedro Valve Lots Improvements
16. Crystal Springs/San Andreas Transmission Upgrade
17. Harry Tracy Water Treatment Plant (HTWTP) Long-Term Improvements
18. Lower Crystal Springs Dam Improvements
19. Pulgas Balancing Reservoir Rehabilitation
20. San Andreas Pipeline No. 3 Installation
21. Local and Regional Groundwater Projects
22. Recycled Water Projects

The PEIR evaluates the SFPUC's proposed water supply option to meet its identified water delivery needs and, at a programmatic level of detail, the key regional facility improvement projects listed above that the SFPUC proposes to construct to meet system performance goals and level of service objectives. These projects are described in Table 3.10 and

Appendix C. In addition, where necessary, project-level CEQA review will be conducted for the facility improvement projects evaluated in this PEIR.

In Sections 4.17 and 5.7, the PEIR analyzes whether the other projects funded through the 2002 voter-approved bond funds that are listed below have the potential to contribute to cumulative impacts in combination with impacts associated with the facility improvement projects evaluated in the PEIR and other reasonably foreseeable future projects.

B. **Regional Projects** that are determined to be independent of the Program for CEQA purposes and are not analyzed as part of the program in this PEIR:

1. Alameda Siphons
2. San Antonio Pump Station Upgrade
3. Pipeline Repair and Readiness Improvements
4. Standby Power Facilities
5. BDPL Nos. 3 and 4 Crossover/Isolation Valve at Hayward Fault
6. SFPUC/EBMUD Intertie
7. Installation of SCADA System – Phase 2 & System Security Upgrades
8. Adit Leak Repair – Crystal Springs/Calaveras
9. Capuchino Valve Lot Improvements
10. Cross Connection Controls
11. New Crystal Springs Bypass Tunnel
12. HTWTP Short-Term Improvements
13. Crystal Springs Pipeline No. 2 Replacement
14. Sunset Reservoir Upgrades – North Basin
15. University Mound Reservoir Upgrades – North Basin

In September 2005, the Notice of Preparation (NOP) on the WSIP PEIR identified most of the projects listed above as projects that might undergo environmental review independent of and possibly in advance of the PEIR (refer to the NOP in Appendix A of this PEIR for brief descriptions of these projects). As a result of reclassification of projects and program refinement since the issuance of the NOP, the San Francisco Planning Department has determined that three other projects not listed in the NOP as such are appropriate for environmental review separate from the PEIR: Alameda Siphons (previously classified as part of the Irvington Tunnel project), San Antonio Pump Station Upgrade and Capuchino Valve Lot Improvements. The Planning Department is preparing or has completed environmental review for all of the projects listed above separate from the PEIR, and the SFPUC has already implemented some of the projects. The Planning Department has determined that these projects may appropriately proceed with environmental review in advance of completion of the WSIP PEIR for several reasons: (1) these projects are necessary irrespective of whether the SFPUC approves the overall WSIP goals and objectives or any other WSIP facility project; (2) construction of the particular project will not increase the normal operating or delivery capacity of the SFPUC's regional system, change the manner in which water is dispersed, increase the storage capacity of the system, or increase or alter the nature of any treatment capacity of the system; (3) these projects do not commit the SFPUC to any other WSIP project; and (4) any cumulative impacts associated with the individual project can be and are adequately addressed by the analysis in the individual environmental review documents. Although the independent utility projects may contribute to the overall reliability of the regional water system, the primary purpose of these projects is to rehabilitate existing facilities and provide flexibility for maintenance and emergency response.

Subsequent to Draft PEIR publication in June 2007 and based on more detailed project information, the San Francisco Planning Department determined that five additional regional WSIP projects, previously identified as Key Regional Projects in category A above, could appropriately proceed with environmental review independent of the WSIP PEIR: Rehabilitation of Existing San Joaquin Pipelines, BDPL Nos. 3 and 4 Crossovers, Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault, Baden and San Pedro Valve Lots Improvements, and Pulgas Balancing Reservoir Rehabilitation (all phases). Thus, these five additional projects have been determined to have independent utility from the overall program analyzed in the WSIP PEIR (SFPUC, 2008b) and can undergo environmental review independent of and possibly in advance of the PEIR.

C. **Local Projects** are located in San Francisco and would only affect the San Francisco component of the water system. These projects entail upgrades to pump stations, reservoir facilities, water transmission lines, and tanks in addition to other similar actions. Environmental review is complete for most of these projects, and many of the projects have been or are in the process of being implemented.

D. **WSIP-Related Activities**, including the Watershed Environmental Improvement Program, Habitat Reserve Program, and Regional Desalination Feasibility Project, which are described in Section 3.12 of this chapter, are in the preliminary planning phase and will be subject to separate CEQA review when they are further defined.

E. **Regional Recycled Water Projects** (note that these are different than the project #22, Recycled Water Projects, listed above under A). The SFPUC expects that some recycled water projects that would be located outside of San Francisco will be developed in coordination with other jurisdictions. As these projects are developed and designed, they will be reviewed to determine the appropriate lead agency and level of environmental review.

F. **Bay Division Pipeline No. 4 Slipline PCCP Sections – Condition Assessment** was identified in the draft 2006 WSIP and NOP as a pipeline rehabilitation project, but has since been redefined and is limited to the assessment of the condition of sections of Bay Division Pipeline No. 4 where vulnerable prestressed concrete cylinder pipe (PCCP) currently exists. No construction activities are proposed at this time. Physical work needed for the assessment, if any, is expected to be minimal and exempt from CEQA.

3.4.7 WSIP PEIR Components

As explained above, the program analyzed in this PEIR consists of the following: a proposed water supply option for both drought and nondrought periods; 22 key regional facility improvement projects, as listed above in Section 3.4.6; and a proposed system operations strategy that would incorporate the proposed facility improvement projects into the existing system and would allow the SFPUC to exercise the proposed water supply option as needed, either to serve dry-year needs or increases in customer purchase requests through 2030.

The proposed levels of service established to achieve the WSIP goals and service performance objectives are discussed below in Section 3.5. The proposed water supply option is presented in Section 3.6, followed by the proposed changes in system operations (Section 3.7). Sections 3.8 through 3.11 describe the key regional facility improvement projects analyzed in the PEIR for implementation under the WSIP, including the facility locations, components, and construction requirements.

3.5 Proposed Levels of Service to Achieve Program Objectives

The WSIP includes proposed levels of service for the regional water system, which are intended to further define the system performance objectives through 2030 and to provide design criteria for the facility improvement projects. The proposed levels of service address the following categories: water quality, seismic reliability, delivery reliability, and water supply. **Table 3.5** summarizes the proposed changes in levels of service with implementation of the WSIP as compared to existing conditions.

TABLE 3.5
EXISTING AND PROPOSED REGIONAL SYSTEM LEVELS OF SERVICE[a]

Operating Parameter	Existing Level of Service (2005)	Proposed Level of Service with WSIP (2030)
Water Quality	Meet all existing local, state, and federal water quality requirements	Meet all local, state, and federal water quality requirements in 2030
Seismic Response After Major Earthquake	Not defined	Provide basic service[b] of 229 mgd within 24 hours; average-day service of 300 mgd within 30 days
Delivery During System Maintenance	Not defined	Average-day demand of 300 mgd
Average Annual Water Supply	265 mgd	300 mgd[c]
Regional System Firm Yield[d]	219 mgd[d]	256 mgd
Drought-Year Rationing	No maximum limit to rationing	Up to 20 percent systemwide rationing

[a] Level of service flow rates are defined on a systemwide basis and are not specific to any customer turnout.
[b] Basic service is defined as winter-time delivery (estimated to be 229 mgd in 2030). The performance objective is to provide delivery to at least 70 percent of the turnouts in each region, with 104, 44, and 81 mgd delivered to the East/South Bay, Peninsula, and San Francisco regions, respectively (Parsons, 2006).
[c] Includes 10 mgd from conservation, recycled water, and groundwater supply programs in San Francisco.
[d] System firm yield is defined as the average annual water delivery that can be sustained by the regional water system during an extended drought. The SFPUC uses an 8.5-year design drought for planning purposes. Currently, due to operating restrictions imposed by the California Division of Safety of Dams on the Calaveras Dam in 2001, the system firm yield is reduced from its normal system firm yield of 226 mgd to about 219 mgd.

SOURCES: SFPUC, 2006a; Parsons, 2006.

3.5.1 Water Quality Level of Service

The purpose of the water quality level of service goals is to ensure compliance with all existing and anticipated federal, state, and local drinking water requirements as well as to provide systemwide watershed management. The regional system currently meets or exceeds existing water quality standards. Existing water quality requirements applicable to the regional system are summarized in Chapter 2, Section 2.4.

The WSIP includes provisions to enhance the SFPUC's ability to maintain compliance with water quality standards under a range of operating conditions, including catastrophic events such as a major earthquake. Projects are proposed to improve both of the regional treatment plants. In addition to supporting the objective of maintaining the filtration avoidance status for Hetch Hetchy water, ongoing/proposed system operations would include continued implementation of source water protection and systemwide watershed management and protection. The Watershed and Environmental Improvement Program (see Section 3.12 for further description) is a related WSIP activity that would further support these objectives.

In addition, implementation of the WSIP would allow the SFPUC to comply with the recently approved Long Term 2 Enhanced Surface Water Treatment Rule (approved in January 2006). The U.S. Environmental Protection Agency established this regulation to reduce disease incidence associated with *Cryptosporidium* and other pathogenic microorganisms in systems that use surface water. This rule includes requirements for all unfiltered systems to treat for *Cryptosporidium*, with the required degree of treatment depending on the source water contamination level. Dates for implementation of this rule depend on the size of the system as well as the source water conditions. The WSIP includes the Advanced Disinfection project (see Section 3.8 for further description) to address the requirements of this rule.

Proposed federal regulations that could affect the SFPUC in the future include the following (the date in parentheses indicates when the regulation was proposed):

- Proposed Ground Water Rule (August 9, 2000)
- Proposed Radon in Drinking Water Rule (November 2, 1999)

The SFPUC's current plans for developing groundwater supplies take into account the proposed Ground Water Rule (see Groundwater Projects, described in Section 3.8), and no significant modification of the WSIP groundwater projects would be needed in the event the rule is adopted. Specifically, the groundwater sources planned for development have been tested and are typically free of bacteria. Nonetheless, the SFPUC would disinfect (with chlorine) all groundwater prior to blending with regional system supplies and distribution to customers, thus adding an additional protective barrier. Furthermore, the SFPUC would conduct regular groundwater monitoring and implement a wellhead protection program to provide further protection. All of these activities would be consistent and ensure compliance with the proposed Ground Water Rule.

The proposed Radon in Drinking Water Rule applies only to systems using groundwater sources. Surface water systems are not affected. At this time, no significant modifications of the WSIP groundwater projects are expected in the event the rule is adopted. The SFPUC will coordinate closely with the U.S. Environmental Protection Agency and California Department of Health Services regarding the regulatory requirements associated with the Radon Rule, and their application to the WSIP groundwater projects, to ensure compliance.

Other water quality regulations of significance to the SFPUC could include the Stage 2 Disinfectants and Disinfection Byproducts Rule, Candidate Contaminant List, California Action Levels, and California Public Health Goals. The SFPUC will address these regulations as appropriate as part of its ongoing operations as well as to ensure consistency with the WSIP water quality levels of service.

3.5.2 Seismic Reliability Level of Service

The WSIP goal for seismic reliability is to reduce the regional system's vulnerability to earthquakes, thereby ensuring water service to customers within a defined period following a major earthquake. As described above in Section 3.4.2, the SFPUC conducted an extensive series of facility reliability and system performance studies, and presented the results to the SFPUC Commission during 2004 to 2005; in January 2005, the Commission selected the levels of service to be achieved under the WSIP.

To improve the seismic reliability of the regional system, critical facilities would be upgraded to meet current seismic standards, thereby improving their ability to withstand seismic damage and reducing the overall vulnerability of the system to earthquake damage. For planning purposes, the earthquake scenarios used to develop seismic upgrade criteria are the largest earthquakes likely to be generated on each of the three major faults—the San Andreas, Hayward, and Calaveras faults—as defined by the U.S. Geological Survey. The seismic upgrade criteria take into account how critical each facility is to the system in restoring customer service following an earthquake. The proposed program would establish seismic criteria appropriate to individual facilities to achieve the required level of seismic reliability in the most cost-effective manner (SFPUC, 2004a).

In addition to upgrading critical facilities to meet current seismic standards, the proposed level of service for seismic reliability addresses the ability of the SFPUC to restore disrupted service after an earthquake, as shown in Table 3.5. The WSIP would provide basic service to the service area within 24 hours after a major earthquake and average-day service within 30 days after a major earthquake. Basic service is defined as average, monthly winter usage, which is projected to be 229 mgd systemwide in 2030. This level of service was broken down for the three customer groups in the service area, with basic service levels of 104, 44, and 81 mgd established for the East/South Bay, Peninsula, and San Francisco regions, respectively. The system performance objective for this level of service is to provide delivery to at least 70 percent of the customer turnouts within each customer group. Assuming that resources, repair materials, and roadway access are available, this level of service would restore delivery of average-day demand to each customer group within 30 days after a major earthquake, which is estimated to be 300 mgd systemwide in 2030. To achieve this level of service, the proposed program includes provisions for redundant facilities, backup/standby power, and stockpiling of supplies/equipment to expedite emergency repairs.

Under the WSIP, the increased level of operational flexibility would also improve the system's overall ability to respond and restore service following an earthquake. As described below for water delivery reliability, the restored water storage capacity in the Bay Area reservoirs proposed under the WSIP would also provide increased seismic reliability for the system, since it would allow water service to resume more rapidly and reliably following a seismic event.

The SFPUC conducted a system assessment to evaluate and compare the performance of the existing system with that of the future system under the WSIP in terms of the system's ability to meet the level of service objectives for seismic reliability (Parsons, 2006). **Table 3.6** presents the results of the performance analysis. Although the model estimates have an estimated uncertainty of 10 percent, the results show a vast improvement in system performance with implementation of the WSIP in all categories. The model results indicate that a major earthquake on the San Andreas, Hayward, or Calaveras fault under existing conditions would result in a drastic disruption of service to all customer groups, and that the ability of the system to recover following an earthquake would be limited. A major earthquake on these faults would result in failure of critical facilities and prolonged outages; customers could be without service for more than 14 days and possibly more than 30 days. With construction and implementation of facility improvement projects under the WSIP, all level of service objectives for seismic reliability would be met or exceeded.

3.5.3 Delivery Reliability Level of Service

The water delivery reliability goal addresses the overall operations of the system with regard to its ability to deliver water to customers under a variety of operating conditions. The goal is to increase the reliability of the regional system to meet customer demand under a range of operating conditions, such as reservoir replenishment requirements during planned maintenance,

TABLE 3.6
SYSTEM ASSESSMENT FOR SEISMIC RELIABILITY LEVELS OF SERVICE[a]

Operating Parameter	WSIP Level of Service Objective[b]	Existing System Performance	Future System Performance with WSIP[c]
Delivery After a Major Earthquake, Total System			
San Andreas Fault	229 mgd	**<30 mgd**	267 mgd
Hayward Fault	229 mgd	**<30 mgd**	278 mgd
Calaveras Fault	229 mgd	**<30 mgd**	297 mgd
Percent of Turnouts Receiving Basic Service After a Major Earthquake, Total System			
San Andreas Fault	70%	**<10%**	79%
Hayward Fault	70%	**<10%**	92%
Calaveras Fault	70%	**<10%**	96%
Post-Earthquake Recovery, Delivery 30 Days After a Major Earthquake, Total System			
San Andreas Fault	300 mgd	**255 mgd**	463 mgd
Hayward Fault	300 mgd	**120 mgd**	463 mgd
Calaveras Fault	300 mgd	378 mgd	463 mgd

NOTE: Boldface type indicates scenarios that would fail to meet the level of service objective.

[a] The earthquake scenarios analyzed were: San Andreas fault—magnitude 7.9 event; Hayward fault—magnitude 7.3 event; Calaveras fault—magnitude 6.9 event.
[b] The level of service objective following a seismic event is defined as: (1) basic service equivalent to average winter-month demand, or 229 mgd, within 24 hours, and (2) average-day demand, or 300 mgd, within 30 days.
[c] Note that future performance indicates greater capacities under the WSIP than the level of service objective of 300 mgd. This is because facilities are sized to meet peak-day demand; 2030 peak-day demand is estimated to be 463 mgd.

SOURCE: Parsons, 2006.

unplanned outages, and loss of any one water source. As described above in Section 3.4.2, the SFPUC conducted an extensive series of facility reliability and system performance studies, and presented the results to the SFPUC Commission during 2004 to 2005; in January 2005, the SFPUC Commission selected the levels of service to be achieved under the WSIP, including measures of the reliability of the regional system to deliver water. As summarized in Table 3.5, the proposed system performance and level of service objective for delivery reliability is 300 mgd for 2030 under the following conditions:

- *Maintenance Conditions*. This scenario measures how much water the system can deliver when one key facility is shut down for planned maintenance at the same time that an unplanned outage occurs. SFPUC operations staff identified the following 12 key facilities affecting delivery reliability: the Harry Tracy and Sunol Valley WTPs; Coast Range, Irvington, Pulgas, and Stanford Tunnels; Crystal Springs Pump Station; Bay Division Pipeline No. 4; San Joaquin Pipeline No. 3; Crystal Springs Bypass Pipeline; San Andreas Pipeline No. 2; and the proposed Bay Division Pipeline No. 5 Tunnel. Although all facilities in the system require planned maintenance at some point, these 12 facilities were selected because they would have the most impact on deliveries during shutdown. Furthermore, it was determined that analyzing these 12 critical facility shutdowns would capture the most significant maintenance condition impacts (Parsons, 2006). The WSIP level of service objective was analyzed based on the shutdown of each of these 12 facilities for maintenance combined with one unplanned outage on one pipeline reach of the Bay Division or San Joaquin Pipelines.

- *Delivery During a Hetch Hetchy Water Quality Event*. This scenario measures how much water the system can deliver in the event of a Hetch Hetchy water quality event. During such an event, the system is required to supply up to 300 mgd of water for treatment at the Harry Tracy and Sunol Valley WTPs. The Harry Tracy WTP would treat a sustained capacity of 140 mgd from the Peninsula reservoirs, while the Sunol Valley WTP would treat a sustained capacity of 160 mgd from some combination of Hetch Hetchy and Alameda sources. System delivery during this type of event is not dependent on operating capacity in the San Joaquin Pipelines.

- *Delivery Impacts Due to Unplanned Outages*. This scenario measures the ability of the system to deliver water when one water source is unavailable. It examines the scenarios with either Hetch Hetchy water, Sunol Valley WTP, or Harry Tracy WTP out of service. The level of service objective is to achieve a systemwide delivery capacity of average-day demand with one water source unavailable.

The SFPUC conducted a system assessment to evaluate and compare the performance of the existing system with that of the future system under the WSIP in terms of the system's ability to meet the level of service objectives for delivery reliability (Parsons, 2006). **Table 3.7** presents the results of the performance analysis.

As indicated in Table 3.7, the regional system under existing conditions cannot meet comparable level of service targets for delivery under most scenarios analyzed. For planned maintenance conditions with one critical facility shutdown concurrently with one unplanned outage, the existing system could not meet average daily demand if any one of the following five critical facilities were shut down for maintenance: the Harry Tracy WTP, Sunol Valley WTP, Irvington Tunnel, Coast Range Tunnel, or Bay Division Pipeline No. 4. However, with implementation of the WSIP, the level of service objective of total system delivery of average-day demand (300 mgd) would be met for all of the critical maintenance conditions.

The system assessment also determined that the existing system would be unable to deliver the average annual demand to customers during a water quality event in the Hetch Hetchy supply for the full range of flow scenarios. Different flow rates were evaluated because system deficiencies vary depending on the flow rate. However, with implementation of the WSIP, the level of service objective of total system delivery of average-day demand (300 mgd) would be met or exceeded for all flow rates.

Delivery impacts due to unplanned outages were also evaluated as a measure of delivery reliability of the system. The system assessment showed that if there were an unplanned outage of the Hetch Hetchy supply under the existing system, the SFPUC could not meet customer demand, since the systemwide delivery capability would be limited to 243 mgd. With implementation of the WSIP projects, this delivery capability would increase to 313 mgd, surpassing the level of service objective.

TABLE 3.7
SYSTEM ASSESSMENT FOR DELIVERY RELIABILITY LEVELS OF SERVICE
(mgd)

Operating Parameter	WSIP Level of Service Objective[b]	Existing System Performance	Future System Performance with WSIP[c]
Delivery During Planned Maintenance with one critical facility shutdown and one unplanned outage[a]			
Harry Tracy WTP Shutdown	300	**273**	359
Sunol Valley WTP Shutdown		**273**	339
Irvington Tunnel Shutdown		**111**	463
Coast Range Tunnel Shutdown		**231**	313[e]
Pulgas Tunnel Shutdown		367	409
Bay Division Pipeline No. 4 Shutdown		**270**	405
San Joaquin Pipeline No. 3 Shutdown		313	421
Crystal Springs Pump Station Shutdown		350	436
Crystal Springs Bypass Pipeline Shutdown		379	463
San Andreas Pipeline No. 2 Shutdown		393	463
Stanford Tunnel Shutdown		344	463
Bay Division Pipeline No. 5 Shutdown[d]		N/A	409
Delivery During a Hetch Hetchy Water Quality Event			
Hetch Hetchy flow rate 70 mgd	300	**243**	313[e]
Hetch Hetchy flow rate 150 mgd		**213**	313[e]
Hetch Hetchy flow rate 230 mgd		**213**	313[e]
Hetch Hetchy flow rate 290 mgd		**213**	313[e]
Delivery Capacity Due to Unplanned Outages			
Hetch Hetchy outage	300	**243**	313[e]

NOTE: Boldface type indicates scenarios that would fail to meet the level of service objective.

a An unplanned outage is assumed to be the worst case of one reach of either the Bay Division or San Joaquin Pipeline out of service.
b The WSIP level of service objective for delivery reliability is defined as average-day demand, or 300 mgd.
c Note that future performance indicates greater capacities under the WSIP than the level of service objective of 300 mgd. This is because facilities are sized to meet peak-day demand; 2030 peak-day demand is estimated to be 463 mgd.
d One of the key regional facility improvement projects under the WSIP, the Bay Division Pipeline Reliability Upgrade.
e Based on completion of the Sunol Valley WTP, Harry Tracy WTP, groundwater/recycled water/conservation program, and partial delivery to Coastside County Water District from Crystal Springs Reservoir.

3.5.4 Water Supply Level of Service

The purpose of the SFPUC's water supply goal is to assure that the SFPUC has an adequate supply of water to deliver to customers during both nondrought and drought periods. For the purposes of this PEIR, the terms "nondrought period" and "drought period" are used as a simplified breakdown of the two basic hydrologic/meteorological conditions (a more detailed breakdown of hydrologic year types is provided in Chapter 5 of this PEIR). Most years are nondrought periods, which refers to typical years or sequences of years during which hydrologic/meteorological conditions can assure adequate SFPUC water supplies to fully meet customer purchase requests and to allow operation of the regional system in normal operating mode. Drought period refers to all other years or sequences of years, when hydrologic/ meteorological conditions indicate that water supplies may not be adequate and the SFPUC needs to modify its operating procedures and implement drought response actions.

The WSIP level of service objectives for water supply are: (1) to fully meet customer purchase requests in nondrought years through the planning year 2030, estimated to be 300 mgd average annual delivery, and (2) to provide drought-year delivery with a maximum systemwide cutback of 20 percent in any one year of a drought. As described in Section 3.4.4, above, the SFPUC, in conjunction with its wholesale customers, conducted extensive studies to determine water demand projections, conservation and recycled water potential, and the extent to which customers receive water supplies from sources other than the SFPUC. The studies ultimately resulted in water purchase estimates from the regional system in 2030, with the wholesale customers projected to purchase 209 mgd and the retail customers projected to purchase 91 mgd, or a total estimated purchase request of 300 mgd. This formed the basis for the water supply level of service for nondrought years.

With respect to drought-year supply, the proposed level of service is to limit rationing to a maximum of 20 percent systemwide in any one year. This corresponds to a required system firm yield of 256 mgd in 2030. System firm yield is the average annual water delivery that can be sustained throughout an extended drought. The SFPUC uses an 8.5-year design drought for planning purposes and for calculating system firm yield. The normal system firm yield is 226 mgd.[19] By 2030, with customer purchase requests of 300 mgd, the system firm yield needed to meet the WSIP goals and objectives to provide adequate water delivery in drought years is estimated to be 256 mgd—an increase of 30 mgd. (Under the current restricted operating condition that limits storage levels in Calaveras Reservoir, the system firm yield is 219 mgd, and an additional 37 mgd of system firm yield would be needed to meet the WSIP 2030 level of service objective of 256 mgd.) The proposed water supply option to meet the projected increase in water deliveries during nondrought and drought periods is described in Section 3.6, below.

3.5.5 Other Goals and Objectives

In addition to program goals in the areas of water quality, seismic reliability, delivery reliability, and water supply, Table 3.2 also lists program goals in the areas of sustainability and cost-effectiveness provided in the SFPUC's January 2006 WSIP description. The SFPUC has included these program goals as fundamental elements of the WSIP, although the WSIP does not establish quantitative levels of service for the sustainability and cost-effectiveness goals.

Enhancing sustainability is part of the SFPUC's ongoing watershed management and operational efforts and is not specifically or exclusively an element of the WSIP. The WSIP enhances sustainability by integrating and incorporating the sustainability objectives listed in Table 3.2 into each of the facility improvement projects. The SFPUC is also taking other actions indirectly related to the WSIP that support sustainability objectives, such as development of the Watershed and Environmental Improvement Program funded through WSIP bond financing (described further in Section 3.12, below, under WSIP Related Activities). The systemwide watershed management and enhancement activities are related to the water quality goals as well as to the overriding program principle of maintaining a clean, unfiltered water source from Hetch Hetchy

[19] Currently, due to operating restrictions imposed by the California Division of Safety of Dams in 2001 on the Calaveras Dam, the system firm yield is reduced from its normal system firm yield of 226 mgd to about 219 mgd.

Reservoir (see Chapter 2, Section 2.4, regarding the Surface Water Treatment Rule and Hetch Hetchy Reservoir) and maintaining a gravity-driven system.

Similarly, the WSIP integrates the cost-effectiveness goals listed in Table 3.2 in the planning, development, and design of facility improvement projects. The SFPUC has developed detailed preliminary cost information on the WSIP and its individual facility improvement projects, and the cost information is provided in the January 2006 program description (SFPUC, 2006a).

3.6 Proposed Water Supply Sources

To achieve the WSIP water supply level of service objectives to fully meet customer purchase requests in nondrought years through 2030 and to provide drought-year delivery with a maximum systemwide rationing of 20 percent, the WSIP's proposed water supply option specifies water sources during drought as well as nondrought periods. The proposed water supply option would serve the projected 35 mgd increase in average annual purchase requests through deliveries from the regional system and through conservation/recycled water/groundwater programs in San Francisco, while limiting customer rationing to a maximum of 20 percent systemwide in any one year.

SFPUC studies indicate that the SFPUC's existing water rights for the current water sources of the regional system in the Alameda, Peninsula, and Tuolumne River watersheds are sufficient to meet current and future water purchases in nondrought years, assuming restored storage capacity in the system's Bay Area reservoirs (SFPUC, 2007a). The SFPUC currently holds entitlements for sufficient water to meet 2030 purchase requests in nondrought years through increased Tuolumne River diversions that could supplement current Tuolumne River diversions and local watershed supplies. However, during drought periods, the SFPUC's existing water supply sources are insufficient to satisfy the WSIP water supply goal under 2005 purchase requests, and this shortage will become more severe by 2030 with the projected increase in purchase requests.

The facilities and facility improvement projects required to implement the proposed water supply option during both nondrought and drought periods are described in greater detail in Section 3.8 of this chapter. Key regional system facility improvements include: increasing SFPUC regional system transmission reliability and redundancy in the San Joaquin and Bay Division Pipelines; restoring full, historical storage capacity in the existing Crystal Springs and Calaveras Reservoirs; developing groundwater wells in San Francisco to supplement the regional water system as well as additional wells in northern San Mateo County to implement the regional groundwater conjunctive-use program; and constructing recycled water treatment facilities and associated distribution systems in San Francisco. Also needed is the implementation of a water recapture project on Alameda Creek, in accordance with the 1997 Memorandum of Understanding (MOU) between the SFPUC and the California Department of Fish and Game (CDFG), as described in Chapter 2, Section 2.3.4. The recapture project in itself would not increase the firm yield of the system; however, it is necessary to avoid the loss of yield since fishery releases from Calaveras Reservoir would be made as a part of the Calaveras Dam Replacement project and the recapture part would be conducted through the Alameda Creek Fishery Enhancement project (both are

WSIP facility improvement projects described in Section 3.8). In addition to these facility improvement projects, other WSIP facility improvement projects (also described in Section 3.8) would be needed to achieve the WSIP level of service performance objectives for water quality, seismic reliability, and delivery reliability the SFPUC has established for the regional system in nondrought and drought years.

3.6.1 Proposed Nondrought Water Supply

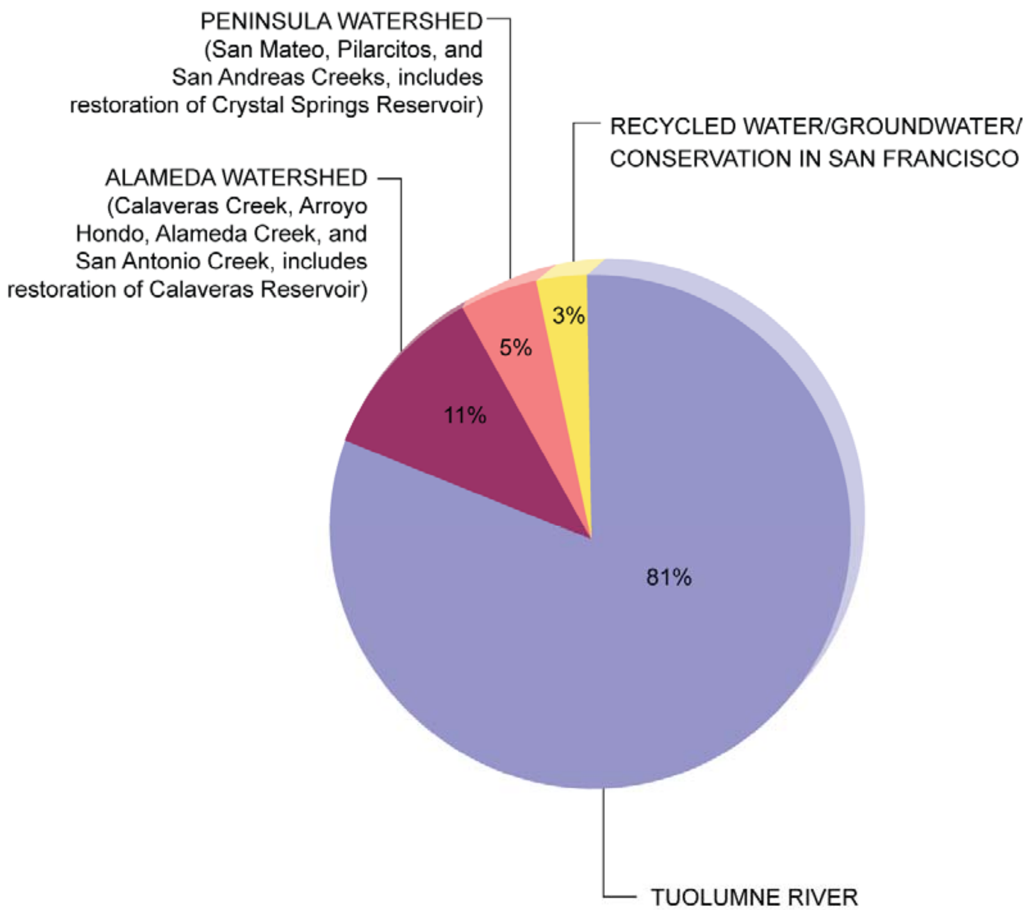
During years with nondrought conditions, the SFPUC proposes to meet the increased 35 mgd in purchase requests through a combination of conservation, water recycling, and groundwater supply programs in San Francisco and increased diversions from the Tuolumne River (SFPUC, 2007a).

Under the proposed WSIP water supply option, the SFPUC would implement conservation, water recycling, and groundwater supply programs in the SFPUC retail service area to achieve the equivalent of 10 mgd of supply every year, including nondrought and drought periods. The SFPUC has determined that 10 mgd of additional supply (including demand management) could be met within San Francisco alone with projects that have already undergone completed preliminary planning phases. These projects would consist of about 2 mgd of local groundwater development, 4 mgd of recycled water projects, and 4 mgd of additional water conservation measures, as described below:

- *Local Groundwater Projects*. One of the WSIP facility improvement projects described in Section 3.8 involves installation of new groundwater production wells in the North Westside Groundwater Basin (located on the west side of San Francisco) to provide an average annual 2 mgd of potable water to augment the regional system water supply sources.
- *Recycled Water Projects*. One of the WSIP facility improvement projects described in Section 3.8 includes treatment, storage, and distribution facilities to provide about 4 mgd of recycled water to irrigation users on the west side of San Francisco based on preliminary estimates of recycled water demand. However, due to ongoing planning efforts and demand projection refinements, the project sizes may be reduced to match the refined demands (SFPUC, 2008a).
- *Additional Conservation Measures*. The SFPUC has identified additional conservation measures to provide about 4 mgd not already included in the 2030 San Francisco retail water demand projections, as summarized in the *2005 Urban Water Management Plan for the City and County of San Francisco* (SFPUC, 2005c). The additional measures were identified as Package C in the *Retail Water Demands and Conservation Potential* (Hannaford and Hydroconsult, 2004) and would be implemented using funding from the SFPUC operating budget.[20] These programs would be in addition to plumbing code savings of 10 mgd already accounted for in the 2030 purchase request for the retail service area (Hannaford and Hydroconsult, 2004).

[20] The study entitled *San Francisco Retail Water Demands and Conservation Potential* (Hannaford and Hydroconsult, 2004) identified three conservation packages—Packages A, B, and C—based on the results of a benefit-cost analysis and identification of potential water conservation measures that either the SFPUC is currently implementing or other water agencies have considered or are currently implementing. Package A consists of the measures San Francisco is currently implementing, Package B includes all elements of Package A plus additional measures that reflect an expansion of the current conservation program, and Package C consists of Package B plus four additional measures. Package C represents an upper bound of conservation that is considered achievable and fundable. The reader is referred to that study for descriptions of specific conservation measures.

The SFPUC proposes to satisfy the remaining 25 mgd of increase in average annual purchase requests with increased use of Tuolumne River water under its existing water rights (see Chapter 2, Section 2.5.1, for discussion of CCSF water rights). The regional system would continue to maximize its use of local watershed water supplies. This increased level of diversions includes the additional deliveries needed to serve 2030 purchase requests as well as to maintain and maximize local storage for unplanned outages and drought needs. **Figure 3.3** depicts the various supply sources and their relative contributions of the proposed water supply option for typical years (nondrought).



Note: Water supply sources (average annual) based on 2030 conditions during nondrought conditions with 300 mgd in total customer deliveries and all WSIP facility improvement projects completed.

SFPUC Water System Improvement Program . 203287

Figure 3.3
WSIP Water Supply Sources, Nondrought Years

Although during nondrought years the SFPUC would be able to meet the increase in future purchase requests with its proposed conservation, water recycling, and groundwater supply programs and additional diversions from the Tuolumne River under existing entitlements, the nature of the proposed supplemental drought supplies would indirectly affect water supplies during nondrought years. For instance, implementation of a groundwater conjunctive-use program in the South Westside Groundwater Basin in San Mateo County would involve the use of regional system water in nondrought years to enable the storage of water from natural recharge for extraction during drought years. Also, the proposed water transfer agreement with TID and MID (described below) could be established to enable a transfer of water every year as an assurance, given the unpredictable nature of droughts in the region. These components of the proposed water supply option are further discussed in Section 3.6.2, below.

3.6.2 Proposed Drought Water Supply

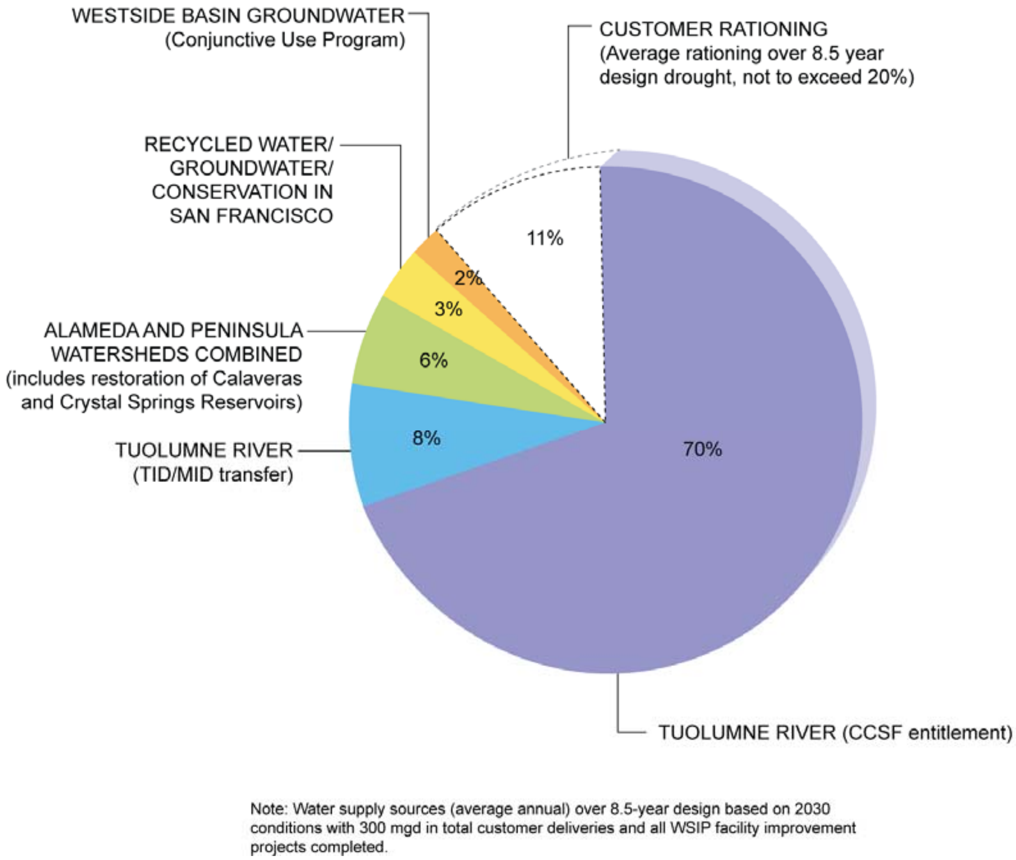
Although the SFPUC can meet projected 2030 water purchases of 300 mgd from existing local supplies combined with existing and increased Tuolumne River diversions in nondrought years, these sources alone have not allowed for full water deliveries during past droughts and cannot be solely relied upon in the future for water deliveries during potential future droughts. During a drought, the SFPUC proposes to serve the 2030 purchase requests, while limiting customer rationing to a maximum of 20 percent systemwide in any one year, with a combination of: (1) existing local watersheds and Tuolumne River resources; (2) conservation, water recycling, and groundwater supply programs in San Francisco (implemented in all years, both drought and nondrought); (3) water transfers; (4) groundwater conjunctive-use programs; and (5) restoration of storage at Crystal Springs and Calaveras Reservoirs (SFPUC, 2007a). **Figure 3.4** depicts the proposed WSIP drought-period water supply described above. The proposed supplemental water sources and estimated amounts that would be developed under the WSIP for use during drought periods to increase the system firm yield from the current 219 mgd[21] to the proposed 2030 level of service of 256 mgd, are described below:

- *Water transfers*. Utilize up to an equivalent of 26 mgd (annual average over 8.5-year design drought) of supplemental Tuolumne River water through water transfer agreements with TID and MID.

  [Additional discussion on the proposed dry-year transfer was prepared in response to comments on the Draft PEIR. Please refer to Section 14.3, Master Response on Proposed Dry-Year Transfer (Vol. 7, Chapter 14).]

- *Restoration of Calaveras and Crystal Springs Reservoirs capacities*. Restore Calaveras and Crystal Springs Reservoirs to historical operational capacities. Restore the historical operating storage capacity at Crystal Springs Reservoir by an equivalent of 1 mgd of water (annual average over 8.5-year design drought) and restore Calaveras Reservoir capacity to provide a equivalent of 7 mgd of water (annual average over 8.5-year design drought).[22] The restoration of reservoir capacities would occur through two of the WSIP facility improvement projects, Lower Crystal Springs Dam Improvements and Calaveras Dam Replacement, as described in Section 3.8.

[21] Currently, due to operating restrictions imposed by the California Division of Safety of Dams on the Calaveras Dam in 2001, the system firm yield is reduced from its normal system firm yield of 226 mgd to about 219 mgd.
[22] The 7 mgd of dry-year supply that would be provided by Calaveras Reservoir storage restoration has been considered in the normal system firm yield of 226 mgd.



SFPUC Water System Improvement Program . 203287

Figure 3.4
WSIP Water Supply Sources, Drought Years

- *Groundwater conjunctive use*. Utilize the extraction component of a groundwater conjunctive-use program in the Westside Groundwater Basin in northern San Mateo County to provide the equivalent of approximately 6 mgd of water (annual average over 8.5-year design drought) through one of the WSIP facility improvement projects, Regional Groundwater Projects, as described in Section 3.8.

In drought years, the SFPUC would implement a multistep drought response program. Under this program, the initial response to a drought would be to initiate the extraction component of the above-described groundwater conjunctive-use program and to continue to fully deliver customer purchase requests during the initial response stage. If drought conditions were to persist, the groundwater extraction would be augmented with the water transfer, which might be sufficient to defer any additional response actions. If necessary, in combination with the supplemental water supplies and within the WSIP goals for drought periods, the SFPUC would then implement up to 20 percent systemwide rationing.

The water transfer program would entail agreements with TID and MID for a supplemental water supply for the SFPUC. Although there are no agreements currently in place, the SFPUC is pursuing this approach with TID and MID. For the purpose of developing the WSIP water supply option, SFPUC assumed that water in excess of TID and MID needs would be made available annually to the SFPUC. Since the SFPUC cannot directly divert water out of Don Pedro Reservoir, the transfer would be made through a mechanism that credits water to the SFPUC's "water bank account" in Don Pedro Reservoir (see Chapter 2, Section 2.5.2, for description of the water bank account). Such a credit would reduce the obligation of the SFPUC to release water from Hetch Hetchy facilities for downstream capture in Don Pedro Reservoir for TID and MID under the Raker Act (see Chapter 2, Section 2.5.1). This reduction in release obligation would lead to additional water being retained in Hetch Hetchy Reservoir, thus increasing the storage available for diversion to the Bay Area to serve drought-year demands. Due to the unpredictable nature of hydrologic conditions and the uncertainties in predicting the timing and duration of drought periods, a pragmatic assumption for the transfer agreement is that the water would be made available to the SFPUC every year regardless of hydrologic conditions, and the payment for the transfer could be structured accordingly. Therefore, the proposed water supply option assumes that the transfer would occur every year, and only during drought years, the SFPUC would be able to retain the additional water in Hetch Hetchy Reservoir so that it would be available to serve customer demands. The proposed water supply option assumes that the water transfer has been sized to provide 27,000 acre-feet as an annual credit to the water bank account of the SFPUC. This transfer would equate to 23 mgd of delivery yield during drought years (average over design drought).

The proposed program includes a facility improvement project to restore Crystal Springs Reservoir capacity; this project would consist of major repairs and improvements to Lower Crystal Springs Dam to provide adequate protection from the probable maximum flood as well as the maximum credible earthquake (as described in Section 3.8). Due to DSOD operational restrictions on the dam, the current capacity of the reservoir is limited to 58,400 acre-feet. The project would restore the historical reservoir capacity of 69,300 acre-feet. This additional storage capacity, once filled with local watershed runoff or Tuolumne River diversions during nondrought years, would be available for use during drought years. When delivered, the additional volume of stored water would equate to an additional 1 mgd of delivery yield during drought years (average over design drought).

Similarly, the WSIP includes a facility improvement project to restore the historical capacity of Calaveras Reservoir through the construction and operation of a replacement dam that meets seismic safety requirements (as described in Section 3.8). Due to DSOD operational restrictions on the dam, the current capacity of the reservoir is restricted to 37,800 acre-feet, and the project would restore the historical reservoir capacity of 96,800 acre-feet. This additional storage capacity, once filled with local watershed runoff, would be available for use during drought years, providing an additional 7 mgd of delivery yield during drought years (average over design drought).

The groundwater conjunctive-use program would provide up to 8,100 acre-feet per year[23] of drought supply to the SFPUC. In nondrought years, the SFPUC would deliver water to customers in northern San Mateo County in excess of their purchase requests. This water would be used by customers “in-lieu” of the groundwater they would normally have pumped to meet part of their demand. The substitution of this pumping with additional SFPUC deliveries would offset groundwater pumping and allow water to be “banked” in the Westside Groundwater Basin aquifer through natural recharge. During a drought, the initial drought response of the SFPUC would be to initiate the extraction of this banked water by these same customers coincident with a reduction in their purchase requests. The total volume of water to be banked during a succession of nondrought years is estimated to be approximately 61,000 acre-feet. This additional volume of water available (storage) would equate to an additional 6 mgd of delivery yield during drought years (average over 8.5-year design drought).

3.7 Proposed System Operations Strategy

Operation of the regional water system is affected by numerous factors, including fluctuations in customer demands; hydrologic and meteorological conditions; physical facilities and infrastructure capacity and maintenance requirements; and multiple institutional parameters. The WSIP addresses the condition of the physical facilities and infrastructure while also planning for and taking into account customer demand, hydrologic/meteorological conditions, and institutional parameters. Under the WSIP, general day-to day operation of the regional water system would essentially remain unchanged, but implementation of the program would allow refinements to the operations strategy to meet the WSIP goals and objectives, thereby increasing system reliability and providing additional flexibility for scheduling repairs and maintenance. The regional system operations would continue to comply with the conditions of all applicable institutional and planning requirements, including:

- Complying with all water quality, environmental, and public safety regulations
- Maximizing use of water from local watersheds
- Assigning a higher priority to water delivery over hydropower generation
- Meeting all downstream flow requirements

The WSIP goals and objectives have resulted in system operating goals and strategies for 2030 (SFPUC, 2007a; CDM, 2005; Parsons-CH2MHILL, 2006). Under the WSIP, the system would be operated to meet the following objectives:

- Optimize use of available supplies by maximizing: (a) use of local resources, (b) carryover storage, and (c) local storage to provide system reliability
- Provide drinking water that meets all regulatory standards

[23] The conjunctive use program has been designed to provide an extraction capacity of approximately 8,100 acre-feet during a dry year, equivalent to about 7 mgd, over 7.5 years. While the initiation of the extraction component of the conjunctive use program would occur as the first response to anticipated drought, the realization of a drought does not typically occur until the second year of a dry sequence. Thus, in the 8.5-year design drought, the extraction component of the conjunctive use program would only occur for 7.5 years. Groundwater pumping of about 7 mgd over 7.5 years is approximately equivalent in volume to 6 mgd over 8.5 years.

- Reliably deliver water to meet the demand of San Francisco, other retail customers, and wholesale customers
- Maintain the regional water system for the benefit of its retail and wholesale customers
- Maintain a gravity-fed system, unfiltered Hetch Hetchy source water, and local filtered water sources

The operations strategy addresses four components of system operation: water supply and storage, water quality, water delivery, and asset management.

3.7.1 Water Supply and Storage Operations Strategy

General Operations

Operation of the water supply and storage aspects of the regional system would continue to be based on the need to ensure reliable, high-quality water to meet customer demand year-round and under a variety of conditions, and implementation of the WSIP would increase reliability and system performance to meet these program goals and objectives. The SFPUC would continue to integrate operation of the local system with that of the Hetch Hetchy system. Local storage system operations would be consistent with applicable regulatory and institutional requirements (described in Chapter 2, Sections 2.4 and 2.5), while balancing maximum use of local water sources, maintaining prudent carryover storage for drought supply, and maximizing storage of local supplies in Bay Area reservoirs.

The SFPUC would continue to operate the Hetch Hetchy system to conserve water from the Tuolumne River watershed for the consumptive domestic and municipal uses of its customers and the production of hydroelectricity, as authorized by the Raker Act (see Chapter 2, Section 2.4). In addition to serving domestic, municipal, and hydropower uses, the Hetch Hetchy system is operated to meet instream flow requirements and to augment flows for whitewater rafting, as described in Chapter 2, Sections 2.5.3 and 2.5.4 and below. The Raker Act requires that the SFPUC recognize the prior rights of TID and MID (see Chapter 2, Section 2.5.1) as well as comply with conditions of the U.S. Department of the Interior (DOI) for the protection of public lands (Raker Act, Section 4); the DOI conditions require minimum instream flow releases for fish and wildlife habitat. The FERC settlement agreement for the New Don Pedro Project (described below under Other Operational Considerations) requires the CCSF "to continue to work cooperatively with the organized and permitted recreational river users (rafters and kayakers) to schedule flows and to communicate daily flow schedules" (FERC, 1996). With implementation of the WSIP, the SFPUC would continue to operate the Hetch Hetchy system in compliance with instream flow requirements and in cooperation with recreational interests on the Tuolumne River. As described in more detail in Chapter 5, Section 5.3.1, system operations under the WSIP would result in a reduction in average monthly storage in Hetch Hetchy Reservoir and a delay in releases from O'Shaughnessy Dam to the Tuolumne River compared to existing conditions.

Local reservoirs in the Alameda and Peninsula watersheds would continue to be operated to maximize the use of local resources for annual water deliveries, drought supply, and emergencies.

Calaveras Reservoir would be restored to its historical operating capacity, and the DSOD restrictions would no longer constrain operations and storage; the SFPUC would generally return to its normal operating procedures, diverting flow from upper Alameda Creek through the Alameda Creek Diversion Tunnel to Calaveras Reservoir. Crystal Springs Reservoir would also be restored to its historical capacity, providing increased local storage. These reservoirs would continue to be operated to avoid releases that could harm SFPUC facilities or otherwise present risks to public health and safety. In general, the local reservoirs would be maintained at a higher level under the WSIP than under current practices in order to maintain and maximize local storage for unplanned outages or drought needs.

Under the WSIP, operation of the Sunol Valley WTP would be modified to take advantage of system flexibility that is not currently available. Under current operations, the SFPUC can filter diversions from the Tuolumne River at Sunol Valley WTP in limited quantities for limited time periods; however, this operation is not typical, since water from Hetch Hetchy does not require filtration. Under normal system operations, raw water from Calaveras Reservoir flows to the Sunol Valley WTP for treatment, and this water source is also used to supply the minimum flows needed to maintain filtration process operations at the WTP. However, with implementation of the WSIP, it is assumed that diversions from the Tuolumne River could be used to meet the minimum flow requirements at the Sunol Valley WTP so that water in Calaveras Reservoir can be maintained at a higher level, thus maximizing local storage for unplanned outages or drought needs.

Under the WSIP, other system improvements that would affect operations include the additional conveyance capacity in system facilities, such as the San Joaquin and Bay Division Pipelines, which would allow for implementation of a regular, planned maintenance schedule for critical facilities. The maintenance schedule would allow for planned outages for critical facilities, during which time the SFPUC would utilize redundant facilities to maintain system deliveries. Depending on the facility subject to maintenance and inspection, the SFPUC would adjust the normal system operation as needed in order to avoid disruption of service to customers.

Additionally, restoration of the historical capacity at Crystal Springs Reservoir would allow the reservoir to be operated with additional storage. Typical operations would be to fill the reservoir whenever possible within the cyclic operational storage goals of the system for maximum local reservoir and system storage.

Nondrought-Year System Operations

In nondrought periods with average or above-average rainfall and snowmelt conditions, the SFPUC proposes to meet the increased purchase requests of 35 mgd through 2030 with increased Tuolumne River diversions and 10 mgd of recycled water, conservation, and groundwater programs in San Francisco. The amount of diversion from the Tuolumne River would vary from year to year, and in some years, particularly after a dry period, a portion of the Tuolumne River diversions would be used to replenish local reservoirs. Under the WSIP, the local reservoirs in the Alameda and Peninsula watersheds would provide an average of about 16 percent of the total water supply, with the Hetch Hetchy system providing about 81 percent and recycled water, conservation, and groundwater programs in San Francisco providing the remaining 3 percent. Seasonal operation of diversions and the reservoir system would essentially continue as currently practiced, although the local reservoirs would generally be maintained at a higher level than under current conditions in order to maintain and maximize local storage for unplanned outages or drought needs.

As part of the WSIP, the SFPUC would utilize a groundwater conjunctive-use program in the Westside Groundwater Basin in northern San Mateo County. Under this program, wholesale customers in this area (such as Daly City, California Water Service Company, and San Bruno, which currently pump groundwater to meet a portion of their potable demand) would receive additional supplies from the regional system during nondrought years to offset their groundwater pumping, and would cease pumping and allow the aquifer to recharge naturally. In exchange, those customers would increase groundwater pumping during drought periods, thereby reducing the amount of their purchase requests during a drought and making more water available for serving regional water system demand.

Drought-Year System Operations

As described above in Table 3.5, the proposed level of service objective for water supply during a drought is to limit rationing to a maximum of 20 percent systemwide reduction in water service in any one year. The proposed WSIP facilities and operations strategy are designed to meet this level of service. Under the WSIP, in response to reduced water supply conditions, the SFPUC would manage drought-year supplies and water deliveries through implementation of a four-stage response program to ensure that water is delivered to customers continuously through the duration of the drought.

The first stage of response would be to implement water supply options specific to drought-year water conditions, namely the conjunctive-use program within the Westside Groundwater Basin and the TID and MID water transfer. As described above in Section 3.6.2, the groundwater conjunctive-use program in the Westside Groundwater Basin would be put into the extraction mode, with the participating customers substituting groundwater for a portion of their otherwise requested system delivery. During this first stage of response and if still needed following implementation of groundwater pumping in the Westside Basin, the water transfer from TID and MID would also supplement the supply available for SFPUC deliveries. Then, as needed for a severe drought, the SFPUC would implement Stages 2 and 3 of the response program in combination with the supplemental dry-year supplies and would initiate water delivery reductions. A Stage 2 response would include up to 10 percent systemwide rationing, and a Stage 3 response would include up to 20 percent systemwide rationing. The procedures include customer notification, customer allocation if necessary, and evaluation of customer performance. Water use reduction programs would remain in place until total system storage is recovered and drought conditions appear to have ended.

During a drought that exceeds the 8.5-year design drought scenario, a fourth stage of response would be implemented. Stage 4 would increase rationing beyond the WSIP proposed level of service goal of 20 percent. However, with implementation of the WSIP facility improvement projects (see Section 3.8) and the proposed water supply option, the Stage 4 response would not be necessary for any drought sequence equal to or less severe than the 8.5-year design drought.

The SFPUC uses total system and local system reservoir storage levels as parameters to indicate response level in the four-stage dry-year response program. The specific storage levels that indicate a certain response are related to demand and water supply resources and are updated as demand and resources change. As part of operations, by April 15 of each year, the SFPUC can project what system storage will be on July 1 based on current storage, rainfall, and snowpack conditions (SFPUC, 2007a).

Other Operational Considerations

Instream Flow Releases

The SFPUC will meet, at a minimum, all current and anticipated legal requirements for protection of fish and other wildlife habitat, as stated in Table 3.2 under the sustainability goal. Current requirements, as described in Chapter 2, Section 2.5.3, include releases from the following SFPUC regional facilities: Lake Lloyd, Lake Eleanor, Hetch Hetchy Reservoir, Moccasin Reservoir, and Calaveras Reservoir. In addition, the National Marine Fisheries Service has raised concerns regarding stream flows in Pilarcitos Creek below Stone Dam, and the SFPUC is currently making experimental releases and undertaking studies in an effort to address these concerns.

TID and MID own and operate Don Pedro Reservoir (built under the New Don Pedro Project) and are solely responsible as project licensees for meeting the Federal Energy Regulatory Commission (FERC) requirements for fishery releases. Nevertheless, under the Fourth Agreement with TID and MID (see Chapter 2, Section 2.5.3), the CCSF may be required to provide water for these FERC-imposed fishery releases from Don Pedro Reservoir if TID and MID demonstrate that their water entitlements are being adversely affected by providing the flows. The CCSF, TID, and MID entered into two funding agreements to implement the FERC Settlement Agreement; the CCSF now pays TID and MID to provide all of the additional water required under the 1996 FERC order amending the requirements for fishery releases from Don Pedro Reservoir.

The current FERC license expires in 2016, at which time TID and MID will be required to apply for a new license for hydroelectric operations on Don Pedro Reservoir. As part of the license renewal, FERC may modify the fishery release requirements. Although the fishery release requirements that FERC may impose in 2016 cannot be anticipated at this time, the SFPUC assumes, for purposes of the WSIP, that it will be able to continue its current agreement with TID and MID to pay them to provide all of the additional water, if any, required for the fishery releases.

There are no regulatory or contractual flood control restrictions on the local reservoirs. With the exception of Calaveras Dam, none of the local reservoirs or dams has requirements for downstream fishery releases. The SFPUC has not implemented the instream flow releases from Calaveras Reservoir that are stipulated under a 1997 MOU with the CDFG due to the DSOD restrictions on the reservoir water level (discussed in Chapter 2, Section 2.5.4). The SFPUC proposes to implement these releases after completion of the Calaveras Dam Replacement project, which is one of the WSIP facility improvement projects. The Calaveras Dam

Replacement project would include new outlet valve structures to provide for the instream flow releases. As part the MOU stipulations (CDFG, 1997), the WSIP facility improvement projects include a flow recapture project downstream of Calaveras Reservoir (referred to as the Alameda Creek Fishery Enhancement project and described in Section 3.8), which would divert water from Alameda Creek back to the SFPUC water supply system corresponding to the amount of any releases made.

Whitewater Rafting Flows

As described in Chapter 2, Section 2.5.4, although there is no regulatory obligation beyond working cooperatively with the rafters, each year, the SFPUC coordinates with the whitewater recreational interests regarding releases from the Hetch Hetchy system. Currently, subject to the availability of water and hydropower needs, the SFPUC attempts to accommodate whitewater recreation in the Tuolumne River below its reservoirs by adjusting the timing and volume of releases from Holm Powerhouse in order to augment river flows for whitewater rafting.

Under the WSIP's proposed water supply option, the SFPUC intends to continue its general practice regarding releases for whitewater rafting in the Tuolumne River and would continue to coordinate its release patterns with the whitewater recreational interests to provide rafting flow patterns similar to current conditions. During the height of the spring runoff, the rafting release would be met through unregulated flow and releases from Hetch Hetchy Reservoir, Lake Eleanor, and Lake Lloyd. Following the end of the runoff season from July through Labor Day weekend, in addition to the minimum instream flow releases, the SFPUC would augment river flows for whitewater rafting through releases at the Holm Powerhouse, subject to the availability of water and the CCSF's need for hydroelectric power generation. As described in Chapter 5, Section 5.3.8, system operations under the WSIP could result in a slight reduction in the number of days of higher flows compared to existing conditions.

3.7.2 Water Quality Operations Strategy

The SFPUC would continue to conduct all system operations to provide reliable, high-quality water year-round as a priority and to maintain a clean, unfiltered water source from the Hetch Hetchy system. The SFPUC's program to assure high-quality water is based on a multi-barrier approach, starting with source water protection, which would continue with implementation of the WSIP. As stated previously, watershed management and source water protection are included under the sustainability objectives for the WSIP, but these efforts are not specifically or exclusively an element of the WSIP.

After source protection, the next step in maintaining high-water quality involves the use of best management practices during operation of transmission system and water treatment facilities. Transmission facilities are operated at appropriate pressures, not only to meet demand but also to avoid possible entry of contaminants into the system and to avoid cross-connection with nonpotable water sources. Treatment facilities would continue to provide disinfection of all water sources, including Hetch Hetchy system water, and filtration of local watershed water sources. The Hetch Hetchy system would continue to be operated and maintained to meet filtration avoidance requirements, and Hetch Hetchy system water would continue to be treated for corrosion control and to reduce exposure to lead and copper from plumbing systems.

The overall water quality operations strategy would not change with implementation of the WSIP, although refinements to system operations would be developed as part of the new and improved treatment facilities. Under the WSIP, the SFPUC would construct a new advanced disinfection facility to provide a higher level of disinfection for the Hetch Hetchy supply, as required by the federal Long Term 2 Enhanced Surface Water Treatment Rule, and the specific operation of this facility would be incorporated into project planning and design. The WSIP also proposes construction of facilities to meet the same requirements for the Lawrence Livermore Laboratory supply. The program also includes funding to support conceptual engineering of improvements at the Sunol Valley and Harry Tracy WTPs; these improvements are not expected to be needed for compliance with this regulation, but could become necessary in the future if source water quality degrades or changes. Other WSIP system improvements to increase water quality reliability involve upgrades to the primary disinfection facilities currently located at Tesla Portal, process improvements to the Harry Tracy WTP, capacity expansions to meet sustainable production requirements at both water treatment plants, construction of the Sunol Valley Treated Water Reservoir to provide a barrier between the treatment plant and the distribution system, improvements to sanitary deficiencies at the Pulgas Balancing Reservoir, and upgrades of various valves and piping to eliminate cross connections. These proposed facility improvement projects are further described in Section 3.8, below.

3.7.3 Water Delivery Operations Strategy

The SFPUC operates the regional transmission system with the overarching goal to reliably deliver water to meet customer demands. While current system operating strategies would generally remain unchanged, implementation of the WSIP would rehabilitate and upgrade existing facilities as well as provide a wider range of operational flexibility, thereby increasing the reliability of the system to deliver water to all customers under a range of operating conditions. For example, proposed improvements to the Baden and San Pedro Valve Lots would increase the system's capability to provide water from Peninsula sources to South Bay customers in the event of a catastrophic failure of water supplies from the Hetch Hetchy and Alameda watersheds.

The WSIP includes a maintenance program that would increase day-to-day reliability and would establish a schedule to allow for the planned shutdown of facilities for inspection and maintenance while continuing to meet customer demands. Currently, the SFPUC has limited ability to take certain facilities out of service for the extended period of time needed to conduct appropriate inspection and maintenance, but the WSIP would provide adequate redundancy of critical facilities to enable inspection and maintenance on a regular schedule. Redundant facilities would also increase the operational flexibility and thus the reliability of water service to customers in the event of an unplanned facility failure or system upset, natural disaster, or other emergency situation. As summarized in Table 3.2, the WSIP includes performance objectives that would maintain water delivery services during planned facility maintenance activities and unplanned outages of key facilities. As described in Section 3.8, the WSIP includes improvements that would provide varying levels of redundancy to the following facilities: Irvington Tunnel, Bay Division Pipelines, and San Joaquin Pipelines.

The proposed system upgrades would optimize local water storage to provide the SFPUC with a local supply in the event of an emergency. At present, depending on hydrologic conditions and the transmission capacity of pipelines, the replenishment of local reservoirs can take more than one year to complete. The addition of redundant facilities and hydraulic capacity upgrades would also increase the system's transmission capability so that local reservoirs in the Alameda and Peninsula watersheds can continue to be replenished during maintenance periods to maintain higher average annual storage levels, thus ensuring that water would be available for use during emergencies or droughts, while also continuing to meet ongoing customer demands.

3.7.4 Maintenance and Asset Management Strategy

As part of operations under the WSIP, the SFPUC would continue to maintain the regional water system. The SFPUC published the *Post-WSIP Preliminary Maintenance Plan for Regional Water Transmission Facilities* (Parsons-CH2MHILL, 2006), which outlines inspection as well as minor and major maintenance activities for the regional system following completion of the WSIP facility improvement projects. Maintenance activities are grouped in a cycle of regular maintenance, repair/replacement, and renewal and are coordinated under an overall asset management program. These activities are described below:

- Regular Maintenance – maximizing and extending the useful life of facilities, including:
  - *Predictive Maintenance* – inspecting and testing facilities to assess conditions, identify problems, and identify the need for repairs.
  - *Preventive Maintenance* – includes scheduled servicing, painting, cleaning, lubrication, and other work performed on a routine basis.
  - *Reactive Maintenance* – includes unscheduled remedial work to address unplanned component failures (e.g., repair of a pipeline leak).
- *Repair and Replacement* – repair or replacement of system components to extend the life of an asset until the renewal phase (e.g., replacement of a limited length of pipeline).
- *Renewal* – renewal or replacement of an asset near the end of its useful service life (e.g., renewal of pipeline through the insertion of steel liners).

The SFPUC's preliminary maintenance plan (Parsons-CH2MHILL, 2006) is based on a 20-year planning horizon. It is a "living document" that will be revised and adapted according to ongoing condition assessments. The plan focuses initially on the major transmission pipelines and tunnels of the regional system, as listed in **Table 3.8**, although the SFPUC has developed a preliminary list of 123 additional facilities requiring maintenance. The maintenance plan can be expanded to a more comprehensive maintenance program to cover the maintenance needs for other facilities in the regional system, including dams, powerhouses, chemical stations, pump stations, treatment plants, balancing reservoirs, valve lots, and other pipelines.

TABLE 3.8
MAJOR WATER TRANSMISSION FACILITIES INCLUDED IN THE INITIAL MAINTENANCE PROGRAM

San Joaquin Pipelines and Hetch Hetchy Tunnels	Bay Division Pipelines and Bay Area Tunnels
Canyon Tunnel	Alameda Siphon No. 1
Mountain Tunnel	Alameda Siphon No. 2
Moccasin Penstocks or Pipelines	Alameda Siphon No. 3
Foothill Tunnel	Alameda Siphon No. 4
San Joaquin Pipeline No. 1	Irvington Tunnel, 1 and 2
San Joaquin Pipeline No. 2	Bay Division Pipeline No. 1
San Joaquin Pipeline No. 3	Bay Division Pipeline No. 2
San Joaquin Pipeline New Segment	Bay Division Pipeline No. 3
Coast Range Tunnel	Bay Division Pipeline No. 4
	Bay Division Pipeline No. 5
	Bay Tunnel
	Stanford Tunnel
	Pulgas Tunnel

SOURCE: SFPUC, 2006c.

The WSIP maintenance goals are generalized, and specific maintenance requirements for individual facilities would depend on actual conditions and risk. The predictive and preventive maintenance goals for the major transmission facilities are shown in **Table 3.9**. The maintenance frequency for pipelines and tunnels varies based on the material composition of each facility. These regular maintenance goals, along with repair/replacement and renewal maintenance goals, have been incorporated into a 20-year timeline that identifies the maintenance schedule for each facility listed in Table 3.8. The maintenance timeline details the expected number of regular, repair/replacement, and renewal maintenance outages and the duration of each outage for specific months and years during the 20-year planning horizon.

TABLE 3.9
PREDICTIVE AND PREVENTIVE MAINTENANCE GOALS

Maintenance Activity	Expected Frequency Interval (years)	Approximate Outage Duration (months)
Pipelines		
Prestressed concrete cylinder pipelines (PCCP)	5	2 – 3
Concrete pipelines	10	2 – 3
Steel pipelines	20	2 – 3
Tunnels		
Rock – lined	20	2 – 3
Rock – unlined	10	2 – 3
Soft Ground – steel liner	20	2 – 3

SOURCE: Parsons-CH2MHILL, 2006.

Currently, the SFPUC attempts to meet maintenance goals to the extent possible; it is generally able to conduct adequate maintenance on treatment and pumping facilities, because these services can typically be performed without completely shutting them down. However, the SFPUC has limited ability to shut down some of the tunnels and pipelines while still meeting customer demand. The transmission system needs additional tunnels and/or pipelines to provide redundant capabilities to enable shutdown, inspection, and maintenance of some major components of the existing system.

Improvements to the transmission system under the WSIP would allow the SFPUC to meet its maintenance goals. The WSIP level of service objective for delivery reliability is to meet the average annual demand of 300 mgd for 2030 under the conditions of one planned shutdown for maintenance concurrent with one unplanned facility outage due to a facility failure caused by a natural disaster or other emergency. Under the WSIP, the regional transmission system has been sized to allow for system demand to be met with a major reach of pipeline, such as one reach of the Bay Division Pipelines, out of service for major maintenance. System operations under the WSIP would allow planned facility inspection, repair, and maintenance without interrupting customer service, and the SFPUC could schedule planned facility shutdowns to accommodate ongoing system demand. Planned shutdowns of major pipeline reaches would occur during the lower demand months of November through March. The proposed program would enable the SFPUC to conduct deferred maintenance and repair work throughout the regional system, thereby extending the useful life of facilities and improving overall system reliability (SFPUC, 2005d).

3.8 Proposed Facility Improvement Projects

To achieve the system performance objectives of the WSIP, the SFPUC has proposed a series of facility improvement projects that would repair, improve, and in some cases expand the physical facilities in the regional system. This PEIR addresses the key regional system projects in the WSIP, as described in Section 3.4.6. **Table 3.10** describes the key regional facility improvement projects that have been identified as necessary to meet the goals and objectives of the WSIP and to support implementation of the proposed water supply option; more detailed information regarding project facilities, operations, locations, construction, and permits is included in Appendix C. **Figure 3.5** shows the locations of the WSIP's key regional facility improvement projects relative to the existing regional system. **Table 3.11** identifies the jurisdictions that would be affected by each of the projects.

The descriptions in Table 3.10 and Appendix C are based on the best available information at this time about each project; however, due to the complexity and extent of the overall program and the varying levels of individual project development, some of the projects have more detailed information than others. The project descriptions presented in this PEIR are of a level of detail appropriate to identify the overall magnitude of effects expected from implementation of the WSIP as a whole. Chapter 4 of this PEIR assesses the potential impacts of implementing the WSIP facility improvement projects listed in Table 3.10 at a program level (see Chapter 1 for a description of program-level impact analyses), including cumulative impacts. While each of these key regional projects is assessed in Chapter 4, the purpose of the analysis is to provide a comprehensive environmental review of the overall range of effects of implementing the WSIP

TABLE 3.10
WSIP FACILITY IMPROVEMENT PROJECTS

No.[a]	Project Title	Principal Type of Facility/ Objectives[b]	Location of Preferred Project[c]	Project Description
San Joaquin Region				
SJ-1	Advanced Disinfection	Treatment / Water Quality	Tesla Portal	This project would provide for the planning, design, and construction of a new advanced disinfection facility for the Hetch Hetchy water supply to comply with the new federal drinking water regulatory requirements contained in the Long Term 2 Enhanced Surface Water Treatment Rule. This regulation is designed to provide treatment for the parasite *Cryptosporidium*. The project is in the planning phase and the SFPUC is evaluating applicable technologies and possible locations to identify the most technologically sound and cost-effective alternative. In addition, the project includes planning and conceptual engineering for providing advanced disinfection facilities at the Sunol Valley and Harry Tracy WTPs. This project may be combined with the Tesla Portal Disinfection project (SJ-5) along with portal modifications, and the need for the Lawrence Livermore project (SJ-2) may be affected by the location and technology selected for this project.
SJ-2	Lawrence Livermore Supply Improvements	Treatment / Water Quality	Thomas Shaft	This project includes design and construction of treatment upgrades for the water supplied to the Lawrence Livermore Laboratory. The project would construct water treatment facilities from the Thomas Shaft of the Coast Range Tunnel. An advanced disinfection facility planned at an upstream location under SJ-1 could affect project design.
SJ-3	San Joaquin Pipeline System	Pipeline / Water Supply, Delivery Reliability	Isolated locations along the existing San Joaquin pipeline corridor	The preferred project would generally be located within the existing San Joaquin Pipeline (SJPL) right-of-way and would include: • Construction of a new 6.4-mile-long, up to 86-inch-diameter fourth San Joaquin Pipeline parallel to the existing three pipelines at the east end of the pipelines, starting at Oakdale Portal, and associated portal modifications. • Construction of two additional crossover facilities between the San Joaquin Pipelines within the existing right-of-way, both located in Stanislaus County, with one about 20 miles east of Modesto and the other about 15 miles west of Modesto, and improvements at the existing Roselle Crossover. • Construction of a new 10-mile-long, up to 86-inch-diameter fourth San Joaquin Pipeline parallel to the existing three pipelines at the west end of the pipelines ending at Tesla Portal. This project would provide additional facilities to upgrade the hydraulic capacity of the San Joaquin Pipeline system to 314 mgd (and a 271-mgd average during system maintenance when a pipeline segment must be taken out of service) and to provide redundancy for prestressed concrete cylinder pipe for reliability. Note: While the current preferred alternative would construct 16 miles of pipeline, as much as 22 miles of pipeline could be constructed depending on the results of a conditions assessment of the existing pipelines.
SJ-4	Rehabilitation of Existing San Joaquin Pipelines	Pipeline / Water Supply, Delivery Reliability	Rehabilitation could occur anywhere along the pipeline corridor, which extends from Oakdale Portal to Tesla Portal	Reconditioning/rehabilitation of the existing San Joaquin Pipelines. There are three existing pipelines, each 47.7 miles long, extending from Oakdale Portal to Tesla Portal: • SJPL-1, riveted steel pipe, 56- to 72-inch internal diameter • SJPL-2, reinforced concrete pipe and welded steel pipe, 61- to 62-inch internal diameter • SJPL3, prestressed concrete cylinder pipe and welded steel pipe, 78-inch internal diameter

TABLE 3.10 (Continued)
WSIP FACILITY IMPROVEMENT PROJECTS

No.[a]	Project Title	Principal Type of Facility/ Objectives[b]	Location of Preferred Project[c]	Project Description
San Joaquin Region (cont.)				
SJ-5	Tesla Portal Disinfection Station	Treatment / Water Quality, Seismic Reliability	Tesla Portal	This project includes the planning, design, and construction of new disinfection facilities for the Hetch Hetchy water supply. The project would replace and upgrade the existing disinfection facilities at the Tesla Portal Disinfection Facility to meet current seismic, safety/fire, and building code standards. The preferred project would include construction of: • New control building and storage room • Pump houses • Chemical storage tanks and feed equipment and sampling systems • Emergency generator, including primary and standby power supplies • Access road It should be noted that the design and location of the Advanced Disinfection project (SJ-1) would affect the design and location of this project.
Sunol Valley Region				
SV-1	Alameda Creek Fishery Enhancement	Other / Water Supply, Sustainability	Structural Alternatives: Alameda Creek in Sunol Valley, downstream of Calaveras Dam	This project would recapture the water released as part of the Calaveras Dam project (SV-2) and return it back to the regional system for use. A number of structural and non-structural recovery alternatives are under consideration for this project, including: a water recapture facility downstream of the Sunol Valley WTP, conjunctive groundwater use, horizontal collector wells, or other groundwater recovery systems yet to be defined. Other alternative designs for this project could be developed. If a structural alternative involving construction of a recapture facility is selected, the recapture facility would be located at the downstream end of the reach of Alameda Creek between the lower Sunol Valley and the confluence with Arroyo de la Laguna. As an alternative to the recapture facility, the SFPUC may coordinate with other water agencies to develop and implement other means of recapturing fishery enhancement flows consistent with the 1997 CDFG MOU.
SV-2	Calaveras Dam Replacement	Storage / Water Supply, Delivery and Seismic Reliability	Sunol Valley, immediately downstream of existing dam and at the Alameda Creek Diversion Dam	This project would provide for the planning, design, and construction of a replacement dam at Calaveras Reservoir to meet seismic safety requirements. The new dam would provide for a reservoir with the same storage capacity as the original reservoir (96,800 acre-feet), but the replacement dam would be designed to accommodate enlargement of the dam in the future. The preferred project would include construction of: • New earthfill dam • New intake tower and new outlet valve for water releases for instream flow requirements • New or rehabilitated outlet works for seismic safety and improved operations and maintenance • New bypass structure at the Alameda Creek Diversion Dam As part of this project, Calaveras Reservoir and the proposed bypass structure at the diversion dam would be operated to release up to 6,300 acre-feet per year (5.5 mgd) of water to Alameda Creek in support of fisheries in compliance with the 1997 CDFG MOU. When flow is available in Alameda Creek, releases would be made through the proposed bypass structure at the Alameda Creek Diversion Dam and would be supplemented as necessary with releases from Calaveras Dam.

TABLE 3.10 (Continued)
WSIP FACILITY IMPROVEMENT PROJECTS

No.[a]	Project Title	Principal Type of Facility/ Objectives[b]	Location of Preferred Project[c]	Project Description
SV-3	Additional 40-mgd Treated Water Supply	Treatment / Water Quality, Delivery Reliability	Sunol Valley WTP and pipeline to connect to the Alameda Siphons or Irvington Tunnel	This project would provide for the planning, design, and construction of an additional 40 mgd of treatment capacity at the Sunol Valley WTP. The project would increase the sustainable capacity of the Sunol Valley WTP to 160 mgd. The planning-level study would evaluate treatment operations protocol and an alternative treatment process. The project would include either retrofitting the existing facilities with a membrane treatment process or expanding the existing facilities with: • New flocculation and sedimentation system • Upgrade of existing filters or addition of three new filters and a new flow distribution chamber

TABLE 3.10 (Continued)
WSIP FACILITY IMPROVEMENT PROJECTS

No.[a]	Project Title	Principal Type of Facility/ Objectives[b]	Location of Preferred Project[c]	Project Description
Sunol Valley Region (cont.)				
SV-3 (cont.)				• New filtered water and backwash piping Additionally, the project would include: • New chemical feed and piping system • Upgrade of the electrical supply system • Miscellaneous piping, valves, and mechanical and electrical work • Approximately two miles of 78-inch-diameter pipe to connect to the Alameda Siphons or Irvington Tunnel
SV-4	New Irvington Tunnel	Tunnel / Delivery and Seismic Reliability	Sunol Valley to Fremont, parallel to and just south of the existing Irvington Tunnel	This project would construct a new tunnel parallel to and just south of the existing Irvington Tunnel to convey water from the Hetch Hetchy system and the Sunol Valley WTP to the Bay Area. The new tunnel would be a redundant water transmission facility to the existing Irvington Tunnel. The preferred project would include construction of: • New 18,200-foot-long, 10-foot-diameter tunnel • New portal at the east end adjacent to the existing Alameda West Portal in the Sunol Valley with connections to the existing Alameda Siphons and proposed new siphon • New portal at the west end adjacent to the existing Irvington Portal in Fremont with connections to the existing Bay Division Pipelines and proposed new pipeline (BDPL Reliability Upgrade, BD-1) • Valves and equipment to control and monitor flows • Modifications to the existing Alameda West and Irvington Portals
SV-5	SVWTP – Treated Water Reservoirs	Storage and Treatment / Delivery Reliability	North of the Sunol Valley WTP	This project would provide for the planning, design, and construction of new treated water storage reservoirs at the Sunol Valley WTP to comply with requirements of the California Department of Health Services. The preferred project would include construction of: • One 5-million-gallon chlorine contact basin • Two 8.75-million-gallon storage basins • New inlet and outlet piping and reservoir drainage system • Pipe bridge over Alameda Creek • Chemical (ammonia and chlorine) storage and feed system • Backup filter washwater supply and filter washwater supply system • Instrumentation and controls and miscellaneous pumping appurtenances to integrate the reservoirs into the existing treatment plant • Expansion of the existing Sunol Valley WTP electrical substation • Two 750-kilowatt diesel-powered emergency generators

TABLE 3.10 (Continued)
WSIP FACILITY IMPROVEMENT PROJECTS

No.[a]	Project Title	Principal Type of Facility/ Objectives[b]	Location of Preferred Project[c]	Project Description
Sunol Valley Region (cont.)				
SV-6	San Antonio Backup Pipeline	Pipeline / Delivery and Seismic Reliability	Sunol Valley between San Antonio Reservoir and San Antonio Pump Station	This project would consist of three proposed facilities: (1) San Antonio Backup Pipeline, a new pipeline (size undetermined) from San Antonio Reservoir to San Antonio Pump Station, about 2 miles long; (2) San Antonio Creek discharge facilities (improvements allowing for the discharge of Hetch Hetchy water and associated road improvements); and (3) Alameda East Portal vent overflow pipeline and portal modifications.
Bay Division Region				
BD-1	Bay Division Pipeline Reliability Upgrade	Pipeline and Tunnel / Water Supply, Delivery and Seismic Reliability	Along existing Bay Division Pipelines Nos. 1 and 2 easement from Fremont to Redwood City	This project would construct a new Bay Division Pipeline No. 5 (BDPL No. 5) from Irvington Tunnel Portal in Fremont to Pulgas Tunnel Portal near Redwood City, consisting of 16 miles of new pipeline and 5 miles of tunnel under San Francisco Bay. Portions of the section of BDPL No. 1 between Edgewood Valve Lot and Pulgas Valve Lot would be removed (approximately 1.4 miles), and existing aboveground and submarine sections of BDPL Nos. 1 and 2 over the five-mile-long section from Newark Valve House to Ravenswood Valve House would be decommissioned (decommissioning is not part of this project). The redundancy provided by the project would increase the overall transmission capacity of the Bay Division pipeline system. The preferred project would include construction of: • New welded-steel pipeline, approximately 72 inches in diameter, extending along the seven-mile reach from Irvington Portal to Newark Valve Lot, located within the existing SFPUC right-of-way of BDPL Nos. 1 and 2 • New “Bay Tunnel” segment of BDPL No. 5, approximately 120 inches in diameter, extending five miles from Newark Valve Lot to Ravenswood Valve Lot, crossing under San Francisco Bay and adjacent marshlands; BDPL Nos. 1 and 2 would tie into the tunnel at both ends and would be decommissioned between Newark and Ravenswood Valve Lots • New welded-steel pipeline, approximately 60 inches in diameter extending along the nine-mile reach from Ravenswood Valve Lot to Pulgas Portal, located within the existing SFPUC right-of-way of BDPL Nos. 1 and 2 • New facilities at eight valve vault lots along the alignment, containing new concrete vaults and control structures that house electrical control panels, isolation valves, mechanical equipment, and cross-connections between BDPL No. 5 and the existing Bay Division Pipelines • Two flow metering vaults at or near Mission Boulevard (in Fremont) and Pulgas Portal areas • New Isolation valves and piping for connecting BDPL No. 5 to Irvington and Pulgas Portals

TABLE 3.10 (Continued)
WSIP FACILITY IMPROVEMENT PROJECTS

No.[a]	Project Title	Principal Type of Facility/ Objectives[b]	Location of Preferred Project[c]	Project Description
Bay Division Region (cont.)				
BD-2	BDPL Nos. 3 and 4 Crossovers	Valve House / Delivery and Seismic Reliability	Three locations adjacent to where BDPL Nos. 3 and 4 traverse Guadalupe River, Barron Creek, Bear Gulch Reservoir	This project would construct three additional crossover facilities along BDPL Nos. 3 and 4 to provide operational flexibility for maintenance or during emergencies. The new crossover facilities would reduce the length of pipe to be removed from service, either for maintenance or for emergencies, and would reduce the duration of outages. Each crossover facility would include construction of: • Four mainline valves and one cross-connect valve • Automatic controlled actuators • Discharge facilities to enable release of water that meets water quality discharge requirements within discrete pipeline segments to surface waters, either for maintenance or emergencies
BD-3	Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault	Pipeline / Seismic Reliability	Along existing BDPL Nos. 3 and 4 in Fremont	This project would provide for the planning, design, and construction of upgraded, seismically resistant sections of the BDPL Nos. 3 and 4 where they cross the Hayward fault. The replacement pipelines would be located between the two new crossover/isolation valves that would be built as part of BDPL Nos. 3 and 4 Crossover/Isolation Valve at Hayward Fault project (a WSIP project determined to be independent of the PEIR). In addition to the replacement pipelines, a new bypass pipeline between the two new crossover/isolation valve vaults could also be built as part of one of the several alternatives being considered for this project.
Peninsula Region				
PN-1	Baden and San Pedro Valve Lots Improvements	Valve House / Delivery and Seismic Reliability	Baden Valve Lot, South San Francisco, San Pedro Valve Lot, Daly City	This project would upgrade valve vaults, valves, and piping at the existing Baden and San Pedro Valve Lots to meet current seismic standards. Work could also be performed at the Pulgas Pump Station and Pulgas Valve Lot as part of transmission reliability. The project would include a new pressure-reducing valve at one of the locations to allow transfer of water between high and low pressure zones from the Harry Tracy WTP to the Peninsula under an emergency scenario.
PN-2	Crystal Springs/ San Andreas Transmission Upgrade	Pipeline / Delivery and Seismic Reliability	Lower Crystal Springs Reservoir to San Andreas Reservoir, including Crystal Springs Pump Station	This project would consist of seismic improvements of facilities that convey water from Crystal Springs Reservoir to the Harry Tracy WTP. This project would increase the transmission capacity of the existing raw water pipeline from Crystal Springs Reservoir to San Andreas Reservoir in order to reliably supply 140 mgd of raw water for treatment at the Harry Tracy WTP. The project would include: • Repair of Upper Crystal Springs Dam discharge culverts • Upgrade and repair of Lower Crystal Springs Dam outlet structures and tunnels conveying water to Crystal Springs Pump Station • Replacement or refurbishment of Crystal Springs Pump Station • Upgrade and repair of the chemical system and Crystal Springs chlorine emergency feed • Improvements to the Crystal Springs/San Andreas Pipeline, including replacement of approximately 1,350 feet of 66-inch-diameter pipeline, general renewal of the remaining pipeline, and addition of new manholes, blowoff valves, and isolation valves; or construction of a new redundant pipeline along a new alignment.

TABLE 3.10 (Continued)
WSIP FACILITY IMPROVEMENT PROJECTS

No.[a]	Project Title	Principal Type of Facility/ Objectives[b]	Location of Preferred Project[c]	Project Description
Peninsula Region (cont.)				
PN-2 (cont.)				• Seismic and hydraulic upgrade and repair of San Andreas outlet facilities • Addition of fish screens on the outlet structures for both Crystal Springs and San Andreas Reservoirs • Repair of two pipelines that convey raw water from San Andreas Reservoir to the Harry Tracy WTP raw water pump station
PN-3	HTWTP Long-Term Improvements	Treatment / Water Quality, Delivery and Seismic Reliability	Harry Tracy WTP	This project would be a seismic retrofit and rehabilitation of the existing building and facility to provide long-term reliability and process improvements. The project would increase the sustained treatment capacity of the plant from 120 to 140 mgd for 60 days. The proposed improvements would include: • Replacement and upgrade of the ozone generation system for primary disinfection • Replacement or upgrade of the existing sedimentation basins at the same location • Improvements to sludge handling facilities • New, redundant pipeline from the treatment works to the finished water storage reservoir • Raw water pump station improvements • Upgrade and replacement of electrical and instrumentation components, including improvements to process and plant security facilities
PN-4	Lower Crystal Springs Dam Improvements	Storage / Water Supply and Delivery Reliability	Lower Crystal Springs Dam	This project would consist of major repairs and improvements to Lower Crystal Springs Dam to provide adequate protection of the dam and downstream areas from the probable maximum flood, as defined by the DSOD. DSOD has placed operational restrictions on the dam, and the capacity of the reservoir is limited to 56,800 acre-feet. The project would restore the historical reservoir capacity of 68,000 acre-feet. The project would be coordinated with San Mateo County, which is concurrently planning the replacement of the existing county bridge built above the crest of the dam. Project elements would include: • Lowering the existing parapet wall on either side of the existing spillway to lengthen the overflow weir (central spillway) from the reservoir • Raising the remaining parapet walls and adding two new spillway bays, one on each side of the existing central spillway • Enlarging the spillway stilling basin to accommodated the probable maximum flood • Installing four gates (with control building) or installing a fixed weir within the spillway to restore the historical storage capacity

TABLE 3.10 (Continued)
WSIP FACILITY IMPROVEMENT PROJECTS

No.[a]	Project Title	Principal Type of Facility/ Objectives[b]	Location of Preferred Project[c]	Project Description
Peninsula Region (cont.)				
PN-5	Pulgas Balancing Reservoir Rehabilitation	Storage / Water Quality, Delivery and Seismic Reliability	Pulgas Balancing Reservoir and mouth of Laguna Creek at south end of Upper Crystal Springs Reservoir	This project would provide for the planning, design, and construction of improvements to the existing Pulgas Balancing Reservoir and associated facilities. The project would include: • Modifications to the inlet/outlet piping (Phase 1, currently under construction) • Design and construction to rehabilitate and/or expand the discharge channel to Crystal Springs Reservoir (or to install a parallel channel) (Phase 2) • Geotechnical investigations, design, and construction of recommended seismic improvements, including repair/replacement of the reservoir walls, floor, and roof (Phase 3) • Restoration of a six- to eight-acre sediment catchment basin in Laguna Creek to also serve as sustainable habitat for San Francisco garter snake and California red-legged frog, including culvert replacement, sediment removal, revegetation, and protective measures to avoid impacts on sensitive species (Phase 4) • Modification of the existing dechlorination process, including modifications to the chemical feed system to enable pH adjustment and dechlorination system to operate reliably (Phase 5)
San Francisco Region				
SF-1	San Andreas Pipeline No. 3 Installation	Pipeline / Delivery and Seismic Reliability	Daly City to San Francisco	This project would replace the out-of-service Baden-Merced Pipeline, which is beyond repair, and would construct a new pipeline extension of the existing San Andreas Pipeline No. 3 from San Pedro Valve Lot in Daly City to Merced Manor Reservoir in San Francisco. It would also connect the existing San Andreas Pipeline No. 2 at Sloat Boulevard in San Francisco and install an additional pipeline to serve the water turnouts along San Andreas Pipeline No. 2. The project would provide seismic reliability and system redundancy for Peninsula and San Francisco customers. The project would include: • New 3.8-mile-long, 36-inch-diameter pipeline • Approximately 0.27 mile of 36-inchdiameter pipeline for three connections between San Andreas Pipelines Nos. 2 and 3 • Removal of the Baden-Merced Pipeline where the new San Andreas Pipeline No. 3 alignment matches the Baden-Merced alignment • Less than 0.1 mile of 12- to 16-inch-diameter new pipeline for five branch connections to user turnouts (three turnouts to Daly City, two turnouts to San Francisco distribution lines) • Installation of line valves and vaults, manholes, cathodic protection and monitoring stations, sample taps, air valves, blowoffs, and other pipeline appurtenances
SF-2	Groundwater Projects	Other / Water Supply	West side of San Francisco and northern San Mateo County	This project includes three groundwater projects: Lake Merced, Local Groundwater, and Regional Groundwater. • The Lake Merced project would address raising the level of Lake Merced in San Francisco using a supplemental source of water, such as treated stormwater, recycled water, groundwater, or SFPUC system water.

TABLE 3.10 (Continued)
WSIP FACILITY IMPROVEMENT PROJECTS

No.[a]	Project Title	Principal Type of Facility/ Objectives[b]	Location of Preferred Project[c]	Project Description
San Francisco Region (cont.)				
SF-2 (cont.)				• The Local Groundwater Projects would include development of 2 mgd of new local groundwater for blending with water in the potable water system in San Francisco. An estimated four wells and well stations would be constructed to develop this new local groundwater. This project would also include the use of an additional 2 mgd of groundwater through replacement of existing irrigation wells at the San Francisco Zoo, Golden Gate Park, and/or other locations, once recycled water were available for irrigation (to be developed under the Recycled Water Projects, SF-3). Two existing wells would be modified to enable emergency supply to local residents in the event of a major earthquake or other disaster. This project would include the pipelines, water treatment equipment, and controls needed to add the groundwater to the municipal supply. The additional water supply developed under this project would be used during both nondrought and drought years. • As part of a regional conjunctive-use project, the SFPUC would construct about 10 new groundwater production wells in San Mateo County to develop about 6 mgd of potable groundwater for use as a supplemental drought-year supply. In nondrought years under this project, the SFPUC would provide potable water from the regional system to customers in Daly City, San Bruno, and South San Francisco to substitute for groundwater currently used for municipal purposes, thereby reducing groundwater pumping and allowing the groundwater basin to recharge naturally. In drought years, the groundwater would be available for local use to supplement the regional system water. This project would require agreements with the affected agencies see (Section 3.13).
SF-3	Recycled Water Projects	Other / Water Supply, Sustainability	Various locations on west side of San Francisco	This project includes recycled water projects in San Francisco and other locations. Projects include Westside Baseline and Harding Park/Lake Merced. This project would provide treatment, storage, and distribution facilities for about 4 mgd of recycled water to users on the west side of San Francisco. Primary users would include Golden Gate Park, Lincoln Park, Lincoln Park Golf Course, Harding Park Golf Course, San Francisco Zoo, Sunset Boulevard medians, and San Francisco State University. As described under Groundwater Projects (SF-2), the SFPUC is also investigating appropriate sources of supply for increasing and maintaining Lake Merced lake levels, including recycled water that has undergone advanced treatment.

[a] The numbering system is consistent to the extent possible with the system presented in the NOP. However, due to regrouping of the projects after publication of the NOP, some projects have been renumbered.
[b] General types of facilities. Objectives refer to the WSIP objectives met by each project; see Table 3.2 for a complete description of WSIP goals and objectives.
[c] See Figure 3.5 for the approximate locations of preferred projects; many of the projects are still in development and the SFPUC may ultimately consider other design options.

facility improvement projects as a whole and to identify programmatic mitigation measures. As further project details and site-specific information are developed, it is possible that individual project effects identified in this document may not occur or additional project effects not identified in this document may occur. Such changes in project details would be addressed during subsequent project-specific environmental review.

[Since publication of the Draft PEIR, the SFPUC modified the project descriptions of two of the facility improvement projects, as reflected in the revisions to Table 3.10. Please refer to Section 13.2, Program Description Changes Affecting System Operations (Vol. 7, Chapter 13, for further discussion).]

As described in Chapter 2, for the purposes of this PEIR, the regional water system is divided geographically into regions (see Chapter 2, Figure 2.1). The WSIP facility improvement projects are located in the following five regions: San Joaquin (SJ), Sunol Valley (SV), Bay Division (BD), Peninsula (PN), and San Francisco (SF). There are no WSIP facility improvement projects in the Hetch Hetchy Region. The San Joaquin Region, covering the system from the Oakdale Portal to the Coast Range Tunnel, includes five improvement projects, three of which are treatment projects and two of which are pipeline projects. The Sunol Valley Region, with six improvement projects, covers a wide variety of facilities, including storage, treatment, tunnel, pipeline, and other facilities. The Bay Division Region, encompassing the south Bay Area, has three improvement projects, primarily related to pipeline, tunnel, and other transmission facilities. There are five improvement projects in the Peninsula Region, including valve houses, pipelines, and treatment and storage facilities. Overlapping with the Peninsula Region, the San Francisco Region includes three projects in northern San Mateo County and San Francisco, with one pipeline project and two water supply projects. For the most part, individual project activities are confined within the region, although two projects in the San Francisco Region have facilities that are also located in the Peninsula Region. This PEIR analyzes 22 key WSIP facility improvement projects, which are located along the regional system from Oakdale Portal on the east to San Francisco on the west. For the purposes of this PEIR, the projects are coded and numbered by region, as shown in Table 3.10 and Figure 3.5; these project numbers are used throughout this PEIR.[24]

Table 3.12 summarizes the preliminary construction and operational assumptions that the SFPUC has developed for the key regional facility improvement projects; **Figure 3.6** presents the preliminary construction schedule. The information presented in Table 3.12 is based on detailed project information tables, which are included in Appendix C of this PEIR; these tables provide additional project information such as site ownership, land acquisition requirements, existing uses, alternative designs, access routes, construction schedule, proximity to waterways, key environmental issues, construction scenario assumptions, and expected permits/approvals. However, all project information presented in this program-level evaluation is considered preliminary and will be subject to further study, design, and refinement during site-specific analyses. For this PEIR, the facility improvement projects are grouped by regional location and are discussed by region below.

[24] The numbering system for the facility improvement projects is consistent, to the extent possible, with the system presented in the Notice of Preparation (NOP). However, due to regrouping of the projects after publication of the NOP, some projects have been renumbered.

Preliminary WSIP Construction Schedule

TABLE 3.12
WSIP FACILITY IMPROVEMENT PROJECTS – CONSTRUCTION AND OPERATIONS ASSUMPTIONS

No.	Project Title	Preferred Location	Existing Land Use	Project Facilities: Pipeline (miles)	Tunnel (miles)	Storage/ Basin (sq. ft.)	Treatment (sq. ft.)	Vaults/ Valve Houses (no. of structures)	Pump Station (no. of structures)	Other Facilities	Construction Area (acres)	Excavation/ Spoils Volume (cubic yards)	Operational Changes
San Joaquin Region													
SJ-1	Advanced Disinfection	Tesla Portal in San Joaquin County.	Existing SFPUC facility site developed with a caretaker's residence, two valve houses, and chlorination facility.	0.2	0	0	20,000	4	0	None	2	TBD	TBD, may require increased manpower.
SJ-2	Lawrence Livermore Supply Improvements	Thomas Shaft in San Joaquin County.	Undeveloped at Thomas Shaft site.	0	0	0	TBD	TBD	TBD	TBD	TBD	TBD	None. This unmanned facility is monitored by a SCADA system 24/7.
SJ-3	San Joaquin Pipeline System	Construction of a new eastern 6.4-mile pipeline (starting at Oakdale Portal) and a new western 10-mile fourth pipeline (ending at Tesla Portal), traversing Tuolumne, Stanislaus, and San Joaquin Counties. Construction of two additional crossover facilities, one about 20 miles east of Modesto and the other about 15 miles west of Modesto.	Alignment traverses areas developed with agricultural, residential, and golf course uses.	16.4[a]	TBD	0	0	2	0	• New valve houses and improvements at Tesla Portal • Two new crossover facilities	100 to 575 (plus up to 70 acres for staging)	424,000	Increased manpower during flow rate changes.
SJ-4	Rehabilitation of Existing San Joaquin Pipelines	Across the Central Valley from Oakdale Portal to Tesla Portal.	Pipelines are routed through open grasslands (sometimes used for grazing), City of Modesto (including linear parks with walking and bike paths), orchards, Tracy Golf Course.	47.7 (each pipeline)	0	0	0	Throttling Stations Nos. 1 & 2; Roselle Crossover; San Joaquin River Valve House	0	None	All work would be within the existing right-of-way.	Conservatively, about 100,000	None
SJ-5	Tesla Portal Disinfection Station	Tesla Portal in San Joaquin County.	Existing SFPUC facility site developed with a caretaker's residence, two valve houses, and chlorination facility.	0	0	0	6,000	0	0	• Administration building (control room and offices) • Pump houses • Chemical storage tanks and feed equipment and sampling systems • Emergency generator, including primary and standby power supplies • Access road	2	TBD	None. This unmanned facility is monitored by a SCADA system 24/7.
			Subtotal (Rounded)	**64+**	**0**	**0**	**26,000**	**6+**	**0**		**±104 to 650**	**±524,000**	
Sunol Valley Region													
SV-1	Alameda Creek Fishery Enhancement	Alameda Creek in Alameda County.	Alternatives would be located in or near Alameda Creek downstream of Sunol Valley WTP.	TBD	0	0	0	0	TBD	A number of structural and non-structural recovery alternatives are under consideration, including: a water recapture facility downstream of the Sunol Valley WTP, conjunctive groundwater use, horizontal collector wells, or other groundwater recovery systems yet to be defined. Other alternative designs for this project could be developed.	TBD	TBD	TBD, depending on alternative selected
SV-2	Calaveras Dam Replacement	Immediately downstream of Calaveras Dam at the south end of the Sunol Valley in Alameda and Santa Clara Counties.	Existing Calaveras Dam.	0	0	62.5 million	0	2	0	• Zoned earthfill dam with open-chute spillway • New intake tower and outlet valve for water releases for instream flow requirements • New or rehabilitated outlet works for seismic safety and improved operations and maintenance • Various instrumentation • Calaveras Road upgrades – TBD	666 (includes borrow areas)	6,300,000 cy total excavation and 4,000,000 cy spoil	Increased maintenance; Calaveras Reservoir would be operated to release up to 6,300 acre-feet per year (5.5 mgd) of water to Alameda Creek to support fisheries.

TABLE 3.12 (Continued)
WSIP FACILITY IMPROVEMENT PROJECTS – CONSTRUCTION AND OPERATIONS ASSUMPTIONS

No.	Project Title	Preferred Location	Existing Land Use	Project Facilities									
				Pipeline (miles)	Tunnel (miles)	Storage/ Basin (sq. ft.)	Treatment (sq. ft.)	Vaults/ Valve Houses (no. of structures)	Pump Station (no. of structures)	Other Facilities	Construction Area (acres)	Excavation/ Spoils Volume (cubic yards)	Operational Changes
Sunol Valley Region (cont.)													
SV-3	Additional 40-mgd Treated Water Supply	Sunol Valley WTP in Sunol Valley, Alameda County.	Undeveloped land immediately adjacent to Sunol Valley WTP facilities.	1.5 to 2	0	42,000	0	0	0	• New flocculation and sedimentation system • Upgrade of existing filters or addition of three new filters and a new flow distribution chamber • New filtered water and backwash piping • New chemical feed and piping system • Upgrade of the electrical supply system • Miscellaneous piping, valves, and mechanical and electrical work • Approximately two miles of 78-inch-diameter pipe to connect to the Alameda Siphons or Irvington Tunnel	1.5	100,000	25% increase in maintenance activities.
SV-4	New Irvington Tunnel	New east tunnel portal would be about 75 feet north or south of Alameda West Portal in the Sunol Valley. New west tunnel portal would be about 175 feet south of existing Irvington Portal within the Fremont city boundary.	Tunnel portals would be located on undeveloped lands near existing SFPUC facilities: Alameda West Portal and Irvington Portal. Lands immediately adjacent to existing portals are undeveloped, except for caretaker's home and water facilities at Irvington Portal and water facilities at Alameda West Portal. There is one residence located south of Alameda West Portal, and residential uses located west of Irvington Portal.	0	3.4	0	0	9 to 12	0	• New Alameda West Portal 2 and Overflow Shaft • New access road to Irvington Portal and Alameda West Portal • New Irvington Portal 2 and air release pipe • Demolition and rebuilding of existing Irvington Portal manifold • Valves and equipment to control and monitor flows • Two new permanent bridges across Alameda Creek. (Note that a total of two bridges are necessary to construct and operate both the New Irvington Tunnel and Alameda Siphons Upgrade projects; the determination of when to build the bridges would depend on which project would be constructed first. Since this determination has not been made to date, the bridges are evaluated under both projects.)	120 (additional area for staging could be required)	190,000	NA
SV-5	SVWTP – Treated Water Reservoirs	Site is within the boundary of the existing Sunol Valley WTP in Sunol Valley, Alameda County.	Site is within boundary of existing Sunol Valley WTP. Site is currently used for temporary equipment or supply storage on an as-needed basis. The Calaveras Nursery is located to the north, and open space is located to the west.	0.3	0	138,200	0	1	0	• Chemical storage and feed system • Pumping system for filter backwashing and other miscellaneous pumping appurtenances • Backup filter backwash system • Washwater supply system • Reservoir drainage system, controls, and instrumentation • Expansion of the existing Sunol Valley WTP electrical substation • Modification of existing valves • Upgrade of existing dechlorination station and miscellaneous piping	10.5	300,000	No
SV-6	San Antonio Backup Pipeline	Pipeline would extend between San Antonio Reservoir and San Antonio Pump Station.	Undeveloped SFPUC lands.	2.3	0	0	0	2	0	• New discharge facilities at San Antonio Creek (at end of the new pipeline) • New pipeline from the existing overflow outlet near Alameda East Portal, passing adjacent to the San Antonio Pump Station, and continuing to the discharge point on Alameda Creek	TBD	51,000 cy total excavation and 37,000 cy spoil	Second pipeline would allow discharge of dechlorinated water to San Antonio Creek during emergency outages. Pipeline would serve as a water supply alternative if the existing San Antonio Pipeline is out of service due to maintenance or emergency.
			Subtotal (Rounded)	**4 to 5**	**3+**	**63 million**	**0**	**14 to 17**	**TBD**		**±800**	**±7 million**

WSIP FACILITY IMPROVEMENT PROJECTS – CONSTRUCTION AND OPERATIONS ASSUMPTIONS

				Project Facilities									
No.	**Project Title**	**Preferred Location**	**Existing Land Use**	**Pipeline (miles)**	**Tunnel (miles)**	**Storage/ Basin (sq. ft.)**	**Treatment (sq. ft.)**	**Vaults/ Valve Houses (no. of structures)**	**Pump Station (no. of structures)**	**Other Facilities**	**Construction Area (acres)**	**Excavation/ Spoils Volume (cubic yards)**	**Operational Changes**
Bay Division Region													
BD-1	Bay Division Pipeline Reliability Upgrade	Within existing easement for the BDPL Nos. 1 and 2, which extends approximately 21 miles from Irvington Tunnel Portal in Fremont to Pulgas Tunnel Portal near Redwood City. Pipeline right-of-way traverses urbanized areas of Fremont, Newark, East Palo Alto, Menlo Park, and Redwood City in Alameda and San Mateo Counties. The five-mile-long tunnel portion extends from Newark to East Palo Alto, running beneath San Francisco Bay and surrounding marshlands. A subsurface easement would be required for this portion.	Pipeline right-of-way traverses commercial, residential, school, and park uses. The pipeline would cross various highways, major roads, minor roads, and railroads. The Bay Tunnel would be underground and would not affect surface land uses, except at the tunnel shafts on either side of the bay. The Newark tunnel shaft site is developed with an existing SFPUC valve house and is surrounded by industrial uses. The Ravenswood tunnel shaft site is bordered by Bay Division Pipeline right-of-way to the south, marshland to the east, Cargill Salt Ponds to the north, and University Avenue and residential uses to the west. Approximately 15 acres of this site is being used for soil remediation and might eventually be used as a maintenance yard.	16	5	0	0	8 valve vaults, with up to 15 vaults total	0	Isolation valves and piping for connection to new Irvington extension and Pulgas Tunnels. One flow meter at each end of the alignment (2 total). Control buildings for electrical and mechanical equipment at each of the valve lots (8 total). New tunnel shafts at Ravenswood and Newark. Final decision on which shaft would be the drive shaft and which would be the receiving shaft is still to be determined. For the drive shaft, the excavated diameter would be approximately 50 feet, with parking for up to 40 construction work vehicles. Staging area would accommodate mucking out materials handling area, on- site power generation (as needed), or a transformer station, ventilation fans and mufflers, water supply, compressed air supply, and miscellaneous temporary construction facilities totaling approximately 30,000 s.f. The receiving shaft would require a demobilization area for disassembly and removal of a tunnel boring machine, materials handling area, onsite power generation (as needed), or a transformer station, ventilation fans and mufflers, water supply, compressed air supply, and miscellaneous temporary construction facilities totaling approximately 11,000 s.f.	165 to 175	Pipeline: 434,000 Tunnel: 260,000 to 355,000	Would increase system capacity to meet 2030 demand, improve drought delivery through increased replenishment of Peninsula reservoirs, and allow more frequent maintenance of the existing Bay Division Pipelines than is now possible. Following construction of the project, the aboveground and submarine sections of BDPL Nos. 1 and 2 from Newark Valve House to Ravenswood Valve House would be decommissioned. The westernmost reach of BDPL No. 1 between Edgewood Valve Lot and Pulgas Valve Lot would be decommissioned.
BD-2	BDPL Nos. 3 and 4 Crossovers	Preferred locations and sites include: (1) Guadalupe River (Site B) in San Jose, Santa Clara County; (2) Barron Creek (Site C) in Palo Alto, Santa Clara County; and (3) Bear Gulch Reservoir (Site C) in Atherton, San Mateo County.	Sites would be located in undeveloped areas on Veterans Administration Medical Center and Gunn High School lands (Barron Creek), Ulistac Natural Area (Guadalupe Creek), and reservoir lands (Bear Gulch).	0	0	0	0	3 valve vaults	0	Valve vaults would be 3,750 sq. ft. each. The discharge location of drainage outfalls would vary depending on site conditions. Piping to connect facility to outfalls. Control buildings for electrical and mechanical equipment at each valve vault (3 total).	0.4 (minimum) at each site	43,500	Would reduce the length of pipe out of service at any one time and reduce the impact of maintenance or unplanned outages of BDPL Nos. 3 or 4 on system flows. Could allow more frequent maintenance than is now possible.
BD-3	Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault	Spans the I-680/Mission Boulevard interchange in Fremont (Alameda County) between Tissiack Place, Cayuga Place, and Indian Hills Road on the north side and Crawford Street on the south side.	Site spans the I-680/Mission Boulevard freeway interchange.	3	0	0	0	0 to 2 (TBD)	0	None	TBD	Phase B: 55,300	Would improve the seismic resistance of BDPL Nos. 3 and 4 across the Hayward fault.
			Subtotal (Rounded)	**19**	**5**	**0**	**0**	**11 to 20**	**0**		**±170 to 180**	**±800,000 to 900,000**	

TABLE 3.12 (Continued)
WSIP FACILITY IMPROVEMENT PROJECTS – CONSTRUCTION AND OPERATIONS ASSUMPTIONS

No.	Project Title	Preferred Location	Existing Land Use	Project Facilities: Pipeline (miles)	Tunnel (miles)	Storage/ Basin (sq. ft.)	Treatment (sq. ft.)	Vaults/ Valve Houses (no. of structures)	Pump Station (no. of structures)	Other Facilities	Construction Area (acres)	Excavation/ Spoils Volume (cubic yards)	Operational Changes
Peninsula Region													
PN-1	Baden and San Pedro Valve Lots Improvements	Baden site: W. Orange Avenue at El Camino Real in South San Francisco, San Mateo County. San Pedro site: San Pedro Road and Junipero Serra Boulevard in Daly City. Pulgas Pump Station: West of Cañada Road adjacent to Pulgas Water Temple in San Mateo County. Pulgas Valve Lot: Edgewood Road near I-280 in San Mateo County.	All work would occur within existing valve lots.	<1	0	0	0	2 at San Pedro; 6 at Baden	2	• Install new valves, pressure and flow meters, motor operators, SCADA valve controls • Modify valves/pumps/sump/vent shaft • Either enlarge existing vault or add new vault at Baden and/or San Pedro Valve Lots	Approximately 2 acres	5,000+	Operation of new PRV at Baden Valve Lot would occur during emergencies only but would be run for maintenance purposes approximately 2 times per year.
PN-2	Crystal Springs/ San Andreas Transmission Upgrade	Facility locations in San Mateo County: • Upper Crystal Springs Dam culverts under Highway 92. • Crystal Springs Outlet Tower Nos. 1 and 2 and Crystal Springs Pump Station located west of I-280 near Skyline Boulevard/Crystal Springs Road intersection, near Hillsborough. • Crystal Springs/San Andreas Pipeline, San Andreas Inlet Structure, San Andreas Outlet Towers Nos. 2 and 3 located west of I-280, generally between Millbrae Avenue and Crystal Springs Road (adjacent to Hillsborough, Burlingame, and Millbrae). • Harry Tracy WTP located east of I-280 and south of Crystal Springs Road in San Mateo County, adjacent to San Bruno.	Project involves repair or replacement of existing SFPUC water facilities. If a new parallel pipeline is needed and an alternative alignment is chosen, an easement may be necessary. The most likely alignments would be within the watershed on lands currently owned by the CCSF.	4.5	0.5**	0	Emergency chemical injection systems at Crystal Springs and San Andreas Reservoirs.	32 existing vaults (number of vaults would most likely be reduced), and new vaults are limited to Crystal Springs Pump Station and outlet of four tunnels.	Renovation of existing pump station or 1 new pump station	• Repair lower culvert linking Upper and Lower Crystal Springs Reservoirs • Upgrade/repair Crystal Springs Outlet Structure Nos. 1 and 2 • Upgrade or replace Crystal Springs Pump Station (including increasing the capacity to transfer water between reservoirs from 80 to approximately 120 mgd, depending on the future modeling (maximum rate would be 140 mgd to match Harry Tracy WTP output), and build new substation (chemical injection equipment is new, only minor strengthening of pipe required) • Renew pipeline sections that are not replaced at San Andreas Reservoir • Depending on alternatives analysis, a new redundant pipeline may be required • Upgrade/repair San Andreas Outlet Structure Nos. 2 and 3 (significant retrofit of San Andreas No. 2 Tunnel may be required) • Repair San Andreas Pipelines Nos. 2 and 3 • Pump station capacity upgrades as required to meet Harry Tracy WTP raw water supply requirements **There are four existing tunnels that would require strengthening and/or retrofit.	TBD	Not specified (estimate up to 9,000 cy)	Increased operations and maintenance due to increased pumping/ transmission capacity.
PN-3	HTWTP Long-Term Improvements	Harry Tracy WTP is located south of Crystal Springs Road in San Mateo County, adjacent to San Bruno and Millbrae.	Harry Tracy WTP site is currently developed with water treatment facilities.	1 to 2	0	2	Project is a treatment facility.	TBD	1	Some of the 16 identified structures would require upgrades. Mechanical, structural, electrical, and process upgrades are expected to be necessary, with known upgrades occurring within existing development footprints. However, structures could be added within the Harry Tracy WTP property. Improvements include disinfection treatment upgrades, raw water pumping upgrades, replacement/upgrade of sedimentation basins at same location, sludge facilities, and power and instrumentation upgrades.	TBD	Not specified	Potential increase in operations and maintenance due to increased sustainable treatment capacity.

WSIP FACILITY IMPROVEMENT PROJECTS – CONSTRUCTION AND OPERATIONS ASSUMPTIONS

				Project Facilities									
No.	**Project Title**	**Preferred Location**	**Existing Land Use**	**Pipeline (miles)**	**Tunnel (miles)**	**Storage/ Basin (sq. ft.)**	**Treatment (sq. ft.)**	**Vaults/ Valve Houses (no. of structures)**	**Pump Station (no. of structures)**	**Other Facilities**	**Construction Area (acres)**	**Excavation/ Spoils Volume (cubic yards)**	**Operational Changes**
Peninsula Region (cont.)													
PN-4	Lower Crystal Springs Dam Improvements	Dam is located west of I-280 and Skyline Boulevard, and south of Crystal Springs Road in San Mateo County.	Lower Crystal Springs Dam is an existing dam, and the Lower Crystal Springs Reservoir level is currently restricted by the CA Division of Safety of Dams (DSOD). The zone around the reservoir that would be inundated under the WSIP is currently undeveloped; however, with implementation of the proposed project, including improvements to the dam and spillway, the reservoir levels would be restored to inundation zone levels that were permissible by DSOD prior to 1983.	0	0	0	0	0	0	• Raise dam parapet wall to provide required freeboard during probable maximum flood (PMF), which could also require strengthening abutments • Lengthen spillway crest to increase discharge capacity • Install new mechanical gates to replace the antiquated stop-log system • Enlarge the stilling basin to accommodate the probable maximum flood discharge. Project cannot be completed until San Mateo County completes the Skyline Boulevard (Highway 35) bridge project.	6 acres	21,000 cy	Increased maintenance (although project would restore historical storage capacity).
PN-5	Pulgas Balancing Reservoir Rehabilitation	Located on the east side of Cañada Road, southeast of the Pulgas Water Temple in San Mateo County.	This project would be located within the areas of the existing Pulgas Balancing Reservoir Pulgas Channel, and Pulgas dechloramination facility as well as near the mouth of Laguna Creek.	0	0	0	0	0	0	Five phases: • New inlet/outlet piping to ensure optimal mixing in reservoir • Replace Pulgas Channel with an enlarged channel to accommodate estimated maximum flow of 250 mgd • Structural rehabilitation and roof replacement • Restore the existing sedimentation basin for the enhancement of habitat as a mitigation • Modify existing dechlorination process – increase capacity of carbon dioxide system and chemical feed systems	TBD	TBD	No
			Subtotal (Rounded)	**±7 to 9**	**0.5+**	**2**	**0**	**8+**	**3+**		**±8**	**±35,000**	
San Francisco Projects													
SF-1	San Andreas Pipeline No. 3 Installation	This pipeline alignment extends from the San Pedro Valve Lot in Daly City (San Pedro Road at Junipero Serra Boulevard) to Merced Manor Reservoir in San Francisco (at Ocean Avenue and 22nd Avenue).	Most of the pipeline would be located within existing roadways, parking lots, and other paved areas, with the remainder crossing through open space corridors in Lake Merced Golf and Country Club and San Francisco Golf Club. Adjacent uses include residential, commercial, school, church, and park uses.	4.17	0	0	0	2	0	• 4.07 miles of 36-inch-diameter and 0.1 mile of 12- to 16-inch-diameter steel pipeline • Removal and/or slurry fill of the existing Baden-Merced Pipeline • Installation of line valves, vaults, and manholes • Installation of cathodic protection systems and monitoring stations, sample taps, air valves, blowoffs, and other pipeline appurtenances	23	44,170	No
SF-2	Groundwater Projects	Local Projects in San Francisco: Lake Merced Pump Station, South Sunset Playground (40th Avenue/Wawona Street), West Sunset Playground (41st Avenue/Quintara Street), Golden Gate Park (Lincoln/42nd Avenue), or alternative locations; North Lake (north side of North Lake in Golden Gate Park, near Fulton Street/43rd Avenue intersection); San Francisco Zoo; Central Pump Station; Pine Lake (Stern Grove), other Golden Gate Park locations. Regional Projects in San Mateo County: up to 10 sites in Daly City and San Bruno and the California Water Service	San Francisco sites already developed with municipal water supply, playground, school parking lot, park, and zoo uses. Regional well sites have not yet been identified.	4.0	0	0	500	0	0	• San Francisco: Install new wells, well stations, and associated pipelines, water treatment equipment, and controls at Lake Merced Pump Station, South Sunset Playground, West Sunset Playground, and Golden Gate Park (or alternate location at Central Pump Station or Francis Scott Key Annex). Modify wells at San Francisco Zoo and North Lake (Golden Gate Park) for emergency supply. Replace wells at San Francisco Zoo, Pine Lake (Stern Grove), Golden Gate Park, and/or other locations (TBD); 2,500 sq. ft. per site. • Regional: Up to 10 new wells and well stations in San Mateo County, Daly City, San Bruno, South San Francisco, and Colma. Wells are estimated to be 600 feet deep.	0.04 acre per site plus pipeline alignments (or 0.7 acre for 18 sites)	TBD	Increased chlorination or chloramination supplies during drought years only, operation inspections, lubrication, calibration of monitoring equipment.

TABLE 3.12 (Continued)
WSIP FACILITY IMPROVEMENT PROJECTS – CONSTRUCTION AND OPERATIONS ASSUMPTIONS

No.	Project Title	Preferred Location	Existing Land Use	Project Facilities: Pipeline (miles)	Tunnel (miles)	Storage/ Basin (sq. ft.)	Treatment (sq. ft.)	Vaults/ Valve Houses (no. of structures)	Pump Station (no. of structures)	Other Facilities	Construction Area (acres)	Excavation/ Spoils Volume (cubic yards)	Operational Changes
San Francisco Projects (cont.)													
SF-2 (cont.)	Groundwater Projects (cont.)	Company's South San Francisco service area (including South San Francisco, Colma, and unincorporated areas of northern San Mateo County). Wells could possibly be located in San Francisco, Burlingame, or Millbrae.											
SF-3	Recycled Water Projects	Treatment site location is TBD; options include the Oceanside Water Pollution Control Plant, San Francisco Zoo overflow parking lot, the site of the old Richmond-Sunset Treatment Plant, and the site of the old McQueen Plant. Treated water storage would be provided at the treatment site as well as offsite; offsite locations include new storage in Lincoln Park (golf course), and the conversion of existing storage in Golden Gate Park. Pipeline alignments would be within city streets.	The Oceanside Water Pollution Control Plant has limited space in an existing room that houses odor control scrubbers; the zoo overflow parking lot is unpaved and in use by the zoo; the Richmond-Sunset site is used for construction spoils storage; and the McQueen site is being used by the Recreation & Park Department as an Urban Forestry Center. Lincoln Park is a golf course, and the Golden Gate Park storage tank is an existing storage facility.	20	0	TBD	Approx. 50,000	0	1 or 2	Utilize existing 2-million-gallon Golden Gate Park Reservoir. Additional storage in the Lincoln Park area. Other potential small booster pumping station(s) have not been identified.	5 to 7	47,200	Increased deliveries and maintenance.
			Subtotal (Rounded)	**28+**	**0**	**0**	**50,500**	**2**	**1 or 2**		**±29 to 31**	**±91,400**	

mgd = million gallons per day
NA = not applicable
SCADA = Supervisory Control and Data Acquisition
sq. ft. = square feet
cy = cubic yards
TBD = to be determined during project design and as part of separate, project-level CEQA review

[a] While the current preferred alternative would construct 16 miles of pipeline, as much as 22 miles of pipeline could be constructed (depending on the results of a condition assessment of the existing pipelines), as well as a new valve house at Oakdale Portal (in addition to Tesla Portal).

3.8.1 San Joaquin Region

Of the five key regional WSIP projects in the San Joaquin Region, most project facilities would be constructed along the San Joaquin Pipelines alignment or at Tesla Portal. As summarized in Table 3.12, implementation of the WSIP in the San Joaquin Region would be expected to result in construction of approximately:

- 16 miles of pipeline between Oakdale Portal and Tesla Portal (SJPL System, SJ-3, and Advanced Disinfection, SJ-1)[25]
- Rehabilitation of the existing San Joaquin Pipelines Nos. 1, 2, and 3 (SJPL Rehabilitation, SJ-4) at locations to be determined, potentially anywhere along its 48-mile length
- 26,000 square feet of treatment facilities at Tesla Portal (Advanced Disinfection, SJ-1, and Tesla Portal Disinfection, SJ-5)

In addition, a small treatment facility could be developed at Thomas Shaft, west of Tesla Portal (under the Lawrence Livermore project, SJ-2), although the design and locations of treatment facilities associated with the Advanced Disinfection (SJ-1), Lawrence Livermore (SJ-2), and Tesla Portal Disinfection (SJ-5) projects are all interrelated and subject to change. In general, program implementation would not alter existing operation and maintenance activities in this region, although there could an increase in chemical usage, truck traffic, and energy usage, all related primarily to the Advanced Disinfection project.

Based on the preliminary WSIP schedule, program-related construction activities in this region are scheduled to occur between 2008 and 2014 and would be expected to result in surface disturbance of as much as 650 acres (99 percent attributable to the SJPL System project, SJ-3). Such disturbance would generate approximately 424,000 cubic yards of excavated material/trench spoils (100 percent attributable to the SJPL System project, SJ-3), though an additional approximately 100,000 cubic yards could result from SJPL Rehabilitation, SJ-4.

3.8.2 Sunol Valley Region

Of the six key regional WSIP projects in the Sunol Valley Region, the largest projects (as defined by the construction duration and extent of earthwork required) would be the Calaveras Dam (SV-2) and New Irvington Tunnel (SV-4) projects. As summarized in Table 3.12, WSIP implementation in the Sunol Valley Region would be expected to result in construction of approximately:

- 4 to 5 miles of pipeline within the Sunol Valley (40-mgd Treated Water, SV-3; Treated Water Reservoirs, SV-5; and SABUP, SV-6)
- Over 3 miles of tunnel between the Sunol Valley and Fremont (New Irvington Tunnel, SV-4)

[25] While the current preferred alternative would construct 16 miles of pipeline, as much as 22 miles of pipeline could be constructed depending on the results of a condition assessment of the existing pipelines.

- Replacement of the existing earthen dam at Calaveras Reservoir (Calaveras Dam, SV-2)
- 180,200 square feet of storage and treatment facilities at the Sunol Valley WTP (40-mgd Treated Water, SV-3, and Treated Water Reservoirs, SV-5)
- 14 to 17 vaults or valve houses at Calaveras Reservoir (SV-2), near Turner Dam and San Antonio Pump Station (SABUP, SV-6), Alameda West Portal and Irvington Portal (New Irvington Tunnel, SV-4), and Sunol Valley WTP (Treated Water Reservoirs, SV-5)
- Pump stations in the Sunol Valley could be developed along Alameda Creek, depending on the alternative implemented (Alameda Creek Fishery, SV-1)

In addition, various other water facilities (piping, pumping, chemical feed, valve, manifold, electrical substation facilities, portable propane- or diesel-powered generators, and propane fuel tanks at some sites) would be constructed in the Sunol Valley (SV-2 through SV-6). Facilities associated with the Alameda Creek Fishery project (SV-1), other than the possible pump stations, have not yet been identified. In general, WSIP implementation would result in a long-term increase in operation, maintenance, and monitoring activities associated with the instream fishery releases and the facilities for recapturing the released water downstream in Alameda Creek and returning it to the regional water supply. There would also be operations and maintenance needs associated with periodic instrumentation calibration, valve cleaning, and increased use of treatment chemicals associated with expanded treatment capacity (Alameda Creek Fishery, SV-1; Calaveras Dam, SV-2; 40-mgd Treated Water, SV-3; and Treated Water Reservoirs, SV-5) in Sunol Valley.

Based on the preliminary WSIP schedule, program-related construction activities would occur between 2008 and 2013, with most work performed in 2009 to 2011. Construction would be expected to result in surface disturbance of approximately 800 acres (98 percent attributable to the Calaveras Dam, SV-2, and New Irvington Tunnel, SV-4, projects) and would generate approximately 7 million cubic yards of excavated material/spoils that would require permanent disposal (90 percent attributable to the Calaveras Dam project).

3.8.3 Bay Division Region

Of the three key regional WSIP projects in this region, most project facilities would be associated with the BDPL Reliability Upgrade project (BD-1). As summarized in Table 3.12, program implementation in the Bay Division Region would be expected to result in construction of approximately:

- 19 miles of pipeline in the East Bay, South Bay, and Peninsula (BDPL Reliability Upgrade, BD-1, and BDPL 3 and 4 Seismic Upgrade at Hayward Fault, BD-3)
- 5 miles of tunnel extending across San Francisco Bay between Newark and East Palo Alto (BDPL Reliability Upgrade, BD-1)
- 11 to 20 valve lots or vaults along the existing rights-of-way of Bay Division Pipelines Nos. 1, 2, 3, and 4 (BDPL Reliability Upgrade, BD-1; BDPL 3 and 4 Crossovers, BD-2; BDPL 3 and 4 Seismic Upgrade at Hayward Fault, BD-3)

In addition, various other appurtenant facilities (isolation valves, piping, drainage outfalls, control rooms, transformers, emergency generators, and electronic equipment) would be constructed in various cities under all three projects in the region. In general, program implementation would not alter existing operation and maintenance activities (e.g., no change chemical deliveries, storage, and use) in this region.

Based on the preliminary WSIP schedule, program-related construction activities would occur between 2009 and 2013. Construction in the Bay Division Region would be expected to result in surface disturbance of approximately 170 to 180 acres (99 percent attributable to BDPL Reliability Upgrade project, BD-1) and would generate approximately 800,000 to 900,000 cubic yards of excavated material/spoils that would require permanent disposal (most attributable to the BDPL Reliability Upgrade project).

3.8.4 Peninsula Region

There are five key regional WSIP projects in this region, and most facilities are attributable to the CS/SA Transmission (PN-2) and Lower Crystal Springs Dam (PN-4) projects. As summarized in Table 3.12, program implementation in the Peninsula Region would be expected to result in construction of approximately:

- 7 to 9 miles of pipeline in San Mateo County, including segments between Lower Crystal Springs Reservoir and San Andreas Reservoir (CS/SA Transmission, PN-2), at Harry Tracy WTP (HTWTP Long-Term, PN-3), and at various valve lots (Baden and San Pedro Valve Lots, PN-1)
- 0.5 mile of tunnel in San Mateo County (CS/SA Transmission, PN-2)
- Raising the Lower Crystal Springs Dam (Lower Crystal Springs Dam, PN-4)
- 2 storage basins at Harry Tracy WTP (HTWTP Long-Term, PN-3)
- About 8 vaults/valves lot in or near South San Francisco and Daly City (Baden and San Pedro Valve Lots, PN-1, and CS/SA Transmission, PN-2)
- 3 to 4 pump stations, new or upgrades (Baden and San Pedro Valve Lots, PN-1; CS/SA Transmission, PN-2; and HTWTP Long-Term, PN-3)
- Replacement and enlargement of discharge channel (Pulgas Balancing Reservoir, PN-5)

Except for the pipeline facilities, most of the projects in this region would generally involve modifying or expanding existing water facilities and would be located in developed areas in San Mateo County or within the cities of Daly City and South San Francisco (Baden and San Pedro Valve Lots, PN-1; CS/SA Transmission, PN-2; and HTWTP Long-Term, PN-3). These projects include installing new valves, pressure and flow meters, or motor operators; modifying, repairing, upgrading, or seismic retrofitting vaults, valves, vent shafts, piping, pumps, sumps, chemical feeds, filters, or other treatment facilities; and rehabilitating or adding structures. Larger projects also include pump station upgrades (CS/SA Transmission, PN-2), reservoir outlet upgrades/repairs (CS/SA Transmission, PN-2), raising the dam parapet at Lower Crystal Springs

Reservoir (Lower Crystal Springs Dam, PN-4), and replacing/enlarging Pulgas Channel at Upper Crystal Springs Reservoir (Pulgas Balancing Reservoir, PN-5).

Program implementation in the Peninsula Region would increase pumping and transmission capacity between Lower Crystal Springs Reservoir and San Andreas Reservoir (CS/SA Transmission, PN-2) as well as increase the sustained treatment capacity at the Harry Tracy WTP (HTWTP Long-Term, PN-3). In addition, raising the parapet at Lower Crystal Springs Reservoir would restore the historical storage capacity (Lower Crystal Springs Dam, PN-4). However, the other WSIP projects in this region would not alter existing operation and maintenance activities in the region.

Based on the preliminary WSIP schedule, program-related construction activities would occur between 2008 and 2013. The extent of surface disturbance associated with projects in this region cannot be estimated at this time because many of the projects are still in the preliminary planning stage. Projects with the potential for extensive surface disturbance include the CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4), and Pulgas Balancing Reservoir (PN-5) projects. Surface disturbance for some projects (Baden and San Pedro Valve Lots, PN-1, HTWTP Long-Term, PN-3, and part of Pulgas Balancing Reservoir, PN-5) would be limited to expanded facilities and staging areas, since these projects would primarily be located within existing development footprints. Program-related construction activities in the Peninsula Region would generate approximately 35,000 cubic yards of excavated material/spoils, attributable mostly to the CS/SA Transmission Upgrade (PN-2) and Lower Crystal Springs Dam (PN-4) projects, with the potential for additional excavation under the Baden and San Pedro Valve Lots, HTWTP Long-Term, and Pulgas Balancing Reservoir projects.

3.8.5 San Francisco Region

Of the three key regional WSIP projects in this region, most of the project facilities would be associated with the San Andreas Pipeline No. 3 Installation project (SF-1) and Recycled Water Projects (SF-3). As summarized in Table 3.12, program implementation in the San Francisco Region would be expected to result in construction of:

- Approximately 28 miles of pipeline in Daly City and San Francisco (SAPL 3 Installation, SF-1; Groundwater Projects, SF-2; and Recycled Water Projects, SF-3)
- An estimated 14 new groundwater wells in San Francisco, Daly City, San Bruno, and South San Francisco (Groundwater Projects, SF-2)
- Approximately 50,000 square feet of treatment facilities for recycled water (Recycled Water Projects, SF-3)

In addition, various other water facilities (line valves, vaults, manholes, cathodic protection systems and monitoring stations, sample taps, air valves, blowoffs, and other pipeline appurtenances) would be constructed in Daly City and San Francisco under the SAPL 3 Installation project (SF-1). Approximately 14 new well stations (which could include new buildings and booster pumps) and associated piping could be installed, and some existing wells in San Francisco could be upgraded under the Groundwater Projects (SF-2).

Program implementation in the San Francisco Region could modify or add treatment facilities for the Groundwater and Recycled Water Projects in San Francisco (SF-2 and SF-3). The other WSIP project in this region (SAPL 3 Installation, SF-1) would not alter existing operation and maintenance activities in the region.

Based on the preliminary WSIP schedule, program-related construction activities would occur between 2009 and 2014. Approximately 30 acres of surface disturbance is estimated for this region. Program-related construction activities in the San Francisco Region would generate approximately 91,000 cubic yards of excavated material/spoils (nearly all attributable to the SAPL 3 Installation, SF-1, and Recycled Water Projects, SF-3).

3.9 Construction Scenarios for Facility Types

Typical construction scenarios for the different types of facilities proposed under the WSIP are described below. These descriptions address the nature, extent, and duration of anticipated construction activities and are used in the programmatic analysis of construction impacts in Chapter 4 of this PEIR. Actual construction activities could vary and would be determined during subsequent, project-specific review of the individual WSIP projects.

3.9.1 Pipelines

Construction of the WSIP facility improvement projects related to water transmission and distribution pipelines would be accomplished using standard pipeline installation methods, generally the open-cut trench method (also referred to as the cut-and-cover construction method) where feasible. In general, cut-and-cover pipeline construction would progress at a rate of approximately 120 to 160 feet per day depending on conditions (e.g., whether the pipeline is located in an urbanized or undeveloped area), the length and size of the pipe segment, number of utility crossings, traffic congestion, and any restrictions on work schedules. However, in areas where there are no obstructions and construction occurs entirely within the SFPUC right-of-way (e.g., where there are no road crossings), the pipeline construction could progress at a rate of up to 300 feet per day. Periodically, staging areas could be required for equipment laydown and for stockpiling backfill and spoils from the trench, but construction disruption associated with pipeline installation would generally be limited to one section at a time rather than the entire length of the alignment.

The key steps in the cut-and-cover construction process would be as follows: (1) surface preparation, (2) trench excavation and shoring, (3) pipe installation, (4) trench backfilling and compacting, and (5) surface restoration. Surface preparation could involve removing structures (such as fences), saw-cutting and removing pavement, or removing vegetation from the surface of the trench area. Equipment used for this activity could include jackhammers, pavement saws, mowers, graders, and loaders. Trench excavation would be done using a backhoe or excavator, and excavated soil of suitable quality would be stockpiled along the trench for later reuse as backfill; where excavated soil is not of suitable quality, engineered fill could be trucked to the site for backfilling. Excess soil would be hauled offsite for disposal.

The depth and width of the trench would depend on the size of the pipeline to be installed. For pipe diameters ranging from 12 to 36 inches, the depth of the trench would range from 5 to 8 feet and the width of the trench from 2 to 5 feet. For larger pipelines (54 to 78 inches in diameter), the depth of the trench would range from 10 to 15 feet and the width of the trench from 8 to 12 feet. There would be a minimum of 3 feet of cover over the pipelines. To protect workers from trench failure, shoring would be required for trenches over 5 feet deep. Depending on the geotechnical characteristics, soil conditions, and the depth of excavation, various methods of shoring could be employed, including use of a shield or trench box, steel plates, sheet piling and beams, or solder piles and lagging, which would be installed with a pile driver or excavator. Typically, sheet-piling would be required for trenches over 10 feet deep in unstable soils, such as sand or heavy clay. If groundwater is encountered during trench excavation, dewatering would typically be required so that the pipe could be installed in dry conditions. Any groundwater produced during dewatering would likely be discharged to the local sewer system, the storm sewer, or a nearby waterway, in compliance with appropriate regulations.

Pipe-bedding materials would then be placed in the stabilized trench, followed by the new segment of pipeline. Pipe segments would be connected, typically with welded joints (for steel pipe) or bell and spigot joints (for ductile iron pipe). Flexible couplings are typically used when the pipe needs special protection from damage due to earthquakes or other soil movement. Depending on the soil conditions, imported pipe-bedding materials could be used to backfill the pipe up to its approximate centerline. The trench would then be backfilled with native soil, to the extent possible, in order to meet applicable compaction requirements. Imported backfill could be necessary for compactibility and stability. For pipelines located within paved roadways, surface restoration would involve repaving the area with new asphalt or concrete pavement. For undeveloped areas, the disturbed area would be graded and revegetated with approved plant materials. Finally, construction debris would be hauled from the site for disposal.

Open-cut construction would not be appropriate for some pipeline crossings of major roadways (including freeways and highways), railroads, environmentally sensitive areas, perennial creeks,[26] or aqueducts/canals. In these cases, several alternative "trenchless" pipeline construction techniques that avoid trenching along the entire length of the pipeline could be utilized as appropriate, including the following:

- Where an aboveground crossing would be appropriate (considering security and access issues), a pipeline could be elevated above ground and either hung beneath an overpass with brackets or supported by footings from below.

- Where an underground crossing is required, the pipeline crossing could be constructed using trenchless methods, such as jack-and-bore or microtunneling, as appropriate.

26 For seasonal creeks, trenched crossings could be accomplished during the dry season, to protect environmentally sensitive habitat (such as riparian habitat).

Jack-and-bore construction requires excavation of a jacking pit at the jacking end and a receiving pit at the other end of each pipeline crossing segment, through which the piping installation equipment is respectively inserted and retrieved. Jacking pits for larger pipelines would be approximately 12 to 20 feet deep, 15 to 20 feet wide, and 30 feet long. Jack-and-bore construction would typically be used for pipeline crossings that are 80 to 300 feet long and for pipe diameters of 30 to 78 inches. Similarly, microtunneling could be used for pipeline segments that are 100 to 1,000 feet long and would be appropriate for areas with coarse soils and rocks and where precise alignment is needed. Microtunneling requires excavation of a shaft at each end of the pipeline crossing, and surface disturbance is limited to either end of the pipeline segment.

- In some cases, where pipeline installation or replacement is not required, it might be possible to slipline some sections of an existing pipeline. This method, which could be employed where the pipeline is straight, would require excavation of access pits at all angle points and on either side of the segment to be sliplined, rather than trenching along the length of the entire segment. Sliplining would involve disturbance of less surface area than cut-and-cover construction. However, as with cut-and-cover construction, periodic staging locations might be needed for equipment laydown and for stockpiling backfill and spoils from the access pits.

3.9.2 Tunnels

Whereas pipeline construction would generally occur during daytime working hours and would affect adjacent uses for a short period of time as construction progresses along the alignment, tunnel construction would typically occur 24 hours per day, seven days a week, and construction activities would be focused at two locations (the entrance and exit tunnel portals) for the duration of tunnel construction.

Tunneling is typically accomplished by mechanical means, with the use of a tunneling machine (such as a tunnel boring machine, or roadheader, or an earth-pressure-balancing tunnel machine) that excavates the tunnel, removes the spoils (or “muck”), and lines the tunnel with concrete segments. Within the tunnel, a narrow-gage railway or tunnel train is built on the concrete segments for delivering supplies into the tunnel, and a conveyor belt is installed to remove tunnel spoils. Spoils from tunnel excavations are typically removed from the tunnel face and deposited outside the portal using various methods, such as a conveyor belt, front-end loader, hoppers, or tunnel train (also known as a muck train). Excavated material stockpiled outside the portal is then loaded onto trucks or barges (if applicable) and transported offsite. Other related tunneling equipment includes a tunnel ventilation fan, muck removal equipment, dewatering and groundwater treatment system, etc. Depending on the tunnel design, vent shafts could be required at certain locations along the tunnel alignment, with associated surface disturbance occurring outside of the tunnel portal areas.

Depending on the subsurface conditions encountered, drilling and controlled detonations might be needed as part of tunnel construction. Controlled detonation is performed by drilling holes in a specified pattern in the rock face of the tunnel excavation, packing the holes with small amounts of explosive and primer, and detonating the explosives using a time delay between successive detonations.

Tunnel construction would start at the entry portal, which would serve as the primary staging area for tunnel construction and require a large construction staging area for the duration of tunneling activities. Removal and transport of tunnel spoils would generally occur at the entry portal, as would equipment storage and deliveries. Depending on the construction specifications, activities at the exit portal could be limited; in some cases, this portal would primarily be used to remove the tunneling equipment upon completion of tunneling. Tunnel portal construction could require grading and construction of an access road and staging areas for construction office trailers, equipment and materials storage, and temporary stockpiling. Tunnel construction would include excavation and construction of a tunnel portal entry or launch shaft, which would serve as the main access for installation of equipment as well as for removal of tunnel spoils. Depending on the depth, size, and location of the tunnel, the portal entry could require shoring and associated supports and/or dewatering systems.

Tunneling operations typically take place 24 hours a day to maximize construction efficiency, since most activities occur underground and cause limited surface disturbance. However, surface activities at the tunnel portals could be suspended during nighttime shifts, depending on the location. Upon completion of tunnel construction, portal areas would generally include construction of permanent tunnel access and maintenance facilities, and construction staging areas would be restored to their original conditions.

3.9.3 Vaults, Valve Lots, and Crossover Facilities

Vaults, valve lots, and crossover facilities are located at discrete sites along the regional system and house a variety of electrical and mechanical equipment used for system operation and maintenance. The design of vaults, valve lots, and crossover facilities varies from project to project and site to site. These structures are generally partially or entirely buried, have a building footprint of about 4,000 square feet (50 feet by 75 feet), and range in depth from 6 to 15 feet below grade. Partially buried vaults can extend up to 30 inches above the ground surface, whereas access doors to completely buried vaults are at grade. Whether or not a vault can be completely buried depends on site-specific conditions, such as depth to groundwater or adjacent uses. Vaults are used to house valves, and control buildings are often associated with them. Control buildings house instrumentation and electrical facilities. Control buildings can be buried, but are more frequently above grade; they are typically small, one-story structures (minimum height of 8 feet) and have power requirements. Some facilities, such as crossover structures, could require permanent discharge facilities to local creeks or other water bodies so that transmission pipelines can be drained prior to maintenance or if needed to conduct emergency repairs.

Construction activities for vaults or valve lots are assumed to be restricted to the immediate vicinity of the site (either existing sites proposed for repair or new sites) and to continue at the same location for the full duration of construction. Construction activities could include excavation and shoring, concrete construction, equipment installation, startup, and testing. Staging areas for equipment storage and temporary stockpiling could also be required. The extent and duration of construction would depend on the specific project.

3.9.4 Pump Stations

As with valve lots, existing or proposed pumping facilities are located at discrete sites along the regional system, but generally require a much larger area and larger equipment than valve lots. The WSIP improvements for this category of facility involve upgrades to pump stations, although there is a possibility that one station would be abandoned and a new station constructed on adjacent developed land. The proposed pumping facility modifications include replacing pumping, electrical, power, and valving systems to allow them to reliably operate at their original capacity. Pump stations typically include a series of pumps, the largest being about 1,000 horsepower. The proposed improvements would include the use of electrically driven pumps, so there would be no additional onsite emissions from internal combustion engines. One pump station has three existing diesel-driven pumps that would remain available for use. All of the new facilities would be designed to comply with current noise abatement ordinances.

Pump station upgrades generally involve replacing existing pumps with new pumps. The buildings that house the pumps would typically remain unchanged.

In general, construction associated with pumping facilities can be phased so that system operations are not interrupted during construction. Construction of new pump stations or rehabilitation of existing stations would generally include the following types of construction activities: partial demolition of existing facilities, removal and replacement of pumps and valves, structural modifications, electrical modifications, power system modifications (which could include backup power), and modifications to the instrumentation and controls.

3.9.5 Treatment Facilities

The WSIP treatment facility projects include constructing a new secondary disinfection facility, upgrading the system's existing primary disinfection facility at Tesla Portal, and expanding/upgrading treatment facilities at both the Sunol Valley and Harry Tracy WTPs. For all of these projects, construction activities would be confined to the proposed site location and immediate vicinity for the duration of construction.

For projects proposed at existing treatment facility locations, all construction activities would be limited to the area within the property boundaries, and changes in operations would involve minor modifications over existing procedures. The general types of proposed modifications to treatment facilities include:

- Process improvements and additions
- Hydraulic system improvements
- Structural/seismic improvements
- Instrumentation and control improvements
- Electrical and power system improvements
- Site grading, paving, and drainage

In general, construction associated with treatment facilities would be phased so that system operations would not be interrupted during construction. Construction of both new and modified treatment facilities would generally include the following types of construction activities: a relatively minor amount of excavation, relocation of existing utilities, demolition, site grading, structural work, mechanical/process system work, electrical work, and instrumentation and controls.

3.9.6 Storage Facilities

The WSIP includes construction or improvement of two types of storage facilities: reservoirs and dams. For both types of facilities, construction activities would occur at the project site and vicinity throughout the duration of construction. There would be about 30 to 40 workers per crew (with one or more crews, depending on the project).

Storage reservoirs can be associated with water treatment facilities or can be an isolated end point in the distribution system. In the SFPUC system, existing storage reservoirs are entirely or partially below grade; construction of new storage reservoirs under the WSIP would involve extensive excavation to accommodate the basin(s), with excavations extending up to approximately 25 feet below grade. Excavated soils would be reused or would be hauled offsite for disposal. A dewatering system could be required if the excavation extends below groundwater elevations. The excavated area would have vertical side walls, which would require shoring by tieback walls, sheet piles, and/or solder piles in select areas; these are typically installed through pile driving or drilling, depending on the type of shoring used. The next phase of construction would involve the placement of steel-reinforced concrete. Following excavation, shoring, and concrete placement, equipment would be delivered and installed. Equipment could include pumping systems, filters, chemical feed equipment, piping, valves, and electrical and instrumentation facilities. Storage basins would require extensive seismic support and strengthening for public safety as well as for compliance with applicable requirements of the DSOD.

Dam improvements associated with the WSIP facilities range from replacing of the earthen dam at Calaveras Reservoir to raising the dam parapet at Lower Crystal Springs Dam. Replacement of Calaveras Dam would involve extensive earthmoving activities, not only to construct the new earthen dam but also to remove a portion of the existing dam. Dam replacement would also require the development of borrow and disposal areas as well as associated access roads between the borrow and fill areas and the dam site. In contrast, the Lower Crystal Springs Dam improvements would require much less earthmoving activities. Raising the dam parapet would primarily involve strengthening dam abutments and upgrading the spillway crest, tilt-weir gates, and stilling basin (below the dam).

3.10 Standard Construction Measures and GHG Reduction Actions

The SFPUC has established standard construction measures and greenhouse gas (GHG) reduction actions that would be implemented as part of all SFPUC projects, including the WSIP projects listed in Table 3.10. The main objective of the standard construction measures is to minimize potential disruption of surrounding neighborhoods during construction and to reduce impacts on existing resources to the extent feasible. The construction measures will be implemented individually for the different facility improvement projects; some measures might not be applicable to individual maintenance or repair projects, and some projects will require the development of more detailed implementation steps as the individual projects are designed and implemented. Each SFPUC project manager, environmental project manager, and contract manager would ensure that every project involving construction work contains uniform provisions to address the issues addressed in the standard construction measures. To that end, each construction contract or project must include the following standard construction measures in either the contract or project implementation procedures, as appropriate. The measures would apply to any project subject to environmental review under CEQA and would be implemented by SFPUC staff or by outside contractors under contract to the SFPUC. Although some of the SFPUC standard construction measures might not be appropriate for certain projects, each measure must be addressed through one of the following: undertaking the activities listed, undertaking further investigation and developing a more detailed work plan to address the issue, or explaining why the measure is not applicable to the particular site.

The standard construction measures to be included in WSIP construction contracts consist of the following ten provisions (SFPUC, 2007b):

1. *Neighborhood Notice*: The SFPUC will provide reasonable advance notification to the businesses, owners and residents of adjacent areas potentially affected by the Water System Improvement Program (WSIP) projects about the nature, extent and duration of construction activities. Interim updates should be provided to such neighbors to inform them of the status of the construction.

   Where schools would be affected, the SFPUC will coordinate with school facility managers to schedule construction for time periods with the least impact on school activities and facilities to ensure student safety and to minimize disruption to educational and recreational uses of the school property.

2. *Seismic and Geotechnical Studies*: Projects will incorporate review of existing information and, if necessary, new engineering investigations to provide relevant geotechnical information about the particular site and project, including a characterization of the soils at the site, and the potential for subsidence and other ground failure. Construction will address any recommendations by such geotechnical reports to ensure seismic stability and reliability of the proposed project. All SFPUC projects must be designed for seismic reliability and minimum potential water loss and property damage. All components of the water system improvement program must be designed to continue water service during a major earthquake.

3. *On-Site Air and Water Quality Measures during Construction*: All construction contractors must take measures to minimize fugitive dust and dirt emissions resulting from the construction, and implement measures to minimize any construction effects on local air and water quality, including a local storm drain system or watercourse. These measures could include preparation of a stormwater pollution prevention plan (SWPPP), if required by the California Regional Water Quality Control Board. At a minimum, construction contractors should undertake the following measures, as applicable, to minimize any adverse effects:

   - Erosion and sedimentation controls tailored to the site and project
   - Dust control plan
   - Placement of straw rolls around each of the nearby stormwater inlets
   - Preservation of existing vegetation
   - Installation of silt fences
   - Use of wind erosion control (e.g. – geotextile or plastic covers on stockpiled soil)
   - Sweeping of nearby streets at least once a day
   - Stabilization of site ingress/egress locations to minimize erosion
   - Spraying the disturbed areas of the site, or any stockpiled soil, with water to minimize fugitive dust emissions

4. *Groundwater*: If groundwater is encountered during any excavation activities, the construction contractor shall prepare a dewatering plan so that water is discharged to the stormwater system in compliance with the local standards and discharge permit requirements.

5. *Traffic*: Each contractor shall prepare a traffic control plan which will minimize the impacts on traffic and on-street parking on any streets affected by construction of the proposed project. As appropriate, SFPUC or the contractor will consult with local traffic and transit agencies.

6. *Noise*: The contractor will comply with local noise ordinances regulating construction noise to the extent feasible, and will undertake efforts to minimize any noise disruption to nearby neighbors and sensitive receptors during construction.

7. *Hazardous Materials*: Appropriate measures will be implemented to characterize and dispose of hazardous materials should they be encountered during excavation and construction. Contract specifications will mandate full compliance will all applicable local, state and federal regulations related to the identification, transportation and disposal of hazardous materials/soils. As necessary, a spill prevention and countermeasure plan will be prepared.

   A qualified environmental professional will conduct any necessary site assessment. The site assessment would include a regulatory database review to identify permitted hazardous materials and environmental cases in the vicinity of each project no more than three months before construction, and a review of appropriate standard information sources to determine the potential for soil or groundwater contamination to occur. Follow-up sampling would be conducted as necessary to characterize soil and groundwater quality prior to construction and, if needed, site investigations or remedial activities would e performed in accordance with applicable laws. The environmental professional would prepare a report documenting the activities performed, summarize the results and make recommendations for appropriate handling of any contaminated materials during construction. A contingency plan would also be prepared identifying measures to be taken should unanticipated contamination be identified during construction. Construction contractors will conduct asbestos and lead abatement in accordance with established regulations.

8. *Biological Resources*: As an initial matter, SFPUC project managers will screen the project site and area to determine whether biological resources may be affected by construction activities. In the event further investigation is necessary, the SFPUC will comply with all requirements for investigation, analysis and protection of biological resources. A qualified biologist must conduct any required biological screening survey. The biologist will review standard information sources to determine special status species with the potential to occur on the project site. The biologist would carry out a site survey by walking or driving over the project site, as appropriate, to note the general resources and whether any habitat for special-status species is present. The biologist would then document the survey with a brief letter report or memo, setting forth the date of the visit, whether habitat for special-status species is present, providing a map or description showing where sensitive areas exist within the site, and identifying any appropriate avoidance measures.

9. *Cultural Resources*: As an initial matter, SFPUC project managers will screen the project site and area to determine whether cultural resources, including archaeological and other historical resources, may be affected by construction activities. In the event further investigation is necessary, the SFPUC will comply with all requirements for investigation, analysis and protection of cultural resources.

   CEQA considers paleontological resources to be "cultural resources." Any screening for cultural resources would include screening for archaeological, paleontological and historic resources. For projects requiring excavation, deep grading, well drilling or tunneling into geologic material at sites identified as having high potential for encountering paleontological resources, a state-registered professional geologist or qualified professional paleontologist will conduct a site-specific evaluation of the paleontological sensitivity. The assessment will include a report of findings for the SFPUC.

   A qualified archaeologist, historian or paleontologist will conduct all cultural resources survey and screening work. Screening surveys for cultural resources would include a cultural resources records search to be conducted at the appropriate office member of the California Historical Resources Information System. A field survey will be conducted if determined necessary after the cultural resources records search. Any impacts on identified cultural resources will be avoided to the extent feasible.

   Any initial historic resource screening will identify historic resources on the project site as well as adjacent to the project site.

   It is possible that project work may affect accidentally discovered buried or submerged cultural resources. Any contractor must distribute the Planning Department archaeological resource "ALERT" sheet to any person involved in soil-disturbing activities. If there is any indication of an archaeological or a paleontological resource during the soils disturbing activity of the project, the contractor shall immediately suspend any soils disturbing activities in the area and notify the SFPUC of such discovery. The SFPUC will then work with the Planning Department's Environmental Review Officer to determine what additional measures should be implemented, based on reports from a qualified archaeological or paleontological consultant.

10. *Project Site*: The SFPUC will conduct construction activities on SFPUC-owned lands to the extent feasible and minimize the need for use of non-SFPUC-owned land during construction. In cases where construction easement or staging areas are needed on non-SFPUC land, the SFPUC will restore these areas to their prior condition so that the owner may return them to their prior use, unless otherwise arranged with the property owner. The site will be maintained to be clean and orderly. Construction staging areas will be sited away from public view where possible. Nighttime lighting will be directed away from residential areas.

    Upon project completion, the construction contractor will return the SFPUC project site to its general condition before construction, including re-grading of the site and re-vegetation of disturbed areas.

In addition, the SFPUC is committed to the following GHG reduction actions as part of the WSIP program. The SFPUC will include the first two measures in all WSIP contractor specifications and implement the third measure during project planning and design, which in addition to having other environmental benefits, would also help reduce GHG emissions.

1. The SFPUC will require that all contractors maintain tire inflation to the manufacturers' inflation specifications.

2. The SFPUC will implement a construction worker education program for all WSIP projects.

3. WSIP projects that include construction of new buildings will consult with the SFPUC Power Enterprise's Energy Efficiency Group to incorporate all applicable energy efficiency measures into the project design. Projects with buildings components will attempt to maximize energy efficiency by exceeding Title 24 minimum requirements by at least 20 percent. Projects with buildings components will attempt to meet or exceed LEED Silver certification as required by the City's Green Building Ordinance.

3.11 Proposed Construction Schedule

Figure 3.6 presents a preliminary master schedule of the construction phases for the key regional WSIP facility improvement projects. The SFPUC developed the preliminary schedule to assure that water delivery service is maintained throughout construction of the numerous projects, but is preparing schedule refinements and adjustments as the projects are further developed and more information is known about construction requirements. As the preliminary schedule indicates, construction of projects is expected to be completed by the end of 2014; there would be an intense period of construction from 2009 to 2010, when 18 of the 22 projects would be under construction concurrently. All WSIP projects would be completed by the end of 2014. The acquisition of supplemental water supplies during droughts would be implemented as needed to match the water delivery needs of the systemwide customers (see Chapter 5, Section 5.1) and is not included on the construction schedule.

3.12 WSIP-Related Activities

As discussed in Section 3.4, above, the SFPUC has included several components under the funding umbrella of the WSIP that are not analyzed in this PEIR. Three of these components—the Watershed Environmental Improvement Program, Regional Desalination Feasibility Study, and Habitat Reserve Program—are indirectly related to the proposed program analyzed in this PEIR and are described below.

3.12.1 Watershed Environmental Improvement Program

The purpose of the Watershed Environmental Improvement Program (WEIP) is to identify, prioritize, protect, and restore lands and natural resources in the vicinity of the SFPUC's regional water system. The WEIP encompasses the entire geographic range of areas that affect or are affected by water system operations, including the Tuolumne River watershed, Alameda Creek watershed, Peninsula watershed, and other SFPUC lands and rights-of-way. The program could include ecosystem and habitat protection, improvements, and restoration projects, addressing such issues as fish passage, riparian habitat degradation, and sensitive species recovery. This program is currently under development, and preliminary WEIP activities have focused on the development of studies and monitoring programs as well as coordination with other projects and work groups with similar goals. Many of the WEIP projects and activities identified at this time consist of the implementation of activities previously identified in the SFPUC's adopted Alameda and Peninsula Watershed Management Plans. CEQA documents have been certified for both plans, so programmatic environmental review of these activities has already been completed. Additional environmental review will be conducted as appropriate as the WEIP projects and activities become further defined.

Although the SFPUC is funding the WEIP through the WSIP bond funds, the WEIP is considered separate from and in addition to the mitigation measures identified in this PEIR. However, the SFPUC is coordinating the projects and activities of the WEIP with the WSIP facility improvement projects and water supply and system operations described in this PEIR, and the general scope of the WEIP is considered in the cumulative impact analyses presented in Chapter 4, Section 4.17, and in Chapter 5, Section 5.7.

3.12.2 Bay Area Regional Desalination Project

This activity consists of the SFPUC's participation with the East Bay Municipal Utility District, Santa Clara Valley Water District, and Contra Costa Water District to study the feasibility of a Bay Area Regional Desalination Plant (BARDP). These regional water agencies have formed a partnership to investigate the feasibility of jointly implementing a desalination project in the Bay Area to improve water supply reliability for the over 5 million people served by the four agencies. The project would produce potable water from seawater or brackish water to meet some of the water supply needs in the agencies' combined service areas (URS, 2003).

The participating agencies are currently preparing a feasibility study for the project and planning for construction of a pilot plant. The feasibility study includes analysis of institutional issues related to implementing the full-scale BARDP and assessment of site and infrastructure options for three potential sites. The possible sites are located along the eastern Contra Costa County shoreline, near the east end of the Bay Bridge in Oakland, and near the Oceanside Water Pollution Control Plant in San Francisco. The pilot plant and related studies are scheduled to be implemented from 2007 to 2008. Assuming a positive outcome from the feasibility study and the pilot plant, it is expected that environmental review of the BARDP would occur in 2009, design in 2010, and construction of the full-scale BARDP in 2012.

The regional desalination project is considered in this PEIR as a potential alternative water supply source. The project is analyzed in Chapter 8 as a component of one of the WSIP variants and is considered in Chapter 9 as part of the CEQA alternatives analysis.

3.12.3 Habitat Reserve Program

The SFPUC is proposing the Habitat Reserve Program (HRP) with the objective of developing and enhancing wetlands and other habitats to be applied toward mitigation of impacts on biological resources resulting from implementation of the WSIP. The program would enhance, restore, create, and preserve habitats on existing SFPUC property and/or on other land to be covered by conservation easements. The HRP would serve as compensation for both temporary and permanent impacts on potentially affected sensitive habitats, including habitats of special-status species, due to construction and operation of the WSIP facility improvement projects as well as implementation of the proposed water supply option (SFPUC, 2006c).

The HRP would provide a comprehensive, coordinated approach to implementing mitigation measures for impacts on biological resources from WSIP actions identified in this PEIR and in project-level CEQA documents for the individual WSIP projects. The SFPUC would coordinate the implementation and management of the HRP with the implementation and management of mitigation measures presented in this PEIR and in project-level CEQA documents. In most cases, the HRP would augment the project-specific mitigation measures, focusing on habitat compensation requirements. The HRP could provide a vehicle for the SFPUC to comply with regulatory permit requirements related to biological resources affected by the WSIP.

The HRP would consolidate habitat enhancement, restoration, creation, and preservation at a select number of mitigation sites located throughout the WSIP program area on CCSF-owned lands or on county, nonprofit, or private lands that are appropriate for conservation easements, if necessary. The HRP would establish performance criteria for habitat enhancement, restoration, creation, and preservation and would include monitoring to ensure that the criteria are satisfied. In addition to enhancing, restoring, creating, or protecting habitat, the HRP could also involve funding research or local projects, purchase of mitigation credits from existing mitigation banks, or participation in regional habitat restoration efforts. Where appropriate, the HRP actions would be coordinated with other ongoing SFPUC activities, including implementation of the Alameda and Peninsula Watershed Management Plans, the Alameda and Peninsula Habitat Conservation Plans (in development), and the WEIP (described above).

As part of the HRP, a preliminary identification has been conducted to determine the types of habitats that could be created as well as potentially suitable mitigation sites. The types of actions being considered under the HRP include: altering existing agricultural uses to enhance or restore habitat; fencing and managing grazing lands; grading, planting, and monitoring vegetation; excavating, grading, and constructing stock ponds and installing water control structures to provide appropriate hydraulic conditions; harvesting local seed stock; and fencing to protect habitats and control non-native species. **Table 3.13** provides a preliminary list of habitat types and possible mitigation sites for each region.

TABLE 3.13
HABITAT RESERVE PROGRAM – PRELIMINARY LIST OF HABITAT TYPES AND MITIGATION SITES

Region	Habitat Type	Potential Location of Mitigation Sites
San Joaquin Region		
	Vernal Pools and Wetland	Stanislaus County, Tuolumne County
	Grassland	San Joaquin County, Stanislaus County
Sunol Valley Region		
	Oak Woodland	Within the Alameda watershed
	Riparian	Along Alameda Creek or its tributaries
	Wetland	Along tributaries to Calaveras and San Antonio Reservoirs
	Serpentine	Within the Alameda watershed
	Grassland	Within the Alameda watershed
Bay Division Region		
	Oak Woodland	Within the Alameda and Peninsula watersheds
	Riparian	Within the Alameda and Peninsula watersheds, or in tributaries to San Francisco Bay
	Freshwater Wetland	Within the Alameda and Peninsula watersheds, or other watersheds draining to San Francisco Bay
	Grassland	Within the Alameda and Peninsula watersheds
	Saline Wetland	Along the San Francisco Bay shoreline
	Tidal Marsh	Along the San Francisco Bay shoreline
Peninsula and San Francisco Regions		
	Oak Woodland	Within the Peninsula watershed
	Riparian	Within the Peninsula watershed or other parts of San Mateo County and San Francisco
	Freshwater Wetland	Within the Peninsula watershed or other parts of San Mateo County and San Francisco
	Grassland	Within the Peninsula watershed or other parts of San Mateo County and San Francisco

SOURCE: SFPUC, 2006c.

The San Francisco Planning Department recently began environmental review of the HRP, and the SFPUC is currently designing the program with the intent of initiating habitat enhancement, restoration, creation, and preservation before or concurrent with the WSIP project activities, and in advance of impacts where possible. The HRP schedule includes environmental review from 2007 to 2008, habitat creation and/or enhancement and negotiation of conservation easements between 2008 and 2010, and monitoring extending from 2009 to 2010 and longer.

Chapter 6 of this PEIR describes mitigation measures for WSIP impacts on biological resources, and the HRP is identified as a potential approach to mitigating WSIP impacts on biological resources. However, CEQA environmental review of the HRP must be completed before the SFPUC can approve and implement the HRP. Once the HRP is approved, the SFPUC can then implement it and apply any habitat creation and/or enhancement towards habitat compensation requirements of WSIP-related mitigation measures as approved by the appropriate regulatory agencies. Otherwise, in the absence or delayed approval of the HRP, where necessary, the SFPUC will develop and implement appropriate habitat compensation mitigation for individual WSIP projects.

3.13 Required Actions and Approvals

The following list sets forth the approvals necessary for overall adoption and approval of the WSIP as described in this chapter, including adoption of the proposed levels of service and water supply option, and general approval of the facility improvement projects.

Each of the individual WSIP facility improvement projects will undergo project-level CEQA review, and CEQA documents developed through those reviews will identify needed approvals by local, state, and federal agencies for individual projects. Table C.6 of Appendix C presents the specific permits and approvals that could be required for individual projects as well as interested agencies that have requested early consultation and coordination with the SFPUC. Several projects are expected to require U.S. Department of the Army permits to comply with the Clean Water Act, which, in turn, will require compliance with the Federal Endangered Species Act, the Clean Water Act Section 401, and the National Historic Preservation Act. Several projects are expected to require Streambed Alteration Agreements from the California Department of Fish and Game and compliance with the California Endangered Species Act. When individual projects undergo CEQA review, the project's environmental documentation will provide more detailed and up-to-date information on the required approvals and need for consultation with interested agencies. The approval and adoption of the overall WSIP as a program and policy are distinct actions from the approvals for individual facility improvement projects.

Approvals and actions applicable to the overall WSIP include:

- *San Francisco Planning Commission*
  - Certifies Final PEIR on the WSIP

- *San Francisco Public Utilities Commission*
  - Reviews Final PEIR and adopts CEQA findings and mitigation monitoring and reporting program
  - Approves and adopts WSIP
- *San Francisco Board of Supervisors*
  - Hears and decides any appeals of the Planning Commission's certification of the Final PEIR

Local, state and federal agency approvals for individual facility improvement projects are listed in Appendix C, Table C.6. Implementation of the WSIP could involve the following additional discussion and actions by the agencies listed below:

- *San Francisco Public Utilities Commission*
  - Approves any water transfer agreements with the Turlock and Modesto Irrigation Districts or other agencies
  - Approves contracts for construction of WSIP facility improvement projects
  - Approves operating agreements for the Westside Basin conjunction-use program
  - Reviews its cost of utility service annually and revises its rate schedules applicable to retail water sales as required[27]
  - Approves any water sales agreements with SFPUC wholesale and retail customers
- *San Francisco Planning Department/Planning Commission*
  - Conducts ongoing environmental review of individual facility improvement projects as well as compliance with mitigation and monitoring reporting program during WSIP implementation
  - Makes determinations of consistency with the San Francisco General Plan, if needed, for projects requiring certain approvals by the Board of Supervisors
- *San Francisco Board of Supervisors*
  - Appropriates funding for implementation of the WSIP projects, including general obligation bond monies and annual budget appropriations
  - May reject rates and charges that the SFPUC establishes for water customers by resolution within 30 days of adoption by the SFPUC
  - Considers appeals of EIR certifications and negative declaration approvals by the San Francisco Planning Department
- *State Water Resources Control Board*
  - Reviews and authorizes any transfer under a post-1914 water right that may be necessary to implement long-term water transfers with the Turlock or Modesto Irrigation Districts

[27] Retail water sales include sales to Lawrence Livermore National Laboratory, the Town of Sunol, and approximately 190 other retail customers (see list of major water customers in Table 3.1). The SFPUC sells water to Groveland Community Services District under the terms of a 1984 contract that allows the water rate to be adjusted every four years.

- *Turlock and Modesto Irrigation Districts*
  - Review and approve water transfer agreements with the SFPUC and/or amendments to the SFPUC's water bank account in Don Pedro Reservoir
- *SFPUC wholesale and retail water customers*
  - Approves any agreements between SFPUC and individual wholesale and retail customers
- *Daly City, California Water Service Company's South San Francisco service area, and San Bruno*
  - Approves operating agreement(s) for the Westside Basin conjunctive-use program (Regional Groundwater Projects, part of SF-2), including approval of new system wells

4 WSIP Facility Projects – Setting and Impacts

4.1 Overview

CHAPTER 4

WSIP Facility Projects – Setting and Impacts

Chapter 4 Sections

4.1 Overview

This chapter addresses the Water System Improvement Program (WSIP) facility improvement projects described in Chapter 3, Section 3.9, and provides a program-level evaluation of the potential environmental impacts of constructing and operating each of the 22 regional WSIP facility projects. This overview section describes key aspects of the approach to analysis that applies to the program-level impact evaluation of WSIP facility projects.

This chapter focuses only on the WSIP projects and does not address the effects of the proposed WSIP water supply and system operations through 2030, which are evaluated separately in Chapter 5. Chapter 5 addresses the effects of the proposed water supply and system operations on the Tuolumne River system, Alameda Creek system, Peninsula system, and Westside Basin Groundwater Resources.

The Chapter 4 impact analysis is based on preliminary information about the individual projects that are proposed for implementation following approval of the WSIP. The project information presented is conceptual in nature, based on readily available information about the projects, types of facilities proposed, and their general site locations. This level of information is appropriate for this programmatic analysis of these projects. This chapter identifies the general types of impacts that could be expected to result from the individual projects, based on existing project information. The information about the individual projects continues to evolve as data about the project sites, design, operation, and effects are refined. All projects will be examined in more detail at the project level. If the individual WSIP projects have additional significant impacts that were not addressed in this Program EIR, the San Francisco Planning Department will prepare EIRs or negative declarations to examine the site-specific and project-specific effects of the individual projects. More detailed information about the individual projects (i.e., construction plans as well as siting and operational details) will be considered in the project-level environmental documents.

Sections 4.2 through 4.15 present program-level impacts associated with each WSIP facility project by environmental resource topic. Section 4.16 presents combined or collective impacts resulting from implementation of multiple WSIP facility projects, also organized by environmental resource topic. Section 4.17 presents cumulative impacts resulting from implementation of the WSIP as a whole in conjunction with other cumulative development.

Scope of the WSIP Facility Impact Analysis

This program-level impact analysis identifies the potential environmental effects of the individual WSIP projects based on general information about each project and project site(s). To date, many of the WSIP projects have been developed at the conceptual level only and only some projects have more detailed siting and design information. Accordingly, this program-level evaluation addresses all projects from a broad, overview perspective. It does not provide detailed, site-specific impact assessment of each project, but rather frames the nature and magnitude of the expected environmental impacts associated with the proposed WSIP projects. Based on these impacts, Chapter 6 identifies the appropriate program-level mitigation measures in general terms; these measures would be refined to specifically apply to each project as the projects are further developed.

Since there are undetermined aspects of many of the WSIP projects at this stage of program planning, this Program Environmental Impact Report (PEIR) errs on the conservative side of impact significance determination and assumes that separate, project-level California Environmental Quality Act (CEQA) review would confirm the existing conditions and degree of impact. The San Francisco Public Utilities Commission (SFPUC) is conducting detailed project development studies on many of the WSIP projects concurrent with preparation of the PEIR. For many of the WSIP projects, project-level CEQA review is being conducted or will be conducted as appropriate to provide additional information and analyses and further address the site-specific impacts outlined in this PEIR. The project-level analyses will consider whether additional project information changes the environmental impact determinations contained in the PEIR about the individual project, and whether the programmatic mitigation measures identified in this PEIR should be refined. Both project-level EIRs and negative declarations are being prepared or will be prepared for many of the WSIP projects. All projects will be assessed to determine whether additional environmental review is required.

[Additional discussion on the appropriate level of detail for environmental analysis was prepared in response to comments on the Draft PEIR. Please refer to Section 14.4, Master Response on PEIR Appropriate Level of Analysis (Vol. 7, Chapter 14).]

Study Area for WSIP Regional Facility Projects

The study area applicable to the WSIP facility projects discussed in this chapter extends from Oakdale Portal on the SFPUC regional water system, which is the easternmost location of any of the WSIP projects (i.e., the San Joaquin Pipeline System project, SJ-3), westward along the regional water system to San Francisco, which is the westernmost location of the WSIP projects. The study area for the WSIP facility projects includes the five regions described in Chapter 2, Section 2.2 and shown in Figure 2.1: the San Joaquin (SJ), Sunol Valley (SV), Bay Division (BD), Peninsula (PN), and San Francisco (SF) Regions (there are five regional WSIP projects located in both San Francisco and northern San Mateo County, overlapping with parts of the Peninsula Region). No WSIP facility projects are proposed east of Oakdale Portal in the Hetch Hetchy region of the regional system, so no discussion of this eastern region is provided in this chapter. The locations of the WSIP projects are shown in Figures 3.5a and 3.5b.

In a few instances (i.e., Section 4.15, Energy Resources, and Section 4.16, Collective Impacts Related to WSIP Facilities), the impact analysis addresses impacts of the *program area* rather than the *study area*. The program area encompasses the entire area affected by the WSIP, from Hetch Hetchy Reservoir to San Francisco.

WSIP Project Names

Chapter 3, Table 3.10, describes each WSIP project and gives the complete project name and number. Throughout this chapter, the WSIP project names are abbreviated and the project number is also referenced. To aid the PEIR reader, a complete WSIP project list is presented as **Figure 4.1-1**. The list gives the full project names, abbreviated project names, and reference numbers and is organized by region.

Proposed Project Sites

The impact analysis in this PEIR is based on project description information provided by the SFPUC with respect to facility location and conceptual project construction and operation scenarios for each of the projects. This information is summarized in Chapter 3 and further detailed in Appendix C.

In cases where the SFPUC has chosen a preferred site location for a particular project, each section in this chapter evaluates the impacts of the WSIP facility improvement projects at their preferred site locations (as listed in Table 3.12 in Chapter 3). Some WSIP projects have alternative locations (specified in Tables 3.10 and 3.11); impacts associated with potential project development at these alternative locations are not evaluated in this PEIR, although generic impacts for each type of facility that could apply to the alternative sites are described. Project location alternatives and alternative site design and layout would be evaluated as appropriate in the project-level CEQA evaluations for select WSIP projects. For some WSIP projects, specific project locations have not yet been developed. In these cases, the program-level analysis considers the range of alternatives presented and a reasonable worst-case scenario regarding the potential environmental impacts that could occur.

GUIDE TO NAMES AND NUMBERS OF WSIP FACILITY IMPROVEMENT PROJECTS

SAN JOAQUIN REGION

No.	Project Title	Abbreviated Project Title
SJ-1	Advanced Disinfection	Advanced Disinfection
SJ-2	Lawrence Livermore Supply Improvements	Lawrence Livermore
SJ-3	San Joaquin Pipeline System	SJPL System
SJ-4	Rehabilitation of Existing San Joaquin Pipelines	SJPL Rehabilitation
SJ-5	Tesla Portal Disinfection Station	Tesla Portal Disinfection

SUNOL VALLEY REGION

No.	Project Title	Abbreviated Project Title
SV-1	Alameda Creek Fishery Enhancement	Alameda Creek Fishery
SV-2	Calaveras Dam Replacement	Calaveras Dam
SV-3	Additional 40-mgd Treated Water Supply	40-mgd Treated Water
SV-4	New Irvington Tunnel	New Irvington Tunnel
SV-5	SVWTP – Treated Water Reservoirs	Treated Water Reservoirs
SV-6	San Antonio Backup Pipeline	SABUP

BAY DIVISION REGION

No.	Project Title	Abbreviated Project Title
BD-1	Bay Division Pipeline Reliability Upgrade	BDPL Reliability Upgrade
BD-2	BDPL Nos. 3 and 4 Crossovers	BDPL 3 and 4 Crossovers
BD-3	Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault	BDPL 3 and 4 Seismic Upgrade at Hayward Fault

PENINSULA REGION

No.	Project Title	Abbreviated Project Title
PN-1	Baden and San Pedro Valve Lots Improvements	Baden and San Pedro Valve Lots
PN-2	Crystal Springs / San Andreas Transmission Upgrade	CS/ SA Transmission
PN-3	HTWTP Long-Term Improvements	HTWTP Long-Term
PN-4	Lower Crystal Springs Dam Improvements	Lower Crystal Springs Dam
PN-5	Pulgas Balancing Reservoir Rehabilitation	Pulgas Balancing Reservoir

SAN FRANCISCO REGION

No.	Project Title	Abbreviated Project Title
SF-1	San Andreas Pipeline No. 3 Installation	SAPL 3 Installation
SF-2	Groundwater Projects	Groundwater Projects
SF-3	Recycled Water Projects	Recycled Water Projects

Guide to Names and Numbers of WSIP Facility Improvement Projects

Impact Significance Determinations

The impact significance criteria used in this PEIR are based on San Francisco Planning Department Major Environmental Analysis (MEA) guidance regarding the environmental effects to be considered significant. MEA guidance is, in turn, based on the CEQA Guidelines Appendix G with some modifications. In cases where potential environmental issues associated with the WSIP are identified but are not clearly addressed by MEA's guidance, additional impact significance criteria are presented. Appendix B of this PEIR presents the MEA Initial Study checklist as applied to the WSIP, and indicates the criteria applicable to the WSIP and discussed in the PEIR. The significance criteria used for each environmental topic/resource area are presented in each section of Chapter 4 following the setting and before the discussion of impacts.

For the impact analyses, the following categories are used to determine impact significance:

> **Not Applicable (N/A).** An impact is considered not applicable to a WSIP project if there is no potential for impacts or the environmental resource does not occur within the project area or the area of potential effect. For example, an impact on a biological resource may not be applicable to some projects if there are no biological resources within the construction or operation zone that could be affected by the project.
>
> **Less than Significant (LS).** This determination applies if there is a potential for some limited impact, but not a substantial adverse effect that qualifies under the significance criteria as a significant impact.
>
> **Less than Significant with Program-Level Mitigation (LSM).** This determination applies to the collective impact analysis only. It indicates a potential for some limited impact after implementation of program-level mitigation measures (those numbered 4.3-1 through 4.15-2, as listed in Chapter 6), but not a substantial adverse effect that qualifies under the significance criteria as a significant impact.
>
> **Potentially Significant, Mitigatable (PSM).** This determination applies if there is the potential for a substantial adverse effect that meets the significance criteria, but mitigation is available to reduce the impact to a less-than-significant level. The impact is labeled "potentially" significant because there is not enough site-specific information at the program level of analysis to determine definitively that it is significant. The impacts identified as "potentially significant" are treated as significant impacts in this PEIR. Separate, project-level CEQA evaluation of the WSIP projects could confirm that the impact is significant for that project or document that the impact is less than significant.
>
> **Potentially Significant, Unavoidable (PSU).** This determination applies to impacts that are significant but for which there appears to be no feasible mitigation available to reduce the impacts to a less-than-significant level. There might be some mitigation available to lessen the impact, but the residual effect remains significant and therefore unavoidable. The impact is labeled "potentially" significant and unavoidable because there is not enough site-specific information at the program level of analysis to determine definitively that it is significant or that mitigation could sufficiently reduce the severity of the impact. When project design or location information is not available at this stage of project planning, the PEIR errs on the conservative side and also applies this determination. The impacts identified as "potentially significant and unavoidable" are treated as significant and

unavoidable impacts in this PEIR. Under both these circumstances, separate, project-level CEQA evaluation of the WSIP projects could confirm that the impact is, in fact, significant and unavoidable for a specific WSIP project or document that the impact is significant but can be mitigated to a less-than-significant level. This determination is also applied if the feasibility of the mitigation is contingent on review and approval by other jurisdictional agencies (i.e., mitigation feasibility is outside SFPUC control).

Significant Unavoidable (SU). This applies to impacts that are significant but for which there appears to be no feasible mitigation available to reduce the impact to a less-than-significant level. The word "potentially" is not used for select impacts where it can be determined during this PEIR process that: (1) the impact would occur, and (2) the impact could not be mitigated to a less-than-significant level.

In determining the significance of a potential WSIP impact, the analysis first describes the nature, magnitude, and severity of a potential effect and determines whether it is potentially significant, less than significant, or not applicable for each WSIP project. The PEIR significance determinations err on the conservative side, since the impact analyses at the program level must generalize the types and classes of impacts as well as the feasibility of mitigation measures to reduce impacts to a less-than-significant level. The feasibility of mitigation measures varies based on project design and existing conditions at each project site. Also, the PEIR conservatively determines impacts to be potentially significant when there is a potential for a specific resource to be affected, even though the presence or absence of the resource has not been determined at this stage of project planning. For example, under Biological Resources, Cultural Resources, and Hazards (Sections 4.6, 4.7, and 4.14, respectively), the analysis indicates that some impacts are potentially significant and require mitigation, but this determination would only apply if the specified resource or condition is actually found to be present on the site. Site-specific conditions will be determined as part of a separate, project-level CEQA review conducted for each WSIP project. Therefore, significance determinations for a particular impact could change when more detailed project descriptions and site-specific information becomes available during these project-level reviews. This PEIR gives a broader overview of potential impacts that is appropriate for a program level of analysis.

As part of the significance determination process, the analysis evaluates whether there are applicable regulations requiring compliance with measures that could reduce a potentially significant impact to a less-than-significant level. If so, compliance with the regulation is assumed, and the impact is considered to be less than significant. The analysis also determines whether there is an applicable SFPUC Alameda or Peninsula Watershed Management Plan (WMP) policy or requirement for WSIP projects located within WMP boundaries. If they apply, compliance with the WMP policies/requirements is assumed, and the impact is considered to be less than significant.

The analysis also considers whether implementation of the SFPUC construction measures could avoid potential impacts. As described in Chapter 3, Section 3.11, the SFPUC has established 10 construction measures that are to be implemented as part of all of its projects. The main objective of these measures is to minimize potential disruption of surrounding neighborhoods during construction and to reduce impacts on existing resources to the extent feasible. Each

SFPUC project manager, environmental project manager, and contract manager would ensure that every project involving construction work contains uniform provisions to address these issues. The measures would apply to any construction activities that require environmental review and are conducted by SFPUC staff or by outside contractors under contract with the SFPUC. If the impact would be less than significant with implementation of the SFPUC construction measures, then no mitigation is identified. However, in most cases, the SFPUC construction measures are not detailed enough to ensure that impacts would be less than significant, so the PEIR identifies more specific mitigation measures that would need to be implemented, sometimes along with or as part of SFPUC construction measures, to ensure impacts are reduced to a less-than-significant level.

In cases where there are no applicable regulations or SFPUC construction measures, or such regulations and measures exist but by themselves would not reduce an impact to a less-than-significant level, then the impact is considered potentially significant. If there are feasible measures available that could reduce these potentially significant impacts to a less-than-significant level, then the impact is considered potentially significant but mitigatable (PSM), and the PEIR identifies mitigation measure(s) to address the potentially significant impact. Impacts described in this chapter are numbered so they can be cross-referenced to the mitigation measures presented in Chapter 6.

Within each section in this chapter, a summary table is included at the beginning of each impact discussion to summarize the potential impacts by project and indicate the level of impact significance. The impact discussion for the WSIP projects is organized by region, and impact significance determinations for each project are repeated in a table under each region for ease of reference. Impacts are numbered by section number, with the corresponding numbers used for mitigation measures in Chapter 6.

4.2 Plans and Policies

4.2 Plans and Policies

4.2.1 Overview

Pursuant to CEQA Guidelines Section 15125(d), Section 4.2 first describes land use plans and policies and the manner in which they apply to WSIP facility improvement projects (Section 4.2.2), and then discusses program consistency with applicable plans (Section 4.2.3). The focus of this section reflects the authority of the agencies discussed herein relative to the WSIP projects and, consequently, the applicability of their planning documents. As described in Chapter 3, Section 3.13, the agencies responsible for approving the overall WSIP and PEIR include the San Francisco Planning Commission, the SFPUC, and the San Francisco Board of Supervisors. Plans and policies addressed in this section include:

- *City and County of San Francisco*. San Francisco General Plan, Accountable Planning Initiative, San Francisco Sustainability Plan.
- *SFPUC*. Alameda and Peninsula Watershed Management Plans, Water Enterprise Environmental Stewardship Policy.
- *U.S. Department of the Interior*. Golden Gate National Recreation Area – Scenic Easement and Scenic and Recreation Easement.
- *Bay Conservation and Development Commission*. San Francisco Bay Plan.
- *Other Agencies*. Local general plans, other regional plans.

The analysis in this section complements that of Section 5.2, which focuses on plans and policies relevant to the effects of proposed changes in WSIP water supply and system operations. Sections 4.3 through 4.15 describe resource-specific plans (e.g., air quality management plans are discussed in Section 4.9, Air Quality; habitat conservation plans are discussed in Section 4.6, Biological Resources), and Chapter 7 describes plans and policies related to growth in population and employment.

4.2.2 Land Use Plans and Policies Potentially Relevant to WSIP Projects

City and County of San Francisco Plans and Policies

The City and County of San Francisco (CCSF) land use plans and policies are primarily applicable to projects within the jurisdictional boundaries of San Francisco, although in some cases they may apply to projects outside of San Francisco. The SFPUC is guided by the San Francisco City Charter along with other city plans and policies. These plans include the San Francisco General Plan, which sets forth the comprehensive, long-term land use policy for San Francisco, and the *San Francisco Sustainability Plan*, which addresses the long-term sustainability[1] of the city. In addition, the SFPUC has adopted various plans and policies that further direct its activities, including the Alameda and Peninsula Watershed Management Plans (WMPs) and the Water Enterprise Environmental Stewardship Policy.

Extraterritorial Lands

Under the San Francisco City Charter,[2] the SFPUC has authority over the management, use, and control of extraterritorial lands; that it, properties outside of the city that the CCSF owns or leases or over which it holds easements. Although the San Francisco General Plan and Sustainability Plan were developed for lands within the jurisdictional boundaries of San Francisco, their underlying goals apply to SFPUC projects on extraterritorial lands. The Alameda and Peninsula WMPs specifically apply to CCSF-owned extraterritorial lands in Alameda, Santa Clara, and San Mateo Counties.

San Francisco General Plan

The San Francisco General Plan sets forth the comprehensive, long-term land use policy for San Francisco. One of the basic goals of the general plan is “coordination of the growth and development of the city with the growth and development of adjoining cities and counties and of the San Francisco Bay Region.” The general plan consists of 10 issue-oriented plan elements—Air Quality, Arts, Commerce and Industry, Community Facilities, Community Safety, Environmental Protection, Housing, Recreation and Open Space, Transportation, and Urban Design. The plan elements that may be relevant to the WSIP facility improvement projects are briefly described below (CCSF, 1988).

Air Quality Element

This element promotes the goal of clean air planning through objectives and policies aimed at adherence to air quality regulations, focusing development near transit services, and advocating alternatives to the private automobile.

Commerce and Industry Element

This element serves as a guide for decisions related to economic growth and change in San Francisco. The three goals of the element—continued economic vitality, social equity (with respect to employment opportunities), and environmental quality—address general citywide objectives as well as objectives for each of the major sectors of San Francisco’s economy.

---

1 Sustainability or sustainable development can be defined as development that meets the needs of the present without compromising the ability of future generations to meet their needs.

2 Section 8B.121 of the City Charter provides that “. . . the Public Utilities Commission shall have exclusive charge of the construction, management, supervision, maintenance, extension, expansion, operation, use and control of all water, clean water and energy supplies and utilities of the City as well as the real, personal and financial assets, that are under the Commission’s jurisdiction or assigned to the Commission under Section 4.132.”

Community Safety Element

This element addresses the potential for geologic, structural, and nonstructural hazards to affect CCSF-owned structures and critical infrastructure. The goal of this element is to protect human life and property from hazards.

Environmental Protection Element

This element addresses the impact of urbanization on the natural environment. The element promotes the protection of plant and animal life and fresh water sources; it also speaks to the responsibility of San Francisco to provide a permanent, clean water supply to meet present and future needs and to maintain an adequate water distribution system.

Urban Design Element

This element promotes the preservation of landmarks and structures with notable historic, architectural, or aesthetic value.

Recreation and Open Space Element

This element contains objectives and policies related to maintaining, creating, and enhancing recreational and open space resources.

The San Francisco General Plan also contains area plans that cover specific geographic areas within the city. One of the area plans, the *Western Shoreline Plan*, covers the western shoreline of San Francisco and includes the location of proposed WSIP facilities in the San Francisco Region (Groundwater Projects, SF-2; Recycled Water Projects, SF-3). The *Western Shoreline Plan* includes the Local Coastal Program under the California Coastal Act of 1976. This area plan addresses objectives to preserve open space, improve public access to the shoreline, and enhance recreation for 10 subareas, including Golden Gate Park, the San Francisco Zoo, and Lake Merced.

Two other San Francisco planning documents that pertain to the western shoreline area could be relevant to WSIP facilities. The *San Francisco Zoo Master Plan* contains polices that address water supply and distribution facilities. This plan calls for developing new irrigation water supplies and improving and maintaining the existing well system. The *Golden Gate Park Master Plan* (adopted by the San Francisco Recreation and Park Commission in October 1998) is intended to "provide a framework and guidelines to ensure responsible and enlightened stewardship of the park." The goal of this plan is to "manage the current and future park and recreation demands while preserving the historic significance of the park." The plan identifies objectives and policies for park landscape, circulation, recreation, visitor facilities, buildings and monuments, utilities and infrastructure, maintenance and operations areas, park management, park funding, and special area plans.

Accountable Planning Initiative

In November 1986, the voters of San Francisco approved Proposition M, the Accountable Planning Initiative, which added Section 101.1 to the City Planning Code to establish eight Priority Policies. These policies are as follows:

1. Existing neighborhood-serving retail uses shall be preserved and enhanced and future opportunities for resident employment in and ownership of such businesses enhanced.

2. Existing housing and neighborhood character shall be conserved and protected in order to preserve the cultural and economic diversity of our neighborhoods.

3. The City's supply of affordable housing shall be preserved and enhanced.

4. Commuter traffic shall not impede Muni transit service or overburden our streets or neighborhood parking.

5. A diverse economic base shall be maintained by protecting our industrial and service sectors from displacement due to commercial office development, and future opportunities for resident employment and ownership in these sectors shall be enhanced.

6. The City shall achieve the greatest possible preparedness to protect against injury and loss of life in an earthquake.

7. Landmarks and historic buildings shall be preserved.

8. Parks and open space and their access to sunlight and vistas shall be protected from development.

In accordance with the Accountable Planning Initiative, prior to issuing a permit for any project, or adopting legislation that requires an initial study under CEQA, or adopting any zoning ordinance or development agreement, and before taking any action that requires a finding of consistency with the general plan, the CCSF is required to find that the project is consistent with the Priority Policies established by Proposition M.

San Francisco Sustainability Plan

The San Francisco Board of Supervisors endorsed the *San Francisco Sustainability Plan* in 1997, but has not committed the CCSF to perform the actions addressed in the plan. The plan serves as a blueprint for sustainability, with many of its individual proposals requiring further development and public comment. The underlying goals of the plan are to maintain the physical resources and systems that support life in San Francisco and to create a social structure that will allow such maintenance. The plan is divided into 15 topic areas, 10 that address specific environmental issues (air quality; biodiversity; energy, climate change, and ozone depletion; food and agriculture; hazardous materials; human health; parks, open spaces and streetscapes; solid waste; transportation; and water and wastewater), and five that are broader in scope and cover many issues (economy and economic development, environmental justice, municipal expenditures, public information and education, and risk management). Under the topic "water" are goals addressing water reuse, water quality, water supply, groundwater supply, and infrastructure. Each topic area in the plan contains a set of indicators to be used over time in determining whether San Francisco is moving in a sustainable direction in that particular area (CCSF, 1997).

San Francisco Municipal Green Building Program

San Francisco's Green Building Program was founded in 1999 when the CCSF adopted the Resource Efficient Building Ordinance, which established green building standards for municipal buildings to increase energy efficiency, conserve CCSF finances, reduce the environmental impacts of demolition, construction, and operation of buildings, and create safe workplaces for CCSF employees and visitors. The ordinance created the inter-departmental Resource Efficient Building (REB) Task Force and charged the San Francisco Department of Environment with implementing the ordinance in partnership with the Department of Public Works and other REB Task Force departments. In 2004, amendments to Chapter 7 of the Environment Code set LEED (Leadership in Energy and Environmental Design) Silver Certification by the U.S. Building Council as the minimum environmental performance requirement for all municipal projects over 5,000 square feet. The REB Task Force assists City departments in compliance with the LEED Silver Certification requirement and helps to determine which projects are applicable for LEED ratings. For all municipal construction projects, including those projects that do not involve buildings and are not required to obtain LEED Silver Certification, the REB Task Force provides recommended best practices and sample specifications for building materials (e.g. recycled content of steel and concrete) (SF Dept of Environment, 2004-2007).

SFPUC Plans and Policies

The SFPUC adopted the Alameda and Peninsula WMPs in 2000 and 2001, respectively. In 2006, the SFPUC adopted the Water Enterprise Environmental Stewardship Policy.

Alameda and Peninsula Watershed Management Plans

As described in Chapter 2, Section 2.3.8, the SFPUC has adopted watershed management plans (CCSF, 2001, 2002) for CCSF-owned lands in the Alameda and Peninsula watersheds to provide a policy framework for the SFPUC to make decisions about activities that are appropriate on watershed lands. The plans provide goals, policies, and management actions that address watershed activities and reflect the unique qualities of each watershed. The WMPs are also intended for use by the SFPUC as watershed management implementation guidelines. Watershed lands are managed by the SFPUC Natural Resources Division, Watershed Resources Management Section.

As part of implementation of the WMPs, the SFPUC reviews all plans, projects, and activities that occur within the Alameda and Peninsula watersheds for conformity with the management plans and for compliance with environmental codes and regulations. To accomplish this, the SFPUC has established a project review team with members from various SFPUC departments as well as the City Attorney's office. Appropriate SFPUC personnel review proposals for new facilities, structures, roads, trails, projects, and leases or for improvements to existing facilities. Projects subject to this review include those that involve construction, digging or earthmoving, clearing, installation, use of hazardous materials, or other disturbance to watershed resources. In addition, projects that involve the issuance of new or revised leases and permits are subject to this review procedure.

For both WMPs, the SFPUC considers water quality protection as the first and foremost goal. The goals and policies are organized around the primary goal of water quality protection and secondary goals pertaining to water supply, natural resources, watershed protection, land use compatibility, fiscal management, and public awareness. The primary and secondary goals common to both watershed management plans are as follows:

- *Primary Goal*: Maintain and improve source water quality to protect public health and safety.
- *Secondary Goals*:
  - Maximize water supply.
  - Preserve and enhance the ecological and cultural resources of the watershed.
  - Protect the watersheds, adjacent urban areas, and the public from fire and other safety hazards.
  - Continue existing compatible uses and provide opportunities for potential compatible uses on watershed lands, including educational, recreational, and scientific uses.

- Provide a fiscal framework that balances financial resources, revenue-generating activities, and overall benefits and an administrative framework that allows implementation of the watershed management plans.
- Enhance public awareness of water quality, water supply, conservation, and watershed protection issues.

Water Enterprise Environmental Stewardship Policy

Adopted in June 2006, the Water Enterprise Environmental Stewardship Policy established the long-term management direction for CCSF-owned lands and natural resources affected by operation of the SFPUC water system within the Tuolumne River, Alameda Creek, and Peninsula watersheds (SFPUC, 2006). It also addresses rights-of-way and properties in urban surroundings under SFPUC management. The policy includes the following:

- The SFPUC will proactively manage the watersheds under its responsibility in a manner that maintains the integrity of the natural resources, restores habitats for native species, and enhances ecosystem function.

- To the maximum extent practicable, the SFPUC will ensure that all operations of the SFPUC water system (including water diversion, storage, and transport), construction and maintenance of infrastructure, land management policies and practices, purchase and sale of watershed lands, and lease agreements for watershed lands protect and restore native species and the ecosystems that support them.

- Rights-of-way and properties in urban surroundings under SFPUC management will be managed in a manner that protects and restores habitat value where available, and encourages community participation in decisions that significantly interrupt or alter current land use in these parcels.

The Environmental Stewardship Policy calls for implementation and update of the Alameda and Peninsula WMPs (described above), development of habitat conservation plans for the Alameda and Peninsula watersheds (described in Section 4.6, Biological Resources), and development and implementation of the Watershed and Environmental Improvement Program (described in Chapter 3, Section 3.12, WSIP-Related Activities), as well as specific integration of this policy into the WSIP and individual infrastructure projects.

Other Land Use Plans and Policies

In some portions of the WSIP study area, the SFPUC may be subject to certain provisions of the land use plans and policies of other agencies, such as the U.S. Department of the Interior and the National Park Service (NPS), which hold easements over some SFPUC property. Several federal, state, and regional agencies have adopted land use plans that establish guidelines regarding appropriate land uses and activities within the boundaries of their respective plans. Federal, state, and regional plans that are applicable to the WSIP are described below.

U.S. Department of the Interior, Golden Gate National Recreation Area – Scenic Easement and Scenic and Recreation Easement

In 1969, the CCSF granted two easements over the vast majority of the Peninsula watershed to the Department of the Interior. The easements were granted to the federal government in order to obtain a change in the route of Interstate 280 (I-280) (and an increase in the federal share of costs) to a less environmentally damaging location further east of Crystal Springs Reservoir. The approximately 19,000-acre Scenic Easement covers the lands west of Crystal Springs and San Andreas Reservoirs. The approximately 4,000-acre Scenic and Recreation Easement applies to lands in the vicinity of I-280. The CS/SA Transmission project (PN-2), Lower Crystal Springs Dam project (PN-4), and the Pulgas Channel and sediment catch basin components of the Pulgas Balancing Reservoir project (PN-5) are within the Scenic Easement, while the Pulgas Balancing Reservoir itself is within the Scenic and Recreation Easement. The easements cover nearly all of the CCSF-owned Peninsula watershed lands and place restrictive covenants on use of the lands that are unrelated to the SFPUC's overall management of the land for utility purposes. The provisions of the easement include:

1. The land shall be preserved in its present natural state and shall not be used for any purpose other than for the collection, storage and transmission of water and protection of water quality, and other purposes which shall be compatible with said use and preserving said land as open-space land;

2. No structures shall be erected upon said land except such structures as may be directly related to and compatible with the aforesaid uses. No trailer shall be placed, used or maintained on said land as a substitute for a caretaker's residential building. The design and location of all buildings except water utilities buildings and appurtenances, shall be subject to the concurrence of a regional representative of the Department of the Interior to be designated by the Secretary of the Interior;

3. No signs, billboards, or advertisements excepting directional signs and identification signs in connection with permitted uses, shall be displayed or placed upon the land;

4. Except as required to accomplish the improvements hereinafter permitted or as otherwise permitted to the Grantor hereunder, the general topography of the landscape shall be maintained in its present condition and no substantial excavation or topographic changes shall be made without the concurrence of a regional representative of the Department of the Interior to be designated by the Secretary of the Interior; and

5. Except as required to accomplish the purposes and uses herein permitted to Grantor, there shall be no cutting or permitting of cutting, destroying or removing any timber or brush without the concurrence in writing by a regional representative of the Department of the Interior to be designated by the Secretary of the Interior.

In 1980, Congress transferred responsibility for administration of the easements to the National Park Service/Golden Gate National Recreation Area (NPS/GGNRA). The legislation provides that the terms of the easements are to be administered by the NPS. The Peninsula watershed is not part of a national park or recreation area *per se*, as the CCSF retains ownership of the land and the NPS has only a limited interest. The NPS can object to development unrelated to utility management or other uses not permitted by the terms of the easements.

California Department of Fish and Game, Game Refuge Designation

In 1931, at the request of the SFPUC (then the San Francisco Water Department), the California Department of Fish and Game (CDFG) designated the Peninsula watershed as a game refuge. Pursuant to Section 10500 et seq. of the California Fish and Game Code, the "taking"[3] of birds or mammals or the use of firearms (or other weapons used for the purpose of taking birds or mammals) within the Peninsula watershed is prohibited without specific authorization.

San Francisco Bay Conservation and Development Commission, San Francisco Bay Plan

The San Francisco Bay Plan (SF Bay Plan), prepared by the San Francisco Bay Conservation and Development Commission (BCDC) in 1968 in accordance with the McAteer-Petris Act of 1965, is an enforceable plan that guides the protection and use of San Francisco Bay and its shoreline. Under the McAteer-Petris Act, BCDC has the authority to issue or deny permit applications for placing fill, extracting materials, or changing the use of any land, water, or structure within the area of its jurisdiction and to enforce policies aimed at protecting the bay and its shoreline.[3a] The SF Bay Plan designates shoreline areas that should be reserved for water-related purposes like ports, industry, public recreation, airports, and wildlife refugees. Since its adoption by BCDC in 1968, the SF Bay Plan has been amended periodically to keep pace with changing conditions and to incorporate new information concerning the bay. The new Bay Division Pipeline Tunnel No. 5 proposed under the BDPL Reliability Upgrade project (BD-1) includes approximately five miles of tunnel under the Don Edwards San Francisco Bay Wildlife Refuge, Newark Slough, and San Francisco Bay. The pipeline would be buried between 100 and 150 feet below mean sea level and result in approximately 355,000 cubic yards of bay mud excavation/spoils. As a result, this project could be subject to SF Bay Plan policies concerning the placement of fill in the bay, dredging, public access, and other policies and provisions contained in the SF Bay Plan (BCDC, 2005), depending on the final siting, construction, and operation of the BDPL Reliability Upgrade project.

Other Jurisdictions, General Land Use Plans[4]

General plans are long-range policy documents to guide the use and future development of private and public lands within the boundaries of a city or county. General plans represent a jurisdiction's official position on issues such as development and resource management.

[3] The term "taking" means to kill, harass, or disturb species or their habitats.

[3a] BCDC has jurisdiction over all of San Francisco Bay up to mean high tide, areas of marsh up to 5 feet above mean sea level, a shoreline band lying 100 feet inland from the bay, as well as salt ponds, managed wetlands, and certain waterways.

[4] A variety of local general plans were reviewed in the preparation of this section. See City of Brisbane, 1994; City of Burlingame, 1969; City of Daly City, 1989; City of Daly City, 1987; City of East Palo Alto, 1999; City of Fremont, 1991; City of Hillsborough, 2005; City of Los Altos, 2002; City of Menlo Park, 1994; City of Millbrae, 1998; City of Milpitas, 1997; City of Modesto, 1997; City of Mountain View, 1992; City of Newark, 1992; City of Palo Alto, 1998; City of Redwood City, 1990; City of Riverbank, 1987; City of San Bruno, 1984; City of San Carlos, 1992; City of San Jose, 1994; City of San Mateo, 1990; City of Santa Clara, 2002; City of South San Francisco, 1999; City of Sunnyvale, 1993a; City of Sunnyvale, 1993b; Alameda County, 1975; Alameda County, 1976; San Joaquin County, 1991; San Mateo County, 1986; Santa Clara County, 1994; Stanislaus County, 1994; Tuolumne County, 1996; Town of Colma, 1987; Town of Woodside, 1988.

California planning law (Government Code Sections 65302–65303) requires that each city or county in the state develop and adopt a general plan that addresses the following subjects: land use, circulation, housing, conservation, open space, safety, and noise. In essence, general plans represent the visions of local governments for their communities' future, and provide the policy framework intended to realize those visions.

Figure 4.2-1 shows the counties, unincorporated areas, and local city jurisdictions in which WSIP facilities would be constructed, repaired, upgraded, or replaced. The following factors affect the application of these communities' general plans to the WSIP:

- *Local Agency Project Approval*. No local agency approvals would be needed for adoption of the overall WSIP (see Section 3.13, Chapter 3). Individual projects could, in select cases, require encroachment permits from local agencies. Separate, project-level CEQA review of the individual WSIP projects will provide more detailed and up-to-date information on the approvals required for each project.

- *Building and Zoning Ordinances*. Building and zoning ordinances represent the most specific expressions of general plan goals, objectives, and policies. State law and judicial interpretation of state law[5] mutually exempt cities and counties from complying with each other's building and zoning ordinances. The SFPUC, which is part of the CCSF, is therefore exempt from complying with the building and zoning ordinances of other cities and counties. This same state law also exempts public utilities and special-purpose local agencies (such as water districts) from complying with local building and zoning ordinances when locating or constructing facilities for the production, generation, storage, treatment, or transmission of water.

- *Local Government Notification and Consistency Determination Requirements*. California Government Code Section 65402(b) requires that the SFPUC inform cities and counties of its plans to construct projects or acquire or dispose of extraterritorial property. The local governments have 40 days to determine project consistency with their general plans; these consistency determinations are advisory to the SFPUC rather than binding. Approval of the WSIP would not trigger the requirements of Section 65402(b), but implementation of the individual WSIP projects would. The SFPUC would notify local governments of WSIP facilities to be constructed, repaired, upgraded, or replaced within the city or county as part of any project-level CEQA process. Prior to project implementation, local governments would be notified pursuant to California Government Code Section 65402(b).

Notwithstanding the above, where CCSF-owned facilities are sited outside of San Francisco, the SFPUC seeks to work cooperatively with local jurisdictions to avoid conflicts with local land use plans and building and zoning codes. For the WSIP, a key issue for local agencies that receive SFPUC water is whether the WSIP adequately addresses community goals regarding water service for existing and future land uses. The cities and counties that receive all or part of their water supply from the SFPUC (not including the CCSF) include:

Atherton	East Palo Alto	Los Altos Hills	Pacifica	San Jose
Belmont	Foster City	Menlo Park	Palo Alto	San Mateo
Brisbane	Fremont	Millbrae	Portola Valley	Santa Clara
Burlingame	Half Moon Bay	Milpitas	Redwood City	South San Francisco
Colma	Hayward	Mountain View	San Bruno	Sunnyvale
Daly City	Hillsborough	Newark	San Carlos	Union City
				Woodside

5 California Government Code Section 53090 et seq.

The intent of the general plans prepared by these communities is to preserve and improve the quality of life for its citizens and to consider growth in a manner that appropriately reflects the community's values; an adequate, reliable water supply is a chief public service needed to accomplish these goals.

A second issue of importance to local agencies is whether implementation of the WSIP would be consistent with community goals regarding resource protection. **Table 4.2-1** presents an overview of general plan policies and goals that address the protection of environmental resources or the mitigation of environmental impacts. All of the issues identified in the table are addressed in this PEIR in one form or another; some specific policies are used as criteria to determine the significance of physical effects on the environment. **Table 4.2-2** lists the significance criteria that directly relate to consistency with plans and policies and indicates where in this chapter the reader can find the impact evaluation.

Habitat Conservation Plans

Habitat conservation plans provide comprehensive, long-term conservation measures for species listed as threatened or endangered under the California and Federal Endangered Species Acts, or for species that could be listed in the future. Section 4.6, Biological Resources, presents a discussion of habitat conservation plans relevant to the WSIP and addresses plan consistency.

4.2.3 Plan Consistency Evaluation

The evaluation of plan consistency is based on the applicability of relevant land use plans and policies to the siting, construction, and operation of WSIP facilities. Because the policy language found in a land use plan is susceptible to varying interpretations, it is often difficult to determine whether a proposed project is consistent or inconsistent with such policies. Further, because land use plans often contain numerous policies emphasizing differing legislative goals, the WSIP projects may be consistent with a general plan, taken as a whole, even though they may appear to be inconsistent with specific policies within the plan. The board or commission that enacted the plan or policy generally determines the meaning of such policies; these interpretations prevail if they are "reasonable," even though other reasonable interpretations are also possible. In light of these considerations, the consistency evaluation in this PEIR represents the best attempt to advise the decision-makers as to whether the proposed program is consistent with applicable land use plans and policies.

Consistency with San Francisco Plans and Policies

San Francisco General Plan

As described above in Section 4.2.2, the San Francisco General Plan addresses elements such as air quality, community safety (including protection from geologic and seismic hazards), environmental protection (including protection of water resources, biological resources, and other natural resources as well as addressing construction-related noise and ambient air quality), and urban design (including protection of historic and visual resources).

TABLE 4.2-1
SUMMARY OF GENERAL PLAN POLICIES OF OTHER JURISDICTIONS BY CEQA RESOURCE TOPIC

Resource Topic	Summary Description
Land Use and Visual Quality	General plan goals, policies, and implementation actions related to land use generally call for the use of an environmental review process to minimize potential impacts of projects, and strive to minimize the impact of construction projects on surrounding land uses.
Geology, Soils, and Seismicity	General plan policies related to geology, soils, and seismicity call for appropriate placement, design, and construction of utilities to minimize damage from seismic and geologic hazards and for the implementation of extra precautionary measures to restore utility services following earthquakes. Effective mitigation measures are required for utilities in areas prone to geologic hazards such as soil erosion, liquefaction, and slope failure.
Hydrology and Water Quality	General plan policies related to hydrology and water quality generally deal with the utilization of erosion control measures and storm water quality controls, the protection of riparian zones, and the conservation of water resources in the natural environment. Dam maintenance and monitoring are prescribed in areas potentially subject to dam failure.
Biological Resources	General plan goals, policies, and implementation programs related to biological resources are aimed at the protection of sensitive wildlife habitat and plants, including wetlands, riparian zones, native hardwoods, open space, and sensitive habitats for rare and endangered fish and wildlife species. Heritage tree programs specify guidelines for the avoidance, protection, and, when necessary, replacement of heritage trees. Use of the CEQA process to ensure that detrimental biological impacts do not occur is prescribed.
Cultural Resources	General plan policies related to cultural resources prescribe procedures to prevent detrimental impacts on archaeological/paleontological sites during construction, and the use of good planning practices to preserve cultural and historic heritage.
Traffic, Transportation, and Circulation	General plan policies related to traffic, transportation, and circulation generally require an impact analysis of new development proposals on traffic and encourage the use of utility corridors and river/ creek rights-of-way for nonmotorized transportation modes such as bicycle and pedestrian facilities.
Air Quality	General plan policies related to air quality call for air quality impact analyses for proposed projects and the use of air quality controls, such as dust abatement measures during construction, to reduce air quality impacts.
Noise and Vibration	General plan policies related to noise and vibration generally establish enforceable noise thresholds, require the use of noise suppression techniques during construction activities, encourage the incorporation of noise reduction techniques in new structures, and call for compliance with noise ordinances during facility operation.
Public Services and Utilities	General plan policies related to public services and utilities call for safeguarding utility lines from rupture or malfunction from natural or manmade hazards.
Recreational Resources	General plan policies related to recreational resources encourage the use of utility corridors and SFPUC rights-of-way for recreational uses such as parks, pedestrian and bicycle trails, open space, and other recreational facilities and programs.
Agricultural Resources	General plan policies related to agricultural resources encourage utilities to route their facilities along property lines to prevent interference with agricultural operations.
Hazards	General plan policies related to hazards call for the proper handling, use, disposal, and transport of hazardous materials and the placement, design, construction, and protection of critical utilities from potential disasters.
Energy Resources	No relevant general plan policies related to energy resources were identified.

TABLE 4.2-2
SIGNIFICANCE CRITERIA RELATED TO CONSISTENCY WITH PLANS AND POLICIES BY CEQA RESOURCE TOPIC

Resource Topic	Significance Criterion
Geology, Soils, and Seismicity (Section 4.4)	Result in the loss of availability of a locally important mineral resource recovery site delineated on a local general plan, specific plan, or other land use plan.
Biological Resources (Section 4.6)	Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance. Conflict with the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, or state habitat conservation plan.
Traffic, Transportation, and Circulation (Section 4.8)	Conflict with adopted policies, plans, or programs supporting alternative transportation (e.g., conflict with policies promoting bus turnouts, bicycle racks, etc.), or cause a substantial increase in transit demand that cannot be accommodated by existing or proposed transit capacity or alternative travel modes).
Noise and Vibration (Section 4.10)	Expose people to or generate noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies. For a project located within an area covered by an airport land use plan (or, where such a plan has not been adopted, within two miles of a public airport or public use airport), expose people residing or working in the project area to excessive noise levels.
Agricultural Resources (Section 4.13)	Conflict with existing zoning for agricultural use or a Williamson Act contract.

The WSIP includes facility improvement projects that would seismically upgrade the SFPUC regional water system facilities and serve the water supply needs of the SFPUC's service area through 2030. Although some of these projects would result in impacts on air quality and natural resources, on the whole the proposed program would mitigate such impacts, restore natural systems, and support the orderly growth and development of San Francisco and the adjoining cities and counties of the San Francisco Bay region.

Implementation of the WSIP would increase community safety by protecting the regional water system from earthquake hazards and providing redundancy in the system in the event that substantial damage and/or a failure of part of the system occurred. The WSIP would, on the whole, be consistent with the San Francisco General Plan.

San Francisco Priority Policies

Of the eight Priority Policies, only the last two would be relevant to the WSIP. The remaining six policies would not be relevant because the WSIP would: be largely constructed outside of San Francisco, be located away from San Francisco neighborhoods, have no effect on or create the need for affordable housing, not result in any commuter automobiles, and not result in commercial office development. The WSIP would have no long-term effect on open space.

With regard to the Priority Policy to protect historic buildings, the WSIP projects that could potentially affect historical resources would be implemented in a manner that is consistent with the Secretary of Interior Standards; most impacts would be mitigated to a less-than-significant level. With regard to the Priority Policy to prepare for earthquakes: one of the primary goals of the proposed program is seismic reliability of the regional water system to reduce vulnerability to earthquakes; the WSIP proposes improvements to meet current seismic standards and would establish and implement a defined level of service response after a major earthquake. The WSIP would, on the whole, be consistent with San Francisco's Priority Policies.

San Francisco Sustainability Plan

The *San Francisco Sustainability Plan* was developed for the purpose of addressing San Francisco's long-term environmental sustainability. The WSIP facility improvement projects would be consistent with the goals of the Sustainability Plan, since it would maintain the physical resources and systems that support life in San Francisco. The WSIP would be inherently consistent with goals pertaining to increasing water reuse, ensuring an adequate water supply under normal and extraordinary conditions, restoring groundwater supplies, and upgrading infrastructure.

San Francisco Municipal Green Building Program

The San Francisco Municipal Green Building Program was developed for the purpose of improving the environmental performance of municipal buildings. The WSIP facility improvement projects would be consistent with the San Francisco Municipal Green Building Program, since all applicable facility improvement projects constructed under the WSIP would be designed, constructed, and operated in accordance with the City's Green Building requirements. The SFPUC would complete and submit LEED checklists to the REB Task Force on all applicable WSIP projects.

Consistency with SFPUC Plans and Policies

Alameda and Peninsula Watershed Management Plans

Generally, the Alameda and Peninsula WMPs guide SFPUC activities that are located within the plans' boundaries. The Alameda WMP would be applicable to six of the WSIP projects located in the Alameda watershed: Alameda Creek Fishery (SV-1), Calaveras Dam (SV-2), 40-mgd Treated Water (SV-3), New Irvington Tunnel (SV-4, which is partially within watershed boundaries), Treated Water Reservoirs (SV-5), and SABUP (SV-6). The Peninsula WMP would be applicable to three of the WSIP projects proposed to be entirely located in the Peninsula watershed: CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4), and Pulgas Balancing Reservoir (PN-5).

The Peninsula and Alameda WMPs are designed to guide the SFPUC's activities with respect to its watershed lands and operation of the regional water system to ensure protection and restoration of watershed resources. The WMP's goals and policies include maximizing the local water supply and improving source water quality to protect public health and safety, which are aligned with the goals of the WSIP. As part of implementing the WMPs, the SFPUC Natural Resources Division will review the WSIP plans, projects, and activities that occur within these watersheds for conformity with the WMPs as well as for compliance with environmental codes and regulations. As a result of this watershed project review process, the WSIP would, on the whole, be implemented in a manner consistent with the WMPs.

Water Enterprise Environmental Stewardship Policy

The WSIP would be consistent with the underlying goals of the Water Enterprise Environmental Stewardship Policy, particularly with respect to the WSIP sustainability goal and the WSIP objective to manage natural resources and physical systems to protect watershed ecosystems. Conversely, the Stewardship Policy implementation strategy specifically calls for integration of the policy into the WSIP. And, as stated above, WSIP projects located in the Alameda and Peninsula watersheds would be required to comply with the respective WMP policies, actions, and design guidelines and feasible mitigation measures. Mitigation measures described in

Chapter 6 identify programmatic approaches to protecting and restoring natural resources and habitats, including measures that would reduce bioregional effects and habitat fragmentation and would enhance ecosystem function.

Consistency of WSIP Projects with Other Applicable Land Use Plans and Policies

As described in Section 4.2.2, federal, state, and regional land use plans establish guidelines regarding appropriate land uses and activities within the boundaries of the respective plans. The relevant land use plans for the WSIP study area are: the GGNRA – Scenic Easement and Scenic and Recreation Easement and the *San Joaquin County Multi-species Conservation Plan and Open Space Plan*. WSIP consistency with habitat conservation plans, including the San Joaquin County's multi-species conservation plan, is addressed in Section 4.6, Biological Resources. WSIP consistency with the GGNRA – Scenic Easement and Scenic and Recreation Easement is presented below.

GGNRA – Scenic Easement and Scenic and Recreation Easement

The proposed WSIP projects in the Peninsula watershed would involve construction of new, or improvements to existing, water utility facilities. Therefore, implementation of these projects is an exercise of the CCSF's reserved rights under the terms of both easements. The WSIP would, on the whole, be consistent with the GGNRA easement covenants.

California Department of Fish and Game, Game Refuge Designation

Implementation of the WSIP projects in the Peninsula watershed would not result in the unauthorized taking of birds or mammals and, therefore, would be consistent with the area's designation as a game refuge.

San Francisco Bay Plan

Implementation of the BDPL Reliability Upgrade project (BD-1) includes construction of a tunnel to replace aboveground pipelines located in San Francisco Bay. Depending on the final scope of work undertaken with respect to this project, SF Bay Plan policies could be relevant to the project. The proposed five-mile tunnel under Don Edwards San Francisco Bay Wildlife Refuge, Newark Slough, and San Francisco Bay is generally straight, which provides for ease in constructability, but is also designed to minimize environmental disruption, particularly with respect to protected species. Programmatic mitigation measures described in Chapter 6, if determined to be applicable, identify measures to protect and restore natural resources and habitats, including special-status species. Compliance with BCDC permitting requirements and consideration of applicable SF Bay Plan policies would also ensure that relevant policies of the SF Bay Plan are addressed and carried out to minimize environmental effects on the bay. The WSIP would, on the whole, be consistent with policies contained in the SF Bay Plan.

Local General Plans

Section 4.2.2 describes the application of local general plans to the WSIP. Determinations of project consistency with general plans would be made by the pertinent land use jurisdictions following preparation of project-specific CEQA documentation and notification by the SFPUC pursuant to state law.

For those counties and cities that receive all or part of their water from the SFPUC, the WSIP would generally be consistent with goals to maintain and improve the quality of life of the local population by increasing the reliability of the water supply now and into the future. The objectives of the WSIP include maintaining high-quality water, reducing system vulnerability to earthquakes, increasing delivery reliability, meeting customer water supply needs, enhancing sustainability, and achieving a cost-effective, fully operational system. Chapter 7 of this PEIR addresses this issue in more detail by comparing the population and employment projections of the jurisdictions that rely on SFPUC water with SFPUC projections for water demand.

Regarding WSIP consistency with community goals related to resource protection, through preparation of this PEIR and attendant scoping and public outreach efforts, the CCSF has systematically identified the significant environmental impacts associated with implementation of the WSIP as well as feasible measures and alternatives to avoid or substantially lessen such effects. The significance criteria used in this PEIR dovetail with the intent of general plan goals and policies related to protecting the environment. As detailed throughout the remaining sections of Chapter 4, most of the environmental impacts attributable to the WSIP are associated with construction, and these impacts would be reduced to less-than-significant levels, either through measures proposed as part of the program or otherwise committed to by the CCSF.

4.3 Land Use and Visual Quality

4.3 Land Use and Visual Quality

This section provides an overview of existing land uses and visual character within the WSIP study area and evaluates potential land use and visual impacts that could result from implementation of the proposed WSIP projects.

4.3.1 Setting

Regional Overview

This section describes the general types of land uses and visual characteristics that occur within the WSIP facilities study area, which extends from Oakdale Portal in Tuolumne County west along the regional system to its terminus in San Francisco. **Figure 4.3-1** characterizes the WSIP study area under two main categories: (1) urbanized, which includes all levels of urban or suburban development, or (2) undeveloped, which includes all types of open space and undeveloped land uses such as parks and agriculture. From east to west, land uses across the WSIP study area generally include rangelands in the Sierra foothills, agricultural and urban and suburban uses in the Central Valley, open space/recreation/watershed areas within the urban fringe, and urban and suburban uses in the San Francisco Bay Area.

San Joaquin Region

Land Use

Most of the areas adjacent to proposed WSIP facility activities in this region are undeveloped and used for agriculture. Cities near existing regional water system facilities include Oakdale, Riverbank, and Modesto in Stanislaus County. Oakdale and Riverbank are generally comprised of rural residential and, more recently, suburban residential uses. Modesto, located in the center of this region, has mainly residential, commercial, school, and park uses.

The SFPUC's facilities in this region include Oakdale Portal on the east, which connects the western end of Foothill Tunnel and the San Joaquin Pipelines. The three San Joaquin Pipelines, which carry water from the Hetch Hetchy facilities, are almost entirely buried for their full 47-mile length (short segments extend aboveground through hilly terrain west of Oakdale Portal). These pipelines extend underground through urban land uses in Modesto and rural residential uses south of Oakdale and Riverbank. Within the western margin of this region in the Tesla Portal vicinity, the San Joaquin Pipelines extend underground through a private golf course (Tracy Golf and Country Club), agricultural land uses, and rural residential development.

Visual Resources

The visual character of the region is typical of the Central Valley, with undeveloped lands along the regional system. Except for the city of Modesto, this region consists mainly of annual grassland, irrigated pasture, and various agricultural crops. The eastern portion of this region in the Oakdale Portal vicinity is almost entirely in agricultural use. In the area of proposed improvements in this portion of the region, Willms Road crosses the program area and is the only public road providing viewing opportunities of the regional system. Most of the SFPUC facilities are underground in this area, and the aboveground facilities are obscured from public view by the topography of the foothills. The central portion of this region includes Modesto, and aboveground facilities (e.g., crossovers) are visible from nearby public roadways. On the west side of the region, the Tesla Portal facilities are aboveground, consisting of about seven buildings and the pipelines/portal structures leading to the Coast Range Tunnel. The Tesla Portal facilities are visible from Vernalis Road and the nearby rural residential development, with distant views of the site available from I-580 (San Francisco Planning Department, 2000b).

Sunol Valley Region

Land Use

The Sunol Valley Region includes facilities in the Sunol Valley within Alameda and Santa Clara Counties and west to the city of Fremont. Existing facilities within this region include storage facilities (Calaveras Reservoir, Calaveras Dam, San Antonio Reservoir, and James H. Turner Dam); transmission facilities (Alameda Siphons, Alameda Creek Diversion Dam and Tunnel, Calaveras Pipeline, San Antonio Pipeline, San Antonio Pump Station, and Irvington Tunnel); treatment facilities (Alameda Disinfection Facility and Sunol Valley Water Treatment Plant [WTP]); and the Irvington Tunnel Portal in Fremont on the west side of the hills.

As shown on Figure 4.3-1, the southern portion of the Sunol Valley and the area surrounding Calaveras Reservoir is mostly undeveloped, while the northern portion of the Sunol Valley includes commercial nurseries and aggregate quarries. The SFPUC system facilities in the Sunol Valley Region lie within the SFPUC's 36,000-acre Alameda watershed lands (see Figure 2.2 in Chapter 2, Existing Regional Water System), consisting primarily of rolling grassland and scattered oak woodlands that cover portions of Alameda and Santa Clara Counties. This area is largely undeveloped with recreational uses such as the Sunol Regional Wilderness, which is located on watershed land owned by the SFPUC and leased by the East Bay Regional Park District. In the western portion of this region, there are large-lot rural residential uses scattered throughout the hills between Sunol Valley and Fremont, and one private residence located about a quarter mile southeast of the existing Alameda West Portal. There are also two SFPUC Land Managers' residences, one near Calaveras Dam and the other near Alameda East Portal. Suburban residential uses on the east side of Mission Boulevard (Highway 238) in Fremont are adjacent to the Irvington Tunnel Portal, which is the westernmost existing SFPUC facility located in this region.

Visual Resources

For the most part, the SFPUC facilities in the Sunol Valley are relatively remote and not accessible to or viewed by the general public, except from Calaveras Road. Distant views of SFPUC facilities may also be available from public trails in the Sunol Regional Wilderness. Alameda and Santa Clara Counties have designated Calaveras Road as a scenic route. Calaveras Reservoir, as viewed from Calaveras Road, is one of the key features of interest (San Francisco

Bay Division Region

Land Use

The Bay Division Region starts in Fremont and covers the general South Bay area, including parts of Alameda, Santa Clara, and San Mateo Counties, extending west to the south end of the Peninsula. The existing regional water system through this region is comprised of transmission facilities, including the Bay Division Pipelines Nos. 1, 2, 3, and 4.

For the most part, the WSIP project sites in this region are within developed urban areas. The urban areas are comprised of typical urban land uses found within a developed area, including residential, commercial, and industrial uses as well as schools, city parks, childcare centers, churches, hospitals, etc. Urban areas where WSIP projects are proposed include the cities of Newark and Fremont in Alameda County; the cities of San Jose, Santa Clara, and Palo Alto within Santa Clara County; and the cities of East Palo Alto, Menlo Park, Atherton, and Redwood City in San Mateo County. (See Chapter 3, Program Description, Table 3.11 for a review of jurisdictions relevant for each WSIP project.)

Undeveloped areas in this region consist primarily of marshland along the bay margin on the east and west sides of the bay, including the 30,000-acre Don Edwards San Francisco Bay National Wildlife Refuge. These undeveloped areas include aboveground portions of the Bay Division Pipelines Nos. 1 and 2 and valve houses.

Visual Resources

SFPUC facilities in the urban areas of the Bay Division Region are almost entirely buried and not distinguishable from the surrounding urban landscape. However, aboveground portions of the Bay Division Pipelines Nos. 1 and 2 and valve houses are present in the undeveloped areas along the east and west margins of the bay; these facilities are visible from the wildlife refuge and marshlands, with remote views available from the Dumbarton Bridge (Highway 84).

Peninsula Region

Land Use

The Peninsula Region is entirely on the Peninsula within San Mateo County. The regional water system facilities within this region include storage, transmission, and treatment facilities. This region spans the urbanized areas between San Francisco Bay and I-280, but also includes the undeveloped SFPUC Peninsula watershed lands (see Figure 2.3), which is the area surrounding the Upper and Lower Crystal Springs Reservoirs, Pilarcitos Reservoir, and San Andreas Reservoir. The watershed area is undeveloped, with heavily forested vegetation on the western slopes and grassland and scattered oak woodlands on the eastern edge.

Urbanized areas in proximity to SFPUC facilities in this region include land uses typically found in developed areas, such as commercial and residential uses, schools, churches, and hospitals. Residential uses adjacent to the Peninsula watershed are located in heavily wooded areas with narrow winding roads, hilly topography, blending with the general forested character of the watershed.

Visual Resources

While many of the SFPUC facilities located within the Peninsula watershed are aboveground structures, they are typically screened by vegetation and blend with the watershed's landscape or are buried. SFPUC reservoir facilities are an integral part of the visual character of the San Mateo County Peninsula.

The California Department of Transportation (Caltrans) has designated I-280 as a scenic highway. Key views in the area include Upper and Lower Crystal Springs Reservoirs and San Andreas Reservoir from I-280; views of Upper and Lower Crystal Springs Reservoirs from Highway 92; and views of Lower Crystal Springs Reservoir and San Andreas Reservoir from the Sawyer Camp Trail, a public hiking/bicycle trail. Features of interest in the area include the Pulgas Water Temple, a large roadside statue of Father Junipero Serra on I-280, the Eugene Doran Memorial Bridge, and the Crystal Springs Dam and vista point. As described in Section 4.2, Plans and Policies, the Peninsula watershed is part of a Scenic Easement and Scenic and Recreation Easement that were developed under a four-party agreement among the City and County of San Francisco (CCSF), the U.S. Department of the Interior, Caltrans, and San Mateo County (San Francisco Planning Department, 2001). Provisions of the easement are described in Section 4.2.2, under U.S. Department of the Interior, Golden Gate National Recreation Area – Scenic Easement and Scenic and Recreation Easement.

San Francisco Region

Land Use

The San Francisco Region includes regional facilities within San Francisco and northern San Mateo County, which overlap with a portion of the geographic area covered in the Peninsula Region. Existing regional water system facilities within this region include storage facilities (University Mound Reservoir, Sunset Reservoir, and Merced Manor Reservoir) and transmission facilities (San Andreas Pipeline, Crystal Springs Pipeline, and Sunset Supply Pipeline).

Most of the SFPUC facilities in the San Francisco Region are located in densely populated, urbanized areas of the west and south sides of the city. Proposed WSIP facilities in San Francisco are located as far north as Lincoln Park, as far south as Lake Merced, and as far east as McLaren Park. Proposed facilities in San Mateo County consist of regional transmission facilities (pipelines) extending from Peninsula facilities to terminal reservoirs in San Francisco. As shown in Figure 4.3-1, land uses in proximity to WSIP facilities in this region are entirely developed, comprising a mix of commercial and residential land uses, including schools, churches, golf courses, cemeteries, and parks.

Visual Resources

The visual setting surrounding SFPUC facility sites in this region is characterized by suburban commercial districts, residential neighborhoods, some industrial areas in northern San Mateo County, and predominantly urban commercial and residential areas in San Francisco.

Regulatory Framework

Please see Section 4.2, Plans and Policies, for a discussion of the regulatory setting related to land use plans and policies and for analysis of the consistency of proposed WSIP projects with relevant plans and policies.

4.3.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to land use and visual quality, but generally considers that implementation of the proposed program would have significant impacts on these resources if it were to:

Land Use

- Physically divide an existing community (Not evaluated in this section, see Appendix B)
- Conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including but not limited to the general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect (Evaluated in Section 4.2, Plans and Policies)
- Have any substantial impact on the existing character of the vicinity (Evaluated in this section)
- Substantially disrupt or displace existing land uses or land use activities (Evaluated in this section)

Visual Quality

- Have a substantial adverse effect on a scenic vista (Evaluated in this section)
- Substantially damage scenic resources, including but not limited to trees, rock outcroppings, and other features of the built or natural environment that contribute to a scenic public setting (Evaluated in this section)
- Substantially degrade the existing visual character or quality of the site and its surroundings (Evaluated in this section)
- Create a new source of substantial light or glare that would adversely affect day or nighttime views in the area or substantially affect other people or properties (Evaluated in this section)

Approach to Analysis

Land Use

This program-level land use analysis evaluates short-term impacts on existing land uses resulting from temporary construction activity as well as long-term impacts resulting from the siting of WSIP project facilities. Impacts specific to recreational and agricultural land uses are discussed in Sections 4.12 and 4.13, respectively.

Generally, construction and operation of most WSIP projects would occur at existing SFPUC facility sites or within existing SFPUC rights-of-way. Some projects would be constructed outside of existing CCSF-owned watersheds, land, or rights-of-way, and additional new land would need to be acquired for facilities and/or for temporary construction easements or staging areas (see Table 4.3-3). Information regarding potential WSIP facility locations and projects that might require land acquisition is based on the project siting and construction information, provided by the SFPUC; this information is summarized in Chapter 3 and further detailed in Appendix C for each of the WSIP projects.

Local planning documents and maps (including maps available electronically via the Internet) were reviewed to characterize existing land uses within proximity to the pipelines, tunnels, vaults/valve lots, pump stations, treatment facilities, and storage facilities proposed under the WSIP.

In suburban and urban areas, a considerable number of schools are located near proposed WSIP project sites (see Table 4.3-2). These schools have been identified because they represent the predominant land use that could be affected by WSIP construction activities. This list of schools is not necessarily a definitive list for each WSIP project site, since facility site locations have not yet been finalized for all WSIP projects. The evaluation of potential impacts on schools provides an indication of the potential extent to which WSIP projects might affect schools and other sensitive land uses.

Potential physical environmental effects on surrounding land uses resulting from implementation of the WSIP projects are addressed in the respective sections of this PEIR, including Section 4.7, Cultural Resources; Section 4.8, Traffic, Transportation, and Circulation; Section 4.9, Air Quality; Section 4.10, Noise and Vibration; and Section 4.12, Recreational Resources.

Visual Resources

The analysis of visual resources identifies potential temporary and permanent adverse visual impacts that WSIP projects could have on scenic vistas, as seen from scenic highways and local scenic roads, or on other visual resources identified by local jurisdictions. For the analysis of impacts on scenic vistas, information was compiled from Caltrans' list of designated scenic highways and from local governments' general plans. Local jurisdictions also identified other visual resources, such as trees, rock outcroppings, viewsheds, ridgelines, gateways, waterways, and open space corridors. It is expected that project-level visual assessments would be completed as part of separate, project-level CEQA review of individual WSIP projects, at which time specific project design information would allow for a more detailed analysis of potential visual effects. Most of the potentially significant permanent visual impacts identified for each region would not likely result in significant impacts at the project level when specific information becomes available concerning the height, mass, and location of structures. However, this PEIR uses a conservative approach in order to identify all visual effects that could possibly be considered significant.

Impact Summary by Region

Table 4.3-1 provides a summary of potential land use and visual quality impacts associated with implementation of the WSIP. The summary includes the expected level of significance of each potential impact.

Construction Impacts

Impact 4.3-1: Temporary disruption or displacement of existing land uses during construction.

The construction of pipelines, tunnels, dams, and other WSIP facilities could result in temporary adverse land use impacts in the WSIP study area by causing a temporary disruption or displacement of existing land uses.

Most WSIP projects would involve improvements to existing SFPUC facilities that would occur within existing facility sites and SFPUC rights-of-way in areas isolated from other developed land uses, thereby reducing the likelihood for temporary land use disruption or conflicts during construction. However, some project facilities would involve construction on CCSF-owned land within densely developed areas or outside of CCSF-owned lands and thus would be more likely to affect adjacent land uses. In some project areas, temporary land use disruption due to adjacent construction activity could generate a combination of effects, including noise, vibration, dust, traffic congestion, and/or access disruption. Each of these potential construction effects is evaluated separately in the following sections: 4.8, Traffic, Transportation, and Circulation; 4.9, Air Quality; and 4.10, Noise and Vibration; however, the intensity or potential combination of these construction effects is considered in this section as a land use disruption issue.

In most cases, construction effects would be relatively short term and intermittent, and land use disruption would be considered less than significant. Furthermore, for all WSIP projects, the SFPUC would implement construction measures to limit certain temporary construction effects on nearby land uses. However, WSIP project construction activities could substantially disrupt certain land use activities in areas where the duration of construction is lengthy and/or these effects, either individually or combined, are particularly intense. For example, schools could be particularly sensitive to a combination of access restriction, noise, and dust from construction activities; these effects could substantially disrupt the indoor or outdoor activities at the school site, making it difficult to effectively continue the existing land use activity during the construction period. The potential for substantial temporary land use disruption is site and project specific and would be further assessed during separate, project-level CEQA environmental review of the WSIP

projects. This program-level analysis considers the general WSIP project location information available at this time, the proximity to uses such as residential areas and schools, and the potential to displace these existing uses during construction.

Temporary land use displacement could result from the short-term use of properties adjacent to WSIP facility sites for equipment and materials staging areas and/or for temporary construction easements. The SFPUC constructs its facilities on CCSF-owned land to the extent feasible. However, in cases where construction easements or staging areas are required on non-CCSF-owned land, uses such as vacant lots, parking lots, and open space (parks and agricultural fields) on private or other public land could be temporarily displaced. The SFPUC and its construction contractors often have flexibility in locating temporary staging areas, and are typically able to identify staging sites that are acceptable to landowners for short-term use. Where a willing property owner makes arrangements for short-term property use during project construction, temporary displacement of an existing land use would be considered a less-than-significant impact. Potential changes in the existing land use character in the vicinity of these staging areas would also be less than significant due to the temporary or short-term nature of construction staging.

In other cases, however, temporary use of non-CCSF-owned land for construction activity or staging could constitute a potentially significant impact if the SFPUC has little to no flexibility in using a certain property, and the owner's use of the property would be halted or substantially reduced as a result of the temporary construction activity (e.g., a property next to an SFPUC facility requires repair or improvement, and that property must be used to access or work on the SFPUC facility). Mitigation measures such as providing the property owner with an acceptable alternate site for the displaced use could mitigate this impact to a less-than-significant level. Such relocation could temporarily alter the land use character in the vicinity of the displaced use; however, this effect would be less than significant due to its temporary nature.

The potential temporary land use conflicts resulting from construction of WSIP facilities are generally described below, first by facility type and then more specifically by region.

Pipelines. Where feasible, WSIP pipeline construction would be accomplished using standard open-cut or cut-and-cover construction methods, progressing at a rate of approximately 120 to 160 feet per day, depending on the presence of road, utility, or stream crossings. Staging areas would be required for stockpiling supplies and equipment close to the construction area. Depending on the location of staging areas and pipeline construction activities in relation to existing land uses, these activities have the potential to cause adverse but temporary land use impacts, either at the staging site or in proximity to pipeline alignments. While these impacts could be significant, they would for the most part be reduced to a less-than-significant level with the incorporation of mitigation measures, such as maintaining access to residences, installing noise barriers to minimize noise effects on adjacent uses, or prohibiting nighttime construction to avoid noise, vibration, and light and glare effects on nearby uses; however, a site-specific analysis would be necessary to characterize the existing land uses and the potential for impacts along each pipeline alignment. The level of impact significance from pipeline projects would depend on the pipeline's proximity to noise-sensitive land uses and the duration of construction at any one location.

Tunnels. Tunnel projects could affect existing land uses in the vicinity of entry/exit portal or shaft locations, which would serve as construction staging areas. Land use impacts could occur if the portals resulted in a disruption of onsite uses, if access to land uses were impeded by construction traffic or grading for new construction access roads, or if construction activities near sensitive land uses (such as residences or schools) lasted for an extended period of time. Tunneling operations typically occur 24 hours per day, as is being proposed by the SFPUC. One of the two tunnel portals (the entry portal) is designated as the location for most of the tunneling activity, involving the removal of the excavated spoils material, staging, and mobilization of the tunnel building materials and crew. While these activities would be temporary, lasting only as long as the tunnel construction requires, the construction activities and effects at the entry portal site are substantial and would last for an extended duration (a year or more). Land use disruption could be a significant effect on sensitive land uses near the active tunnel portal site. The level of impact significance from tunnel projects would depend on the project's proximity to existing land uses and the duration and severity of the impact.

Vaults, Valve Lots, and Crossover Facilities. These facilities would be constructed at isolated locations near existing SFPUC facilities along the regional system. Design would vary by location, but facilities would typically occupy approximately 4,000 square feet and would be partially or completely buried. Surface structures might be constructed to house associated electrical controls and emergency generators. Crossover structures could require permanent discharge or drainage piping for maintenance or emergency repairs. Construction activities would be confined to the immediate site vicinity. If these facilities are located in or near existing land uses, they could temporarily disrupt such uses.

Pump Stations. The WSIP includes proposals to construct new pump stations and to upgrade existing pump stations along the regional system. Upgrading pump stations, which would involve removing equipment and replacing it with new equipment, would not affect existing land uses. The construction of new pump stations could temporarily affect existing land uses if proposed facility sites are located on or in close proximity to existing uses.

Treatment Facilities. The WSIP includes proposals to upgrade and expand treatment facilities at two treatment plants as well as at the system's primary disinfection facility. Construction activities at existing treatment plants would occur within the property boundaries or on SFPUC lands and would not be expected to affect existing land uses. Temporary construction impacts associated with a new treatment facility would depend on the site location in relation to existing land uses.

Storage Facilities. The WSIP calls for improvements to water storage facilities, including reservoirs and dams. For reservoirs, construction activities would include excavation at the reservoir location, offsite hauling of excavated soils, installation of new pumping and electrical equipment, and seismic strengthening. Dam improvements would include raising the dam parapet wall at Lower Crystal Springs Dam and replacing Calaveras Dam. Construction activities at these WSIP project sites would not likely affect existing land uses since these projects are generally within undeveloped areas on property owned by the CCSF, except for offsite staging areas and adjacent access roadways in the Lower Crystal Springs Dam vicinity.

San Joaquin Region

Impact 4.3-1: Temporary disruption or displacement during construction		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	LS

The WSIP project sites within this region would be located in largely undeveloped areas that generally contain open space or agricultural uses. Of the five WSIP projects in the San Joaquin Region, three of the projects (Advanced Disinfection, SJ-1; Lawrence Livermore, SJ-2; and Tesla Portal Disinfection, SJ-5) would involve improvements at existing SFPUC facility sites that are situated in undeveloped areas and currently used for water system purposes. Thus, these projects would have a *less than significant* effect on existing land uses, since they would not disrupt or displace land uses during construction.

The SJPL System project (SJ-3) would entail construction of a new valve house at the Tesla Portal facility, open-trench construction of approximately 16 to 22 miles of pipeline, and construction of two crossover facilities for the existing San Joaquin Pipeline system. Most construction would occur within the existing SFPUC right-of-way, but additional right-of-way could be required to accommodate the pipeline, access roads, associated power facilities, or construction staging, depending on the final locations selected. The 10-mile western segment of the pipeline would extend through residential areas as well as the Tracy Golf and Country Club, which is located on both sides of the freeway. The temporary construction impacts of the SJPL System project could be *potentially significant* in this area due to the proximity of adjoining residential uses (in some cases residences could be within 100 feet of the right-of-way); the potential land use disturbance and disruption would primarily be associated with noise and recreation impacts.

The SJPL Rehabilitation project (SJ-4) would involve a condition assessment to determine the need for the rehabilitation of the existing San Joaquin Pipelines. Project construction, if needed, would occur at discrete locations along the pipeline alignment, although construction requirements for this project have not yet been identified. Since these pipelines extend through the city of Modesto and the southern margins of Riverbank and Oakdale, this project could result in temporary conflicts with existing rural suburban and urban land uses during construction, particularly through Modesto, which could be *potentially significant*. There are several schools located near this pipeline alignment, as listed in **Table 4.3-2**. The potential land use impacts of this project would be evaluated in more detail as part of separate, project-level CEQA review, which would identify appropriate mitigation measures, if needed, to reduce impacts to a less-than-significant level.

The potentially significant, temporary construction impacts associated with the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects on adjacent land uses could be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #1 (neighborhood notice), Construction Measure #3 (reduction of construction-related emissions), Construction Measure #5 (traffic control plan), Construction Measure #6 (compliance with local noise ordinances to the extent feasible), and Construction Measure #10 (construction site maintenance/ restoration), as well as mitigation measures identified in Chapter 6 under 4.8, Traffic,

[a] Because many WSIP project locations are still under development by the SFPUC, this preliminary list is not considered definitive, but rather serves to highlight project areas where schools could be affected by the WSIP projects.

SOURCE: ESA+Orion (compiled from map review).

Transportation, and Circulation (Measures 4.8-1a and 4.8-1b); 4.9, Air Quality (Measures 4.9-1a, 4.9-1b, and 4.9-2a); 4.10, Noise and Vibration (Measures 4.10-1a, 4.10-2a, 4.10-2b, 4.10-3a, and 4.10-3b); and 4.12, Recreational Resources (Measure 4.12-1). It is expected that the SFPUC and its contractors would be able to make arrangements with willing property owners for temporary staging areas such that displacement of existing land uses would not be a significant impact. Separate, project-level CEQA review would be conducted on these projects to determine if potential land use disruption impacts would occur and to refine the mitigation measures to address site-specific conditions if appropriate.

Sunol Valley Region

Impact 4.3-1: Temporary disruption or displacement of existing land uses during construction		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	PSU
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	LS

The WSIP project sites in the Sunol Valley Region are largely within undeveloped areas or Alameda watershed lands. Construction impacts associated with the Alameda Creek Fishery (SV-1) and Treated Water Reservoirs (SV-5) projects would be *less than significant*, as construction activities would occur on or near existing SFPUC facilities currently used for water system purposes, or within undeveloped areas that are not in the immediate vicinity of sensitive developed land uses.

The Calaveras Dam project (SV-2) would replace the existing Calaveras Dam and restore the capacity of Calaveras Reservoir. This project would require closure of the southern section of Calaveras Road during the two- to three-year construction period, temporarily blocking access to the Sunol Regional Wilderness from the south. The Sunol Regional Wilderness would remain accessible from the north during project construction, and this temporary impact would therefore be *less than significant*. The effects of closing Calaveras Road are discussed in detail in Section 4.8, Traffic, Transportation, and Circulation, and Section 4.12, Recreational Resources. The 40-mgd Treated Water project (SV-3) would include improvements to the Sunol Valley WTP as well as construction of a two-mile pipeline to connect to the Alameda Siphons or the New Irvington Tunnel. This project would also use Calaveras Road for access, but would not require temporary closure of this road. This project would also require temporary and permanent use of private property for installation of the new pipeline within a new easement.

Project construction of the Calaveras Dam (SV-2), 40-mgd Treated Water (SV-3), and SABUP (SV-6) projects would temporarily disrupt access from Calaveras Road to adjacent land uses, including nurseries, quarry operations, and large-lot residential uses. This impact would be temporary and intermittent and would be *less than significant* with implementation of SFPUC Construction Measure #5 (traffic control plan), which is designed to preserve access to these land uses. Establishment of a permanent easement across private property for the new pipeline and potential temporary use of additional private property during construction under the 40-mgd Treated Water and SABUP projects would displace land now used in the Sunol Valley area for agriculture (ranchland or nurseries); however, given the relatively narrow swath of land required for pipeline installation, the extent of this displacement and the potential for land use disruption on surrounding land would be *less than significant*. In addition, following project completion, agricultural use on the surface could likely resume.

Construction of the New Irvington Tunnel project (SV-4) would require construction of two new tunnel portals and associated construction staging areas. The new portal in the Sunol Valley would be about 75 feet south of the existing Alameda West Portal, and the new portal in Fremont would be about 175 feet south of the existing Irvington Portal. The new portal in the Sunol Valley would be in the vicinity of a privately owned ranch located to the south. In addition, construction staging would require temporary use of the northern portion of the private ranch property for construction staging. As currently planned, the majority of the tunneling construction activity and staging would occur at the new portal in the Sunol Valley. As a result, the ranch property would experience 24-hour construction effects for the full duration of the tunneling activity. Although implementation of several SFPUC construction measures (#1, neighborhood notice; #3, reduction of construction-related emissions; #6, compliance with local noise ordinances to the extent feasible; #10, construction site maintenance/restoration) and other mitigation measures identified in this PEIR (Traffic Measure 4.8-1, Air Quality Measures 4.9-1 and 4.9-2, and Noise Measures 4.10-1 through 4.10-3) would reduce the impact of the tunneling activity on the neighboring ranch property, the residual impacts would remain *potentially significant and unavoidable*. Separate, project-level CEQA review of this project would determine the extent and severity of this impact and determine if mitigation measures could reduce the effects to a less-than-significant level. On the west end of the tunnel, the new west portal would be constructed in the vicinity of single-family residences located west of the Irvington Portal in the city of Fremont. Although this portal would not host the majority of the tunneling activity, tunnel completion activity at this portal would have the potential to significantly disrupt nearby residential uses. This activity would take place over a period of months, involve 24-hour construction work at times, and occur in close proximity to several homes.

With the exception of construction disruption effects at the two new portals for the New Irvington Tunnel (SV-4), the potential short-term land use disruption effects at WSIP project sites in this region would be less than significant with implementation of SFPUC Construction Measure #1 (neighborhood notice), Construction Measure #3 (reduction of construction-related emissions), Construction Measure #5 (traffic control plan), Construction Measure #6 (compliance with local noise ordinances to the extent feasible), and Construction Measure #10 (construction site maintenance/restoration).

The potential land use impacts associated with the Calaveras Dam project (SV-2), 40-mgd Treated Water project (SV-3), and the New Irvington Tunnel (SV-4) would also be evaluated in more detail as part of separate, project-level CEQA review. This review would identify appropriate mitigation measures, if needed, to reduce this impact to a less-than-significant level.

Bay Division Region

Impact 4.3-1: Temporary disruption or displacement of existing land uses during construction		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	PSM
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	LS

The Bay Division facilities are located in urbanized areas that are more densely developed than the outlying study area regions. Construction of the BDPL Reliability Upgrade (BD-1), BDPL 3 and 4 Crossovers (BD-2), and BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) projects could potentially affect existing land uses, since WSIP construction would occur in densely developed areas and near uses that are potentially sensitive to construction effects such as schools and residences.

Of the WSIP projects proposed for construction in the Bay Division Region, the BDPL Reliability Upgrade project (BD-1) would have the most extensive impact on existing land uses. This project would consist of approximately 16 miles of pipeline and 5 miles of bay tunnel extending from Fremont and Newark in southern Alameda County through East Palo Alto, Menlo Park, and Redwood City and unincorporated areas in the central-eastern portion of San Mateo County.

There are a number of schools located on, adjacent to, or near the BDPL Reliability Upgrade (BD-1) pipeline alignment, as listed in Table 4.3-2. While the 16-mile project alignment crosses a wide range of land uses, schools are called out because these facilities are particularly sensitive to construction emissions and noise impacts, more vulnerable to safety hazards, and typically do not have alternative locations where construction impacts could be avoided. Depending on the specific location, schedule, and type of construction activity, temporary conflicts with and disruption to school uses during construction could be *potentially significant*, particularly along the open-trench sections of the pipeline. However, pipeline construction activities would move to the next segment as installation of the pipeline occurs, so that construction activities for this pipeline project would generally not occur at any one location for an extended period of time.

The BDPL Reliability Upgrade project's (BD-1) *potentially significant* impact related to land use disruption during construction would be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #1 (neighborhood notification), Construction Measure #3 (reduction of construction-related emissions), Construction Measure #5 (traffic control plan), Construction Measure #6 (compliance with local noise ordinances to the extent feasible), and Construction Measure #10 (construction site maintenance/restoration), in addition to mitigation measures identified in Chapter 6 (under 4.8, Traffic, Transportation, and Circulation (Measures 4.8-1a and 4.8-1b); 4.9, Air Quality (Measures 4.9-1c, 4.9-1d, and 4.9-2a); and 4.10, Noise and Vibration (Measures 4.10-1a, 4.10-2a, 4.10-2b, 4.10-3a, and 4.10-3b). The potential land use impacts of this project would be evaluated in more detail as part of separate, project-level CEQA review, during which appropriate, site-specific mitigation measures would be tailored as needed to reduce impacts to a less-than-significant level.

The BDPL 3 and 4 Crossovers project (BD-2) would involve construction of pipeline crossovers at three separate locations along a 32-mile stretch of the existing Bay Division Pipelines Nos. 3 and 4. One of these crossover locations would be near an existing water storage facility. The two other locations would be near Barron Creek, adjacent to the running track and sports fields at Gunn High School in Palo Alto, and another would be near an existing publicly accessible nature area. Temporary construction impacts could be *potentially significant* in areas adjacent to these two crossovers, but could be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #1 (neighborhood notification), Construction Measure #3 (reduction of construction-related emissions), Construction Measure #5 (traffic control plan), Construction Measure #6 (compliance with local noise ordinances to the extent feasible), and Construction Measure #10 (construction site maintenance/restoration), as well as mitigation measures identified in Chapter 6 (under 4.8, Traffic, Transportation, and Circulation (Measures 4.8-1a and 4.8-1b); 4.9, Air Quality (Measures 4.9-1c, 4.9-1d, and 4.9-2a); and 4.10, Noise and Vibration (Measures 4.10-1a, 4.10-2a, 4.10-2b, 4.10-3a, and 4.10-3b).

The third WSIP project in the Bay Division Region is the BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3). Construction would be conducted in existing SFPUC right-of-way on either side of the I-680/Mission Boulevard interchange. As there are no sensitive land uses nearby, temporary construction impacts of BD-3 would be *less than significant.*

Peninsula Region

Impact 4.3-1:	**Temporary disruption or displacement of existing land uses during construction**	
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS

Construction of the Baden and San Pedro Valve Lots (PN-1) and HTWTP Long-Term (PN-3) projects within the Peninsula Region would occur on existing SFPUC facility sites; thus, no land use disruption or displacement would occur. Although there is residential development near the Baden and Harry Tracy WTP facility sites, it is expected that with implementation of SFPUC Construction Measure #1 (neighborhood notification), Construction Measure #3 (reduction of construction-related emissions), Construction Measure #5 (traffic control plan), Construction Measure #6 (compliance with local noise ordinances to the extent feasible), and Construction Measure #10 (construction site maintenance/restoration), temporary community disruption impacts during construction would be *less than significant.*

The CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4), and Pulgas Balancing Reservoir (PN-5) projects are located in unincorporated San Mateo County, outside of urbanized areas. Construction activities for these facilities would not affect existing land uses, with the exception of recreational uses. These projects are in the vicinity of recreational facilities on the Peninsula watershed, including Crystal Springs Golf Course and Sawyer Camp Trail (CS/SA Transmission project) and the Pulgas Water Temple (Pulgas Balancing Reservoir). Lower Crystal Springs Dam construction activity would be coordinated with the County’s replacement of the San Mateo County Bridge. This bridge, along with a nearby vista point, provides sightseeing opportunities of the reservoir. There is a parking area north of the bridge for sightseers. Project construction could disturb recreational users and disrupt recreational uses. This impact would be *less than significant* for these three projects with implementation of SFPUC Construction Measure #1 (neighborhood notification), Construction Measure #3 (reduction of construction-related emissions), Construction Measure #5 (traffic control plan), Construction Measure #6 (compliance with local noise ordinances to the extent feasible), and Construction Measure #10 (construction site maintenance/restoration). Potential temporary land use impacts during project construction would be assessed in more detail as part of separate, project-level CEQA review for each of these three projects.

San Francisco Region

Impact 4.3-1: Temporary disruption or displacement of existing land uses during construction		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	PSM
Recycled Water Projects	SF-3	PSM

Within the San Francisco Region, all WSIP facilities would be constructed in a dense urban environment with a mix of uses, including schools. The SAPL 3 Installation (SF-1) project could result in potentially significant short-term disturbance of adjacent residential land uses due to the proximity of residences along the pipeline alignment in some locations (less than 25 feet in some areas). Although pipeline construction activities do not generally occur for extended periods of time in any one area, in some cases, such as in areas of jack-and-bore operations or difficult construction (e.g., around other existing major underground utilities), construction activities could occur for several weeks. If construction activities occurred for extended periods near residences, schools, or other sensitive uses, the combination of construction effects (including noise, vibration, dust, traffic congestion, and access restrictions) could result in significant short-term land use disruption impacts. This *potentially significant* impact would be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #1 (neighborhood notification), Construction Measure #3 (reduction of construction-related emissions), Construction Measure #5 (traffic control plan), Construction Measure #6 (compliance with local noise ordinances to the extent feasible), and Construction Measure #10 (construction site maintenance/restoration), as well as mitigation measures identified in Chapter 6 (under 4.8, Traffic, Transportation, and Circulation (Measures 4.8-1a and 4.8-1b); 4.9, Air Quality (Measures 4.9-1c, 4.9-1d, and 4.9-2a); and 4.10, Noise and Vibration (Measures 4.10-1a, 4.10-2a, 4.10-2b, 4.10-3a, and 4.10-3b).

The SAPL 3 Installation (SF-1) project could also require additional rights-of-way for construction staging, stockpiling, and laydown areas. While it is expected that the SFPUC and its contractors would be able to make arrangements with willing property owners for temporary staging areas (such that displacement of existing land uses would not be a significant impact), there is the potential for significant short-term land use displacement to occur. Implementation of SFPUC Construction Measure #1 and Construction Measure #10 result in a less than significant impact on displacement of existing land uses.

Under the Groundwater Projects (SF-2), new groundwater wells would be installed at various locations within San Francisco and the upper Peninsula region in urban, suburban, and perhaps open space areas. One proposed location for a new well is Francis Scott Key Elementary School in San Francisco (in the parking lot of the annex structures). Well installation involves 24-hour drilling activities, which could disrupt sensitive land uses such as schools and nearby residential uses. This *potentially significan*t impact would be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #1 (neighborhood notification, including the provision for coordinating the construction schedule with school facility managers), Construction Measure #3 (reduction of construction-related emissions), Construction Measure #5 (traffic control plan), Construction Measure #6 (compliance with local noise ordinances to the extent feasible), and Construction Measure #10 (construction site maintenance/restoration), as well as mitigation measures identified in Chapter 6 (under 4.8, Traffic, Transportation, and Circulation

(Measures 4.8-1a and 4.8-1b); 4.9, Air Quality (Measures 4.9-1c, 4.9-1d, and 4.9-2a); and 4.10, Noise and Vibration (Measures 4.10-1a, 4.10-2a, 4.10-2b, 4.10-3a, and 4.10-3b). Potential impacts associated with these projects would be assessed in more detail as part of separate, project-level CEQA review.

The Recycled Water Projects (SF-3) facilities would be constructed within urban residential and commercial neighborhoods in San Francisco. Potential sites for treatment and storage facilities are located adjacent to the San Francisco Zoo and in the vicinity of Lincoln Park. Temporary construction impacts could be *potentially significant* in some areas, such as near schools and close to residences. Implementation of SFPUC Construction Measure #1 (neighborhood notification), Construction Measure #3 (reduction of construction-related emissions), Construction Measure #5 (traffic control plan), Construction Measure #6 (compliance with local noise ordinances to the extent feasible), and Construction Measure #10 (construction site maintenance/restoration), as well as mitigation measures identified in Chapter 6 (under 4.8, Traffic, Transportation, and Circulation (Measures 4.8-1a and 4.8-1b); 4.9, Air Quality (Measures 4.9-1c, 4.9-1d, and 4.9-2a); and 4.10, Noise and Vibration (Measures 4.10-1a, 4.10-2a, 4.10-2b, 4.10-3a, and 4.10-3b) would reduce temporary construction effects of the Recycled Water Projects to a less-than-significant level. It is expected that the SFPUC and its contractors would be able to make arrangements with willing property owners for temporary staging areas such that displacement of existing land uses would not be a significant impact. Potential impacts of proposed recycled water facilities would be assessed in more detail as part of separate, project-level CEQA review.

Long-Term Facility Siting Impacts

Impact 4.3-2: Permanent displacement or long-term disruption of existing land uses.

This section addresses potential impacts on existing land uses associated with permanent operation and siting of WSIP facility projects in each region. Siting and operation of proposed WSIP facilities could, under certain circumstances, result in adverse impacts on existing land uses in the project regions. Adverse land use impacts would not be expected to occur for WSIP facilities constructed on CCSF-owned land used for water system purposes, as these projects would neither displace or relocate an existing land use nor change an existing water system use. Therefore, WSIP projects on CCSF-owned land would not result in adverse effects on surrounding uses, as land use conditions would remain similar. For WSIP projects where acquisition of non-CCSF-owned land would be required to build, operate, or access a WSIP project facility or facility component (e.g., discharge outfall of a pipeline), adverse impacts could occur if the WSIP facilities located on non-CCSF-owned property were not compatible with the surrounding land uses or would result in the permanent displacement of an existing land use.

Most of the WSIP projects would be located on CCSF-owned property on, or adjacent to, existing SFPUC facilities, and the SFPUC would seek to locate any required ancillary or additional easements on CCSF-owned land to the extent feasible. Eight WSIP projects have been identified to date that would require acquisition of additional permanent easements or property (see **Table 4.3-3**). (In developing detailed plans for the WSIP projects, the SFPUC may identify other land acquisition requirements for WSIP projects in addition to those listed here. This program-level analysis describes the nature and magnitude of potential land use effects that could result from such land acquisition.) Additional land acquisition could be required to access existing or new facilities, construct new facility components, and/or to expand or upgrade existing facilities. In most cases, land acquisition would be required for new pipeline alignments and relatively minor facility components such as access roads, power utilities, or a new discharge outfall. Land acquisition would almost always occur next to or near existing SFPUC facilities sites that are within existing SFPUC right-of-way and that have been zoned or designated as a public facility or water system use. Acquisition of permanent easement and property could have a significant land use effect if such acquisition displaced an existing use that would be difficult to relocate. For WSIP projects located entirely on CCSF-owned property and where no land acquisition is required (as listed in Table 4.3-3), displacement or relocation of an existing land use would not occur, and land use impacts related to displacement would not be applicable.

San Joaquin Region

Impact 4.3-2: Permanent displacement or long-term disruption of existing land uses		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	N/A
SJPL System	SJ-3	PSU
SJPL Rehabilitation	SJ-4	N/A
Tesla Portal Disinfection	SJ-5	LS

The WSIP project sites in the San Joaquin Region are within largely undeveloped areas that contain open space or agricultural uses, except for the city of Modesto, a moderately dense urban center. Three projects in this region could require land acquisition outside of the SFPUC right-of-way.

The Advanced Disinfection (SJ-1), SJPL System (SJ-3), and Tesla Portal Disinfection (SJ-5) projects could each require land acquisition outside of the SFPUC right-of-way for power equipment and structures and access roads. Generally, a relatively narrow strip of land would be required to extend new or additional power service infrastructure to the site (i.e., underground or aboveground powerlines), and a small additional site could be required for power station facilities. Given that these three project sites are for the most part located in undeveloped, agricultural areas, it is likely that power facilities could be sited along the margin of existing roads and/or private properties without causing significant land use displacement or disruption. For the Advanced Disinfection and Tesla Portal Disinfection projects, this impact is expected to be *less than significant*.

Agriculture is the predominant land use along the pipeline segments of the SJPL System project (SJ-3); however, rural and suburban residential and recreational uses are also located adjacent to the alignment, including the Tracy Golf and Country Club near I-580. Since the locations of power supply facilities have not yet been determined, the PEIR analysis errs on the conservative side and has determined that any permanent displacement of these existing residential or recreational uses would be a *potentially significant and unavoidable* impact. It is possible that this impact could be reduced to a less-than-significant level by implementing the recommendations of facility siting studies for power facilities and access roads (Measure 4.3-2). Although it is expected

TABLE 4.3-3
POTENTIAL LAND ACQUISITION REQUIRED OUTSIDE OF SFPUC RIGHT-OF-WAY

No.	Project Title	Potential Need for Permanent Easement or Land Acquisition
SJ-1	Advanced Disinfection	Land possibly needed for associated power infrastructure requirements.
SJ-2	Lawrence Livermore Supply Improvements	None at Thomas Shaft site.
SJ-3	San Joaquin Pipeline System	Additional right-of-way/easement possibly needed for associated power requirements and access roads. Presumably, power facilities would be located near two new crossovers (both located in Stanislaus County, with one about 20 miles east of Modesto and the other about 15 miles west of Modesto).
SJ-4	Rehabilitation of Existing San Joaquin Pipelines	None
SJ-5	Tesla Portal Disinfection Facility	Land possibly needed for associated power infrastructure requirements.
SV-1	Alameda Creek Fishery Enhancement	None
SV-2	Calaveras Dam Replacement	None
SV-3	Additional 40-mgd Treated Water Supply	Easement possibly needed across private property for new pipeline.
SV-4	New Irvington Tunnel	Could need additional right-of-way/easement for access to new west portal in Fremont.
SV-5	SVWTP – Treated Water Reservoirs	None
SV-6	San Antonio Backup Pipeline	Potential land acquisition to be determined (possible easement for new pipeline).
BD-1	Bay Division Pipeline Reliability Upgrade	Easements could be required along the existing Bay Division Pipeline right-of-way for access along the alignment. An easement could be required north of the Hayward fault crossing. Other easements would be required in the areas near the beginning (Irvington Portal area) and terminus (Newark Valve House area) of the eastern pipeline segments within Fremont and Newark; and the beginning (Ravenswood Valve House) and terminus (Edgewood Valve Lot) at the eastern segment within East Palo Alto and the unincorporated Edgewood community in San Mateo County.
BD-2	BDPL Nos. 3 and 4 Crossovers	Additional right-of-way/easement could be needed for permanent discharge outfalls at all three locations. Preferred locations are in undeveloped areas on Veterans Administration Medical Center–Gunn High School lands (Barron Creek), Ulistac Natural Area (Guadalupe Creek), and reservoir lands (Bear Gulch).
BD-3	Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault	None
PN-1	Baden and San Pedro Valve Lots Improvements	None
PN-2	Crystal Springs/San Andreas Transmission Upgrade	Land acquisition to be determined.
PN-3	HTWTP Long-term Improvements	None
PN-4	Lower Crystal Springs Dam Improvements	None
PN-5	Pulgas Balancing Reservoir Rehabilitation	None
SF-1	San Andreas Pipeline No. 3 Installation	None
SF-2	Groundwater Projects	None within San Francisco for local projects (these would be on CCSF-owned property or in public right-of-way). Regional projects – acquisition to be determined. None in San Francisco (all sites located on city property, except one located at Francis Scott Key School on school district property).
SF-3	Recycled Water Projects	None but proposed sites on CCSF-owned property developed with other uses. Treatment Plant Site: Oceanside Water Pollution Control Plant / San Francisco Zoo vicinity; Storage: Golden Gate Park (existing 2-million-gallon reservoir); another could be required in the Lincoln Park area, which is owned/operated by the San Francisco Recreation & Park Department.

SOURCE: SFPUC (see Appendix C, Table C.1).

that power supply facilities could be located to avoid permanent impacts on existing land uses, the significance of any potential land use impacts would be evaluated as part of separate, project-level CEQA review, and this evaluation would determine if impacts could be mitigated to a less-than-significant level. Following project construction and installation of power supply facilities, no long-term disruption of adjacent land uses would result from operation of the pipelines.

The Lawrence Livermore (SJ-2) and SJPL Rehabilitation (SJ-4) projects would not require acquisition of land or right-of-way. Therefore, these projects would not have long-term land use impacts due to permanent displacement or disruption of existing land uses, and this impact would *not apply*.

Sunol Valley Region

Impact 4.3-2: Permanent displacement or long-term disruption of existing land uses		
Alameda Creek Fishery	SV-1	N/A
Calaveras Dam	SV-2	N/A
40-mgd Treated Water	SV-3	PSU
New Irvington Tunnel	SV-4	LS
Treated Water Reservoirs	SV-5	N/A
SABUP	SV-6	PSU

Two projects in this region, the 40-mgd Treated Water (SV-3) and New Irvington Tunnel (SV-4), would require acquisition of land outside of the existing SFPUC right-of way.

The Treated Water Reservoirs (SV-5) project would be entirely contained within existing SFPUC facilities, and therefore this impact would not be applicable to this project. The Alameda Creek Fishery (SV-1) and Calaveras Dam (SV-2) projects would involve development of new facilities on currently undeveloped sites, but entirely within Alameda watershed lands owned by the CCSF. Therefore, these projects would not displace or disrupt any existing land uses, and this impact would *not apply* to these projects. The SFPUC has not yet determined if land would need to be acquired for the SABUP project (SV-6). However, to address the remote possibility that acquisition of additional pipeline easement on private property might be necessary, the PEIR analysis errs on the conservative side and has determined that any permanent displacement of existing uses would be a *potentially significant and unavoidable* impact. It is possible that this impact could be reduced to a less-than-significant level by implementing the recommendations of facility siting studies (Measure 4.3-2). Although it is expected that project facilities could be located to avoid permanent impacts on existing land uses, the significance of any potential land use impacts would be evaluated as part of separate, project-level CEQA review, and this evaluation would determine if impacts could be mitigated to a less-than-significant level.

The 40-mgd Treated Water project (SV-3) could require a permanent easement across private property adjacent to the Sunol Valley WTP for a new pipeline, although a specific alignment for this pipeline has not yet been determined. Existing land uses in the Sunol Valley, besides SFPUC water system facilities and public open space and recreation uses, include rangeland, nurseries, and quarries. The proposed easement would occupy a relatively narrow strip of land, and it is likely that the existing land use activities could return following pipeline installation. While it is expected that the proposed pipeline easement could be located without significant permanent impacts on existing land uses (i.e., the need to relocate the existing use), the PEIR analysis errs on the conservative side and has determined that any permanent impacts on existing uses would be a *potentially significant and unavoidable* impact. It is possible that this impact could be reduced to a less-than-significant level by implementing the recommendations of facility siting studies (Measure 4.3-2). Although it is expected that project facilities could be located to avoid permanent impacts on existing land uses, the significance of any potential land use impacts would be evaluated as part of separate, project-level CEQA review, and this evaluation would determine if impacts could be mitigated to a less-than-significant level.

The New Irvington Tunnel project (SV-4) would require construction of two new tunnel portals and associated construction staging areas. This project also involves construction of a new access road within existing SFPUC right-of-way to accommodate truck traffic during construction and provide permanent site access. The new road would be located within the SFPUC's existing Bay Division Pipeline easement up to the Irvington Portal area, adjacent to residences in Fremont. This existing right-of-way extends through a residential neighborhood and creates an undeveloped, open space corridor behind these homes. The proposed access road would be a distinct change of land use from the current condition and use. Although this change in use could be significant during the construction phase when the road would be used by construction vehicles (see Impact 4.3-1, above), long-term use of this road would be limited to SFPUC maintenance vehicles and would be a continuation of an existing SFPUC water-related corridor and use (i.e., an access road), which would limit the potential for long-term disruption of existing residences. Therefore, this impact would be *less than significant*.

The New Irvington Tunnel project (SV-4) would also require acquisition of several parcels of land in the vicinity of the existing Irvington Tunnel in order to extend the new access road to the new portal on the west side of the new tunnel. This land is currently undeveloped and zoned for large-lot residential use. The proposed new access road could reduce the size and alter the configuration of some of these undeveloped parcels, but would not preclude future residential development and use in this area. Potential effects with respect to future residential use of this area would be less than significant.

Bay Division Region

Impact 4.3-2: Permanent displacement or long-term disruption of existing land uses		
BDPL Reliability Upgrade	BD-1	PSU
BDPL 3 and 4 Crossovers	BD-2	LS
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	N/A

The BDPL Reliability Upgrade (BD-1) and BDPL 3 and 4 Crossovers (BD-2) projects would be located in densely urbanized areas that include a mix of land uses. The BDPL Reliability project involves approximately 16 miles of pipeline and 5 miles of bay tunnel extending from Fremont and Newark in southern Alameda County through East Palo Alto, Menlo Park, and Redwood City and unincorporated areas in the central-eastern portion of San Mateo County. The existing right-of-way crosses through urban areas with a mix of land uses, including residential and school uses. A narrow strip of additional land adjacent to the existing SFPUC right-of-way would need to be acquired for pipeline easements along the BDPL Reliability Upgrade alignment. This additional land would be on the order of 5 to 15 feet wide, extending up to one-half mile or more. New easements could be required in areas north of the Hayward fault crossing, and in the vicinities of the Newark and Ravenswood Valve Houses and the Edgewood Valve Lot. Except for the Hayward fault location in a residential area, the proposed easements are adjacent to existing SFPUC facilities and are within undeveloped lands in industrial or open space areas; in the Hayward fault crossing location, the pipeline extends through residential areas.

Establishing this additional easement would impose some restrictions on land uses within the easement, but would not necessarily prohibit continuation of the existing land use. For example, the new easement might be established along the border of residential backyards adjacent to the current Bay Division Pipeline right-of-way or along the border of a park where the open areas, playfields, and gardens now present could be restored following pipeline installation. Similarly, the new easement might extend across a commercial property in a back parking lot or storage area, the use of which could be restored following pipeline construction. In other cases, some existing structures might need to be relocated, which could restrict the current use. In general, land uses and activities that make use of open, outdoor space could likely continue within the new easement area, while uses that involve permanent structures would need to be relocated, outside of the easement. In such cases, it might be possible to relocate structures such as garages or storage facilities elsewhere on the same property but outside the required easement area, thus resulting in a minor modification of the existing site use and land use configuration. The site-specific impacts on existing land uses of establishing additional pipeline easements would be analyzed in separate, project-level CEQA review of the BDPL Reliability Upgrade project (BD-1). While it is expected that the proposed pipeline easement could be located without the need to relocate an existing use, the PEIR analysis errs on the conservative side and has determined that any permanent impacts on existing uses would be a *potentially significant and unavoidable* impact. It is possible that this impact could be reduced to a less-than-significant level by implementing the recommendations of facility siting studies (Measure 4.3-2). Although it is expected that project facilities could be located to avoid permanent impacts on existing land uses, the significance of any potential land use impacts would be evaluated as part of separate, project-level CEQA review, and this evaluation would determine if impacts could be mitigated to a less-than-significant level. This project, an underground pipeline, would not result in long-term operational effects that would be incompatible with surrounding uses and thus would not result in permanent land use disruption.

Within the BDPL Reliability Upgrade project (BD-1) alignment, a number of existing land uses or improvements have encroached onto the SFPUC right-of-way, including residential fencing, schoolyards, play fields, landscaping, and parking lots. These uses would be removed or would be otherwise authorized (e.g., SFPUC leases or permits) according to the policies and procedures set forth in the SFPUC Right-of-Way Encroachment Removal Policy (SFPUC, 2007). The removal or authorization of these encroachments is not part of the BDPL Reliability Upgrade, as the SFPUC would enforce its encroachment removal policy with or without implementation of this project. Therefore, removal of these uses would not constitute a permanent displacement or change in land use for purposes of this PEIR.

The BDPL 3 and 4 Crossovers project (BD-2) would involve construction of pipeline crossovers at three separate locations along a 32-mile stretch of the existing Bay Division Pipelines Nos. 3 and 4. Additional right-of-way or easements could be required for discharge outfalls associated with the crossover facilities at three locations: Guadalupe Creek in Santa Clara, Bear Gulch Reservoir in Atherton, and Barron Creek in Palo Alto. The proposed outfalls would be installed within creek corridors; although temporary disruption of such uses as recreation trails might occur, these uses would be restored following installation, and no long-term displacement of existing land use activities would occur. The crossover and discharge outfall near Barron Creek is adjacent to the running track and sports fields at Gunn High School in Palo Alto; it is not known at this time if any easement would be required on the school property. However, placement of a new crossover facility near an open sports field would not restrict, disrupt, or displace existing uses. Also, the crossover facility would be located near, and would be similar in use to, the existing outfall facility at Barron Creek and thus would not constitute a change in use. This project would not result in long-term operational effects that would be incompatible with surrounding uses and thus would not result in permanent land use disruption. Therefore, these long-term operational impacts would be *less than significant*.

The BDPL 3 and 4 Seismic Upgrade at Hayward Fault project (BD-3) would involve improvements at an existing CCSF-owned facility site that is currently used for water system purposes. No new land uses would be introduced to this site, nor would this project require the acquisition of additional property. Therefore, this would not displace or disrupt any existing land uses, and this impact would *not apply*.

Peninsula Region

Impact 4.3-2: Permanent displacement or long-term disruption of existing land uses		
Baden and San Pedro Valve Lots	PN-1	N/A
CS/SA Transmission	PN-2	PSU
HTWTP Long-Term	PN-3	N/A
Lower Crystal Springs Dam	PN-4	N/A
Pulgas Balancing Reservoir	PN-5	N/A

The five WSIP project sites within the Peninsula Region would be located within existing SFPUC facilities or on SFPUC right-of-way or property. They would not involve the acquisition of additional land, with the possible exception of the CS/SA Transmission project (PN-2). Therefore, with the possible exception of PN-2, this impact would *not apply* to these projects.

At this time, the SFPUC believes that the CS/SA Transmission project (PN-2) would not require additional easement or land acquisition. If replacement of the existing pipeline were needed, a new parallel pipeline would most likely be located on the SFPUC property within the Peninsula watershed. However, since the need for and location of a new alignment has not been determined, to address the remote possibility that additional pipeline easement might be needed on private property, the PEIR analysis errs on the conservative side and has determined that any permanent impacts on existing uses would be a *potentially significant and unavoidable* impact. It is possible that this impact could be reduced to a less-than-significant level by implementing the recommendations of facility siting studies (Measure 4.3-2). Although it is expected that project facilities could be located to avoid permanent impacts on existing land uses, the significance of any potential land use impacts would be evaluated as part of separate, project-level CEQA review, and this evaluation would determine if impacts could be mitigated to a less-than-significant level.

San Francisco Region

Impact 4.3-2: Permanent displacement or long-term disruption of existing land uses		
SAPL 3 Installation	SF-1	N/A
Groundwater Projects	SF-2	PSU
Recycled Water Projects	SF-3	PSU

The SAPL 3 Installation project (SF-1) would involve the installation, repair, or replacement of up to 4.17 miles of pipeline through densely populated urbanized areas. The SFPUC expects that this project would not require additional easement or land acquisition, and permanent land use impacts would *not apply*.

In some cases, existing land uses have encroached onto the SFPUC right-of-way along this alignment, including two golf courses, mature landscaping, and permanent or temporary structures. These uses would either be removed or would be authorized according to the policies and procedures set forth in the SFPUC Right-of-Way Encroachment Removal Policy (SFPUC, 2007). The removal or authorization of these encroachments is not part of the SAPL 3 Installation project, but would be implemented in accordance with the SFPUC policy as part of its ongoing right-of-way maintenance program. Thus, while the SAPL 3 Installation project would necessitate SFPUC action on these encroachments in a timely manner to accommodate the WSIP schedule, such enforcement action is not part of the WSIP project, and any effects of implementing such enforcement actions are not analyzed in this PEIR. Enforcement actions will occur irrespective of whether the WSIP projects are implemented.

The Groundwater Projects (SF-2) and Recycled Water Projects (SF-3) could require additional right-of-way to accommodate wells and recycled storage, treatment, and pumping facilities. The Groundwater Projects would result in the installation of new wells, wells stations, and associated piping. Potential sites that could be affected include Francis Scott Key School or other sites in San Francisco and northern San Mateo County. While it is expected that the proposed groundwater and recycled water facilities could be located without significant permanent impact on existing land uses (i.e., the need to relocate the existing use), the PEIR analysis errs on the conservative side and has determined that any permanent impacts on existing uses would be a *potentially significant and unavoidable* impact. It is possible that this impact could be reduced to a less-than-significant level by implementing SFPUC Construction Measure #6 (compliance with local noise ordinances to the extent feasible) and Construction Measure #10 (locating staging areas away from public view and directing nighttime lighting away from residential areas) as well as recommendations of facility siting studies (Measure 4.3-2). Although it is expected that project facilities could be located to avoid permanent impacts on existing land uses, the significance of any potential land use impacts would be evaluated as part of separate, project-level CEQA review, and this evaluation would determine if impacts could be mitigated to a less-than-significant level. With Measure 4.3-2, the Groundwater Projects are not expected to result in long-term operational effects that would be incompatible with surrounding uses, and thus would not result in permanent land use disruption; wells and associated facilities are generally small utility type structures that would not alter the use of an existing site.

Recycled Water Projects (SF-3) facilities could require land acquisition for a new treatment facility at or near the Oceanside Water Pollution Control Plant (WPCP) or within Golden Gate Park, as well as multiple storage facilities for recycled water in the vicinity of Lincoln Park, Golden Gate Park, and the San Francisco Zoo. These facilities could also affect recreation and visitor-oriented uses at the zoo, Golden Gate Park, and the Lincoln Park golf course. The Recycled Water Projects (SF-3) could establish more substantial treatment and/or pump station facilities in residential areas. Since facility locations are undetermined at this stage of project planning, the PEIR analysis errs on the conservative side and has determined that any permanent impacts on existing uses would be a *potentially significant and unavoidable* impact. It is possible that this impact could be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #6 (compliance with local noise ordinances to the extent feasible) and Construction Measure #10 (locating staging areas away from public view and directing nighttime lighting away from residential areas) as well as the recommendations of facility siting studies (Measure 4.3-2). Although it is expected that project facilities could be located to avoid permanent impacts on existing land uses, the significance of any potential land use impacts would be evaluated as part of separate, project-level CEQA review, and this evaluation would determine if impacts could be mitigated to a less-than-significant level.

Visual Quality

This analysis identifies three potential impacts on visual quality. The first type of impact is the temporary construction-related effect that WSIP projects could have on vistas, as seen from scenic highways and local scenic routes, or on the visual character of a community. The second is the permanent visual impact that projects would have on these same vistas or on visual character. The third impact relates to new sources of light and glare that could be created through implementation of WSIP projects.

Impact 4.3-3: Temporary construction-related adverse impacts on scenic vistas or the visual character of a community.

WSIP projects could result in temporary construction-related impacts on scenic vistas, depending on the location of the WSIP project in relation to those resources. With implementation of SFPUC Construction Measure #10 (maintaining a clean and orderly site, locating staging areas away from public view, and directing nighttime lighting away from residential areas), this impact would be less than significant.

All Regions

Construction activities typically have only temporary effects on visual quality and therefore are generally considered to have a less-than-significant impact. However, construction projects that would be located at one site for a year or more could result in construction-related visual impacts. Although pipeline projects progress along the alignment and typically affect a specific location for a short period of time (less than one year), staging areas associated with these projects could be used for more than one year. In addition, any projects involving nighttime construction (e.g., tunnel portals or shafts) would require lighting, and adjacent areas could be subject to visual impacts associated nighttime lighting for more than one year. Based on the construction schedule presented in Chapter 3 (Figure 3.6) and Appendix C (Table C.4), construction activities associated with all WSIP projects would occur for at least one year. It should be noted, however, that construction of some of these projects could actually last for less than a year.

Although construction activities associated with all WSIP projects could occur over one year or longer, temporary visual impacts would be *less than significant* with implementation of SFPUC Construction Measure #10 (maintaining a clean and orderly site, locating staging areas away from public view, and directing nighttime lighting away from residential areas).

Impact 4.3-4: Permanent adverse impacts on scenic vistas or the visual character of a community.

The long-term visual impacts of WSIP projects could be potentially significant, depending on site selection, facility scale and design, and location relative to public viewing opportunities. The major factor affecting visual impacts is the visibility of the proposed improvements. Pipelines and tunnels are typically underground and would have no permanent visual impacts. Treatment facilities, storage basins, vaults and valve houses, crossovers, and other facilities can be partially buried, but in general have a visible aboveground component. Construction of permanent new facilities as well as renovation or repair of existing facilities could result in negative aesthetic effects, depending on the existing character of the project site and the degree of proposed changes, such as the height and mass of proposed structures or whether mature trees would be removed. **Table 4.3-4** summarizes key information used to assess potential visual impacts, including aboveground structures proposed as part of each project, scenic roads and highways in the vicinity of each project site, site visibility from these scenic roads, and other considerations.

San Joaquin Region

Impact 4.3-4: Permanent adverse impacts on scenic vistas or visual character		
Advanced Disinfection	SJ-1	PSM
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	N/A
Tesla Portal Disinfection	SJ-5	PSM

The Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) projects would construct new buildings at the Tesla Portal facility. The Advanced Disinfection project would construct a new structure up to 35 feet high, and four partially buried vaults up to 30 inches high. The Tesla Portal Disinfection (SJ-5) project involves building a structure up to 30 feet high. These projects could also require the purchase of additional land for associated power supply facilities, depending on the final locations selected (see Table 4.3-4). There are distant views of the Tesla Portal facility from I-580, a Caltrans-designated scenic highway (from I-5 to the Alameda County line) and a San Joaquin County–designated scenic route (where I-5 and I-580 are combined). These two projects would expand the existing cluster

TABLE 4.3-4
POTENTIAL PERMANENT VISUAL IMPACTS OF WSIP PROJECTS

Project No.	Project Name	Proposed New Permanent Aboveground Structures	Scenic Routes in the Project Region	Would WSIP Facilities Be Visible from Scenic Routes or Other Visually Sensitive Areas?	Visual Considerations (including whether WSIP project is located in Alameda or Peninsula Watershed Management Plan [WMP] areas)	Impact Significance Determination
SJ-1	Advanced Disinfection	*Tesla Portal*: ▪ 1 new structure (up to 35 feet high) ▪ 4 partially buried vaults (typically up to 30 inches high) ▪ Modification of Tesla Portal	*Caltrans:* ▪ I-580 from I-5 to Alameda County line *San Joaquin County:* ▪ I-580 and I-5 (where combined)	Yes, distant views of this building would be available from I-580.	There are about seven existing structures at Tesla Portal that are currently visible from I-580, and this project would expand the cluster of buildings currently visible from this road. Potentially significant impacts would be reduced to less than significant with implementation of mitigation measures to ensure visual compatibility with existing adjacent SFPUC facilities.	PSM
SJ-2	Lawrence Livermore Supply Improvements	New structures at Thomas Shaft (size, height, appearance to be determined)	*San Joaquin County:* ▪ Corral Hollow Road	No, depending on building height. Facility located approximately 1.5 miles south of Corral Hollow Road where topography and distance would limit the potential for visibility.	Thomas Shaft not visible from Corral Hollow Road.	LS
SJ-3	San Joaquin Pipeline System	▪ No new buildings ▪ 2 partially buried vaults at crossover locations (typically up to 30 inches high) ▪ Modification of Oakdale Portal	*Caltrans:* ▪ I-580 from I-5 to Alameda County line ▪ I-5 from Merced County line to San Joaquin County line *San Joaquin County:* ▪ I-580 and I-5 (where combined)	No, facilities near scenic roads would be underground and not visible. No pipelines are currently visible from Willms Road and this would not change with this project. Although this road is not designated as a scenic road, Willms Ranch, a California landmark, is located on Willms Road.	Vaults would be visible, but they would not be located near scenic roads.	LS
SJ-4	San Joaquin Pipeline Rehabilitation	None, existing pipelines would be rehabilitated.	*Caltrans:* ▪ I-580 from I-5 to Alameda County line ▪ I-5 from Merced County line to San Joaquin County line *San Joaquin County:* ▪ I-580 and I-5 (where combined)	No change in visibility from scenic roads compared to existing conditions.	Existing pipelines are mostly underground, with some aboveground sections at the east end (west of Oakdale Portal) in agricultural areas, and rehabilitation would not alter visibility.	N/A
SJ-5	Tesla Portal Disinfection Station	*Tesla Portal*: ▪ 1 new structure to replace/upgrade existing disinfection facility (up to 30 feet high)	*Caltrans:* ▪ I-580 from I-5 to Alameda County line *San Joaquin County:* ▪ I-580 and I-5 (where combined)	Yes, distant views of this building would be available from I-580.	Since there are existing structures at Tesla Portal that are currently visible from I-580, this project would expand the cluster of buildings currently visible from this road. Mitigation measures would ensure visual compatibility with existing adjacent SFPUC facilities.	PSM

TABLE 4.3-4 (Continued)
POTENTIAL PERMANENT VISUAL IMPACT OF WSIP PROJECTS

Project No.	Project Name	Proposed New Permanent Aboveground Structures	Scenic Routes in the Project Region	Would WSIP Facilities Be Visible from Scenic Routes or Other Visually Sensitive Areas?	Visual Considerations (including whether WSIP project is located in Alameda or Peninsula Watershed Management Plan [WMP] areas)	Impact Significance Determination
SV-1	Alameda Creek Fishery Enhancement	*Alameda Creek, downstream from Sunol Valley WTP*: ▪ Facilities not yet determined	*Alameda and Santa Clara Counties:* ▪ Calaveras Road	Yes, new facilities could be visible from Highway 84/Niles Canyon Road, Calaveras Road, or I-680, if any aboveground facilities are located in segments of Alameda Creek that are currently visible from these roadways.	All project alternatives would be located within the Alameda WMP area. With implementation of the WMP's required design guidelines and mitigation measures, visual impacts would be less than significant.	PSM
SV-2	Calaveras Dam Replacement	*Calaveras Dam site*: ▪ Replacement of dam, spillway, and inlet tower (maximum height of dam: 220 feet from foundation to dam crest) ▪ 2 vaults (typically up to 30 inches high)	*Alameda and Santa Clara Counties:* ▪ Calaveras Road	Yes, views could be available from immediately surrounding ridges, with distant views possible from the Sunol Regional Wilderness (although topography would likely block distant views). Although the dam would not be visible from Calaveras Road, the reservoir, borrow areas, and the road between the borrow areas and dam could be visible from this road and trails within the Sunol Regional Wilderness.	The dam itself is not visible from Calaveras Road, but the reservoir as well as potential changes in the surrounding topography (from borrow areas and access roads) would be visible from Calaveras Road and trails within the Sunol Regional Wilderness. The project would alter views of the reservoir and surrounding hillsides when water levels are raised and oak woodland cover is removed in areas subject to excavation and grading. WMP design guidelines and mitigation measures would help to minimize visual impacts somewhat from Calaveras Road.	PSU
SV-3	Additional 40-mgd Treated Water Supply	*Sunol Valley WTP*: ▪ One new building (up to 10 feet high)	*Alameda and Santa Clara Counties:* ▪ Calaveras Road	No, existing Sunol Valley WTP facilities are not visible from Calaveras Road, since trees in the Alameda Creek riparian corridor screen views of facilities from this road. Likewise, proposed facilities would not be visible from this road.	The new building would not be visible from Calaveras Road. With implementation of the WMP's required design guidelines, any potential visual impacts from the new building (up to 10 feet high) at the Sunol Valley WTP facility would be less than significant.	LS
SV-4	New Irvington Tunnel	*New Irvington Tunnel East Portal in Sunol Valley and West Portal in Fremont*: ▪ New portals ▪ 9–12 concrete vaults to be built across the fault (typically up to 30 inches high) ▪ Modification of Irvington Portal and Alameda West Portal	*Alameda and Santa Clara Counties:* ▪ Calaveras Road	Yes, distant views of the new and existing portals in the Sunol Valley could be available from Calaveras Road, although the riparian corridor along Alameda Creek could obscure these views. Views of the new and existing portals east of Mission Boulevard in Fremont could be visible from nearby homes to the west, but these homes would obscure views of the portal from Mission Boulevard.	With the implementation of the WMP's required design guidelines and mitigation measures, visual impacts on Calaveras Road due to the new portal and vaults in the Sunol Valley would be less than significant. Mitigation measures would reduce visual impacts of the new portal in Fremont.	PSM

TABLE 4.3-4 (Continued)
POTENTIAL PERMANENT VISUAL IMPACT OF WSIP PROJECTS

Project No.	Project Name	Proposed New Permanent Aboveground Structures	Scenic Routes in the Project Region	Would WSIP Facilities Be Visible from Scenic Routes or Other Visually Sensitive Areas?	Visual Considerations (including whether WSIP project is located in Alameda or Peninsula Watershed Management Plan [WMP] areas)	Impact Significance Determination
SV-5	SVWTP – Treated Water Reservoirs	Sunol Valley WTP: ▪ 1 new structure (up to 15 feet high) ▪ 1 new vault	*Alameda and Santa Clara Counties:* ▪ Calaveras Road	No, existing Sunol Valley WTP facilities are not visible from Calaveras Road, since trees in the Alameda Creek riparian corridor screen views of facilities from this road. Likewise, proposed facilities would not be visible from this road.	The new building would not be visible from Calaveras Road. With implementation of the WMP's design guidelines, potential visual impacts from the proposed structure (up to 15 feet high) at the Sunol Valley WTP facility would be less than significant.	LS
SV-6	San Antonio Backup Pipeline	Alameda East Portal: ▪ 2 new vaults ▪ Modification of Alameda East Portal	*Alameda and Santa Clara Counties:* ▪ Calaveras Road	Yes, views of any aboveground features associated with the discharge facility could be available from Calaveras Road, although the Alameda Creek riparian corridor would likely obscure these views. All pipeline facilities would be underground, and long-term views from this road would not be altered.	With implementation of the WMP's design guidelines and mitigation measures, visual impacts from the new vaults (up to 30 inches high) on Calaveras Road would be less than significant.	PSM
BD-1	Bay Division Pipeline Reliability Upgrade	8 electrical control buildings at valve lots (up to 30 feet high) and tunnel shaft facilities at Ravenswood and Newark Valve Houses	*Alameda County, Cities of Fremont and Newark (routes and interchanges):* ▪ Dumbarton Freeway (Dumbarton Bridge/Highway 84) and Newark Boulevard ▪ Dumbarton Freeway (Dumbarton Bridge/Highway 84) and Thornton Avenue ▪ Nimitz Freeway (I-880) and Thorton Avenue ▪ Nimitiz Freeway (I-880) and Mowry Avenue ▪ Nimitz Freeway (I-880) and Stevenson Boulevard ▪ I-880 from the northern city limits to the southern city limits ▪ Mission Boulevard (northern city limits to I-880) ▪ Fremont Boulevard (northern city limits to Warm Springs Boulevard)	Possibly, depending on proximity of one-story buildings to scenic roads, although the visibility of project facilities at tunnel shafts from I-880 and Dumbarton Freeway/Highway 84 would be limited by level topography and intervening development. With the level topography in the bay vicinity (Ravenswood Valve House near East Palo Alto and Newark Valve House in Newark), intervening vegetation obscures views of the tunnel portal areas from scenic roadways or waterways. In addition, industrial buildings located south of Thornton Avenue and west of Willow Street block views of the Newark Valve House from Thornton Avenue and the Dumbarton Freeway. Views of the easternmost pipeline alignment from I-680 would also be obscured by distance (approximately one-half mile north of the freeway), intervening development and landscape trees.	New one-story buildings could be visible from adjacent roadways (and possibly scenic roadways depending on their location), but they would be located near existing development, which is adjacent to most of the pipeline alignment. Mitigation measures would reduce potential visual impacts of new vaults by addressing architectural design, landscaping plans, landscape screens, and tree removal.	PSM

TABLE 4.3-4 (Continued)
POTENTIAL PERMANENT VISUAL IMPACT OF WSIP PROJECTS

Project No.	Project Name	Proposed New Permanent Aboveground Structures	Scenic Routes in the Project Region	Would WSIP Facilities Be Visible from Scenic Routes or Other Visually Sensitive Areas?	Visual Considerations (including whether WSIP project is located in Alameda or Peninsula Watershed Management Plan [WMP] areas)	Impact Significance Determination
BD-1 (cont.)	Bay Division Pipeline Reliability Upgrade (cont.)		▪ Washington Boulevard (Fremont to Mission Boulevards) ▪ Mowry Avenue (from I-880 to Mission Boulevard) ▪ Stevenson Boulevard (from I-880 to Mission Boulevard) ▪ Thornton Avenue in Newark ▪ Newark Slough and Mowry Slough in Newark *City of East Palo Alto:* ▪ University Avenue (an important gateway to the city) *San Mateo County* ▪ *Edgewood Road from Alameda de las Pulgas to Cañada Road*			
BD-2	BDPL Nos. 3 and 4 Crossovers	3 new aboveground control buildings and/or vaults along the Bay Division Pipeline (3 to 8 feet high)	*City of Palo Alto:* ▪ Junipero Sierra Boulevard/ Foothill Expressway *Town of Woodside:* ▪ I-280 ▪ Highway 84	Possibly, although crossover facilities would generally be located away from public streets due to their proximity to creeks, rivers, and other waterways. However, nearby scenic roads include: ▪ Foothill Boulevard, adjacent to Veterans Administration Medical Center and near Gunn High School (Barron Creek) ▪ I-280 and Highway 84, near Bear Gulch Reservoir	New buildings would be 3 to 8 feet high. Existing visual character of the three crossover sites, including views from public rights-of-way, would be considered for all permanent aboveground facilities, if applicable. New building adjacent to Bear Gulch Reservoir could be visible from nearby residential development. The new building at Barron Creek would be near the Veterans Administration Medical Center and Gunn High School, while the building at Guadalupe Creek would be located in the Ulistac Natural Area. Mitigation measures would reduce potential visual impacts of the control buildings at these locations by addressing architectural design, landscaping plans, landscape screens, and tree removal.	PSM

TABLE 4.3-4 (Continued)
POTENTIAL PERMANENT VISUAL IMPACT OF WSIP PROJECTS

Project No.	Project Name	Proposed New Permanent Aboveground Structures	Scenic Routes in the Project Region	Would WSIP Facilities Be Visible from Scenic Routes or Other Visually Sensitive Areas?	Visual Considerations (including whether WSIP project is located in Alameda or Peninsula Watershed Management Plan [WMP] areas)	Impact Significance Determination
BD-3	Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault	None	▪ I-880 from Fremont's northern city limits to its southern city limits ▪ Mission Boulevard (northern city limits to I-880)	N/A	N/A	N/A
PN-1	Baden and San Pedro Valve Lots Improvements	*San Pedro Valve Lot*: ▪ 2 structures *Baden Valve Lot*: ▪ 4 new structures (all new structures, 1 to 3 feet high)	*Caltrans:* ▪ I-280 from Highway 17 to I-80 north of First Street in San Francisco	Possibly, but views would be limited. Baden Valve Lot located west of El Camino Real (Highway 82), and trees along the west side of this street obscure views of this facility. San Pedro Valve Lot is adjacent to I-280 and Junipero Serra Boulevard and would be visible from these streets.	Proposed facilities would be located within these existing valve lots and would not significantly alter existing views of these facilities. Expected low height (1 to 3 feet) would minimize the potential for changes in views.	LS
PN-2	Crystal Springs/ San Andreas Transmission Upgrade	1 or 2 existing structures could be replaced and would be the same height as existing structures (25 feet high).	*Caltrans:* ▪ I-280 from Highway 17 to I-80 north of First Street in San Francisco *Santa Clara County and City of San Mateo:* ▪ Highway 35 (northern end of the Skyline Scenic Recreation Route) ▪ Skyline Boulevard (in the Crystal Springs Reservoirs vicinity) ▪ Crystal Springs Road ▪ Black Mountain Road	Yes, structures in the Crystal Springs Pump Station vicinity could be visible from Highway 35/Skyline Road bridge over Lower Crystal Springs Dam or Crystal Springs Road, but views would be limited by elevational differences and vegetation.	Potentially visible, but the existing pump station structure is currently visible and within the Peninsula WMP area. Implementation of the WMP's design guidelines for structures and roads within the watershed plan area and mitigation measures addressing visual impacts from vegetation/tree removal would reduce visual impacts to less than significant.	PSM
PN-3	HTWTP Long-Term Improvements	To be determined	*Caltrans:* ▪ I-280 from Highway 17 to I-80 north of First Street in San Francisco	Possibly; this project is located east of I-280, but views of this facility are limited by intervening topography and trees. This site is already developed with structures associated with water facilities.	Locations and designs of any above-ground facilities/structures have not yet been determined, but they would be located within the existing water treatment facility. Since this site is already developed with water facilities, the project is not expected to significantly alter existing views of this facility. However, due to the visual sensitivity of the area, any change in visual character would be a potentially significant impact. Mitigation	PSM

TABLE 4.3-4 (Continued)
POTENTIAL PERMANENT VISUAL IMPACT OF WSIP PROJECTS

Project No.	Project Name	Proposed New Permanent Aboveground Structures	Scenic Routes in the Project Region	Would WSIP Facilities Be Visible from Scenic Routes or Other Visually Sensitive Areas?	Visual Considerations (including whether WSIP project is located in Alameda or Peninsula Watershed Management Plan [WMP] areas)	Impact Significance Determination
PN-3 (cont.)	HTWTP Long-Term Improvements (cont.)				measures would reduce potential visual impacts of the control buildings at these locations by addressing architectural design, landscaping plans, landscape screens, and tree removal.	
PN-4	Lower Crystal Springs Dam Improvements	To be determined	*Caltrans:* ▪ I-280 from Highway 17 to I-80 north of First Street in San Francisco *San Mateo County and City of San Mateo:* ▪ Highway 35 (northern end of the Skyline Scenic Recreation Route) ▪ Skyline Boulevard (in the Crystal Springs Reservoirs vicinity) ▪ Crystal Springs Road ▪ Black Mountain Road	Yes, existing dam is visible from Highway 35/Skyline Road bridge over this dam and scenic overlook located west of this road. Also, visible from I-280 and Crystal Springs Road.	This dam would be visible from a number of scenic roads and scenic overlooks, and visual sensitivity of this structure would be high. The dam is located in the Peninsula WMP area and would be subject to WMP design guidelines. Design of the dam parapet wall has not yet determined, but would be evaluated as part of separate, project-level CEQA review. Implementation of the WMP's design guidelines would reduce the visual impacts of new structures, and additional mitigation measures would be required to specifically address changes in views from visually sensitive areas. Raising the water levels in the reservoir could also affect views from the scenic overlook (see Chapter 5 for more discussion). However, the scenic quality of the reservoir vicinity would not change with this project.	PSM
PN-5	Pulgas Balancing Reservoir Rehabilitation	No new structures, but includes work on the Pulgas Channel.	*Caltrans:* ▪ I-280 from Highway 17 to I-80 north of First Street in San Francisco *San Mateo County:* ▪ Cañada Road	Yes, any changes to Pulgas Channel would be visible from Cañada Road, a designated scenic route. Scenic vistas from I-280 would not be affected by this project, since this freeway is located almost one mile to the east. Project would be located adjacent to Pulgas Water Temple, an important visual and historic resource, and cross under Cañada Road.	Any required tree/vegetation removal could alter views of the Pulgas Channel from Cañada Road. This facility is located in the Peninsula WMP area, and any changes to the reservoir facility or channel would be subject to WMP design guidelines. Additional mitigation measures would be required to specifically address vegetation/tree removal.	PSM

TABLE 4.3-4 (Continued)
POTENTIAL PERMANENT VISUAL IMPACT OF WSIP PROJECTS

Project No.	Project Name	Proposed New Permanent Aboveground Structures	Scenic Routes in the Project Region	Would WSIP Facilities Be Visible from Scenic Routes or Other Visually Sensitive Areas?	Visual Considerations (including whether WSIP project is located in Alameda or Peninsula Watershed Management Plan [WMP] areas)	Impact Significance Determination
SF-1	San Andreas Pipeline No. 3 Installation	2 new structures to replace out-of-service pipeline (up to 8 feet high) 2 vaults (typically up to 30 inches high)	*Caltrans:* ▪ I-280 from Highway 17 to I-80 north of First Street in San Francisco ▪ Highway 1: from Highway 35 to Highway 101 North of the Golden Gate Bridge	Yes, this pipeline alignment traverses the Lake Merced Golf & Country Club and San Francisco Golf Club.	Depending on location, new structures (up to eight feet high) could be visible from visually sensitive areas like the Lake Merced Golf & Country Club and San Francisco Golf Club. Pipeline construction could result in visual impacts due to damage or loss of mature trees at Lake Merced Golf & Country Club and San Francisco Golf Club. Mitigation measures would be required to minimize potential visual impacts due to facility design and loss of trees.	PSM
SF-2	Groundwater Projects	*San Francisco*: ▪ 6 new structures for wells and well stations *Northern San Mateo County*: 10 new structures	*Caltrans:* ▪ I-280 from Highway 17 to I-80 north of First Street in San Francisco *City of Colma:* ▪ El Camino Real ▪ Hillside Boulevard ▪ Junipero Serra Boulevard	Possibly, depending on final locations of facilities. Facilities could be within the scenic viewshed of I-280, Great Highway, Lake Merced, Pine Lake, San Francisco Zoo, and/or Golden Gate Park.	The potential for visual impacts would depend on final locations. Up to 16 single-story structures could be developed at various locations on the west side of San Francisco or in northern San Mateo County. These buildings would be small in scale and located generally in urbanized areas. Mitigation measures would reduce potential visual impacts by addressing architectural design, landscaping plans, landscape screens, and tree removal, as appropriate.	PSM
SF-3	Recycled Water Projects	1 to 4 new structures (for a recycled water treatment facility at or near Oceanside Water Pollution Control Plant) (up to 40 feet high)	*Caltrans:* ▪ Highway 1/19th Avenue	Possibly; if the recycled water treatment facility is located in the vicinity of the San Francisco Zoo and Oceanside WPCP, it could be visible from the Great Highway and Skyline Boulevard (Highway 35).	Any new facilities (up to 40 feet high) in the vicinity of the San Francisco Zoo and Oceanside WPCP could affect views from the Great Highway, Skyline Boulevard (Highway 35), or other scenic routes in this area. At 40 feet high, this building might have to be constructed partially below grade in order to minimize visual impacts on nearby scenic roads. Mitigation measures would reduce potential visual impacts by addressing architectural design, landscaping plans, landscape screens, and tree removal, as appropriate.	PSM

of buildings at the Tesla Portal facility that can be viewed at a distance from I-580. The two buildings and aboveground portions of the four vaults would alter the visual character of the area by intensifying the scale and mass of buildings and structures at the Tesla Portal site. Because the surrounding area is largely undeveloped, impacts on scenic vistas and visual character could be *potentially significant*. However, with implementation of mitigation measures addressing architectural design (Measure 4.3-4a), landscaping plans (Measure 4.3-4b), landscape screens (Measure 4.3-4c), and tree removal (Measure 4.3-4d), these potentially significant impacts could be reduced to a less-than-significant level.

The Lawrence Livermore project (SJ-2) would involve improvements at Thomas Shaft, an existing SFPUC facility site. Because the new structures have not been designed, their size, height, and appearance are not yet known. The closest scenic route is Corral Hollow Road (as designated by San Joaquin County), which is approximately 1.5 miles north of the project. Given the distance from the facility and the surrounding topography, the project would not likely be visible from Corral Hollow Road. The impact on the visual character and resources due to this project would be *less than significant*.

The SJPL System project (SJ-3) would build two partially buried vaults (up to 30 inches high) at crossover locations. The nearby scenic routes are I-580 (as designated by Caltrans from I-5 to the Alameda County line), I-5 (as designated by Caltrans from the Merced County line to the San Joaquin County line), and I-580 and I-5 (as designated by San Joaquin County where the two routes combine). The SJPL System's facilities are underground near these scenic routes. These vaults would be visible but would not be located near the scenic roads. Therefore, the visual impact from this project would be *less than significant*.

The SJPL Rehabilitation project (SJ-4) would involve work on existing pipelines. There would be no change in visibility from scenic roads (which are the same roads listed for the SJPL System project above). The existing pipelines are mostly underground, but there are aboveground sections at the east end (west of the Oakdale Portal); however, the rehabilitation of these pipelines would not alter their visibility or the visual character of the area. Therefore, the impact on visual resources from this project would be *not applicable*.

Sunol Valley Region

Impact 4.3-4: Permanent adverse impacts on scenic vistas or visual character		
Alameda Creek Fishery	SV-1	PSM
Calaveras Dam	SV-2	PSU
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	PSM

All of the Sunol Valley Region projects are located within the Alameda Watershed Management Plan (WMP) area. The plan describes the following design guidelines (under *"Action des 5"*) that would apply to these projects:

- Where grading is necessary, contour slopes and landforms to mimic the surrounding environment as much as possible

- Design and site new roads and trails to minimize grading and the visibility of cut banks and fill slopes
- Incorporate architectural siting/design elements that are compatible with the applicable surrounds
- Site, shield, and direct downward exterior lighting such that it is not highly visible or obtrusive
- Maintain the silhouette of new structures below the skyline of bluffs, cliffs, or ridges
- Design any new structural additions to historic structures to harmonize with older structural features and comply with scenic easements and aesthetic guidelines
- Encourage the salvage and selective reuse of building features if historic structures are demolished

Views of the Calaveras Dam project (SV-2) would be available from the immediately surrounding ridges, and distant views could also be visible from the Sunol Regional Wilderness. The borrow areas and possibly access roads associated with this project would be visible from Calaveras Road, which is designated by Alameda and Santa Clara Counties as a scenic route. Although the dam itself would not be visible from this road, the reservoir and surrounding hillsides, are considered important visual features in the Alameda watershed. Excavation and grading activities associated with this project would require removal of a large area of existing oak woodland cover. This removal of vegetation would create visual discontinuity within the existing pattern of oak woodland cover on the north- and east-facing slopes in the immediate vicinity of the dam. Although these areas of disturbance would be contoured and revegetated, to the extent feasible, as part of the proposed project, fast-growing grasses and scrub would cover the disturbed areas until a cover of oak woodland could mature. Due to the visual sensitivity of the area and the extent of surface disturbance that would occur, implementation of design guidelines in the Alameda WMP and mitigation measures addressing architectural design (Measure 4.3-4a), landscaping plans (Measure 4.3-4b), landscape screens (Measure 4.3-4c), and tree removal (Measure 4.3-4d) would be required to help reduce potential visual impacts. However, because recovery of oak woodland on disturbed areas could require decades, the visual discontinuity in the cover and color of vegetation would persist for decades as evidence of ground disturbance. The impact of site disturbance would therefore extend beyond the construction phase and would be considered a long-term, *potentially significant and unavoidable* visual impact of the project.

The tunnel component of the New Irvington Tunnel project (SV-4) would be buried, but the portals at either end of the tunnel would be visible. Between 9 and 12 concrete vaults (up to 30 inches high) would also be built along the tunnel alignment. Project facilities at the new tunnel portal and modifications at the existing portal could be visible at a distance from Calaveras Road in the Sunol Valley, although the riparian corridor at Alameda Creek could obscure these views. Views of the new portal east of Mission Boulevard in Fremont could be visible from nearby homes to the west, but these homes would partially obscure views of the portal from Mission Boulevard. The project's impact on the visual character of the Sunol Valley and the adjacent neighborhood in Fremont at tunnel portals would be *potentially significant*, but could be reduced to a less-than-significant level with implementation of design guidelines in the Alameda WMP and mitigation measures addressing architectural design (Measure 4.3-4a), landscaping plans (Measure 4.3-4b), landscape screens (Measure 4.3-4c), and tree removal (Measure 4.3-4d).

While the design of the Alameda Creek Fishery project (SV-1) has not yet been determined, it is likely to include facilities on or adjacent to Alameda Creek downstream of the Sunol Valley WTP. This project could be visible from Highway 84/Niles Canyon Road or I-680 (both designated by Caltrans as scenic highways) or from Calaveras Road. Any removal of riparian vegetation along Alameda Creek to accommodate project facilities could alter the visual character of this reach of the creek. Depending on final design and siting of project facilities, implementation of the Alameda Creek Fishery project could result in *potentially significant* changes in the visual character of this reach of Alameda Creek. The project's impact could be reduced to a less-than-significant level with implementation of design guidelines in the Alameda WMP and mitigation measures addressing architectural design (Measure 4.3-4a), landscaping plans (Measure 4.3-4b), landscape screens (Measure 4.3-4c), and tree removal (Measure 4.3-4d).

The SABUP project (SV-6) would construct two new vaults that could be visible from Calaveras Road, although the Alameda Creek riparian corridor would likely obscure these views. All pipeline facilities would be underground, and long-term views from this road would not be altered. However, any removal of riparian vegetation along San Antonio or Alameda Creeks to accommodate outfall and pipeline facilities could alter the visual character of these creeks. Depending on final design and siting of the various project facilities, implementation of this project could result in *potentially significant* changes in the visual character of San Antonio and Alameda Creeks. The project's impact could be reduced to a less-than-significant level with implementation of design guidelines in the Alameda WMP and mitigation measures addressing architectural design (Measure 4.3-4a), landscaping plans (Measure 4.3-4b), landscape screens (Measure 4.3-4c), and tree removal (Measure 4.3-4d).

Two projects would construct new buildings at the Sunol Valley WTP. The 40-mgd Treated Water project (SV-3) would construct a new 10-foot-high building. The Treated Water Reservoirs project (SV-5) would construct a new structure (up to 15 feet high) and one new vault. The water treatment plant is not visible from Calaveras Road because trees in the Alameda Creek riparian corridor block the view. With implementation of the WMP's design guidelines, the visual impacts from these projects would be *less than significant*.

Bay Division Region

Impact 4.3-4: Permanent adverse impacts on scenic vistas or visual character		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	PSM
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	N/A

The BDPL Reliability Upgrade project (BD-1) would consist primarily of underground pipelines and a tunnel, which would not be visible from any scenic highways. Although tunnel portal staging areas could be visible during tunnel construction, there would not be any permanent aboveground structures associated with tunnel portals. In any case, the level topography in the bay vicinity (Ravenswood Valve House near East Palo Alto and Newark Valve House in Newark) and intervening vegetation obscure views of the tunnel portal areas from scenic roadways or waterways. In addition, industrial buildings located south of Thornton Avenue and west of Willow Street block views of the Newark Valve House from Thornton Avenue and the Dumbarton Freeway. The project would also construct eight new structures for electrical controls with aboveground heights of up to 30 feet. The new one-story buildings could be visible from adjacent roadways (and possibly scenic roadways, depending on their location), which could alter the visual character of adjacent areas, a *potentially significant* impact. However, the project's impact could be reduced to a less-than-significant level with implementation of mitigation measures addressing architectural design (Measure 4.3-4a), landscaping plans (Measure 4.3-4b), landscape screens (Measure 4.3-4c), and tree removal (Measure 4.3-4d).

Because the BDPL Reliability Upgrade project (BD-1) traverses mostly developed urban locations—many of which are older, established residential areas—construction of the project could result in the damage or loss of mature trees adjacent to the SFPUC right-of-way, which would alter the visual character of these communities. This *potentially significant* impact could be reduced to a less-than-significant level with implementation of mitigation measures addressing landscaping plans (Measure 4.3-4b), landscape screens (Measure 4.3-4c), and tree removal (Measure 4.3-4d).

The BDPL Nos. 3 and 4 Crossovers project (BD-2) would construct three new aboveground control buildings and/or vaults along the existing Bay Division Pipeline alignments. These structures would be 3 to 8 feet high. The proposed structure at Barron Creek in Palo Alto could be visible from nearby Foothill Boulevard to the south, a designated scenic route, but adjacent structures associated with Gunn High School and the Veterans Administration Medical Center would obscure views of this facility from this and other nearby roadways. The proposed structure at Bear Gulch Reservoir in Atherton could be visible from nearby residences, but topography would block visibility from the closest designated scenic routes, I-280 to the west and Highway 84 to the north. The proposed structure at Guadalupe Creek could be visible from the adjacent Ulistac Natural Area, Tasman Drive, and development in Santa Clara. Due to the proximity of existing development to these three facility sites, proposed structures could adversely affect the existing visual character, a *potentially significant* impact. However, the project's impact could be reduced to a less-than-significant level with implementation of mitigation measures addressing architectural design (Measure 4.3-4a), landscaping plans (Measure 4.3-4b), landscape screens (Measure 4.3-4c), and tree removal (Measure 4.3-4d).

The BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) would not result in the construction of any new permanent aboveground structures. Therefore, the impact on scenic vistas or visual character from this project would be *not applicable*.

Peninsula Region

Impact 4.3-4: Permanent adverse impacts on scenic vistas or visual character		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	PSM
HTWTP Long-Term	PN-3	PSM
Lower Crystal Springs Dam	PN-4	PSM
Pulgas Balancing Reservoir	PN-5	PSM

The CS/SA Transmission project (PN-2) could involve the replacement or upgrade of various aboveground structures in the vicinity of the Crystal Springs Reservoir, San Andreas Reservoir, and Harry Tracy WTP. The largest structure to be upgraded or replaced would be the Crystal Springs Pump Station, and the new structure would maintain its current 25-foot maximum height. The structures in the Crystal Springs Pump Station vicinity could be visible from Highway 35 (Skyline Road Bridge over Lower Crystal Springs Dam) or Crystal Springs Road, both designated scenic routes, but these views would be limited somewhat by elevational differences and intervening vegetation. Due to the visual sensitivity of this area, any changes to scenic vistas or the existing visual character associated with project facilities would be a *potentially significant* impact. Any changes to the existing pump station structure or development of new structures would be subject to the Peninsula WMP design guidelines for structures and roads within the watershed plan area (the same as the design guidelines for the Alameda WMP, presented above under the Sunol Valley Region). Implementation of the WMP's guidelines would reduce impacts, but mitigation measures addressing architectural design (Measure 4.3-4a), landscaping plans (Measure 4.3-4b), landscape screens (Measure 4.3-4c), and tree removal (Measure 4.3-4d) would also be required to reduce potential visual impacts to a less-than-significant level.

The structures to be constructed at the Harry Tracy WTP as part of the HTWTP Long-Term project (PN-3) have not yet been designed or located. Although this facility is located immediately east of I-280 (a designated scenic highway), views of the facility from the highway are limited by intervening topography and trees. Since this site is already developed with water treatment structures, the project is not expected to significantly alter existing views of this facility from surrounding areas. However, given the visual sensitivity of the area, any change in the visual character would be considered a *potentially significant* impact. Since the Harry Tracy WTP is located outside the WMP area and is not subject to WMP design guidelines, mitigation measures addressing architectural design (Measure 4.3-4a), landscaping plans (Measure 4.3-4b), landscape screens (Measure 4.3-4c), and tree removal (Measure 4.3-4d) would be required to reduce potential visual impacts to a less-than-significant level.

The Lower Crystal Spring Dam project (PN-4) would make major repairs and improvements to the dam to provide adequate protection from the probable maximum flood. The project would restore the reservoir's historical capacity of 69,300 acre-feet (from the current level of 58,400 acre-feet). The project would lower the existing parapet wall to lengthen the overflow weir from the reservoir; raise the remaining parapet walls and add one new spillway bay on each side of the central spillway; and install four gates (with a control building) and a fixed weir. The dam is visible from a number of scenic roads and scenic overlooks, and the visual sensitivity of this structure would be high. Therefore, any changes in scenic vistas and visual character as a result of the Lower Crystal Spring Dam project would be a *potentially significant* impact. Raising the water levels in the reservoir could also alter views from the scenic overlook (see Chapter 5 for more discussion), although this project would not change the scenic quality of the reservoir vicinity. The dam is located in the Peninsula WMP area and would be subject to WMP design guidelines. The dam parapet wall has not yet been designed, but would be evaluated as part of separate, project-level CEQA review. Implementation of the WMP's design guidelines would require new structures to be consistent in design with existing SFPUC facilities, thus reducing potential visual impacts. However, implementation of mitigation measures addressing architectural design (Measure 4.3-4a), landscaping plans (Measure 4.3-4b), landscape screens (Measure 4.3-4c), and tree removal (Measure 4.3-4d) could be required to specifically address changes in views from visually sensitive areas and reduce visual impacts in these areas to a less-than-significant level.

The Pulgas Balancing Reservoir project (PN-5) would not construct new buildings but would modify the Pulgas Channel. Any changes to the Pulgas Channel would be visible from Cañada Road, a designated scenic route. Scenic vistas from I-280 would not be affected by this project, since this freeway is located almost one mile to the east. This project would be located adjacent to the Pulgas Water Temple, an important visual and historic resource, and would cross under Cañada Road. Any required tree or vegetation removal could alter views of the Pulgas Channel from Cañada Road, a *potentially significant* visual impact. Potential changes in views from Cañada Road would be evaluated as part of separate, project-level CEQA review. This facility is located in the Peninsula WMP area, and any changes to the reservoir facility or channel would be subject to WMP design guidelines. However, due to the visual sensitivity of the area, it is expected that additional mitigation measures addressing architectural design (Measure 4.3-4a), landscaping plans (Measure 4.3-4b), landscape screens (Measure 4.3-4c), and tree removal (Measure 4.3-4d) could be required to specifically address changes in views from visually sensitive areas and reduce visual impacts to a less-than-significant level.

The Baden and San Pedro Valve Lots project (PN-1) would construct two structures, which would be 1 to 3 feet tall. The Baden Valve Lot is located west of El Camino (Highway 82), and trees and fencing along the west side of this street obscure views of this facility. The San Pedro Valve Lot is adjacent to I-280 and Junipero Serra Boulevard, and existing facilities are visible from these streets. Caltrans has designated I-280 as a scenic highway (from the Santa Clara County line to north of the city limit in San Bruno). Proposed facilities would be located within these existing valve lots and would not significantly alter the existing visual character of these facilities or vicinity. The proposed height of project facilities (1 to 3 feet) would also minimize the potential for changes in views. Therefore, the visual impact from this project would be *less than significant*.

San Francisco Region

Impact 4.3-4: Permanent adverse impacts on scenic vistas or visual character		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	PSM
Recycled Water Projects	SF-3	PSM

The SAPL 3 Installation project (SF-1) would construct two new structures (up to 8 feet high) and two new vaults (up to 30 inches high). The pipeline alignment traverses or extends along the boundary of the Lake Merced Golf & Country Club and San Francisco Golf Club properties. The alignment would be within the viewshed of I-280 and 19th Avenue in San Francisco, both scenic routes. Depending on location, new structures (up to 8 feet high) could be visible from sensitive areas such as these two golf clubs. Pipeline construction could result in visual impacts if damage or loss of mature trees were to occur at the Lake Merced Golf & Country Club or the San Francisco Golf Club. The visual impacts from this project could be *potentially significant*, but implementation of mitigation measures addressing architectural design (Measure 4.3-4a), landscaping plans (Measure 4.3-4b), landscape screens (Measure 4.3-4c), and tree removal (Measure 4.3-4d) would reduce potential visual impacts to a less-than-significant level.

The Groundwater Projects (SF-2) would build new wells and well stations in San Francisco and San Mateo Counties. The facilities could be within the viewsheds of I-280 and the Great Highway, both designated scenic routes, as well as Lake Merced, Pine Lake, San Francisco Zoo, and/or Golden Gate Park. The potential for visual impacts would depend on the final locations. Up to 16 single-story structures could be developed at various locations on the west side of San Francisco or in northern San Mateo County. These buildings would be small in scale and generally located in urbanized areas, reducing the potential for adverse changes to the existing surrounding visual character. Therefore, visual impacts would be *potentially significant*, but implementation of mitigation measures addressing architectural design (Measure 4.3-4a), landscaping plans (Measure 4.3-4b), landscape screens (Measure 4.3-4c), and tree removal (Measure 4.3-4d) would reduce potential visual impacts to a less-than-significant level.

The Recycled Water Projects (SF-3) would construct up to four new structures for a recycled water facility. The structures could be visible if the recycled water treatment facility is located in the vicinity of the San Francisco Zoo and Oceanside WPCP, which are visible from the Great Highway and Skyline Boulevard (Highway 35) as well as from within Golden Gate Park. Any new facilities (up to 40 feet high) in the vicinity of the San Francisco Zoo and Oceanside WPCP could affect views from the Great Highway, Skyline Boulevard (Highway 35), or other scenic roads in this area, a *potentially significant* impact. With implementation of mitigation measures addressing architectural design (Measure 4.3-4a), landscaping plans (Measure 4.3-4b), landscape screens (Measure 4.3-4c), and tree removal (Measure 4.3-4d), as appropriate, these potentially significant impacts would be reduced to a less-than-significant level.

Impact 4.3-5: New permanent sources of light and glare.

Some of the WSIP projects would involve the installation of permanent new outdoor lighting on aboveground project components. Lighting design information is not yet available for WSIP projects. It is expected that visual impacts associated with light and glare would be evaluated as part of separate, project-level CEQA review when more detailed project designs become available.

All Regions

Development of some WSIP projects, particularly those located in urban areas, would have the potential to introduce new sources of light and glare. Until project-specific design information becomes available, this impact is considered *potentially significant* for all WSIP projects. However, two of these WSIP projects involve the rehabilitation or development of underground facilities only except for existing vaults (SJPL Rehabilitation, SJ-4, and BDPL 3 and 4 Seismic Upgrade at Hayward Fault, BD-3). Since there are no new aboveground structures, the potential need for outdoor lighting would be low. It is expected that implementation of design measures to limit lighting effects (Measure 4.3-5) would reduce this impact to a less-than-significant level for all WSIP projects.

4.4 Geology, Soils, and Seismicity

4.4 Geology, Soils, and Seismicity

4.4.1 Setting

Regional Physiography

California has an extremely varied landscape and physiography, which ranges from broad, nearly flat valleys to jagged, glaciated mountains. To help distinguish these areas, California has been divided into 12 geomorphic provinces that are topographic-geologic groupings of convenience based primarily on landforms and geologic history (Norris and Webb, 1976). WSIP facilities would be located within two geomorphic provinces of California: the Coast Ranges and Great Valley provinces. The westernmost facility in the San Joaquin Region (Lawrence Livermore, SJ-2) and all facilities in the Sunol Valley, Bay Division, Peninsula, and San Francisco Regions are located in the Coast Ranges Geomorphic Province. The remaining San Joaquin Region facilities are located on the eastern and western edges of the Great Valley Geomorphic Province.

Coast Ranges Geomorphic Province

The Coast Ranges province extends approximately 600 miles, from the Santa Ynez River in Santa Barbara County to the Oregon border in northern Humboldt County. The region consists of northwest-trending mountain ranges, broad basins, and elongated valleys generally parallel to the San Andreas fault. The Coast Ranges are generally divided in two sub-provinces, north and south of San Francisco Bay. In the Coast Ranges, older, consolidated rocks are characteristically exposed in the mountains but are buried beneath younger, unconsolidated alluvial fan and fluvial sediments in the valleys and lowlands. In the coastal lowlands, these younger sediments commonly interfinger with marine deposits.

The portions of the program area in the Coast Ranges province are located in the southern Coast Ranges sub-province. The major geographic features in this area include: the Diablo Range, Santa Cruz Mountains, San Francisco Peninsula, and San Francisco Bay.

Great Valley Geomorphic Province

The Great Valley province is an elongated depression that lies between the Coast Ranges and the Sierra Nevada. It is about 430 miles long and 75 miles wide. At its extreme northern and southern ends, the elevation is about 400 feet. At its center, east of San Francisco Bay, it is slightly below sea level.

The Great Central Valley is actually two large valleys lying end to end, each drained by a major river. The Sacramento Valley is drained by the Sacramento River, and the San Joaquin Valley is drained by the San Joaquin River. The confluence of these two rivers is east of San Francisco Bay. This area, the Sacramento–San Joaquin Delta, was formerly a massive wetland. It is now one of California's important agricultural areas. The Great Valley is a trough in which sediments have been deposited almost continuously since the Jurassic (about 160 million years ago). Sands and gravel over 30,000 feet deep lie upon Sierran basement rocks that extend downward at an angle from the western slope of the Sierra Nevada. Great oil fields have been found in southernmost San Joaquin Valley and along its southwestern margin.

Regional Geologic Hazards

Slope Failure

Slope failures, commonly referred to as landslides, include many phenomena that involve the downslope displacement and movement of material, either triggered by static (i.e., gravity) or dynamic (i.e., earthquake) forces. Exposed rock slopes undergo rockfalls, rockslides, or rock avalanches, while soil slopes experience soil slumps, rapid debris flows, and deep-seated rotational slides. Slope stability can depend on a number of complex variables, including the geology, structure, and amount of groundwater, as well as external processes such as climate, topography, slope geometry, and human activity. The factors that contribute to slope movements include those that decrease the resistance in the slope materials and those that increase the stresses on the slope.

Landslides can occur on slopes of 15 percent or less, but the probability is greater on steeper slopes that exhibit old landslide features such as scarps, slanted vegetation, and transverse ridges. Landslides typically occur within slide-prone geologic units that contain excessive amounts of water or are located on steep slopes, or where planes of weakness are parallel to the slope angle.

The best available predictor of where slides and earth flows might occur is the distribution of past movements (Nilsen and Turner, 1975). In 1997, the U.S. Geological Survey (USGS) released a preliminary map and geographic information system (GIS) database that provides a summary of the distribution of landslides evident in the landscape of the San Francisco Bay region (USGS, 1997). The map is a digitized nine-county compilation of existing landslides that has been used to divide the area into four landslide zones. These four zones are designated as follows:

- *Mostly Landslide*. Consists of mapped landslides, intervening areas typically narrower than 1,500 feet, and narrow borders around landslides; defined by drawing envelopes around groups of mapped landslides.

- *Many Landslides*. Consists of mapped landslides and more extensive intervening areas than in “mostly landslide”; defined by excluding areas free of mapped landslides; outer boundaries are quadrangle and county limits to the areas in which this unit was defined.

- *Few Landslides*. Contains few, if any, large mapped landslides, but locally contains scattered small landslides and questionably identified larger landslides; defined in most of the region by excluding groups of mapped landslides, but defined directly in areas containing the “many landslides” unit by drawing envelopes around areas free of mapped landslides.

- *Flat Land*. Areas of gentle slope at low elevations that have little or no potential for the formation of slumps, landslides, or earth flows, except along stream banks and terrace margins; defined by the distribution of surficial deposits (Wentworth, 1997).

Unsuitable Soils

Soil mapping by the U.S. Department of Agriculture, Natural Resources Conservation Service (NRCS) has provided information on surface and near-surface subsurface soil materials in the program area. A generalized soil map for the state of California, generated using GIS data provided in the NRCS State Soil Geographic (STATSGO) database, was used to identify soil conditions at the WSIP project sites. The STATSGO map combines individual soil units from more detailed maps into larger map units of soils with similar general characteristics. The distribution of soil units is highly variable within the program area. Although tables of soil characteristics are included in the STATSGO database, the data in the tables are divided into a much greater level of detail than the map and cannot be directly correlated to the generalized map units on the STATSGO soil map. These data could not be effectively used to evaluate specific soil parameters along the alignments; therefore, the following discussions regarding the potential for corrosive, expansive, and erodible soil conditions provide only a general discussion of these potential soil issues.

Corrosive Soils

Corrosivity of soils is commonly related to several key parameters: soil resistivity, the presence of chlorides and sulfates, oxygen content, and pH. Typically, the most corrosive soils are those with the lowest pH and highest concentration of chlorides and sulfates. Wet/dry conditions can result in a concentration of chlorides and sulfates as well as movement in the soil that tends to break down protective corrosion films and coatings on the surface of building materials. High-sulfate soils are also corrosive to concrete and may prevent complete curing, reducing its strength considerably. Low pH and/or low-resistivity soils can corrode buried or partially buried metal structures.

Expansive Soils

Expansive soils are characterized by their ability to undergo significant volume change (i.e., to shrink and swell) due to variations in soil moisture content. Changes in soil moisture can result from rainfall, landscape irrigation, utility leakage, roof drainage, and/or perched groundwater.[1] Expansive soils are typically very fine grained with a high to very high percentage of clay.

Squeezing Ground

Squeezing ground is a time-dependent phenomenon usually associated with tunnel construction through a fault zone. Squeeze occurs when the in-situ stresses are high relative to the strength of the material. A high stress-to-strength ratio causes a slow creep of ground around the tunnel toward the excavated opening (Brown et al., 1981). Squeezing ground occurs when soil pressure above the tunnel leads to a lateral squeezing of the tunnel walls, and can cause tunneling difficulties that require special tunneling techniques. Squeezing ground conditions are expected where shear zones[2]

1 Perched groundwater is a local saturated zone above the water table. It typically exists above an impervious layer (such as clay) with limited extent.

2 A shear zone is a zone of rock fracturing consisting of many closely spaced, roughly parallel, discontinuous cracks. Shear zones typically occur along faults.

are encountered, especially within the Hayward Fault Zone. This phenomenon can be controlled and is further discussed in the impact analysis.

Mineral Resources

Mineral resources in central California include a mix of fuel and nonfuel resources. Fuel resources in the central California region consist of oil and gas, which are found in the San Joaquin Region. Nonfuel resources, found in all of the regions, include gravel and sand, aggregate, clay, stone/rock, and salt. Sand, clay, gravel, and rock products are the most important mineral resources in California and are still actively mined or quarried in the Sunol Valley. As discussed in Section 4.14, Hazards, the western segment of the SJPL System (SJ-3) alignment passes between the Vernalis and Southwest Vernalis Gas Fields. Active gas wells in the Vernalis Field are more than one mile north of the alignment, although plugged and abandoned dry oil exploration holes are located about one-half mile from the alignment.

Regional Faulting and Seismic Hazards

Seismicity

The San Francisco Bay Area is situated near the boundary between two major tectonic plates, the Pacific Plate to the southwest and the North American Plate to the northeast. Since the Miocene (approximately 23 million years ago), about 200 miles of right-lateral slip has occurred along the San Andreas Fault Zone to accommodate the relative movement between these two plates. This movement has juxtaposed the granitic rocks southwest of the San Andreas fault with the Franciscan rocks lying to the northeast. The movement between the Pacific Plate and the North American Plate generally occurs across a 50-mile zone extending from the San Gregorio fault in the southwest to the Great Valley Thrust Belt to the northeast. In addition to the right-lateral slip movement between tectonic plates, a compressional component of relative movement has developed during the last 3.5 million years between the Pacific Plate and the Sierran micro-plate of the North American Plate at the latitude of San Francisco Bay (Fenton and Hitchcock, 2001). Strain produced by the relative motions of these plates is relieved by right-lateral strike-slip faulting on the San Andreas and related faults, and by vertical reverse-slip displacement on the Great Valley and other thrust faults in the central California area.

The San Francisco Bay Area and surrounding areas are characterized by numerous geologically young faults. These faults can be classified based on the following criteria (CGS, 1999):

- *Historically Active*. Faults that have generated earthquakes accompanied by surface rupture during historic time (approximately the last 200 years) and faults that exhibit aseismic fault creep.[3]
- *Active*. Faults that show geologic evidence of movement within Holocene time (approximately the last 11,000 years).

3 Fault creep is movement along a fault that does not entail earthquake activity.

- *Potentially Active*. Faults that show geologic evidence of movement during the Quaternary (approximately the last 1.6 million years).
- *Inactive*. Faults that show direct geologic evidence of inactivity during all of Quaternary time or longer.

Although it is difficult to quantify the probability that an earthquake will occur on a specific fault, this classification is based on the assumption that if a fault has moved during the Holocene epoch, it is likely to produce earthquakes in the future.

Thrust faults have no surface expression and have been located using subsurface geologic and geophysical methods. Since movement along these faults occurs on subsurface planes, the activity classification is predominantly based on historical earthquakes and microseismic activity along the fault, unlike faults with surface expression.

Because periodic earthquakes accompanied by surface displacement can be expected to continue in the program area through the lifetime of the proposed WSIP projects, the effects of strong groundshaking and fault rupture are of primary concern with respect to the safe operation of WSIP facilities. **Figure 4.4-1** shows the locations of active and potentially active faults (representing possible seismic sources) in the program vicinity. **Table 4.4-1** indicates the faults in the program vicinity that represent substantial potential seismic sources. The USGS Working Group on California Earthquake Probabilities (WG02) concluded that there is a 62 percent probability of a strong earthquake (magnitude ≥6.7) occurring in the San Francisco Bay region in a 30-year period between 2003 and 2032 (USGS, 2003).

The San Andreas, San Gregorio, Hayward, Rodgers Creek, Calaveras, and Greenville strike-slip faults[4] are active faults of the San Andreas system that predominantly accommodate lateral movement between the North American and Pacific tectonic plates. Active blind- and reverse-thrust faults[5] in the program vicinity include the Monte Vista–Shannon, Mount Diablo, Great Valley 7, and Great Valley 8 faults. The eastern portions of the SFPUC regional water system may also be affected by movement on the potentially active Foothills Fault System, which comprises range-front faults[6] in the Sierra Nevada foothills that are responsible for the uplift of the Sierra Nevada mountains.

Groundshaking

An earthquake is classified by the amount of energy released, which traditionally has been quantified using the Richter scale. Seismologists have begun using a moment magnitude (M) scale because it provides a more accurate measurement of the size of major and great earthquakes. For earthquakes of less than M 7.0, the moment and Richter magnitude scales are

4 Strike-slip faults involve the two blocks moving parallel to each other without a vertical component of movement.
5 A reverse fault is one with predominantly vertical movement in which the upper block moves upward in relation to the lower block; a thrust fault is a low-angle reverse fault. Blind-thrust faults are low-angled subterranean faults that have no surface expression.
6 Range-front faults are faults along the front of mountain ranges responsible for the uplift of the mountains.

nearly identical. For earthquake magnitudes greater than M 7.0, readings on the moment magnitude scale are slightly greater than a corresponding Richter magnitude.

The intensity of the seismic shaking, or strong ground motion, during an earthquake is dependent on the distance between the project area and the epicenter of the earthquake, the magnitude of the earthquake, and the geologic conditions underlying and surrounding the project area. Earthquakes occurring on faults closest to the project area would most likely generate the largest ground motions.

A review of historical earthquake activity during the period from 1800 to 2004 indicates that 23 earthquakes of M 6.0 or greater occurred within and near the program area during this timeframe. **Table 4.4-2** presents a summary of significant and/or damaging earthquakes.[7] There were an additional 35 earthquakes in the program area with magnitudes between M 5.5 and M 6.0 during this time period, including numerous aftershocks of larger earthquakes.

The intensity of earthquake-induced ground motions can be described using peak ground accelerations, represented as a fraction of the acceleration of gravity (g).[8] The interactive California Geological Survey (CGS) Probabilistic Seismic Hazard Assessment map (CGS, 2007) provides data to estimate peak ground accelerations in California. Taking into consideration the uncertainties regarding the size and location of earthquakes and the resulting ground motions that can affect a particular site, the map depicts peak ground accelerations with a 10 percent probability of being exceeded in 50 years, which equals an annual probability of 1 in 475 of being exceeded each year.

Another commonly used measure of earthquake intensity is the Modified Mercalli Scale, which is a subjective measure of the strength of an earthquake at a particular place as determined by its effects on people, structures, and earth materials. **Table 4.4-3** presents the Modified Mercalli Scale for Earthquake Intensity, along with approximate earthquake magnitudes and average peak accelerations associated with each intensity value.

Fault Rupture

Surface rupture occurs when movement on a fault deep within the earth breaks through to the surface. Surface ruptures associated with the 1906 San Francisco earthquake extended for more than 260 miles, with displacements of up to 21 feet. However, not all earthquakes result in surface rupture. The Loma Prieta earthquake of 1989 caused major damage in the San Francisco Bay Area, but the fault movement did not break through to the ground surface.

---

[7] In Table 4.4-2, the estimated magnitude of the 1868 earthquake on the Hayward fault is 7.0; however, as presented in Table 4.4-1, the USGS estimates the maximum earthquake magnitude on this fault at 6.7. This discrepancy is likely due to inaccuracies in estimating earthquake magnitudes prior to use of the sophisticated earthquake measurement equipment in existence today.

[8] Acceleration of gravity (g) = 980 centimeters per second squared. 1.0 g of acceleration is a rate of increase in speed equivalent to a car traveling 328 feet from rest in 4.5 seconds.

TABLE 4.4-1
SIGNIFICANT ACTIVE AND POTENTIALLY ACTIVE FAULTS

Fault Name	Estimated Maximum Earthquake Magnitude[a,b]	Approximate Fault Segment Length (miles)[b]	Average Recurrence Interval (years)[c]	Fault Type and Dip Direction[b]	Approximate Slip Rate (mm/yr)[b,d]
San Andreas (Peninsula)	7.2	53	229	Right-Lateral Strike-Slip, 90 degrees	17.0
San Andreas (North Coast South)	7.4	118	223	Right-Lateral Strike-Slip, 90 degrees	24.0
San Gregorio (North)	7.2	68	392	Right-Lateral Strike-Slip, 90 degrees	7.0
Monte Vista–Shannon	6.7	28	2,400[c]	Blind Thrust, 60 degrees west	0.4
Hayward (Northern)	6.5	22	155	Right-Lateral Strike-Slip, 90 degrees	9.0
Hayward (Southern)	6.7	33	161	Right-Lateral Strike-Slip, 90 degrees	9.0
Rodgers Creek	7.0	38	205	Right-Lateral Strike-Slip, 90 degrees	9.0
Calaveras (Northern)	6.8	28	187	Right-Lateral Strike-Slip, 90 degrees	6.0
Calaveras (Central)	6.2	37	54	Right-Lateral Strike-Slip, 90 degrees	15.0
Mount Diablo	6.7	15	389	Reverse Thrust, 38 degrees northeast	2.0
Greenville (North)	6.7	17	644	Right-Lateral Strike-Slip, 90 degrees	2.0
Greenville (South)	6.6	15	623	Right-Lateral Strike-Slip, 90 degrees	2.0
Great Valley 7	6.7	28	560[c]	Reverse Thrust, 15 degrees west	1.5
Great Valley 8	6.6	25	540[c]	Reverse Thrust, 15 degrees west	1.5
Foothills Fault System	6.5	223	12,500[c]	Normal Right-Lateral Oblique, 75 degrees east	0.05

[a] The maximum earthquake magnitude is the strongest earthquake that appears capable of occurring under the presently known tectonic framework, using the Richter scale.
[b] Fault parameters from CGS, 2002, and USGS, 2003.
[c] Recurrence Intervals from USGS, 2003.
[d] References to fault slip rates are traditionally presented in millimeters per year.

Fault rupture almost always follows preexisting faults, which are zones of weakness. Rupture may occur suddenly during an earthquake or slowly in the form of fault creep. Sudden displacements are more damaging to structures because they are accompanied by shaking. Fault creep is the slow rupture of the earth's crust. The Hayward fault where it crosses highly developed areas in Contra Costa and Alameda Counties exhibits fault creep, which offsets and deforms curbs, streets, buildings, and other structures that lie on the fault trace.

TABLE 4.4-2
SIGNIFICANT HISTORICAL EARTHQUAKES

Date	Earthquake Magnitude[a]	Name, Location, or Region Affected	Associated Fault	Comments[b]
June 1838	Assumed between 6.8 and 7.4	San Francisco Area	San Andreas	This earthquake is associated with probable rupture of the San Andreas fault from Santa Clara to San Francisco (approximately 37 miles). Walls were cracked at Mission Dolores and in Monterey.
October 8, 1865	6.5	Santa Cruz Mountains	San Andreas	Caused severe damage in New Almaden, Petaluma, San Francisco, San Jose, Santa Clara, and Santa Cruz resulting in $500,000 in property damage. Ground cracks, heaving, and subsidence were noted in several areas.
October 21, 1868	7.0	Hayward	Hayward	Felt throughout northern California and Nevada. Resulted in 30 deaths and $300,000 in property damage. Occurred on the Hayward fault with rupture from Berkeley to Fremont. Caused severe damage in the East Bay and San Francisco.
June 20, 1897	6.2	Gilroy	Calaveras	Felt from Woodland to San Luis Obispo. Resulted in building collapse in the Santa Clara Valley. Fissures were noted on the Calaveras fault southeast of Gilroy.
April 18, 1906	7.8	San Francisco Earthquake, San Francisco	San Andreas	This earthquake and the resulting fires caused approximately 3,000 deaths and $524 million in damage ($24 million from the earthquake alone). Destruction from this earthquake occurred at distances of up to 350 miles from the epicenter.
July 1, 1911	6.4	Morgan Hill	Calaveras	Located on the Calaveras fault, caused substantial damage in Gilroy and the Santa Clara Valley. Felt as far away as Reno, Nevada.
January 24, 1980	5.8	North of Livermore Valley	Greenville	Occurred on the Greenville fault with surface rupture of approximately nine miles. Resulted in numerous injuries and $11.5 million in property damage (primarily at Lawrence Livermore Laboratory).
April 24, 1984	6.2	Morgan Hill Earthquake, Morgan Hill	Calaveras	Earthquake was felt from San Francisco to Bakersfield and was located near the epicenter of the 1911 earthquake in Morgan Hill. Resulted in injuries and approximately $8 million in property damage.
October 17, 1989	6.9	Loma Prieta Earthquake, Santa Cruz Mountains	San Andreas	Largest earthquake to occur on the San Andreas fault since 1906. Resulted in 63 deaths, over 3,000 injuries, and an estimated $6 billion in property damage. Severe damage occurred from San Francisco to Monterey and in the East Bay, and included damage and destruction of buildings, roads, bridges, and freeways.

[a] Earthquake magnitudes and locations before 1932 are estimated based on reports of damage and felt effects (Toppozada et al., 1978, 1981, and 1982). Magnitudes reported using the Richter scale.
[b] Earthquake damage information primarily compiled from NEIC, 2007, and Berkeley Seismological Laboratory, 2007. Estimates of property damage values are in dollars valued to the year of damage.

TABLE 4.4-3
MODIFIED MERCALLI SCALE FOR EARTHQUAKE INTENSITY

Intensity Value	Intensity Description	Approximate Earthquake Magnitude (Richter)	Average Peak Acceleration
I	Not felt except by a very few persons under especially favorable circumstances.	1.0–3.0	
II	Felt only by a few persons at rest, especially on upper floors on buildings. Delicately suspended objects may swing.		<0.015 g
III	Felt noticeably indoors, especially on upper floors of buildings, but many people do not recognize it as an earthquake. Standing motor cars may rock slightly, vibration similar to a passing truck. Duration estimated.	3.0–3.9	
IV	During the day felt indoors by many, outdoors by few. At night, some awakened. Dishes, windows, doors disturbed; walls make cracking sound. Sensation like heavy truck striking building. Standing motor cars rocked noticeably.	4.0–4.9	0.015–0.03 g
V	Felt by nearly everyone, many awakened. Some dishes and windows broken; a few instances of cracked plaster; unstable objects overturned. Disturbances of trees, poles may be noticed. Pendulum clocks may stop.		0.03–0.08 g
VI	Felt by all, many frightened and run outdoors. Some heavy furniture moved; and fallen plaster or damaged chimneys. Damage slight.	5.0–5.9	0.08–0.15 g
VII	Everybody runs outdoors. Damage negligible in buildings of good design and construction; slight to moderate in well-built ordinary structures; considerable in poorly built or badly designed structures; some chimneys broken. Noticed by persons driving motor cars.		0.15–0.25 g
VIII	Damage slight in specially designed structures; considerable in ordinary substantial buildings, with partial collapse; great in poorly built structures. Panel walls thrown out of frame structures. Fall of chimneys, factory stacks, columns, monuments, walls. Heavy furniture overturned. Sand and mud ejected in small amounts. Changes in well water. Persons driving motor cars disturbed.	6.0–6.9	0.25–0.45 g
IX	Damage considerable in specially designed structures; well-designed frame structures thrown out of plumb; great in substantial buildings, with partial collapse. Buildings shifted off foundations. Ground cracked conspicuously. Underground pipes broken.		0.45–0.60 g
X	Some well-built wooden structures destroyed; most masonry and frame structures destroyed with foundations; ground badly cracked. Rails bent. Landslides considerable from riverbanks and steep slopes. Shifted sand and mud. Water splashed (slopped) over banks.	7.0 and higher	0.60–0.80 g
XI	Few, if any, masonry structures remain standing. Bridges destroyed. Broad fissures in ground. Underground pipelines completely out of service. Earth slumps and land slips in soft ground. Rails bent greatly.		0.80–0.90 g
XII	Damage total. Practically all works of construction are damaged greatly or destroyed. Waves seen on ground surface. Lines of sight and level are distorted. Objects are thrown upward into the air.		>0.90 g

SOURCE: Bolt, 1988.

Although future earthquakes could occur anywhere along the length of the faults listed in Table 4.4-1, only regional strike-slip earthquakes of magnitude 6.0 or greater are likely to be associated with surface fault rupture and offset (CGS, 1996). It is also important to note that earthquake activity and fault rupture due to unmapped subsurface fault traces is a possibility that is not predictable.

Liquefaction

Liquefaction is a phenomenon in which saturated granular sediments temporarily lose their shear strength during periods of earthquake-induced, strong groundshaking. The susceptibility of a site to liquefaction is a function of the depth, density, and water content of the granular sediments and the magnitude of earthquakes likely to affect the site. Saturated, unconsolidated silts, sands, silty sands, and gravels within 50 feet of the ground surface are most susceptible to liquefaction. Liquefaction-related phenomena include vertical settlement from densification, lateral spreading, ground oscillation, flow failures, loss of bearing strength, subsidence, and buoyancy effects.

Holocene-age alluvial sediments are especially prone to liquefaction. Older alluvial sediments deposited during the Pleistocene epoch are generally not liquefiable because they are more consolidated. Artificial fills, especially those placed on the San Francisco Bay margins prior to about 1950, are also highly prone to liquefaction.

Lateral Spreading

Of the liquefaction hazards, lateral spreading generally causes the most damage. This is a phenomenon where large blocks of intact, nonliquefied soil move downslope on a liquefied substrate of large aerial extent (Youd et al., 1978). The mass moves toward an unconfined area, such as a descending slope or stream-cut bluff, and can occur on slope gradients as gentle as 1 degree. Drainages and swales between hill slopes are generally filled by alluvium,[9] colluvium,[10] landslide debris, and slope wash. Unconsolidated deposits often develop soils along steep and shallow slopes in these areas.

Earthquake-Induced Settlement

Settlement of the ground surface can be accelerated and accentuated by earthquakes. During an earthquake, settlement can occur as a result of the relatively rapid rearrangement, compaction, and settling of subsurface materials (particularly loose, noncompacted, and variable sandy sediments). Settlement can occur both uniformly and differentially (i.e., where adjoining areas settle at different rates). Areas are susceptible to differential settlement if underlain by compressible sediments, such as poorly engineered artificial fill or bay mud.

Seismic Slope Instability/Ground Cracking

Earthquake motions can also induce substantial stresses in slopes, causing earthquake-induced landslides or ground cracking when the slope fails. Earthquake-induced landslides can occur in

---

9 Alluvium consists of unconsolidated mixtures of gravel, sand, clay, and silt typically deposited by streams.
10 Colluvium is a loose deposit of rock debris accumulated through the action of gravity at the base of a cliff or slope.

areas with steep slopes that are susceptible to strong ground motion during an earthquake. The 1989 Loma Prieta earthquake triggered thousands of landslides over an area of 770 square miles.

San Joaquin Valley (San Joaquin Region)

Physiography

WSIP facilities in the San Joaquin Valley lie within and on the margins of California's Great Valley Geomorphic Province. The San Joaquin Valley is an elongated, asymmetrical structural trough approximately 250 miles long and averaging 35 miles wide (Davis et al., 1959). The valley lies between the Coast Ranges Geomorphic Province to the west and the Sierra Nevada Range Geomorphic Province to the east. Traversing from southwest to northeast, the WSIP facilities span from the eastern end of the Coast Ranges, across the San Joaquin Valley floor, and onto the western foothills of the Sierra Nevada. Ground surface elevations along the western portion of this region range from a peak of approximately 825 feet at the existing Thomas Shaft facility in the Coast Ranges (where Lawrence Livermore, SJ-2, would be located) to an approximate elevation of 325 feet near the base of these mountains at Tesla Portal (where Advanced Disinfection, SJ-1, and Tesla Portal Disinfection, SJ-5, would be located) to a low elevation of approximately 30 feet along the existing San Joaquin Pipeline alignments (where SJPL System, SJ-3, and SJPL Rehabilitation, SJ-4, would be located). Along the eastern segment of the existing San Joaquin Pipeline system, elevations reach a peak of approximately 825 feet in the Sierra foothills at Oakdale Portal (USGS, 1989, 1994).

Geology

WSIP facilities in the San Joaquin Valley region span a nearly flat alluvial plain that forms the San Joaquin Valley within the Great Valley Geomorphic Province. The Great Valley is a large, northwest-trending structural trough that has been filled with several thousand feet of sedimentary and volcanic rocks.

In the program area, the sedimentary and volcanic sequence typically consists of marine sedimentary rocks that range in age from Jurassic to Cretaceous, overlain by Cenozoic to Quaternary continental deposits. The marine sedimentary rocks in the region are comprised of undifferentiated Upper Cretaceous sedimentary rocks, and sandstones and shales of the Panoche and Marino Formations.

The continental rocks comprise moderately consolidated sedimentary rock and volcanic deposits that outcrop in the foothills along the flanks of the Central Valley, and poorly consolidated alluvial deposits containing gravel, sand, silt, and clay that are present on the valley floor. The moderately consolidated sedimentary and volcanic deposits typically occupy the eastern margin of the Great Valley and consist of andesitic mudflow breccia[11] of the Mehrten Formation, and rhyolitic tuff[12] and sedimentary rocks of the Valley Springs Formation (Wagner et al., 1990).

---

11 Breccia is a coarse-grained rock composed of angular broken rock fragments in a fine-grained matrix. Andesitic mudflow breccia is formed by a mudflow composed primarily of volcanic rock fragments of andesitic composition.

12 Tuff is a rock composed of compacted volcanic ash varying in size from fine sand to coarse gravel. Rhyolitic tuff is comprised of ash similar in composition to granite.

Shallow alluvial deposits (Quaternary) that span the valley floor in the program area include alluvial fan deposits along the eastern margin of the Coast Ranges, and floodplain and riverbank deposits of the Dos Palos, Modesto, Riverbank, and Turlock Lake Formations (Wagner et al., 1990).

Beneath the Coast Ranges and the western side of the Central Valley, the sedimentary rocks are underlain by a basement complex of Mesozoic-age metamorphic rocks of the Franciscan Complex (Wagner et al., 1990). Beneath the Sierra foothills and the eastern side of the Central Valley, the sedimentary and volcanic sequence rocks are underlain by a basement complex of Mesozoic-age granitic and metamorphic rocks, including the Salt Springs and Merced Falls Slates and the Gopher Ridge Volcanics (Wagner et al., 1990). The structure of these basement rocks beneath the sedimentary deposits on the floor of the San Joaquin Valley region is poorly known (Wagner et al., 1990).

Seismicity

The San Joaquin Valley region of California is relatively seismically inactive compared to the west-neighboring San Francisco Bay and South Bay regions. Although no faults are known to displace the sediments underlying WSIP facilities in the Central Valley, earthquakes on any of the active faults in the greater Bay Area could produce groundshaking and associated seismic hazards at WSIP facilities in the region. For example, the great earthquake of 1906 on the San Andreas fault caused Level IV to VI intensity (Modified Mercalli Scale) across the San Joaquin Valley where WSIP facilities currently exist (USGS, 2007). The nearest fault to WSIP facilities in the San Joaquin Valley capable of producing strong groundshaking is the Great Valley 7 fault, which the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects cross at the western margin of the region. The Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) projects at Tesla Portal and the Lawrence Livermore project (SJ-2) at Thomas Shaft are also located over this thrust fault. Historical earthquakes on the Great Valley faults include an M 6.5 in 1983 (Segment 6), an M 6.5 in 1892 (Segment 4), and an M 6.0 in 1866 (Segment 7) (USGS, 1996).

South Bay (Sunol Valley and Bay Division Regions)

Physiography

WSIP facilities in the South Bay lie within the Coast Ranges Geomorphic Province. Significant physiographic features in the South Bay include San Francisco Bay and the broad alluvial fans (or flatlands) that were formed between the mountain ranges and the bay. The surrounding mountain ranges that bound the South Bay are the Santa Cruz Mountains on the south and west and the Diablo Range to the east.

The San Antonio and Calaveras Reservoirs are located in long, narrow valleys within the Diablo Range. The reservoirs occupy the La Costa Valley and the Calaveras Valley, respectively. Floor elevations in the La Costa Valley range from approximately 320 feet at the dam on the east side of the valley to 560 feet on the west side. Ground surface elevations along the WSIP facilities range from about 300 feet at the northeasterly base of the Santa Cruz Mountains to sea level across the San Francisco Bay margin, then to an elevation of up to approximately 1,000 feet through the Diablo Range.

Geology

WSIP facilities in the South Bay are located within the Bay Division and Sunol Valley Regions. Facilities within the Bay Division Region cross sediments of San Francisco Bay and alluvial soils of the Santa Clara Valley. Facilities at the western end of the Bay Division Region also cross into bedrock at the northeastern flank of the Santa Cruz Mountains. Facilities within the Sunol Valley Region primarily traverse bedrock materials of the Diablo Range. Some facilities lie within the valley floors, such as in the Sunol Valley, Calaveras Valley, and La Costa Valley, where alluvial soils overlie the bedrock.

San Francisco Bay, a dominant feature in the South Bay, occupies a Late Pliocene structural depression that has been flooded several times in response to Pleistocene glacial cycles. Sediment deposition within the basin now occupied by the bay has been strongly influenced by ocean-level fluctuations. During periods of glacial advance, sea levels were lower, leaving the basin dry and subject to alluvial deposition, stream channel erosion, and aeolian (wind-related) processes. During periods of glacial retreat, sea levels rose, flooding the basin and resulting in fluvial deposition of fine-grained sediments at the bottom of the bay. The upper sediments within and along the margins of the bay include younger bay mud that has been deposited during and after the melting of the Wisconsin continental glaciers. The younger bay mud in the South Bay is up to approximately 60 feet thick (CDMG, 1969). Underlying the younger bay mud are sequences of alluvial and bay deposits consisting of sand, gravel, clay, and silt associated with previous ocean-level fluctuations. Bedrock underlying San Francisco Bay is predominantly of Jurassic and Cretaceous age and grouped within the Franciscan Complex. Bedrock depths range from about 200 feet near the northern bay crossing of the WSIP facilities to well over 1,000 feet toward the south. Historical development around the bay margins has included placement of artificial fill materials bayward of the natural shoreline, significantly altering the shoreline and reducing the size of the bay.

Flatlands, created by alluvial deposition of locally derived sediments, are found between the bay margins and the surrounding hills. Alluvial soils in the flatlands were deposited during the Quaternary period (during the last 1.8 million years). Alluvial soils range widely from fine-grained clay and silt on the broader, more gently sloping portions of the Santa Clara Valley to coarse-grained sand and gravel along the active or buried historical stream channels and at higher elevations along the range fronts. The upper tens of feet of soil within the Santa Clara Valley tend to be interstratified clay, silt, sand, and gravel as a result of the depositional history of the area. Alluvial soils extend to great depths in the Santa Clara Valley, with bedrock surfaces measuring well over 1,000 feet deep.

Sunol Valley Region

The WSIP facilities within the Sunol Valley Region are predominantly located within bedrock units of the Diablo Range, including marine sedimentary rocks comprised of sandstone, shell breccia, shale, chert, and pebble conglomerates. The marine sedimentary rocks are locally known as Neroly Formation, Briones Formation, Claremont (Monterey) Formation, Temblor Sandstone, and Irvington Gravels (Santa Clara Formation). These predominantly Tertiary-age formations overlie Mesozoic basement rocks consisting of Creatceous marine sedimentary rocks, primarily of the Niles Canyon and Panoche Formations west of the Hayward fault, and of the Franciscan Complex east of the fault. Alluvial deposits consisting of unconsolidated silt, clay, sand, and gravel overlie the bedrock in the valley areas.

Franciscan serpentinite,[13] an ultramafic[14] rock, and Franciscan mélange,[15] both of which may contain chrysotile (a form of naturally occurring asbestos[16]), occur at Calaveras Dam (SV-2). No serpentinite is mapped near the Alameda Creek Fishery (SV-1), 40-mgd Treated Water (SV-3), or Treated Water Reservoir (SV-4) projects at the Sunol Valley Water Treatment Plant (WTP), or near the New Irvington Tunnel (SV-4) or SABUP (SV-6) projects.

Bay Division Region

WSIP facilities within the Bay Division Region near the northeastern flank of the Santa Cruz Mountains are primarily located on sedimentary and meta-sedimentary bedrock units. The facilities cross units of Plio-Pliestocene-age Santa Clara Formation, marine sedimentary rocks of Eocene age, and Franciscan Complex sandstone.

The Santa Clara Formation is a fluvially deposited, unconsolidated to lightly consolidated unit of bedded conglomerate, sandstone, siltstone, and claystone. These deposits contain significant amounts of montmorillonite clay,[17] which renders the bedrock and the residual soils derived from the bedrock expansive. The next older formations were deposited in a marine environment during the Eocene epoch of the Tertiary period and are comprised of sandstone and mudstone. These formations are underlain by the Franciscan Complex, which is also exposed at the ground surface at the furthest northwest reaches of the South Bay.

The Franciscan Complex is of Jurassic and Cretaceous age and consists of mafic[18] and ultramafic basement rocks and sedimentary rocks that were deposited in a deep ocean environment and subsequently transported to the western margin of the North American Plate by tectonic forces. In the Bay Division Region, the Franciscan Complex is mapped only on the west side of the bay and is predominantly comprised of sandstone. However, geophysical testing in support of the BDPL Reliability Upgrade project (BD-1) indicates the presence of a buried ridge of Franciscan Complex rock, consisting of highly weathered and intensely fractured serpentinite, sandstone, and shale, approximately 1,000 feet west of the Newark Shaft. Serpentinite contains naturally

[13] Serpentinite is a rock consisting of one or more serpentine minerals. Serpentine is a naturally occurring group of minerals that can be formed when ultramafic rocks are metamorphosed during uplift to the earth's surface. This rock type is commonly associated with ultramafic rock along faults. Small amounts of chrysotile asbestos, a fibrous form of serpentine minerals, are common in serpentinite.

[14] Ultramafic rocks are formed in high-temperature environments well below the surface of the earth.

[15] Mélange is a mixture of rock materials of differing sizes and types generally contained within a sheared matrix.

[16] Asbestos is a term used for several types of naturally occurring fibrous materials found in many parts of California.

[17] Montmorillonite clay is an expansive type of clay that undergoes large changes in volume with changes in water content.

[18] Mafic rocks are igneous rocks containing a group of dark-colored minerals, composed chiefly of magnesium and iron.

occurring asbestos in the form of chrysotile, which could be encountered during tunneling for the BDPL Reliability Upgrade project.

Seismicity

The South Bay is a very seismically active area. The active faults within and adjacent to the region are the Hayward, Calaveras, San Andreas, and Monte–Vista Shannon faults. The Hayward and Calaveras faults cross or are adjacent to WSIP facilities, and the San Andreas and Monte Vista–Shannon faults are in close proximity to other facilities in the South Bay.

San Francisco Peninsula (San Francisco and Peninsula Regions)

Physiography

The San Francisco Peninsula is located in the central portion of the Coast Ranges Geomorphic Province of California. The mountains and hills of the San Francisco Peninsula are separated from the parallel range of the East Bay Hills by San Francisco Bay. WSIP projects located on the San Francisco Peninsula traverse the northern and eastern foothills of the Santa Cruz Mountains, the San Andreas Fault Zone, and flatlands adjacent to San Francisco Bay.

The elevations of facilities in this region range from approximately 30 feet along Crystal Springs Pipeline No. 2 near the bay to 525 feet at the Harry Tracy WTP in the hills adjacent to the San Andreas Fault Zone.

Geology

The San Francisco Peninsula region lies directly east of the San Andreas fault and is underlain by basement rock composed of tectonically mixed rock of Cretaceous to Jurassic age known as the Franciscan Complex. On the San Francisco Peninsula, the Franciscan Complex is locally capped by Tertiary, Quaternary, and Recent marine and nonmarine sedimentary deposits. The geologic units expected to be encountered during construction of the facility improvement projects include artificial fill, bay mud, colluvium, alluvium, stream channel deposits, and alluvial fans. Bedrock units in this region are the Colma Formation, Santa Clara Formation, Merced Formation, Whiskey Hill Formation, and Franciscan Complex, which consist of greenstone, sandstone, serpentinite, mélange, and chert.

The geologic units exposed at the surface consist primarily of artificial fill, alluvium, colluvium, and stream channel deposits of Holocene and Quaternary age; marine sandstone, siltstone, and claystone of Pliocene and Pleistocene age; and Cretaceous- and Tertiary-age sandstone, shale, chert, greenstone, and serpentinite units of the Franciscan Complex and the Whiskey Hill Formation (Brabb et al., 1998).

Plio-Pleistocene sandstone, siltstone, and claystone of the Merced Formation overlies Franciscan rocks over large areas, particularly near the Baden and San Pedro Valve Lots (PN-1) and SAPL 3 Installation (SF-1) projects. Holocene bay mud is not exposed at the surface but underlies the artificial fill along the San Francisco Bay margin, and is expected to be encountered in excavations in the program area.

In the Peninsula Region, most of the proposed WSIP projects are underlain by significant amounts of Franciscan ultramafic bedrock (primarily serpentinite) and mélange. These units contain naturally occurring asbestos in the form of chrysotile, which could be encountered during excavation for the CS/SA Transmission (PN-2) and Lower Crystal Springs Dam (PN-4) projects.

Seismicity

The major active faults in the Peninsula Region and San Francisco Extended Regions are part of the San Andreas Fault System—a complex system of right-lateral, strike-slip faults that includes the San Andreas, San Gregorio, Hayward, and Calaveras faults. These faults have produced measurable historic ground motion and movement. The Peninsula segment of the San Andreas Fault is nearest to all of the projects in this region and the CS/SA Transmission project (PN-4) could potentially cross this fault. The CGS estimates that the Peninsula segment of the San Andreas Fault is capable of producing an earthquake of maximum moment magnitude 7.2, with a recurrence interval on the order of 200 years (Cao et al., 2003). None of the other faults cross a WSIP project.

Regulatory Framework

Alquist-Priolo Earthquake Fault Zoning Act

Surface rupture is the most easily avoided seismic hazard. The Alquist-Priolo Earthquake Fault Zoning Act was passed in 1972 to mitigate the hazard of surface faulting to structures for human occupancy. In accordance with this act, the state geologist established regulatory zones, called "earthquake fault zones," around the surface traces of active faults and published maps showing these zones. Within these zones, buildings for human occupancy cannot be constructed across the surface trace of active faults. Each earthquake fault zone extends approximately 200 to 500 feet on either side of the mapped fault trace, because many active faults are complex and consist of more than one branch. There is the potential for ground surface rupture along any of the branches.

Title 14 of the California Code of Regulations, Section 3601(e), defines buildings intended for human occupancy as those that would be inhabited for more than 2,000 hours per year. None of the WSIP projects that would be constructed within an Alquist-Priolo Earthquake Fault Zone meet this criterion.[19] Therefore, this act does not apply to the WSIP projects.

[19] The Advanced Disinfection project (SJ-1) and Recycled Water Projects (SF-3) could include construction of facilities for human occupancy, and the HTWTP Long-Term project (PN-5) would include improvements at a facility for human occupancy, but none of these projects would be constructed within an Alquist-Priolo Earthquake Fault Zone.

Seismic Hazards Mapping Act

The Seismic Hazards Mapping Act was passed in 1990 following the Loma Prieta earthquake to reduce threats to public health and safety and to minimize property damage caused by earthquakes. The act directs the Department of Conservation to identify and map areas prone to the earthquake hazards of liquefaction, earthquake-induced landslides, and amplified groundshaking. For structures intended for human occupancy, the act requires site-specific geotechnical investigations to identify potential seismic hazards and formulate mitigation measures prior to permitting most developments designed for human occupancy within the Zones of Required Investigation. Only two of the WSIP projects would involve buildings for human occupancy within a Zone of Required Investigation (HTWTP Long-Term, PN-3, and Recycled Water Projects, SF-3).[20] However, the seismic hazard maps are useful tools for identifying areas with the potential for liquefaction and earthquake-induced landslides.

As of January 2006, 110 official seismic hazard zone maps showing areas prone to liquefaction and landslides had been published in California, and more are scheduled in the future. Most of the mapping has been performed in Southern California and the San Francisco Bay Area. Twenty-two official maps for the San Francisco Bay Area have been released, with preparation of 19 additional maps for San Mateo, Santa Clara, Alameda, and Contra Costa Counties planned or in progress. The CGS has no current plans to map San Joaquin County.

Surface Mining and Reclamation Act

In accordance with the Surface Mining and Reclamation Act of 1975, the state has established a mineral land classification system to help identify and protect mineral resources in areas that are subject to urban expansion or other irreversible land uses that would preclude mineral extraction. Protected mineral resources include construction materials, industrial and chemical mineral materials, metallic and rare minerals, and nonfluid mineral fuels. The act directs the state geologist to classify (identify and map) the nonfuel mineral resources of the state to show where economically significant mineral deposits occur and where they are likely to occur based on the best available scientific data. Nonfuel mineral resources include: metals such as gold, silver, iron, and copper; industrial minerals such as boron compounds, rare-earth elements, clays, limestone, gypsum, salt, and dimension stone; and construction aggregate, which includes sand, gravel, and crushed stone. Many areas of the state have been mapped using the California Mineral Land Classification System to identify areas with known mineral resources. This system provides guidance for identifying Mineral Resource Zones (MRZs) based on these four general categories:

- *MRZ-1*. Areas where adequate information indicates that no significant mineral deposits are present, or where it is judged that little likelihood exists for their presence.
- *MRZ-2*. Areas where adequate information indicates that significant mineral deposits are present, or where it is judged that a high likelihood exists for their presence.

[20] The Advanced Disinfection project (SJ-1) and Recycled Water Projects (SF-3) could include construction of facilities for human occupancy, but only the Recycled Water Projects would potentially be located in a Zone of Required Investigation. Although HTWTP Long-Term would include improvements to a facility for human occupancy, seismic hazards mapping has not been conducted in San Mateo County, and the improvements would not be subject to the Seismic Hazards Mapping Act unless mapping has been completed at the time of construction.

- *MRZ-3*. Areas containing mineral deposits, the significance of which cannot be evaluated.
- *MRZ-4*. Areas where available information is inadequate for assignment to any other zone.

Pipeline and other public engineering projects are not subject to Surface Mining and Reclamation Act regulation.

California Building Code

The 2001 California Building Code (CBC) is based on the 1997 Uniform Building Code, with the addition of more extensive structural seismic provisions. The CBC is contained in the California Code of Regulations, Title 24, or the California Building Standards Code, and is a compilation of three types of building standards from three different origins:

- Building standards that have been adopted by state agencies without change from building standards contained in national model codes
- Building standards that have been adopted and adapted from the national model code standards to meet California conditions
- Building standards, authorized by the California legislature, that constitute extensive additions not covered by the model codes that have been adopted to address particular California concerns

Title 24, Part 2, Volume 2, Chapter 16 of the California Code of Regulations contains definitions of seismic sources and the procedure used to calculate seismic forces on structures. As the proposed WSIP projects lie within Uniform Building Code Seismic Zones 3 and 4, provisions for design would follow the requirements of Chapter 16.

SFPUC General Seismic Design Requirements

The SFPUC's *General Seismic Design Requirements* (SFPUC, 2006) set forth consistent criteria for the seismic design and retrofit of all facilities and components of the regional water system. In accordance with these design requirements, every WSIP project must have project-specific design criteria based on the seismic environment and importance of the facility in achieving water service delivery goals in the event of a major earthquake.[21] The design criteria are based on the referenced codes, standards, and industry publications, but would exceed these requirements for facilities that are located in a severe seismic environment and are needed to achieve water service delivery goals. Covered facilities include offices, operating centers, water treatment plants, water storage structures, pumping plants, pipelines, tunnels, and related equipment. Dams and associated components under the jurisdiction of the California Division of Safety of Dams (DSOD) and/or the Federal Energy Regulatory Commission (FERC) may be subject to additional design criteria and seismic evaluation methodology. For this type of project, the DSOD and/or FERC would be consulted to determine appropriate criteria and methodology.

[21] In the *General Seismic Design Requirements*, the term "major earthquake" is defined as an earthquake of Richter magnitude 7.8 or larger on the San Andreas fault, 7.1 or larger on the Hayward fault, or 6.8 or larger on the Calaveras fault.

Under these design requirements, each facility is evaluated for its necessity in meeting the water service delivery goals and assigned a seismic performance class for the purposes of determining appropriate seismic design criteria. Facilities needed to achieve a basic level of service within 24 hours of a major earthquake are assigned a seismic performance class of Critical. This class includes structures and components of the storage, distribution, treatment, and control system, with either no redundancy or with redundancy that have common-cause failure modes (such as the same fault crossing) and for which the failure would result in an unacceptable service level. Facilities needed for emergency response, such as emergency operations centers and emergency repair response centers, are classified as Critical. Facilities needed to achieve the specified level of service within 30 days of a major earthquake are classified as Important. This class includes structures and components of the storage, distribution, treatment, and control systems with some level of redundancy or for which failure would not result in an unacceptable level of service. Other facilities, such as administrative centers, repair shops, service centers, and similar support facilities, are classified as Standard. These facilities are not needed to achieve the water service delivery goals of the WSIP and might not be repaired following a major earthquake for economic reasons. Many of the planned WSIP projects are classified as Critical.

4.4.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to geology, soils, and seismicity, but generally considers that implementation of the proposed program would have a significant impact if it were to:

- Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:
  - Rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the state geologist for the area or based on other substantial evidence of a known fault (refer to Division of Mines and Geology Special Publication 42),
  - Strong seismic groundshaking,
  - Seismic-related ground failure, including liquefaction,
  - Landslides (Evaluated in this section)
- Result in substantial soil erosion or the loss of topsoil (Evaluated in this section)
- Be located on a geologic or soil unit that is unstable, or that would become unstable as a result of the project, and potentially result in onsite or offsite landslide, lateral spreading, subsidence, liquefaction, or collapse (Evaluated in this section)
- Be located on expansive or corrosive soil, creating substantial risks to life or property (Evaluated in this section)
- Have soils incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems where sewers are not available for the disposal of wastewater (Not evaluated in this section, see Appendix B)

- Substantially change the topography or any unique geologic or physical features of the site (Evaluated in this section)

Implementation of the proposed program would have a significant impact related to mineral resources if it were to:

- Result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state (Not evaluated in this section, see Appendix B)
- Result in the loss of availability of a locally important mineral resource recovery site delineated in a local general plan, specific plan, or other land use plan (Not evaluated in this section, see Appendix B)
- Encourage activities which result in the use of large amounts of fuel, water, or energy, or use these in a wasteful manner (Evaluated in Section 4.15, Energy Resources)

Approach to Analysis

The WSIP includes water system improvement projects that would ensure the SFPUC can maintain an adequate water supply in the event of a major earthquake, with the goals of restoring basic service within 24 hours of a major earthquake and meeting average-day demand within 30 days. To meet these goals, projects are included that: (1) strengthen and improve the seismic resistance of many of the water system components, and (2) provide system redundancy so that water service can be maintained should a component of the system fail. Each of these projects would be constructed in accordance with the SFPUC's *General Seismic Design Requirements* (described above in the Setting), which require a site-specific investigation and development of project-specific design criteria based on the seismic performance class of the facility and site-specific geologic and seismic hazards, including fault rupture, ground motions generated by earthquakes (groundshaking), slope instability, liquefaction, and loss of soil strength. Implementation of these design requirements would ensure that water service delivery goals are achieved in the event of a major earthquake. Collectively, this is a beneficial impact of the WSIP, as discussed in Section 4.16, Collective WSIP Impacts. Potential seismic hazards related to the operation, siting, and design of the WSIP projects are considered less than significant for each WSIP project, given compliance with the *General Seismic Design Requirements*. This section also analyzes geology, soils, and seismicity impacts that could occur during construction, and impacts associated with locating projects in areas of expansive or corrosive soils.

Although all WSIP projects in the Sunol Valley Region (located in the Alameda Creek watershed) and the CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4), and Pulgas Balancing Reservoir (PN-5) projects (located in the Peninsula watershed) would be required to comply with the following Alameda and Peninsula Watershed Management Plan (WMP) policies and actions, compliance with the *General Seismic Design Requirements* would incorporate the intent of these policies and actions, and they are not further discussed below:

- *Policy S7*: Require adequate seismic and static geohazards engineering studies for proposed facilities, infrastructure, and utilities easements within the watershed.

- *Policy S8*: Require that utility pipelines within the watershed meet current seismic standards and comply with applicable hazardous materials regulations.
- *Action des2.2*: Prior to the approval of construction of any new facility or structure, within the watershed but outside of an Alquist-Priolo Earthquake Fault Zone, require appropriate geotechnical evaluations to assure that the structure can withstand the effects of a seismic event. If the facility or structure is intended for human occupancy and sited over active fault traces, design and construction should comply with the policies and provisions of the Alquist-Priolo Earthquake Fault Zoning Act.

Impact Summary by Region

Table 4.4-4 provides a summary of the geology, soils, and seismicity impacts associated with implementation of the WSIP.

Construction Impacts

Impact 4.4-1: Slope instability during construction.

Destabilization of natural or constructed slopes could occur as a result of construction activities due to excavation and/or grading operations. Excavations for new and replacement pipelines, building foundations, tunnel portals, and temporary access roads and work areas could result in slope instability, potentially triggering slope failures that could result in landslides, slumps, soil creep, or debris flows. Slope failures are more likely to occur in areas with a history of previous failure and in weak geologic units exposed on unfavorable slopes, such as areas mapped by the USGS (1997) as having “many landslides” or areas of weak, fault-sheared rock. Such slope failures could damage WSIP or other nearby facilities and properties.

For projects located in areas with a low potential for landslides, this impact would be less than significant, but the site-specific information analyzed in accordance with SFPUC Construction Measure #2 (seismic and geotechnical studies) and during separate, project-level CEQA review could either confirm the program-level determination of less than significant or provide a basis to revise this determination.

For projects in areas with an identified landslide hazard, it could be necessary to conduct a quantified landslide analysis (Measure 4.4-1) and implement the recommendations of the investigation to reduce impacts to a less-than-significant level, although the need for mitigation would be determined during separate, project-level CEQA review of each WSIP project. All Sunol Valley and Peninsula Region projects located in the Peninsula watershed would also be required to comply with the following WMP policies related to slope instability:

- *Policy S5*: Minimize damage from potential mass movement hazards by avoiding construction or other disturbances in known dormant landslides and on slopes greater than 30 percent, without proper engineering.
- *Policy S6*: Conduct (for CCSF-owned) and require (for easements) inspection of facilities and utilities near active landslide areas and fault traces following earthquakes and slope failures to assess their stability and integrity, and complete repairs or further monitoring as needed to prevent geohazards.

TABLE 4.4-4
POTENTIAL IMPACTS AND SIGNIFICANCE – GEOLOGY, SOILS, AND SEISMICITY

Projects	Project Number	Impact 4.4-1: Slope instability during construction	Impact 4.4-2: Erosion during construction	Impact 4.4-3: Substantial alteration of topography	Impact 4.4-4: Squeezing ground and subsidence during tunneling	Impact 4.4-5: Surface fault rupture	Impact 4.4-6: Seismically induced groundshaking	Impact 4.4-7: Seismically induced ground failure, including liquefaction and settlement	Impact 4.4-8: Seismically induced landslides or other slope failures	Impact 4.4-9: Expansive or corrosive soils

LS = Less than Significant impact, no mitigation required
PSM= Potentially Significant impact, can be mitigated to less than significant
N/A = Not Applicable

San Joaquin Region

Impact 4.4-1: Slope instability during construction		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	PSM
SJPL System	SJ-3	N/A
SJPL Rehabilitation	SJ-4	N/A
Tesla Portal Disinfection	SJ-5	LS

The USGS has not mapped the landslide distribution in the San Joaquin Region. The Lawrence Livermore project (SJ-2) is located in landslide-prone Franciscan Complex units on moderate to steep slopes of the Diablo Range. Excavation and grading for construction at this site could potentially trigger landslides that could cause damage to the facility or nearby properties. Because this project is located in an area of potential landslide susceptibility, impacts related to construction-triggered landslides are considered *potentially significant,* but would be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #2 (seismic and geotechnical studies) and preparation of a quantified landslide analysis (Measure 4.4-1).

The Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) projects are located on gentle hills underlain by Plio-Pleistocene-age, nonmarine sedimentary deposits with a low potential for landslides. If any slope failures did occur due to substantial excavation into the slope, it is expected that they would be minor surficial failures and not likely to cause damage. Therefore, impacts related to construction-triggered landslides would be *less than significant* for these projects.

The remaining San Joaquin Region projects (SJPL System, SJ-3, and SJPL Rehabilitation, SJ-4) would not be located on substantial slopes; therefore, the potential for construction-triggered landslides would be low, and this impact would *not apply* to these projects.

Sunol Valley Region

Impact 4.4-1: Slope instability during construction		
Alameda Creek Fishery	SV-1	PSM
Calaveras Dam	SV-2	PSM
40-mgd Treated Water	SV-3	PSM
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	PSM
SABUP	SV-6	PSM

All of the Sunol Valley Region projects (Alameda Creek Fishery, SV-1; Calaveras Dam, SV-2; 40-mgd Treated Water, SV-3; New Irvington Tunnel, SV-4; Treated Water Reservoirs, SV-5; and SABUP, SV-6) are located at least partially on and/or adjacent to gentle to moderately steep slopes of the Alameda Creek drainage and Diablo Range foothills, in areas mapped as “mostly landslides” (USGS, 1997). These areas are primarily underlain by sheared Miocene and Cretaceous sedimentary bedrock and sheared Franciscan Complex. Existing landslides are also mapped adjacent to the Calaveras Dam site (SV-2). Because these projects are located in an area of potential landslide susceptibility, impacts related to construction-triggered landslides are considered *potentially significant*. However, with implementation of SFPUC Construction Measure #2 (seismic and geotechnical studies) and preparation of a quantified landslide analysis (Measure 4.4-1), impacts related to slope stability would be reduced to a less-than-significant level. Compliance with policies related to slope instability (S5 and S6) of the Alameda WMP, described above, would also be required.

Bay Division Region

Impact 4.4-1: Slope instability during construction		
BDPL Reliability Upgrade	BD-1	LS
BDPL 3 and 4 Crossovers	BD-2	N/A
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	N/A

All proposed WSIP projects in the Bay Division Region (BDPL Reliability Upgrade, BD-1; BDPL 3 and 4 Crossovers, BD-2; and BDPL 3 and 4 Seismic Upgrade at Hayward Fault, BD-3) would be located on flat and gently sloping terrain adjacent to San Francisco Bay in areas designated as "flat land," but with areas mapped as "few landslides" on both ends of the BDPL Reliability Upgrade alignment (USGS, 1997). Therefore, this impact would *not apply* to the BDPL 3 and 4 Crossovers and BDPL 3 and 4 Seismic Upgrade at Hayward Fault projects. Although both ends of the BDPL Reliability Upgrade pipeline alignment would be located in areas mapped as "few landslides," impacts related to construction-triggered landslides would be *less than significant* because any slope failures that did occur due to substantial excavation into the slopes are expected to be minor surficial failures and not likely to cause damage.

Peninsula Region

Impact 4.4-1: Slope instability during construction		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	PSM
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	PSM

The HTWTP Long-Term (PN-3) and Pulgas Balancing Reservoir (PN-5) project sites would be located on or adjacent to sloping terrain, where there are small areas designated as "mostly landslides" and several existing landslides are mapped along the edges of the Harry Tracy WTP (GTC, 2005). Because these projects are located in an area of potential landslide susceptibility, impacts related to construction-triggered landslides are considered *potentially significant,* but would be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #2 (seismic and geotechnical studies) and preparation of a quantified landslide analysis (Measure 4.4-1). Compliance with policies related to slope instability (S5 and S6) of the Peninsula WMP, described above, would also be required for the Pulgas Balancing Reservoir project.

The Baden and San Pedro Valve Lots (PN-1), CS/SA Transmission (PN-2), and Lower Crystal Springs Dam (PN-4) projects are located on the flat-to-sloping terrain of the foothills and San Andreas Fault Zone, in areas primarily designated as "few landslides" (USGS, 1997). Therefore, this impact would be *less than significant* for these projects.

San Francisco Region

Impact 4.4-1: Slope instability during construction		
SAPL 3 Installation	SF-1	LS
Groundwater Projects	SF-2	PSM
Recycled Water Projects	SF-3	PSM

The Local Groundwater Projects (SF-2) would be constructed in the vicinity of the San Francisco Zoo, in the Sunset District, and in Golden Gate Park. Because the CGS has not mapped areas of landslide susceptibility at these sites, the potential for construction-related landslides is low for this project. However, construction-triggered landslides could occur during the construction of the Regional Groundwater Projects

(SF-2); the associated wells would not likely be constructed in a landslide-prone area, but the pipelines could cross areas of potential landslide susceptibility in San Mateo County. In addition, the Recycled Water Projects (SF-3) could include construction of a storage tank in Lincoln Park where the CGS has mapped a zone of landslide susceptibility. Therefore, impacts related to construction-triggered landslides are considered *potentially significant* for both projects, but would be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #2 (seismic and geotechnical studies) and preparation of a quantified landslide analysis (Measure 4.4-1).

The SAPL 3 Installation project (SF-1) is proposed on flat and gently sloping terrain adjacent to San Francisco Bay and the surrounding hills in areas designated as "flat land" and "few landslides" (USGS, 1997). Therefore, impacts related to construction-triggered landslides would be *less than significant* for this project.

Impact 4.4-2: Erosion during construction.

Construction activities such as backfilling, grading, and compaction can remove stabilizing vegetation and expose areas of loose soil that, if not properly stabilized during construction, can be subject to soil loss and erosion by wind and stormwater runoff. Newly constructed and compacted engineered slopes can also undergo substantial erosion through dispersed sheet-flow runoff, and more concentrated runoff can cause the formation of small erosional channels and larger gullies, each compromising the integrity of the slope and resulting in significant soil loss.

All Regions

Impact 4.4-2: Erosion during construction		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	LS
Tesla Portal Disinfection	SJ-5	LS
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	LS
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	LS
BDPL Reliability Upgrade	BD-1	LS
BDPL 3 and 4 Crossovers	BD-2	LS
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	LS
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS
SAPL 3 Installation	SF-1	LS
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	LS

All WSIP facilities requiring grading or excavation could be subject to soil loss and erosion by wind and stormwater runoff. Although erosion can be a common construction-related occurrence, especially during wintertime construction projects, all WSIP projects would be required to implement SFPUC Construction Measure #3 (onsite air and water quality measures during construction), which requires the implementation of erosion control measures, as described in Impact 4.5-1 (see Section 4.5, Hydrology and Water Quality). This measure would require preparation of a stormwater pollution prevention plan for projects disturbing more than one acre of land outside of San Francisco; preparation of an erosion control plan in accordance with Article 4.1 of the

San Francisco Public Works Code for projects within San Francisco; and implementation of erosion and sedimentation controls tailored to the site and project for projects outside of San Francisco that disturb less than one acre of land. As summarized in Impact 4.5-1, projects located in the Alameda and Peninsula watersheds would also be required to comply with the erosion control actions of the Alameda and Peninsula WMPs. With implementation of these required measures, impacts related to erosion during construction would be *less than significant* for all WSIP projects.

Impact 4.4-3: Substantial alteration of topography.

Substantial alteration of topography (defined as changes in the character of the slope and gradient due to grading, excavation, or cut and fill) could result in unstable slopes or increased wind or water erosion due to resultant drainage pattern changes and/or slope changes. These potential geologic impacts are discussed above under Impacts 4.4-1 and 4.4-2.

San Joaquin, Bay Division, Peninsula, and San Francisco Regions

Impact 4.4-3: Substantial alteration of topography		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	LS

HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS
SAPL 3 Installation	SF-1	LS
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	LS

Although projects in the San Joaquin, Bay Division, Peninsula, and San Francisco Regions would require some excavation or grading, most of these projects are located in previously disturbed areas, or the grading or excavation associated with the projects is not expected to significantly alter the topography. Furthermore, SFPUC Construction Measure #10 (project site) would require construction contractors to return the WSIP project sites to the general condition that existed before construction, which would include regrading the sites and revegetating disturbed areas. Therefore, impacts related to the substantial alteration of topography would be *less than significant* for projects in these regions.

Sunol Valley Region

Impact 4.4-3: Substantial alteration of topography		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	LS
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	LS

In the Sunol Valley Region, the excavation of borrow pits and grading of hills for the new spillway, required for construction of the Calaveras Dam project (SV-2), as well as improvements at the Irvington Portal under the New Irvington Tunnel project (SV-4) would substantially alter topography and could result in increased wind or water erosion. However, this impact would be *less than significant* with implementation of SFPUC Construction Measure #3 (onsite air and water quality measures during construction), which requires erosion control measures and preparation of a stormwater pollution prevention plan, and SFPUC Construction Measure #10 (project site), which requires the construction contractor to restore project sites to the general condition that existed before construction, and which would include regrading the site and revegetating disturbed areas. For the Calaveras Dam project (SV-2), implementation of the following Alameda WMP action would further reduce impacts related to the alteration of topography to a less-than-significant level:

- *Action des5*: Prior to approval of new construction activities or renovation/alteration of existing facilities, structures, or roads, ensure that the following design guidelines are met:

  A. Where grading is necessary, slopes and landforms shall be contoured to mimic the surrounding environment as much as possible.

  B. Design and site new roads and trails to minimize grading and the visibility of cut banks and fill slopes.

The other Sunol Valley Region projects (Alameda Creek Fishery, SV-1; 40-mgd Treated Water, SV-3; Treated Water Reservoirs, SV-5; and SABUP, SV-6) would require some excavation or grading. However, many of these projects are located in previously disturbed areas, or the grading or excavation associated with these projects would not appreciably alter the topography. Furthermore, SFPUC Construction Measure #10 (project site) would require construction contractors to return the WSIP project sites to the general condition that existed before construction, which would include regrading the sites and revegetating disturbed areas. Therefore, impacts related to the substantial alteration of topography would be *less than significant* for these projects.

Impact 4.4-4: Squeezing ground and subsidence during tunneling.

The effects of squeezing ground could occur during tunnel construction and the ground surface overlying the proposed tunnels could subside due to tunnel excavation, damaging interior supports and resulting in potential health and safety hazards. Squeezing ground is a common construction challenge for tunnel projects, especially in sheared materials such as those expected during the excavation of proposed WSIP tunnels. Although the effects of squeezing ground can damage a tunnel’s interior support structure and sometimes cause injury to workers, standard engineering design would reduce the potential for this phenomenon to compromise the structural integrity of the tunnel structure or cause tunneling delays. Design might include reinforcing the tunnel excavation with steel rib-type supports; blocking in areas of crushed and sheared material; installing immediate face, roof, and sidewall support for stability in areas of crushed and squeezing ground; and using shotcrete to strengthen sidewalls and faces when the tunnel excavation is not advanced within about a day.

Additionally, with subsurface excavation projects such as tunneling, there is a potential that the ground surface could subside in response to the removal of subsurface materials. Subsidence occurs when the earth materials above the tunnel lose the capacity to support the overlying weight as the tunneling progresses. Subsidence can damage overlying structures such as homes and other buildings, as well as infrastructure such as roadways and utilities, and can also endanger the health and safety of construction workers. However, the tunnel interior would be reinforced by support elements to maintain the tunnel opening and minimize subsidence during tunneling.

San Joaquin Region, Peninsula, and San Francisco Regions

Impact 4.4-4: Squeezing ground and subsidence during tunneling		
Advanced Disinfection	SJ-1	N/A
Lawrence Livermore	SJ-2	N/A
SJPL System	SJ-3	N/A
SJPL Rehabilitation	SJ-4	N/A
Tesla Portal Disinfection	SJ-5	N/A
Baden and San Pedro Valve Lots	PN-1	N/A
CS/SA Transmission	PN-2	N/A
HTWTP Long-Term	PN-3	N/A
Lower Crystal Springs Dam	PN-4	N/A
Pulgas Balancing Reservoir	PN-5	N/A
SAPL 3 Installation	SF-1	N/A
Groundwater Projects	SF-2	N/A
Recycled Water Projects	SF-3	N/A

Impacts related to squeezing ground and subsidence would *not apply* to any projects in the San Joaquin, Peninsula, or San Francisco Regions because none of the projects in these regions would involve tunneling.

Sunol Valley Region

Impact 4.4-4: Squeezing ground and subsidence during tunneling		
Alameda Creek Fishery	SV-1	N/A
Calaveras Dam	SV-2	N/A
40-mgd Treated Water	SV-3	N/A
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	N/A
SABUP	SV-6	N/A

Although squeezing ground could become an issue during construction of the New Irvington Tunnel project (SV-4), tunnel damage would not likely occur, because standard engineering design would reduce the potential for this phenomenon to compromise the structural integrity of the tunnel structure or cause tunneling delays. However, subsidence could become an issue during the construction of this project; therefore, impacts related to subsidence during tunneling would be *potentially significant,* but would be reduced to a less-than-significant level by use of internal supports during tunneling, as described above, and implementation of a subsidence monitoring program (Measure 4.4-4) to detect potential ground movement well before major subsidence occurs. Corrective action, such as increased tunnel support, would be implemented if measured displacement reached a designated minimum trigger amount. This impact would be evaluated in greater detail as part of separate, project-level CEQA review for this project, and specific triggers for corrective action would be addressed during that review.

None of the other Sunol Valley Region projects (Alameda Creek Fishery, SV-1; Calaveras Dam, SV-2; 40-mgd Treated Water, SV-3; Treated Water Reservoirs, SV-5; or SABUP, SV-6) would involve tunneling. Therefore, impacts related to squeezing ground and subsidence would *not apply* to these projects.

Bay Division Region

Impact 4.4-4: Squeezing ground and subsidence during tunneling		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	N/A
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	N/A

Although squeezing ground could become an issue during construction of the BDPL Reliability Upgrade project (BD-1), tunnel damage would not likely occur, because standard engineering design would reduce the potential for this phenomenon to compromise the structural integrity of the tunnel structure or cause tunneling delays. However, subsidence could become an issue during the construction of this project; therefore, impacts related to subsidence during tunneling would be *potentially significant*, but would be reduced to a less-than-significant level by use of internal supports during tunneling, as described above, and implementation of a subsidence monitoring program (Measure 4.4-4) to detect potential ground movement well before major subsidence occurs. Corrective action, such as increased tunnel support, would be implemented if measured displacement reached a designated minimum trigger amount. This impact would be evaluated in greater detail as part of separate, project-level CEQA review for this project, and specific triggers for corrective action would be addressed during that review.

None of the other Bay Division Region projects (BDPL 3 and 4 Crossovers, BD-2 and BDPL 3 and 4 Seismic Upgrade at Hayward Fault, BD-3) would involve tunneling. Therefore, impacts related to squeezing ground and subsidence would *not apply* to these projects.

Operations, Siting, and Design Impacts

Seismic Hazard Impacts

Impact 4.4-5: Surface fault rupture.

Although construction of the WSIP facilities would not alter the seismic environment or increase the risk of fault rupture, there is the potential for proposed improvements to be damaged by surface fault ruptures. Ground rupture most commonly occurs along preexisting faults, which are zones of weakness, and can occur slowly as fault creep (the slow rupture of the earth's crust along a fault) or more suddenly as earthquakes. The rate of movement along a fault can range from approximately 0.1 to 25 millimeters per year (mm/yr). This gradual movement can displace the ground surface and structures (such as buildings, roads, or fences) built over the trace of the fault, causing structural damage but generally not injury to people. Sudden movement resulting from an earthquake is more damaging than fault creep because it generally includes greater and more sudden displacement of the ground surface and is accompanied by groundshaking.

Because the SFPUC water system carries water from the Sierra Nevada to the San Francisco Bay Area, the crossing of several regional faults is unavoidable. Many of the WSIP facility projects include seismic upgrades and redundant features at fault crossings (as discussed by region below), which would enable the SFPUC to meet the water service delivery goals of the WSIP. These facilities would be designed to withstand fault rupture or maintain water service in accordance with the *General Seismic Design Requirements*.

The Alquist-Priolo Earthquake Fault Zoning Act prohibits construction of a structure for human occupancy within 50 feet of the trace of a known active fault. None of the WSIP facilities proposed for human occupancy are located within an Alquist-Priolo Earthquake Fault Zone.

The Sunol Valley and Peninsula Region projects located in the Peninsula watershed would also be required to comply with the following WMP policies related to fault rupture:

- *Policy S4*: Minimize damage from future seismic hazards by avoiding construction of facilities in active fault zones and traces, where feasible.
- *Policy S6*: Conduct (for CCSF-owned) and require (for easements) inspection of facilities and utilities near active landslide areas and fault traces following earthquakes and slope failures to assess their stability and integrity, and complete repairs or further monitoring as needed to prevent geohazards.

San Joaquin Region

Impact 4.4-5: Surface fault rupture		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	LS
Tesla Portal Disinfection	SJ-5	LS

Although the Advanced Disinfection (SJ-1), Lawrence Livermore (SJ-2), and Tesla Portal Disinfection (SJ-5) projects and the west end of the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects would be constructed over the Great Valley 7 blind-thrust fault, there is no surface fault rupture associated with this thrust fault. There are no Alquist-Priolo Earthquake Fault Zones mapped in the San Joaquin Region. Therefore, the potential for fault rupture in this region is considered low, and impacts related to fault rupture would be *less than significant* for all San Joaquin Region projects.

Sunol Valley Region

Impact 4.4-5 Surface fault rupture		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	LS
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	LS

Several of the WSIP facilities within the Sunol Valley Region lie within or cross the Calaveras Fault Zone. The Calaveras Fault Zone is expressed as numerous strands that form a zone tens of feet to more than 1,500 feet in width. North of Calaveras Reservoir, the fault is characterized by sparse seismicity, but would probably rupture to the surface in moderate to large earthquakes (Bryant and Cluett, 2000).

The Alameda Creek Fishery (SV-1), 40-mgd Treated Water (SV-3), Treated Water Reservoirs (SV-5), and SABUP (SV-6) projects would each include construction of structures within the Alquist-Priolo Earthquake Fault Zone for the Calaveras fault (CGS, 2000). However, the SABUP project would provide a redundant pipeline to the existing San Antonio Pipeline, and new discharge facilities would allow discharge to San Antonio Creek during an emergency outage. These projects would be designed and constructed in accordance with the *General Seismic Design Requirements*, which would ensure that water service delivery goals are met after an earthquake, and impacts related to fault rupture would be *less than significant*.

Although the Alquist-Priolo Earthquake Fault Zone extends beneath Calaveras Reservoir, the dam is located outside of the zone. The Calaveras Dam (SV-2) and New Irvington Tunnel (SV-4) projects would not cross or be located within 50 feet of an active fault trace. Therefore, impacts related to fault rupture would be *less than significant* for these projects.

Implementation Alameda WMP policies related to fault rupture (S4 and S6), described above, would also be required for all Sunol Valley Region projects.

Bay Division Region

Impact 4.4-5: Surface fault rupture		
BDPL Reliability Upgrade	BD-1	LS
BDPL 3 and 4 Crossovers	BD-2	LS
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	LS

Both Bay Division Pipelines Nos. 1 and 2 and Pipelines Nos. 3 and 4 cross the southern segment of the Hayward fault. Most of the fault exhibits fault creep between 3 and 6 mm/yr, although the historical creep rate has been as high as 9 mm/yr near the southern part of the southern segment of the Hayward fault (Bryant and Cluett, 2000). In 1868, a substantially damaging earthquake of M 7.0 occurred on this segment of the Hayward fault, with a rupture length of approximately 32 miles.

The BDPL Reliability Upgrade project (BD-1) crosses the Hayward fault and would include construction of new seismically improved pipeline between the Irvington and Pulgas Portals, and the BDPL 3 and 4 Seismic Upgrade at Hayward Fault project (BD-3) would include construction of upgraded, seismically resistant sections of the Bay Division Pipelines Nos. 3 and 4 where they cross the Hayward fault (CGS, 2000). Because these projects would be designed and constructed in accordance with the *General Seismic Design Requirements*, impacts related to fault rupture would be *less than significant* for these projects.

The crossovers that would be constructed under the BDPL 3 and 4 Crossovers project (BD-2) would not be located within an Alquist-Priolo Earthquake Fault Zone. Therefore, impacts related to fault rupture would be *less than significant* for this project.

Peninsula Region

Impact 4.4-5: Surface fault rupture		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS

The active trace of the San Andreas fault and the associated Alquist-Priolo Earthquake Fault Zone cross the San Andreas Reservoir and Dam. In this area, the San Andreas Fault Zone is expressed as several overlapping and parallel strands that form a linear valley, ranging from several hundred feet to approximately one-half mile wide. The San Andreas fault passes under the eastern abutment of the dam and, although there was an 8-foot shearing movement along the rift during the 1906 earthquake, there was no damage to the dam (SFPUC, 2007). Two studies conducted to evaluate the rupture potential and seismic safety at the San Andreas Dam (ESA, 1980 and 1983) found no faulting in the west abutment or valley immediately downstream of the dam during the last 5,000 years. The studies concluded that fault rupture in the dam vicinity over the past 7,500 years has been confined within a fairly narrow zone (100 to 150 feet wide) in an area east of and within the eastern abutment of the dam, and that, in the unlikely event of rupture through the dam, the clayey fill and native materials within and underlying the dam would be able to withstand some offset without catastrophic failure of the dam.

The CS/SA Transmission project (PN-2) includes seismic improvements to facilities that convey water from Crystal Springs Reservoir to the Harry Tracy WTP, including the Crystal Springs Pump Station, Crystal Springs/San Andreas Pipeline, and pipelines that convey raw water to the Harry Tracy WTP pump station. This project could be located almost entirely within the Alquist-Priolo Earthquake Fault Zone for the San Andreas fault (CGS, 2000), and the Crystal Springs/San Andreas Pipeline to be improved or replaced under this project would parallel the fault; however, the project would be designed and constructed in accordance with the *General Seismic Design Requirements*, and impacts related to fault rupture would thus be *less than significant.* Implementation of Peninsula WMP policies related to fault rupture (S4 and S6), described above, would also be required.

The HTWTP Long-Term (PN-3), Lower Crystal Springs Dam (PN-4), and Pulgas Balancing Reservoir (PN-5) projects as well as the Pulgas Pump Station to be improved under the Baden and San Pedro Valve Lots project (PN-1) are located in close proximity to the Alquist-Priolo Earthquake Fault Zone for the San Andreas fault. However, because they are outside of the zone, it is not expected that these projects would be affected by fault rupture. Other improvements under the Baden and San Pedro Valve Lots project would not be located within 50 feet of or in proximity to an active fault trace. Therefore, impacts related to fault rupture would be *less than significant* for these projects. Implementation of Peninsula WMP policies related to fault rupture (S4 and S6), described above, would be required for the Lower Crystal Springs Dam and Pulgas Balancing Reservoir projects.

San Francisco Region

Impact 4.4-5: Surface fault rupture		
SAPL 3 Installation	SF-1	LS
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	LS

There are no active faults or Alquist-Priolo Earthquake Fault Zones mapped in the city of San Francisco where the Local Groundwater Projects (SF-2) and Recycled Water Projects (SF-3) would be constructed. Although the SAPL Installation project (SF-1) includes pipeline installation south of San Francisco and in the city itself, the pipeline would not cross an Alquist-Priolo Earthquake Fault Zone. The Regional Groundwater Projects in San Mateo County would be constructed to the east of the Alquist-Priolo Earthquake Fault Zone for the San Andreas fault. Therefore, the potential for fault rupture is considered low, and impacts related to fault rupture would be *less than significant* for the three projects in this region.

Impact 4.4-6: Seismically induced groundshaking.

Groundshaking is the most widespread effect of earthquakes and poses a greater seismic threat than local ground rupture. Depending on the level of groundshaking, an earthquake could damage buildings, pipelines, valves, control facilities, tunnels, and pump stations, resulting in a disruption of water service and/or endangering the health and welfare of people. Damage to treatment facilities could affect the ability of the SFPUC to provide treated water to its customers, and damage to storage facilities could reduce the amount of storage available in the regional water system. Such damage could require short-term, temporary service interruptions for inspections and repairs, and long-term repairs could also be required. However, facilities constructed under the WSIP would meet current seismic standards in accordance with the *General Seismic Design Requirements*, thereby improving their ability to withstand seismic damage due to groundshaking.

San Joaquin Region

Impact 4.4-6: Seismically induced groundshaking		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	LS
Tesla Portal Disinfection	SJ-5	LS

Although there are few active or potentially active faults within the San Joaquin Region, several faults in the greater Northern California region are capable of producing groundshaking in the region. Most notable of these faults are the San Andreas, Hayward, San Gregorio, Calaveras, and Great Valley faults. The western portion of this region (at the eastern margin of the Diablo Range) is closest to these faults. The following WSIP projects or facilities would be located in this area: Advanced Disinfection (SJ-1), Lawrence Livermore (SJ-2), the western pipeline segments of the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4), and Tesla Portal Disinfection (SJ-5). Because of the type of rock beneath them, these facilities could be subject to groundshaking magnitudes ranging from 20 to 50 percent of gravity (0.2 to 0.5 g). However, due to its distance from these regional seismic sources, the eastern pipeline segment of the SJPL System and SJPL Rehabilitation projects are expected to experience lower groundshaking magnitudes, ranging from 10 to 20 percent of gravity (0.1 to 0.2 g). These approximate values are presented in this document for general review and estimation of potential seismic groundshaking and are not intended for the purpose of project design. All WSIP projects would be designed and constructed in accordance with the *General Seismic Design Requirements*. Therefore, impacts related to groundshaking would be *less than significant* for all San Joaquin Region projects.

Sunol Valley, Bay Division, Peninsula, and San Francisco Regions

Impact 4.4-6: Seismically induced groundshaking.		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	LS
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	LS
BDPL Reliability Upgrade	BD-1	LS
BDPL 3 and 4 Crossovers	BD-2	LS
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	LS
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS
SAPL 3 Installation	SF-1	LS
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	LS

Active and potentially active faults capable of producing strong groundshaking are located within and near each of the Sunol Valley, Bay Division, Peninsula, and San Francisco Regions. Most notable of these faults are the San Andreas, Hayward, San Gregorio, Calaveras, and Greenville faults. WSIP facilities in any of these regions could experience strong groundshaking from a seismic event on one of these faults. Anticipated groundshaking magnitudes in each region are summarized in **Table 4.4-5** and range from approximately 50 to 70 percent of gravity (0.5 g to 0.7 g). These approximate values are presented in this document for general review and estimation of potential seismic groundshaking in each region and are not intended for the purpose of project design.

TABLE 4.4-5
APPROXIMATE GROUND MOTIONS EXPECTED IN EACH REGION
(10% probability of being exceeded in 50 years)

Region	Range of Approximate Peak Ground Acceleration (g)[a,b]
Sunol Valley	0.72 – 0.73
Bay Division	0.50 – 0.71
Peninsula	0.68 – 0.72
San Francisco	0.55 – 0.69

[a] Ground motions are expressed as a fraction of the acceleration due to gravity (g) and have a 10% probability of being exceeded in 50 years.
[b] Ground motion values are the same for firm rock (conditions on the boundary between site categories B and C, as defined by the building code), soft rock (site category C), and alluvium (site category D).

SOURCE: CGS, 2007.

All WSIP projects would be designed and constructed in accordance with the *General Seismic Design Requirements.* Therefore, impacts related to ground shaking would be *less than significant* for all WSIP projects in the Sunol Valley, Bay Division, Peninsula, and San Francisco Regions.

Impact 4.4-7: Seismically induced ground failure, including liquefaction and settlement.

Liquefaction-related phenomena can include lateral spreading, ground oscillation, loss of bearing strength, subsidence, and buoyancy effects, all of which can damage to structures. During the loss of bearing capacity, large deformations can occur within the soil mass. Damage from liquefaction and lateral spreading is generally most severe when liquefaction occurs within 15 to 20 feet of the ground surface. The WSIP projects most likely to suffer damage from liquefaction-related phenomena are foundations for structures, vaults, and pipelines.

Seismically induced settlement can occur in areas underlain by compressible sediments. Stream channel deposits and recent valley alluvium are generally the most susceptible to earthquake-induced settlement. Additionally, artificial fills, especially fills placed before 1965 and those placed on top of bay mud, are highly susceptible to mobilization and densification, resulting in earthquake-induced subsidence.

For this analysis, areas susceptible to liquefaction were identified based on mapping conducted by the CGS and USGS. As required by the Seismic Hazards Mapping Act, the CGS has mapped areas of liquefaction potential within portions of the program area, and additional mapping is underway or planned. The USGS has issued a GIS map and report that includes liquefaction susceptibility mapping for the San Francisco Bay Area (USGS, 2000). For this mapping, the USGS has assigned liquefaction susceptibility designations of very low, low, moderate, high, and very high based on the geologic unit (type and age of deposit) and depth to groundwater.

Because the regional water system carries water from the Sierra Nevada to the San Francisco Bay Area, the crossing of many areas of moderate to very high liquefaction susceptibility is unavoidable. However, many of the WSIP facility projects include improvements to the water system within these areas (as discussed below by region), which would enable the SFPUC to meet the water service delivery goals of the WSIP, and these facilities would be designed to withstand liquefaction and settlement or maintain water service in accordance with the *General Seismic Design Requirements*.

Pipelines and Related Facilities. Where pipelines are buried in soil overlying deeper liquefiable soil layers, liquefaction of the deeper layers can result in substantial lateral spreading of the upper competent soil layer. Lateral spreading can extend several hundred feet from a slope, and displacements of tens of feet can occur if soil conditions are especially favorable for liquefaction and if earthquake shaking is of sufficient duration. Lateral spreading was responsible for most of the pipeline failures in San Francisco during the 1989 Loma Prieta earthquake.

During an earthquake, underground utilities tend to fail at the interface between a softer unit and a stiffer unit due to the settlement that occurs within the softer unit, a phenomenon known as differential settlement. The unconsolidated sediments underlying water crossings are typical examples of such conditions. During the Loma Prieta earthquake, differential settlement due to groundshaking resulted in water pipeline ruptures in the Marina District of San Francisco. Differential settlement is of most concern, as it can cause the uneven movement of pipelines, resulting in substantial damage to pipelines, including cracks and breakage.

Other Facilities. Liquefaction can result in a loss of bearing capacity, subsidence, and lateral spreading, all of which can cause serious building foundation failures, and naturally buoyant structures such as underground storage tanks can also be raised above ground. In response to seismically induced settlement, buildings and other structures can settle and tilt. Differential settlement is of most concern because it can cause uneven movement of foundations, resulting in significant damage to structures.

San Joaquin Region

Impact 4.4-7: Seismically induced ground failure, including liquefaction and settlement		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	LS
Tesla Portal Disinfection	SJ-5	LS

Seismic hazard maps have not been prepared for the San Joaquin Valley, and the CGS does not indicate plans for completing maps for this region. However, some areas are potentially liquefiable, including near-surface soils comprised of sandy and gravelly alluvial deposits and areas of shallow groundwater along the eastern margin of the Coast Ranges, where the following WSIP projects or facilities would be located: Advanced Disinfection (SJ-1), Lawrence Livermore (SJ-2), Tesla Portal Disinfection (SJ-5), and the western pipeline segments of the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects. However, the SJPL System project would include construction of a fourth pipeline parallel to the existing pipelines as well as two crossover facilities, and the SJPL Rehabilitation project includes a conditions assessment and rehabilitation of the existing San Joaquin Pipelines where improvements are needed. Rehabilitation of the pipelines to current seismic design criteria would improve the reliability of the San Joaquin Pipelines and reduce the potential for failure in the event of liquefaction or settlement. Because each of these projects would be designed and constructed in accordance with the *General Seismic Design Requirements*, impacts related to liquefaction and other seismically induced ground failures are considered *less than significant* for all San Joaquin Region projects.

Sunol Valley Region

Impact 4.4-7: Seismically induced ground failure, including liquefaction and settlement		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	LS
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	LS

Of the six WSIP projects in the Sunol Valley Region, a seismic hazard map has been prepared only for an area covering the western portion of the New Irvington Tunnel (SV-4, shown on the Niles quadrangle); based on this mapping, the western portion of the New Irvington Tunnel does not pass beneath any zones of potential liquefaction. The CGS plans to prepare a seismic hazard map for the La Costa Valley quadrangle, where many of the Sunol Valley projects would be constructed.

The USGS liquefaction susceptibility mapping delineates areas of moderate to very high liquefaction potential in the Sunol Valley Region. The highest liquefaction potential is in areas of Quaternary deposition on the valley floor and along the drainage of Alameda Creek. The

Alameda Creek Fishery project (SV-1) and the pipeline component of the 40-mgd Treated Water project (SV-3) would be located in areas with moderate to very high liquefaction susceptibility. A portion of the SABUP project (SV-6) would also be located in areas with moderate to very high liquefaction susceptibility. However, this project would provide a redundant pipeline to the existing San Antonio Pipeline, and new discharge facilities would allow discharge to San Antonio Creek during an emergency outage. Because these projects would be designed and constructed to withstand liquefaction and settlement in accordance with the *General Seismic Design Requirements*, impacts related to liquefaction and other seismically induced ground failures are considered *less than significant* for these projects.

The Calaveras Dam (SV-2), New Irvington Tunnel (SV-4), and Treated Water Reservoirs (SV-5) projects are located in areas designated as having low to very low susceptibility to liquefaction; therefore, potential impacts related to liquefaction and other seismically induced ground failures would be *less than significant* for these projects.

Bay Division Region

Impact 4.4-7: Seismically induced ground failure, including liquefaction and settlement		
BDPL Reliability Upgrade	BD-1	LS
BDPL 3 and 4 Crossovers	BD-2	LS
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	LS

The Niles and Newark seismic hazard maps cover the segment of the BDPL Reliability Upgrade project (BD-1) to the east of the bay, and maps are planned or under preparation for the segment of this project to the west of the bay. Based on existing seismic hazard mapping, most of the eastern segment of the BDPL Reliability Upgrade traverses a zone of potential liquefaction. USGS mapping also indicates that the eastern segment of the pipeline traverses areas of moderate to very high liquefaction susceptibility.

The existing Bay Division Pipelines Nos. 3 and 4 traverse a broad area mapped by the CGS as having liquefaction potential, and by the USGS as having moderate to very high liquefaction susceptibility. These liquefaction-susceptible areas are located along the San Francisco Bay margins, where recent deposition has created a thick stratum of Holocene-age alluvium (greater than 60 feet in some areas). Significant bay filling has also created more liquefaction-prone areas of artificial fill. The BDPL 3 and 4 Crossovers (BD-2) and BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) projects would be constructed on these existing pipeline segments in an area of liquefaction potential.

The BDPL Reliability Upgrade project (BD-1) would include construction of new seismically improved pipeline between the Irvington and Pulgas Portals; the BDPL 3 and 4 Crossovers (BD-2) would increase the reliability of water service delivery by reducing the amount of pipeline that would need to be taken out of service at one time; and the BDPL 3 and 4 Seismic Upgrade at Hayward Fault project (BD-3) would include construction of upgraded, seismically resistant sections of the Bay Division Pipelines Nos. 3 and 4 where they cross the Hayward fault. Because these projects would be designed and constructed to withstand liquefaction and settlement in accordance with the *General Seismic Design Requirements*, impacts related to liquefaction and other seismically induced ground failures are considered *less than significant* for all Bay Division Region projects.

Peninsula Region

Impact 4.4-7: Seismically induced ground failure, including liquefaction and settlement		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS

The CGS plans, but has yet to prepare, seismic hazard maps delineating areas of potential liquefaction for the Peninsula Region to the south of San Francisco. USGS mapping delineates areas of moderate liquefaction potential at the south end of Lower Crystal Springs Reservoir, where the Pulgas Balancing Reservoir project (PN-5) would be constructed, and between the Lower and Upper Crystal Springs Reservoirs, where the Crystal Springs/San Andreas Pipeline would be repaired or replaced under the CS/SA Transmission project (PN-2). However, whether repaired or replaced, this pipeline would improve the reliability of water conveyance from Crystal Springs Reservoir to the Harry Tracy WTP. Because these projects would be designed and constructed to withstand liquefaction and settlement in accordance with the *General Seismic Design Requirements*, impacts related to liquefaction and other seismically induced ground failures are considered *less than significant* for these projects.

Other WSIP facilities in this region are located in areas underlain by Pleistocene and older bedrock units that have low to very low liquefaction susceptibility as mapped by the USGS. Therefore, the potential for liquefaction at the remaining facilities in this region is low, and impacts related to liquefaction other seismically induced ground failures would be *less than significant* for the Baden and San Pedro Valve Lots (PN-1), HTWTP Long-Term (PN-3), and Lower Crystal Springs Dam (PN-4) projects.

San Francisco Region

Impact 4.4-7: Seismically induced ground failure, including liquefaction and settlement		
SAPL 3 Installation	SF-1	LS
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	LS

Based on CGS seismic hazard mapping, the SAPL 3 Installation project (SF-1) could cross several small areas of potential liquefaction in the vicinity of Lake Merced. However, the project would repair and replace portions of the existing Crystal Springs Pipeline No. 2 to improve the seismic reliability of the water system. Final locations have not been selected, but the Local Groundwater Projects (SF-2) and Recycled Water Projects (SF-3) could be constructed in areas of potential liquefaction mapped by the CGS in the vicinity of Lake Merced and along the coastline in the Sunset District and Golden Gate Park to the north. The CGS plans, but has yet to prepare, seismic hazard maps for the Peninsula Region to the south of San Francisco, where the Regional Groundwater Projects (SF-2) would be constructed. However, these projects would be designed and constructed to withstand liquefaction in accordance with the *General Seismic Design Requirements*, and impacts related to liquefaction and other seismically induced ground failures would be *less than significant* for all San Francisco Region projects.

In addition, if the Recycled Water Projects (SF-3) are located in a CGS zone of potential liquefaction, construction of the treatment plant under this project would be required to comply with Seismic Hazards Mapping Act requirements (described in the Setting), because the plant would likely be staffed for more than 2,000 hours per year. The applicability of this act would be determined during separate, project-level CEQA environmental review of this project.

Impact 4.4-8: Seismically induced landslides or other slope failures.

Impact 4.4-8: Seismically induced landslides or other slope failures		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	N/A
SJPL Rehabilitation	SJ-4	N/A
Tesla Portal Disinfection	SJ-5	LS
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	LS
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	LS
BDPL Reliability Upgrade	BD-1	LS
BDPL 3 and 4 Crossovers	BD-2	N/A
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	N/A
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS
SAPL 3 Installation	SF-1	LS
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	LS

As discussed in Impact 4.4-1, many WSIP projects would be located in areas mapped as "many landslides" (USGS, 1997). Therefore, the potential exists for seismically induced ground failure in the form of landsliding or ground-cracking at these sites. Slope instability (including landslides, earth flows, and debris flows) could undermine foundations, cause distortion and distress to overlying structures, and displace or destroy project components. However, all WSIP projects would be designed and constructed to withstand or avoid seismically induced landslides in accordance with the *General Seismic Design Requirements.* Therefore, impacts related to seismically induced landslides or other slope failures would be *less than significant* for all WSIP projects located in an area susceptible to landslides. Implementation of Alameda WMP Policies 55 and 56 described in Impact 4.4-1 would also be required for projects located in the Alameda and Peninsula watersheds. Similar to Impact 4.4-1, this impact would *not apply* to projects located outside of areas susceptible to landslides.

None of the WSIP facilities intended for human occupancy are located in areas mapped by the CGS as having the potential for seismically induced landslides, and these facilities would thus not be subject to the Seismic Hazards Mapping Act. If seismic hazard mapping is completed in San Mateo County by the time of construction, improvements at the Harry Tracy WTP under the HTWTP Long-Term project (PN-3) could be subject to Seismic Hazards Mapping Act requirements (described in the Setting).

Geologic Hazard Impacts

Impact 4.4-9: Expansive or corrosive soils.

Problematic soils, including corrosive and expansive soils, can cause damage to structures and buried utilities and can also increase required maintenance. Depending on the degree of corrosivity of the subsurface soils, building materials such as concrete, reinforcing steel in concrete structures, and bare-metal structures exposed to these soils can deteriorate, eventually leading to structural failures. Expansion and contraction of expansive soils in response to changes in moisture content can lead to differential and cyclical movements that can cause damage and/or distress to structures and equipment.

Some of the natural soil types identified within the WSIP project areas are known to be corrosive or expansive. Under the CBC, the expansive characteristics of a soil would be determined according to Uniform Building Code Standard 18-2, and the soil classified according to CBC Table 18A-1-B. For projects located on soil with an expansion index greater than 20, a geotechnical investigation could be required. If the soil expansion index varies with depth, the variation would be included in the engineering analysis of the effects of expansive soils on the structure. The report for the geotechnical investigation would provide a recommended foundation type, design criteria (including bearing capacity), and provisions to protect against the effects of expansive soils. The geotechnical report would also identify the total and differential settlement that could occur.

Examples of measures that could be taken to correct for expansive soils include removing unsuitable subgrade soils and replacing them with engineered fill, supporting structures on deep-pile foundation systems, densifying compactable subgrade soils with in-situ techniques, and placing moisture barriers above and around expansive subgrade soils to help prevent variations in soil moisture content. Examples of measures that could be taken to correct for corrosive soils include installing cathodic protection systems to protect buried metal utilities, using coated or nonmetallic (i.e., concrete or PVC) pipes not susceptible to corrosion, and constructing foundations using sulfate-resistant concrete.

All WSIP projects are located in an area of potentially corrosive or expansive soil, as discussed below; therefore, this impact is considered potentially significant for all projects. However, the site-specific information analyzed in accordance with SFPUC Construction Measure #2 (seismic and geotechnical studies) and during separate, project-level CEQA review would either confirm the program-level determination or provide a basis to revise this determination.

San Joaquin Region

Impact 4.4-9: Expansive or corrosive soils		
Advanced Disinfection	SJ-1	PSM
Lawrence Livermore	SJ-2	PSM
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	PSM

Based on the STATSGO Map (described in the setting), the distribution of soil units in the San Joaquin Region is highly variable. **Table 4.4 6** summarizes the characteristics of the major soil types that could be encountered during construction of the new pipeline

TABLE 4.4-6
MAJOR SOIL TYPES FOR SAN JOAQUIN REGION PROJECTS

Unit ID	Soil Association	Description	Shrink/Swell Potential	Risk of Corrosion: Concrete	Risk of Corrosion: Uncoated Steel
CA402	Auburn–Whiterock–Rock Outcrop	Soils consist of silt loam and loam.[a] Shallow soils formed on amphibolite schists and other metasedimentary rock types.	Low to High	Low to Moderate	Moderate to High
CA431	Pentz–Peters–Pardee	Predominantly shallow soils formed in material weathered from andesitic tuffaceous sediments, some soils formed in mixed alluvium. Soils consist of clay, fine sandy loam, and gravelly to cobbly loam.	Low, with some areas of Moderate to High	Low to Moderate	Moderate to High
CA469	Capay–El Sloyo–Vernalis	Very deep soils consisting of clay, clay loam, and silty clay loam that form on fine-grained alluvial fans and flats.	Moderate to High	Low to Moderate	High
CA470	Carbona–Capay–Calla	Soils consist of clays and clay loams. Deep soils formed in fine alluvial fans and terraces.	Moderate to High	Low to Moderate	High
CA484	Vernalis–San Emigdio–Garretson	Soils consist of clay loam, loam, sandy loam, gravelly loam, and gravelly sandy loam. Very deep soils that form on alluvial fans and floodplains.	Low to Moderate	Low	Moderate to High
CA485	Capay–Zacharias–Stomar	Very deep soils formed in fine-grained alluvium consisting of clay and clay loam.	Low to High	Low to Moderate	Moderate to High

[a] Loam soil composed of sand, silt, clay, and organic matter in evenly mixed particles of various sizes.

SOURCES: NRCS, 1994 and 2007.

segments and disinfection facilities. Some soil types exhibit a high shrink/swell potential and some exhibit a high risk of corrosion to uncoated steel. Therefore, impacts related to expansive and corrosive soils would be *potentially significant* for all San Joaquin Region projects (Advanced Disinfection, SJ-1; Lawrence Livermore, SJ-2; SJPL System, SJ-3; SJPL Rehabilitation, SJ-4; and Tesla Portal Disinfection, SJ-5). However, implementation of SFPUC Construction Measure #2 (seismic and geotechnical studies) and characterization of the extent of expansive and corrosive soils (Measure 4.4-9), including conformance with CBC requirements, would reduce this impact to a less-than-significant level.

Sunol Valley Region

Impact 4.4-9: Expansive or corrosive soils		
Alameda Creek Fishery	SV-1	PSM
Calaveras Dam	SV-2	PSM
40-mgd Treated Water	SV-3	PSM
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	PSM
SABUP	SV-6	PSM

Soils in the Sunol Valley Region consist of one soil association, the Millsholm–Los Osos–Los Gatos Association. **Table 4.4-7** summarizes the characteristics of this soil type. The major soil type in this region exhibits a moderate shrink/swell potential and a high risk of corrosion to uncoated steel. Therefore, impacts related to expansive and corrosive soils are *potentially significant* for the Sunol Valley Region projects (Alameda Creek Fishery, SV-1; Calaveras Dam, SV-2; 40-mgd Treated Water, SV-3; New Irvington Tunnel, SV-4; Treated Water Reservoirs, SV-5; and SABUP, SV-6), but would be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #2 (seismic and geotechnical studies) and characterization of the extent of expansive and corrosive soils (Measure 4.4-9), including conformance with CBC requirements.

TABLE 4.4-7
MAJOR SOIL TYPES FOR SUNOL VALLEY REGION PROJECTS

Unit ID	Soil Association	Description	Shrink/Swell Potential	Risk of Corrosion: Concrete	Risk of Corrosion: Uncoated Steel
CA423	Millsholm–Los Osos–Los Gatos	Moderately deep to shallow soils formed in material weathered from sandstone and shale consisting of clay, clay loam, loam,[a] and sandy loam.	Low, some areas of Moderate	Low to Moderate	Moderate to High

[a] Loam soil composed of sand, silt, clay, and organic matter in evenly mixed particles of various sizes.

Bay Division Region

Impact 4.4-9: Expansive or corrosive soils		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	PSM
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSM

The distribution of soil types in this region is also highly variable, with soils of varying expansive and corrosive properties. **Table 4.4-8** summarizes the characteristics of the major soil types that could be encountered during construction of the new pipeline and new pipeline interties, valve structures, and crossover facilities. Some soil types exhibit a high shrink/swell potential and some exhibit a high risk of corrosion to uncoated steel. Therefore, impacts related to expansive and corrosive soils are *potentially significant* for the all projects in this region (BDPL Reliability Upgrade, BD-1; BDPL 3 and 4 Crossovers, BD-2; and BDPL 3 and 4 Seismic Upgrade at Hayward Fault, BD-3), but would be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #2 (seismic and geotechnical studies) and characterization of the extent of expansive and corrosive soils (Measure 4.4-9), including conformance with CBC requirements.

TABLE 4.4-8
MAJOR SOIL TYPES FOR BAY DIVISION REGION PROJECTS

Unit ID	Soil Association	Description	Shrink/Swell Potential	Risk of Corrosion: Concrete	Risk of Corrosion: Uncoated Steel
CA202	Reyes–Novato–Tamba	Deep soils formed in alluvium next to bays and in marshes consisting of silty clay, clay, and mucky clay.	Moderate to High	Low to High	High
CA240	Clear Lake–Pescadero–Cropley	Deep to very deep soils formed in fine-grained alluvium. Soil types include clay, silty clay, and silty clay loam.[a]	Low to High	Low to Moderate	Moderate to High
CA242	Danville–Botella–Urban Land[b]	Very deep soils formed in alluvial fans and terraces consisting of clay, sandy clay loam, silty clay loam, sandy clay, and clay loam.	Moderate to High	Low to Moderate	Moderate to High
CA592	Urban Land–Xerorthents[c]–Accelerator	Deep soil formed in material weathered from soft sandstone and siltstone. Consists of loam, clay, and gravelly clay loam.	Low to High	Low to Moderate	Moderate to High
CA593	Accelerator–Fagan–Urban Land	Deep soil formed in material weathered from soft sandstone and siltstone. Consists of loam, clay loam, clay, and gravelly clay loam.	Low to High	Low to Moderate	Moderate
CA595/596	Associations including varying amounts of Urban Land, Xerorthents, and Botella	Very deep soils formed in alluvium from sedimentary rocks consisting of silty clay loam, sandy clay, and clay loam.	Moderate to High	Moderate to High	Moderate to High

4.5 Hydrology and Water Quality

4.5 Hydrology and Water Quality

4.5.1 Setting

WSIP facility improvement projects would be located in several major watersheds within and near the San Francisco Bay and San Joaquin River areas, and major project activities would occur in or adjacent to water bodies that support substantial beneficial uses for both wildlife and humans. Major water bodies in the WSIP program area are shown in **Figure 4.5-1**. This section discusses the major water bodies or watersheds that could be affected by the WSIP projects and identifies potential flooding issues in the vicinity of WSIP projects.

San Joaquin Region

The Tuolumne River, Stanislaus River, San Joaquin River, Delta-Mendota Canal, and California Aqueduct are the major water bodies within this region (Figure 4.5-1).

Tuolumne River

The Tuolumne River and watershed are described in Chapter 5, Section 5.3, Tuolumne River System and Downstream Water Bodies.

Stanislaus River

The Stanislaus River is a tributary to the San Joaquin River, which flows westward from the Sierra Nevada roughly parallel to and north of the Tuolumne River; the Hetch Hetchy Aqueduct runs between these two rivers. The North and Middle Forks of the Stanislaus River originate in Alpine County, while the South Fork originates in the Emigrant Wilderness north of Yosemite National Park. All three forks converge before the river enters New Melones Reservoir.

Delta-Mendota Canal

The Delta-Mendota Canal is a 120-mile-long component of the Central Valley Project, a system of irrigation and hydroelectric canals and dams. The Delta-Mendota Canal is used for irrigation water. The Tracy Pumping Plant is located at the northern end of the canal and diverts water to it from the Delta Cross Channel. The canal runs south along the western edge of the San Joaquin Valley and ends at the San Joaquin River near the town of Mendota, just west of Fresno. The Hetch Hetchy Aqueduct crosses over the canal west of Modesto. The Delta-Mendota Canal is operated by the Delta-Mendota Water Authority, which is responsible for maintaining the quality of the water discharged from the south end of the canal.

San Joaquin River

The San Joaquin River originates from Thousand Island Lake near Mount Ritter, high on the western slopes of the Sierra Nevada, in the Ansel Adams Wilderness near Mammoth Mountain. The San Joaquin River drains most of the area from the southern border of Yosemite National Park south to Kings Canyon National Park, making it the second largest river drainage in the state. The river emerges from the foothills at the former town of Millerton; Friant Dam, located in Millerton since 1944, forms Millerton Lake. From the foothills, the river flows west to the trough of the Central Valley, where its major tributaries include the Stanislaus River, Tuolumne River, Merced River, Calaveras River, and Mokelumne River; it then flows north to the Sacramento–San Joaquin Delta and on to San Francisco Bay. The Hetch Hetchy Aqueduct crosses the river west of Modesto.

California Aqueduct

The California Aqueduct is a concrete-lined aqueduct that transports water from Northern California to Southern California. It is the main water transport structure of the State Water Project and, at nearly 450 miles in length, is the longest water channel in California. The aqueduct, built by the California Department of Water Resources, begins at the Sacramento River Delta and carries water south through the Central Valley, where it often parallels Interstate 5 (I-5). Here, the coastal branch splits off in a southwesterly direction to serve the central coast. The Hetch Hetchy Aqueduct crosses over the California Aqueduct west of Modesto. At Bakersfield, water is pumped up 2,000 feet to cross the Tehachapi Mountains.

Corral Hollow Watershed

Both the Advanced Disinfection (SJ-1) and the Tesla Portal Disinfection (SJ-5) facilities would be located at Tesla Portal, which is in the Corral Hollow Creek watershed on the eastern flank of the Coast Ranges in San Joaquin County. This watershed is within the overall Old River watershed but is hydraulically divided from the watershed by I-580, the California Aqueduct, and the Delta-Mendota Canal. Surface drainages in the Corral Hollow Creek watershed are not well defined due to limited precipitation. However, no surface runoff from the Tesla Portal site or the surrounding area contributes water to the aqueduct or canal or directly to Corral Hollow Creek.

Flooding

The San Joaquin Pipeline system crosses a 3.6-mile-wide section of the 100-year flood zone of the San Joaquin River (FEMA, 2004). The pipeline system crosses no other 100-year flood zones in the San Joaquin Region.

Sunol Valley Region

Alameda Creek Watershed

All of the Sunol Valley Region projects are located in the Alameda Creek watershed on watershed lands owned by the City and County of San Francisco (CCSF) (see Figure 2.2 in Chapter 2). The Alameda Creek watershed is the largest drainage in the southern San Francisco Bay region, encompassing 633 square miles, and includes remote wildlands along upper Alameda Creek within the Sunol and Ohlone Regional Wilderness Preserves and SFPUC Alameda watershed lands. The watershed is comprised of the Livermore Drainage Unit and the Southern Alameda Creek Drainage Unit (SFPUC, 2001).

SFPUC Water System Improvement Program . 203287

Figure 4.5-1b
Major Streams and Rivers

All of the Sunol Valley Region projects are located in the Southern Alameda Creek Drainage Unit; this unit encompasses 175 square miles, of which approximately one-third, or approximately 36,000 acres, are owned by the CCSF. These landholdings are split between Alameda County (23,000 acres) and Santa Clara County (13,000 acres). Major water bodies located within the southern Alameda Creek watershed, and on CCSF-owned lands, include the Calaveras and San Antonio Reservoirs, Alameda Creek, Arroyo Hondo, Calaveras Creek, and San Antonio Creek (see Figure 4.5-1).

The SFPUC Alameda watershed lands include primary and secondary watershed lands. The 30,000 acres of primary watershed lands are tributary to the San Antonio and Calaveras Reservoirs and Alameda Creek. The 6,000 acres of secondary watershed lands are tributary to Alameda Creek below Calaveras Dam, San Antonio Dam, and the Alameda Creek Diversion Dam. The Calaveras Dam (SV-2), 40-mgd Treated Water (SV-3), and Treated Water Reservoirs (SV-5) projects and part of the Alameda Creek Fishery project (SV-1) are located in the CCSF-owned primary watershed lands, the most sensitive lands in terms of water quality protection. The New Irvington Tunnel (SV-4), and SABUP (SV-6) projects as well as the majority of the Alameda Creek Fishery project are located in the CCSF-owned secondary watershed lands.

Alameda Creek

Alameda Creek flows from its headwaters near Mount Hamilton northward through the Alameda watershed and the Sunol Valley, where it is joined by Arroyo de la Laguna. Alameda Creek then exits SFPUC lands through Niles Canyon and eventually drains to San Francisco Bay.

Calaveras Reservoir

Calaveras Reservoir is located at the southern end of the Alameda watershed; it is formed by Calaveras Dam, which is an earthen dam structure. The reservoir, originally constructed in 1913 and completed in 1925, collects and stores water from the local watershed, including drainage from Calaveras Creek and Arroyo Hondo, and has a tributary watershed area of approximately 98 square miles. The Alameda Creek Diversion Dam and Tunnel, constructed from 1925 to 1931 following completion of Calaveras Dam, divert flows and drainage from Alameda Creek to Calaveras Reservoir. Local runoff collected in Calaveras Reservoir is routed to the Sunol Valley Water Treatment Plant (WTP) by gravity flow through the Calaveras Pipeline.

Calaveras Reservoir is currently operating under restrictions imposed by the California Department of Water Resources, Division of Safety of Dams (DSOD) due to concern regarding the seismic stability of the dam. These restrictions allow the reservoir to be filled to about 40 percent of its maximum capacity; at this level, the reservoir has a surface area of 1.35 square miles and a storage capacity of 37,800 acre-feet.

San Antonio Reservoir

San Antonio Reservoir is formed by the James H. Turner Dam, an earthen dam completed in 1965. San Antonio Reservoir has a surface area of 1.3 square miles and a storage capacity of 50,300 acre-feet. The reservoir has a tributary watershed area of about 40 square miles and impounds water from San Antonio Creek. In addition to storing local runoff, San Antonio Reservoir is used to store Calaveras Reservoir surplus water, Hetch Hetchy water, and has received water from the South Bay Aqueduct during an extended drought. Water from San Antonio Reservoir is conveyed through the San Antonio Pipeline to the Sunol Valley WTP.

Flooding

Alameda Creek flows through much of the Sunol Valley Region, and stream flow is largely regulated by operation of the Calaveras and San Antonio Reservoirs, owned by the CCSF, and the Del Valle Reservoir, owned and operated by the California Department of Water Resources. Within the WSIP study area, the Alameda Creek Fishery (SV-1) and SABUP (SV-6) projects are located in 100-year flood zones designated on flood insurance maps (FEMA, 2000b). There are no mapped 100-year flood zones upstream of these projects, where the remainder of the Sunol Valley Region projects would be located.

Groundwater Resources

None of the proposed WSIP projects would substantially affect groundwater resources of the Sunol Valley, as described in Section 5.4.4. However, the New Irvington Tunnel project (SV-4) would penetrate marine rocks of the Diablo Range, which is composed of interbedded permeable sandstone and relatively impermeable shale (Water Infrastructure Partners, 2005). While these rocks do not produce commercial quantities of groundwater, they do produce some local domestic or stock water supplies, primarily through springs and shallow dug wells. In the 1930s, there were 104 wells, springs, or piezometers in the vicinity of the Irvington Tunnel, many of which are no longer in use or have been abandoned. The quality of water from these rocks tends to be poor.

Bay Division Region

The Bay Division Region includes many watersheds defined by intermittent and perennial drainages. Pipeline and related projects in this region would be constructed across or near numerous creeks and other water bodies; the main water bodies are shown in Figure 4.5-1. On the east side of San Francisco Bay, the right-of-way of the existing Bay Division Pipelines Nos. 1 and 2, where the BDPL Reliability Upgrade project (BD-1) would be constructed, crosses the following major water bodies: Mission Creek, Agua Caliente Creek, and Newark Slough. On the west side of the bay, the right-of-way of the Bay Division Pipelines Nos. 1 and 2 crosses Ojo de Agua Creek and Cordilleras Creek. The pipeline right-of-way also crosses unnamed creeks, drainages, and flood control channels on both sides of the bay. Major creeks or water bodies crossed by or near the right-of-way for the existing Bay Division Pipelines Nos. 3 and 4, where the BDPL 3 and 4 Crossovers (BD-2) and BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) would be constructed, include Barron Creek, Bear Gulch Reservoir, and the Guadalupe River.

Most of the creeks and flood control channels in each of the watersheds traversed by a Bay Division Region project discharge to sloughs in the tidal flats of South San Francisco Bay. Much of the land at the bay’s shore has been altered to form evaporative salt ponds, with drainage routed around dikes to the various sloughs.

Flooding

Flooding in the Bay Division Region occurs primarily along the bay margins and along individual streams. An extensive network of flood control channels has been constructed throughout this region, and flood control improvements have been made to many of the streams to contain the 100-year and 500-year floods. In some areas, flood flows are contained by levees.

Peninsula Region

Major water bodies in this region are shown in Figure 4.5-1. The primary watershed in the Peninsula Region is within the CCSF-owned Peninsula watershed, including the San Mateo Creek watershed and the Pilarcitos Creek watershed. Peninsula Region projects located at least partially in the Peninsula watershed include the Baden and San Pedro Valve Lots (PN-1), CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4), and the Pulgas Balancing Reservoir (PN-5) projects. The Lower Crystal Springs Dam project would also be located in the San Mateo Creek watershed.

Peninsula Watershed

The Peninsula watershed encompasses 23,000 acres of the San Francisco Peninsula, which is owned by the CCSF (see Figure 2.3 in Chapter 2). The watershed is located in central San Mateo County and includes the San Andreas and Upper and Lower Crystal Springs Reservoirs, adjacent to I-280 and the Pilarcitos Reservoir to the northwest.

Crystal Springs Reservoir

While originally built as two separate reservoirs, Upper and Lower Crystal Springs Reservoirs are connected through a culvert beneath Highway 92, so there is free exchange between the two reservoirs. Upper Crystal Springs Dam is an earthen dam built in 1877. Lower Crystal Springs Dam, a concrete gravity dam built on San Mateo Creek in 1888, was raised a few feet in 1891 and again in 1911. The combined Crystal Springs Reservoir has a design capacity of 69,320 acre-feet and a catchment area of 22.5 square miles, with 13.5 and 9 square miles in the drainages of the upper and lower reservoirs, respectively. The water level in Crystal Springs Reservoir has been lowered in accordance with a DSOD mandate and cannot be raised to its original level unless Lower Crystal Springs Dam is renovated to safely contain the probable maximum flood. This mandate has reduced the available water storage to an interim operating capacity of 58,400 acre-feet.

San Andreas Reservoir

San Andreas Reservoir is an earth-fill dam originally constructed in 1870. The reservoir has a tributary area of 4.4 square miles and provides a total of 19,000 acre-feet of storage.

Pilarcitos Reservoir

Pilarcitos Reservoir is formed by an earthen dam that was constructed in 1864 and raised in 1871. Stone Dam, a masonry-arch dam built in 1871, is located two miles downstream of Pilarcitos Reservoir. Pilarcitos Reservoir has a tributary area of 6 square miles and provides a total of

3,100 acre-feet of storage. The upper watershed has the highest annual rainfall on the Peninsula (42 inches).

Flooding

Flooding in the Peninsula Region is primarily related to individual streams, and flood control improvements have been made to many of the streams to contain the 100-year and 500-year floods. None of the Peninsula Region projects are located within or cross a 100-year floodplain.

San Francisco Region

There are currently no natural surface water bodies or streams in San Francisco, with the exception of Lobos Creek (which flows through the Presidio), San Francisco Bay, which borders the east and north sides of the city, and the Pacific Ocean to the west. Historically, there were small creeks flowing to the bay, but most of the creeks were filled during development of the city. Lake Merced is the only major open water body in San Francisco (see Figure 4.5-1).

Freshwater drainage in San Francisco has been almost entirely diverted to the city's combined sewer and stormwater system, which collects and transports both sanitary sewage and stormwater runoff in the same set of pipes. The stormwater drainage is conveyed through the combined sewer system, treated, and eventually discharged through outfalls and overflow structures along the shoreline. Water treatment plants on both the east and west sides of the city provide full secondary treatment for all dry-weather flow, and storage and discharge structures provide the equivalent of primary treatment for wet-weather flows when the treatment capacity of the water treatment plants is reached. Flows from these structures are discharged through combined sewer discharge structures located along the city's bayside and ocean waterfronts. Wet-weather flows are intermittent throughout the rainy season, and combined sewer discharges vary in nature and duration depending largely on the intensity of individual rainstorms.

Lake Merced

Lake Merced, described in Section 5.6, Westside Basin Groundwater Resources, is comprised of four lake bodies (North Lake, East Lake, South Lake, and Impound lake). As the largest freshwater body in San Francisco, Lake Merced supports numerous recreational activities.

Flooding

San Francisco is not presently mapped by the Federal Emergency Management Agency (FEMA), but localized flooding does occur during periods of intense precipitation, especially in low-lying areas where storm drains become clogged with debris.

Regulatory Framework

Water Quality Regulations

The federal Clean Water Act and subsequent amendments, under the enforcement authority of the U.S. Environmental Protection Agency (U.S. EPA), was enacted "to restore and maintain the chemical, physical, and biological integrity of the Nation's waters." The Clean Water Act gave the U.S. EPA the authority to implement pollution control programs such as setting wastewater standards for industry. The act also set water quality standards for surface waters and established the National Pollutant Discharge Elimination System (NPDES) program to protect water quality. Under Section 402 of the act, discharge of pollutants to navigable waters is prohibited unless the discharge is in compliance with an NPDES permit. The U.S. EPA determined that California's water pollution control program has sufficient authority to manage the NPDES program under state law in a manner consistent with the Clean Water Act. Therefore, implementation and enforcement of the NPDES program is conducted through the California State Water Resources Control Board (SWRCB) and the nine Regional Water Quality Control Boards (RWQCBs). These agencies also implement the Waste Discharge Requirements (WDR) Program, which regulates discharges of waste to land under the California Water Code as well as discharges of waste into waters of the state that are outside federal jurisdiction, as defined under the Clean Water Act.

The RWQCBs regulate water quality under the Porter-Cologne Water Quality Control Act through the regulatory standards and objectives set forth in water quality control plans (referred to as Basin Plans) prepared for each region. The Basin Plans identify existing and potential beneficial uses and provide numerical and narrative water quality objectives to protect those uses. The San Francisco Bay RWQCB (Region #2) is responsible for protection of the beneficial uses of San Francisco Bay Area water resources, including water bodies in the Sunol Valley, Bay Division, Peninsula, and San Francisco Regions. The San Francisco Bay RWQCB adopted its Basin Plan in 1995, and most recently revised the plan in December 2006. The Central Valley RWQCB (Region#5) has regulatory authority over water bodies in the San Joaquin Region. The Central Valley RWQCB adopted its Basin Plan in 1998, and most recently revised the plan in October 2007.

Beneficial Uses

Beneficial uses serve as a basis for establishing water quality objectives and discharge prohibitions to attain the goal of achieving the highest water quality consistent with the maximum benefit to the people of the state. Beneficial uses are designated in Basin Plans for surface waters and groundwater basins, and in the case of the San Francisco Bay Basin, wetlands. **Table 4.5-1** lists the designated beneficial uses for those water bodies that could be affected by the WSIP. The beneficial uses of the water bodies generally apply to all tributaries.

Impaired Water Bodies and Total Maximum Daily Loads

In accordance with Section 303(d) of the Clean Water Act, state governments must present the U.S. EPA with a list of "impaired water bodies," defined as those water bodies that do not meet water quality standards, even after point sources of pollution have installed the minimum required levels of pollution control technology. The law requires the development of actions, known as

TABLE 4.5-1
DESIGNATED BENEFICIAL USES

Water Body	Designated Beneficial Uses
San Joaquin Region	
San Joaquin River	MUN (potential), AGR, IND, MIGR, REC-1, REC-2, WARM, SPWN, WILD
California Aqueduct	MUN, AGR, IND, REC-1, REC-2, WILD
Delta-Mendota Canal	MUN, AGR, REC-1, REC-2, WARM, WILD
Sunol Valley Region	
Alameda Creek	AGR, COLD, GWR, MIGR, REC-1, REC-2, SPWN, WARM, WILD
Arroyo Hondo	COLD, FRSH, MUN, REC-1, REC-2, SPWN, WARM, WILD

San Francisco Bay, South	COMM, EST, IND, MIGR, NAV, RARE, REC-1, REC-2, SHELL, SPWN (potential), WILD

Beneficial Uses Key:

MUN (Municipal and Domestic Supply); AGR (Agriculture); REC-1 (Body Contact Recreation); REC-2 (Noncontact Recreation); WARM (Warm Freshwater Habitat); COLD (Cold Freshwater Habitat); MIGR (Fish Migration); SPWN (Fish Spawning); WILD (Wildlife Habitat); NAV (Navigation); GWR (Groundwater Recharge); FRSH (Freshwater Replenishment); RARE (Preservation of Rare and Endangered Species); SHELL (Shellfish Harvesting); COMM (Ocean, Commercial, and Sport Fishing); EST (Estuarine Habitat); IND (Industrial Service Supply); PROC (Industrial Process).

Note: Beneficial uses for specific wetland sites affected by the WSIP facility improvement projects in the San Francisco Bay region will be determined as needed based on the process described in the San Francisco Bay Basin Plan.

total maximum daily loads (TMDLs), to improve water quality of impaired water bodies. The TMDL is the quantity of a pollutant that can be safely assimilated by a water body without violating water quality standards. The listing of a water body as impaired does not necessarily suggest that the water body cannot support the beneficial uses; rather, the intent is to identify the water body as requiring future development of a TMDL to maintain water quality and reduce the potential for future water quality degradation. NPDES permits for water discharges must take into account the pollutant from which a water body is listed as impaired. Specific requirements for the permits would be specified in the TMDL for that pollutant.

Table 4.5-2 lists the water bodies in the program area that could be affected by WSIP projects and are identified on the Section 303(d) list of impaired water bodies, indicates the planned date for TMDL completion (based on information provided by the SWRCB), and identifies the water bodies for which a TMDL has been approved.

TABLE 4.5-2
SECTION 303(D) LIST OF IMPAIRED WATER BODIES

Water Body	Pollutant	Potential Source	Status of TMDL Preparation and Approval[a]
San Joaquin Region			
San Joaquin River	Boron	Agriculture	Planned (2006)

[a] The date of planned TMDL completion is provided in the 303(d) lists from the SWRCB. Although the planned date of completion has been passed for many of the TMDL projects, approved TMDLs have not been completed as of February 2006.

SOURCE: SWRCB, 2006a and 2006b.

Construction in Waters of the State and of the United States

The Regional Water Quality Control Board (RWQCB) has regulatory authority over construction in waters of the United States and waters of the state, including activities in wetlands, under both the Clean Water Act and the State of California's Porter-Cologne Water Quality Control Act (California Water Code, Division 7). Under the Clean Water Act, the RWQCB has regulatory authority over actions in waters of the United States through the issuance of water quality certifications under Section 401 of the Clean Water Act, which are issued in conjunction with permits issued by the Army Corps of Engineers (Corps) under Section 404 of the Clean Water Act. When the RWQCB issues a Section 401 certification for a project, the project is also regulated under State Water Resources Control Board Order No. 2003-0017-DWQ, "General Waste Discharge Requirements for Dredge and Fill Discharges That Have Received State Water Quality Certification," which requires compliance with all conditions of the water quality certification. Activities in areas that are outside the jurisdiction of the Corps (e.g., isolated wetlands, vernal pools, or stream banks above the ordinary high water mark) are regulated by the RWQCB under the authority of the Porter-Cologne Act. Activities that lie outside of Corps jurisdiction may require the issuance of either individual or general waste discharge permits.

The California Department of Fish and Game (CDFG) has jurisdiction over any activity that could affect the bank or bed of any stream that has value to fish and wildlife. If any changes are proposed along a creek or waterway within its jurisdiction, a streambed alteration agreement would be required under California Fish and Game Code Sections 1601 and 1603. Refer to Section 4.6, Biological Resources, for additional information.

Section 401 of the Clean Water Act provides the SWRCB and the RWQCBs with the regulatory authority to waive, certify, or deny any proposed federally permitted activity that could result in a discharge to surface waters of the state. To waive or certify an activity, these agencies must find that the proposed discharge will comply with state water quality standards, including protection of beneficial uses and water quality objectives. If these agencies deny the proposed activity, the federal permit cannot be issued. This water quality certification is generally required for projects involving the discharge of dredged or fill material to wetlands or other water bodies, as described in Section 4.6, Biological Resources.

NPDES Waste Discharge Regulations

The NPDES program requires all facilities that discharge pollutants into waters of the United States to obtain a permit. The discharge permit provides two levels of control for the protection of water quality: technology-based limits and water-quality-based limits. Technology-based limits are based on the ability of dischargers in the same category to treat wastewater, while water-quality-based limits are required if technology-based limits are not sufficient to provide protection of the water body. Water-quality-based effluent limitations required to meet water quality criteria in the receiving water are based on criteria specified in the National Toxics Rule, the California Toxics Rule, and the Basin Plan. NPDES permits must also incorporate TMDL waste load allocations when they are developed.

In 1972, the NPDES regulations initially focused on municipal and industrial wastewater discharges, followed by stormwater discharge regulations, which became effective in November 1990. NPDES permits for wastewater and industrial discharges specify discharge prohibitions and effluent limitations and also include other provisions (such as monitoring and reporting programs) deemed necessary to protect water quality. In California, the SWRCB and the RWQCBs implement and enforce the NPDES program.

Municipal Stormwater Permits

Stormwater in San Joaquin, Stanislaus, Tuolumne, Alameda, Santa Clara, and San Mateo Counties is managed in accordance with an NPDES permit from the San Francisco Bay or Central Valley RWQCB. These permits contain a comprehensive plan to reduce the discharge of pollutants to the "maximum extent practicable" and mandate that participating municipalities implement an approved stormwater management plan. The stormwater programs incorporate best management practices (BMPs) that include construction controls (such as a model grading ordinance), legal and regulatory approaches (such as stormwater ordinances), public education and industrial outreach (to encourage the reduction of pollutants at various sources), inspection activities, wet-weather monitoring, and special studies.

The RWQCBs added provision C.3 to municipal stormwater permits for Alameda, Santa Clara, and San Mateo Counties in 2003. In accordance with these updated requirements, new development and redevelopment projects are required to incorporate treatment measures and other appropriate source control and site design features to reduce the pollutant load in stormwater discharges and manage runoff flows. The required schedule for compliance is based on the size and type of project. Group 1 projects were required to comply with these requirements by February 15, 2005. This group includes previously undeveloped sites and redevelopment projects that involve the creation or replacement of one or more acre of impervious surfaces. Group 2 projects were required to comply with these requirements by August 15, 2006. These include new and redevelopment projects that involve the creation or replacement of 10,000 square feet or more of impervious surfaces.

The C.3 requirements are similar for all counties. However, local municipalities are phasing in these requirements, and specific procedures and application requirements may differ from one municipality to another. Reconstruction projects located within a public street or road right-of-way, such as some pipeline projects proposed as part of the WSIP, are exempt from the C.3 requirements where both sides of the right-of-way are developed.

San Francisco currently holds NPDES permits adopted by the RWQCB that cover the Oceanside Water Pollution Control Plant, the South East Water Pollution Control Plant, the North Point Wet Weather Facility, and all of the wet-weather facilities, including combined sewer discharges to the bay or ocean. The permits specify discharge prohibitions, dry-weather effluent limitations, wet-weather effluent performance criteria, receiving water limitations, sludge management practices, and monitoring and reporting requirements. The permits prohibit discharges from the combined sewer structures during dry weather, and require wet-weather discharges to comply with the nine minimum controls specified in the federal Combined Sewer Overflow Control Policy, including compliance with a specified number of combined sewer discharges.

Construction stormwater discharges from sites served by the combined sewer system are subject to the requirements of Article 4.1 of the San Francisco Public Works Code, which incorporates and implements the City's NPDES permit and the nine minimum controls described in the federal Combined Sewer Overflow Control Policy. The nine minimum controls include development and implementation of a pollution prevention program. At a minimum, the City requires that a project sponsor develop and implement an erosion and sediment control plan to reduce the impact of runoff from construction sites that are 0.5 acre or more in size. The City must review and approve the erosion and sediment control plan prior to implementation, and conducts periodic inspections to ensure compliance with the plan. Discharges during dewatering must also comply with Article 4.1, as supplemented by Order No. 158170.

Small areas within San Francisco, including Lake Merced, are served by separate stormwater systems that discharge without treatment of the stormwater. Discharges from these systems are regulated under the Statewide General Permit for Stormwater Discharges from Small Separate Storm Sewer Systems.

Regionwide General NPDES Permit for Discharges from Surface Water Treatment Facilities for Potable Supply

The San Francisco Bay RWQCB has issued the Regionwide General NPDES Permit for Discharges from Surface Water Treatment Facilities for Potable Supply (Order No. R2-2003-0062, NPDES General Permit No. CAG382001) to regulate the quality of discharges from water treatment plants to surface water (RWQCB, 2003). Covered discharges include filter backwash water discharge and storage/settling basin discharge; discharges from treatment unit overflow and broken waterlines within the treatment facility; leakage water; treatment unit dewatering/drainage water; treatment system flushing water during startup after facility shutdown; onsite water storage facility drainage; and excess raw water released from the treatment facility. The requirements of this general permit supersede other stormwater permitting requirements regulating discharges to the storm sewer system at a covered facility.

To obtain coverage under the general permit, the discharger must complete a notice of intent, including a description of all discharges that would be covered by the permit, water quality data for each discharge point, receiving water information, a site location map, a flow chart showing the general route taken by the effluent from intake to discharge, and a site-specific BMP plan. All dischargers must comply with the self-monitoring program required by the general permit, file annual reports in accordance with the standard provisions and reporting requirements for NPDES surface water discharge permits, and annually update the BMP plan.

If the discharger plans any modifications or maintenance at the facility that may result in a violation of effluent limitations or an alteration of discharge locations, the discharger is required to submit a schedule for approval by the RWQCB 30 days before the changes are made. The schedule must include a description of the modifications or maintenance, including the altered discharge characteristic or location(s) and its purpose; the period of the modification or maintenance; and steps taken to reduce, eliminate, and prevent occurrence of noncompliance.

General Order for Dewatering and Other Low Threat Discharges to Surface Waters

The Central Valley RWQCB has issued a General Order for Dewatering and Other Low Threat Discharges to Surface Waters (Order No. 5-00-175, NPDES No. CAG995001) to regulate the quality of discharges considered to have a low threat to water quality, including discharges from water supply systems (RWQCB, 2000). Similar to other NPDES permits, to obtain coverage under the general permit the discharger must complete a notice of intent. All dischargers must comply with specified effluent limitations and the self-monitoring program required by the general permit. Water suppliers with numerous discharge points may elect to prepare a pollution prevention plan and monitoring and reporting program rather than identify and monitor each discharge as required by the notice of intent and monitoring and reporting program.

Construction Stormwater NPDES Permit

The federal Clean Water Act prohibits discharges of stormwater from construction projects unless the discharge is in compliance with an NPDES permit. The SWRCB is the permitting authority in California and has adopted a Statewide General Permit for Stormwater Discharges Associated with Construction Activity (Construction General Permit) that encompasses one or more acres of soil disturbance (SWRCB, 1999). Construction activity includes clearing, grading, excavation, stockpiling, and reconstruction of existing facilities involving removal or replacement.

In general, the NPDES stormwater permitting requirements for construction activities require that the landowner and/or contractor submit a notice of intent and develop and implement a storm water pollution prevention plan (SWPPP). The SWPPP includes a site map(s) showing the construction site perimeter, existing and proposed buildings, lots, roadways, stormwater collection and discharge points, general topography both before and after construction, and drainage patterns across the site. The SWPPP must also specify BMPs that will be used to protect stormwater runoff as well as the placement of those BMPs; a visual monitoring program; a chemical monitoring program for non-visible pollutants to be implemented if there is a failure of BMPs; and a sediment monitoring plan if the site discharges directly to a water body listed as an impaired water body for sediment. Measures for erosion and sediment control, construction waste handling and disposal, and post-construction erosion and sediment control must also be addressed, along with methods to eliminate or reduce non-stormwater discharges to receiving waters.

The SWRCB is in the process of reissuing the Construction General Permit and released a preliminary draft of the new permit on March 2, 2007 (SWRCB, 2007). When adopted, this permit will replace the 1999 Construction General Permit, and, as proposed, would require the permittee to implement additional minimum BMPs as well as specific analytical procedures to determine whether the BMPs implemented on a construction site are (1) preventing further impairment due to sediment in stormwaters discharged directly into waters listed as impaired for sediment or silt, and (2) preventing non-visible pollutants in stormwater discharges from construction sites from causing or contributing to exceedances of water quality objectives. In addition, all sites would be required to meet new development and redevelopment performance standards to minimize or mitigate hydromodification impacts. As proposed, the permit allows for a risk-based permitting approach and specifies water quality action levels, numeric effluent levels, and detailed management practices. Under the new permit, the SWPPP must be prepared by a qualified SWPPP developer; the SWPPP would be much more limited and would be meant to demonstrate compliance with the detailed permit requirements, with less discretion in how these requirements are met. The permit would also enable public review and hearings on permit applications.

Construction Stormwater NPDES Permit for Small Linear Projects

The SWRCB considers certain projects involving the installation of underground and overhead utilities, such as installation of infrastructure, as small linear underground/overhead projects (referred to as small LUPs). Construction activities required for these projects have a lower potential to affect water quality via runoff than traditional construction projects because the projects are typically shorter in duration and constructed within or around hard paved surfaces, thus resulting in minimal disturbed land area at the close of the construction day. To simplify the stormwater permitting process for these projects, the SWRCB has issued the Statewide LUP General Permit for small LUPs that disturb more than one acre but less than five acres of land (SWRCB, 2003a). The LUP General Permit covers projects associated with private or municipal development projects, such as those operated by the LUP owner or operator, to relocate facilities in advance of pending developments or redevelopments or to provide new facilities.

Under the LUP General Permit, the owner/operator must submit the required notices; prepare a SWPPP specifying BMPs to control and reduce discharges of pollutants associated with construction stormwater runoff into storm drains and receiving waters; eliminate or reduce non-stormwater discharges to the storm sewers and receiving waters; and monitor the construction site to ensure that all BMPs are implemented, maintained, and effective. Permit requirements, such as the notification requirements, minimum SWPPP elements, and the amount and degree of monitoring vary depending on the complexity of the small LUP.

Waste Discharge Requirements

All point-source discharges of waste to land that do not involve the discharge of pollutants to surface waters are regulated under the WDR program implemented by the RWQCBs, including groundwater produced during dewatering as well as clear water (discharges to surface water are regulated under the NDPES program described above). Under this program, a discharger must complete a report of waste discharge with the appropriate RWQCB in order to obtain waste discharge requirements. These requirements, adopted under the WDR Program, protect surface water by either prohibiting the discharge of a pollutant to waters of the U.S. or identifying requirements for discharge to surface waters that are not waters of the U.S. They protect groundwater by identifying requirements for waste containment, treatment, and control. The report of waste discharge must include: a description of the facility or activity responsible for the discharge; the location of the operation; a description of the discharge by type, quality, quantity, interval, and method of discharge; identification of the source water contributing or transporting the waste; a water flow and location map identifying all discharge points; and a statement noting whether an environmental document has been or must be prepared. Filing of a report of waste discharge requires a fee, standard forms, and supporting technical information. The RWQCB can waive filing of a report or adopt waste discharge requirements. General orders have been prepared for certain types of similar discharges.

Statewide General Waste Discharge Requirements for Discharges to Land with a Low Threat to Water Quality

The SWRCB has issued the Statewide General Waste Discharge Requirements for Discharges to Land with Low Threat to Water Quality (Order No. 2003-003-DWQ) (SWRCB, 2003b) to regulate discharges to land that are considered to have a low threat to water quality. Categories of covered discharges include wastes from the installation of borings and wells, clear water discharges, small dewatering projects, and miscellaneous discharges. In accordance with this permit, all dischargers must comply with all applicable Basin Plan provisions, including any prohibitions and water quality objectives governing the discharge. In addition, the discharge of waste may not cause the spread of groundwater contamination. Discharges must be made to land owned or controlled by the discharger, unless the discharger has a written lease or agreement with the landowner.

Similar to the NPDES program, dischargers seeking coverage under this permit must submit a notice of intent to comply with the terms and conditions of this general permit or a report of waste discharge, fees, a project map, evidence of CEQA compliance, and a discharger monitoring plan.

The plan must include a list of all pollutants believed to be present in the discharge, the approximate concentration of pollutants in the discharge, monitoring locations, monitoring frequencies, and a reporting schedule.

Discharges to land listed as a hazardous materials site are not eligible for coverage under this general permit. In addition, discharges that could have a significant impact on biological resources, cultural resources, aesthetics, or air quality, or that could significantly alter the existing drainage pattern of a discharge site or surroundings are not eligible for coverage. Other discharges not covered under this permit are those that would significantly physically divide an established community, significantly conflict with any applicable land use plan, policy, or regulation of an agency, or significantly conflict with any applicable habitat or community conservation plan.

Discharge of Chlorinated Water

Because chlorine is toxic to aquatic life in both freshwater and saltwater, the SWRCB considers that every discharger that uses chlorine has the potential to cause acute toxicity due to total residual chlorine (TRC) in freshwater and chlorine-produced oxidants (CPO) in saltwater. However, the approach to regulating residual chlorine in discharges varies between regions. To facilitate a consistent approach, the SWRCB has proposed the Total Residual Chlorine and Chlorine-Produced Oxidants Policy of California to establish TRC and CPO objectives that apply to all inland surface waters, enclosed bays, and estuaries throughout the state to protect aquatic life beneficial uses; establish consistent procedures that apply to non-stormwater NPDES permits to regulate TRC and CPO discharges; and establish a basis for equitable compliance determination to adequately enforce violations of the TRC and CPO effluent limitations in non-stormwater NPDES permits (SWRCB, 2006c). The policy will also establish monitoring and reporting requirements to demonstrate compliance with effluent limitations. If adopted, the requirements of this policy will supersede all other numeric TRC or CPO objectives and implementation provisions for TRC and CPO in existing Basin Plans.

Recycled Water

The California Water Code defines recycled water (alternatively called reclaimed water) as “water which, as a result of treatment of waste [water], is suitable for a direct beneficial use or a controlled use that would not otherwise occur.” Recycled water is wastewater that has been highly purified through multiple stages of treatment to meet stringent and protective health and safety standards set by the California Department of Health Services (DHS). Federal laws provide regulation of recycled water through the Water Pollution Control Act of 1972 (also referred to as the Clean Water Act) and its related amendments. However, the State of California has primary responsibility for the development of regulations regarding the treatment and distribution of recycled water and operation of recycled water facilities. The following laws govern the use of recycled water in California:

- California Health and Safety Code (Division 104; Part 12)
- California Water Code (Division 7; Chapters 2, 6, 7, and 22)
- California Code of Regulations, Title 22 (Division 4; Chapters 1, 2, and 3)
- California Code of Regulations, Title 17 (Division 1; Chapter 5)

Recycled water laws are enforced by DHS and the San Francisco Bay RWQCB. In January 1996, the San Francisco Bay RWQCB adopted General Reuse Order 96-011 (RWQCB, 1996). This order applies to publicly owned wastewater and water agencies that are currently recycling water, or propose to do so in the future. The order authorizes domestic wastewater reuse by producers, distributors, and users throughout the region through a local agency administered program. An agency may apply for the order through the notice of intent process. General Order 96-011 replaces individual reuse orders for those agencies choosing to be included under General Order 96-011. The intent of the order is to streamline the permitting process and delegate the responsibility of administering water reuse programs to local agencies to the fullest extent possible.

In accordance with this order, the recycled water must meet DHS water quality reuse criteria, as specified in Sections 60301 through 60355 of Title 22 of the California Code of Regulations. These regulations provide specific treatment requirements as well as water quality criteria appropriate for the intended use of the recycled water. In addition, the order specifies prohibitions on the application of recycled water to ensure that this water does not enter a surface water body or otherwise degrade surface or groundwater quality. Recycled water that is treated to higher standards (i.e., advanced treatment) can be discharged to surface water bodies, including water bodies that allow body-contact water recreational activities (Section 60301.620).

An agency that produces recycled water must submit a notice of intent and technical report to both the RWQCB and DHS, including a description of the existing or proposed treatment, storage, and transmission facilities for water reuse; the types of applications for which the recycled water will be used; a description of the agency's water reuse permit program; a description of the reuse program administration specifying how the permitting system for regulating users will be implemented and how compliance with the DHS reuse criteria will be approved; and any additional site-specific information that is appropriate. The order becomes effective upon written approval of the notice of intent by the RWQCB.

The producer of recycled water must establish and enforce rules and regulations for recycled water uses that govern the design and construction of recycled water facilities and the reuse of recycled water in accordance with DHS reuse criteria. The producer must also develop a water reuse monitoring program in accordance with the self-monitoring requirements of the order, submit an annual monitoring report to the RWQCB, and conduct periodic inspections of the user's facilities and operations to monitor and assure compliance with the conditions of the producer's permit and Order 96-011.

In groundwater basins that are a significant source of drinking water, the RWQCB can require a salt management plan if there is a likely potential for salt buildup from irrigation with recycled water. In addition, the DHS is preparing Groundwater Recharge Reuse regulations for the use of recycled water for recharge of groundwater by surface spreading or subsurface injection (DHS, 2007), and a separate NPDES permit is required for use of recycled water for these purposes.

The CCSF's Reclaimed Water Ordinance, contained in Article 22 of the San Francisco Public Works Code, specifies that certain development projects of 40,000 square feet or more, and irrigated areas of 10,000 square feet or more that are located within designated Reclaimed Water Use Areas must use recycled water for nonpotable uses unless an exemption is granted. The owner, operator, or manager of a development project or irrigation system must register with the SFPUC (part of which was formerly known as the San Francisco Water Department) and obtain a reclaimed water use certificate for the reclaimed water system, and the SFPUC may inspect any recycled water operations to ensure compliance with the Reclaimed Water Ordinance, including mandatory use of recycled water. Golden Gate Park, Lincoln Park, Lincoln Park Golf Course, San Francisco Zoo, Sunset Boulevard medians, San Francisco State University, and Harding Park, which would use recycled water under the Recycled Water Projects (SF-3), and Lake Merced, which could be supplemented with recycled water under the Local Groundwater Projects (SF-2), are all located in a Reclaimed Water Use Area.

Dam Safety Regulations

The California Water Code entrusts the regulatory Dam Safety Program to the DSOD, which regulates dams that are 25 feet or more in height or have an impounding capacity of 50 acre-feet or more.[1] The principal goal of this program is to avoid dam failure and thus prevent loss of life and destruction of property. DSOD staff makes periodic inspections of dams and reservoirs under DSOD jurisdiction for the purpose of determining their safety, and may require dam owners to perform work to safeguard life and property. Construction of any new dam or the repair or alteration of an existing dam requires DSOD approval.

The California Office of Emergency Services dam failure inundation mapping and emergency procedure program requires the preparation of inundation maps, provides for inundation map waivers, and establishes emergency procedures for the evacuation and control of populated areas below dams under the jurisdiction of the DSOD. Inundation maps are prepared by the dam owner and represent the best estimate of where water would flow if a dam failed completely and suddenly with a full reservoir; copies of the maps are sent to the city and county emergency service coordinators of affected local jurisdictions. Based on approved inundation maps or information obtained in preparation of a waiver, cities and counties with territory in the mapped inundation areas are required to adopt emergency procedures for the evacuation and control of populated areas below dams where death or personal injury could occur.

Alameda County Watercourse Protection Ordinance

Chapter 13.12 of the Alameda County General Ordinances is the Watercourse Protection Ordinance, which requires permits from the County Director of Public Works for the following activities in all unincorporated lands within Alameda County:

- Discharging into or connecting any pipe or channel to a watercourse
- Modifying the natural flow of water in a watercourse
- Development within a setback, as defined by the ordinance

[1] Small dams with a height of 6 feet or less or an impounding capacity of 15 acre-feet or less are not subject to DSOD regulations.

- Depositing or planting materials in or removing any material from a watercourse, including its banks, except as required for necessary maintenance
- Constructing, altering, enlarging, connecting to, changing, or removing any structure in a watercourse
- Placing any loose or unconsolidated material along the side of or within a watercourse or so close to the side as to cause a diversion of the flow, or to cause a probability of such material being carried away by stormwater passing through the watercourse

This ordinance does not apply to the primary watershed lands owned by the SFPUC, but does apply to private lands in the watershed.

4.5.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to hydrology and water quality, but generally considers that implementation of the proposed program would have a significant hydrologic or water quality impact if it were to:

- Violate any water quality standards or waste discharge requirements (Evaluated in this section)
- Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of preexisting nearby wells would drop to a level that would not support existing land uses or planned uses for which permits have been granted) (Evaluated in this section)
- Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation on or off the site (Evaluated in this section)
- Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on or off the site (Evaluated in this section)
- Create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff (Evaluated in this section)
- Otherwise substantially degrade water quality (Evaluated in this section)
- Place housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other authoritative flood hazard delineation map (Not evaluated in this section, see Appendix B)
- Place within a 100-year flood hazard area structures that would impede or redirect flood flows (Evaluated in this section)

- Expose people or structures to a significant risk of loss, injury, or death involving flooding, including flooding as a result of the failure of a levee or dam (Not evaluated in this section, see Appendix B)
- Expose people or structures to a significant risk of loss, injury, or death involving inundation by seiche, tsunami, or mudflow (Not evaluated in this section, see Appendix B)

Approach to Analysis

This program-level analysis of water quality impacts is based on a general characterization of the potential for water quality degradation and increased erosion, sedimentation, and runoff attributable to the construction and operation of WSIP facility improvement projects and legal requirements for managing these issues. Mitigation measures are provided as necessary to mitigate potential impacts that could be significant even with implementation of SFPUC construction measures and compliance with legal requirements. In general, implementation of the WSIP projects would not have direct long-term effects on the hydrology or water quality of regional and local surface waters. However, short-term construction impacts could result in erosion and sedimentation or discharge of construction-related pollutants to local water bodies, causing water quality effects. Operation of some projects could also result in the discharge of chlorinated or chloraminated water, treated stormwater, or recycled water to water bodies, causing potential water quality effects. Through compliance with existing regulations and established project procedures as well as implementation of mitigation measures specified in this section, these impacts would be less than significant.

Impact Summary by Region

Table 4.5-3 provides a summary of the WSIP facility-related impacts by region.

Construction Impacts

Impact 4.5-1: Degradation of water bodies as a result of erosion and sedimentation or a hazardous materials release during construction.

In the absence of proper controls, construction activities associated with implementation of the WSIP adjacent to and through creeks could degrade water quality. Activities involving soil disturbance, such as excavation, soil stockpiling, or grading, adjacent to or near creeks or storm drains could result in substantial erosion and sedimentation, particularly if construction were to occur during the rainy season. Where construction or trenching activities would occur along the creek banks or would cross a creek, the potential for effects to creeks would increase due to the proximity of construction activities and the limited space for the construction easement. Sedimentation to the creeks would degrade water quality and could also increase channel siltation, reduce the flood-carrying capacity, and affect associated habitats (see Section 4.6, Biological Resources, for a discussion of facility impacts on aquatic habitats). In addition, the temporary storage of diesel and use of construction equipment could accidentally release construction-related chemicals, such as oil, grease, and fuel, which could degrade water quality.

TABLE 4.5-3
POTENTIAL IMPACTS AND SIGNIFICANCE – HYDROLOGY AND WATER QUALITY

Projects	Project Number	4.5-1: Degradation of water bodies as a result of erosion and sedimentation or a hazardous materials release during construction	Impact 4.5-2: Depletion of groundwater resources	Impact 4.5-3a: Degradation of water quality due to construction dewatering discharges	Impact 4.5-3b: Degradation of water quality due to construction-related discharge of treated water	Impact 4.5-4: : Flooding and water quality impacts associated with impeding or redirecting flood flows	Impact 4.5-5: Degradation of water quality and increased flows due to discharges to surface water during operation	Impact 4.5-6: Degradation of water quality as a result of alteration of drainage patterns or an increase in impervious surfaces

LS = Less than Significant impact, no mitigation required
PSM= Potentially Significant impact, can be mitigated to less than significant
N/A = Not Applicable

All WSIP projects would be required to implement SFPUC Construction Measure #3 (onsite air and water quality measures during construction), which requires the implementation of erosion control measures. For projects located outside of San Francisco that disturb more than one acre of land, construction activities would have to comply with the applicable NPDES permit implemented by the RWQCB. For construction of WSIP pipeline projects involving disturbance of one to five acres of land, the requirements of the LUP General Permit would apply. For construction of WSIP projects involving disturbance of one or more acres of land and pipeline projects involving more than five acres of temporary land disturbance, the requirements of the NPDES Construction General Permit would apply.

In accordance with these permits, the SFPUC or its contractor(s) would submit the required notices, develop a SWPPP, and implement site-specific BMPs in accordance with the SWPPP to control and reduce discharges of sediments and pollutants associated with construction stormwater runoff into storm drains and any receiving waters. These practices would include a provision requiring the placement of drip pans underneath heavy equipment that is stored overnight to prevent leaks of hydraulic fluids, oil, grease, or fuels from reaching an adjacent waterway or stormwater collection system.

The SWPPP would also include protection measures for the temporary onsite storage of diesel fuels used during construction, including requirements for secondary containment and berming of the diesel storage area or any chemical storage areas to contain a potential release and to prevent any such release from reaching an adjacent waterway or stormwater collection system. Non-stormwater discharges to the storm sewers and receiving waters would be eliminated or reduced and monitoring would be conducted to ensure that all BMPs are implemented, maintained, and effective. The control measures would also be consistent with the appropriate local guidelines for stormwater control and policies and actions of the SFPUC's Alameda and Peninsula Watershed Management Plans (WMPs) for projects located in these watersheds.

For projects located within San Francisco, the construction contractor(s) would obtain approval from the SFPUC and would comply with all permit requirements for the control of construction-related stormwater. Subject to the requirements of Article 4.1 of the San Francisco Public Works Code, the contractor(s) would be required, at a minimum, to develop and implement an erosion and sediment control plan to reduce the impact of runoff from the construction site. The erosion and sediment control plan must be reviewed and approved by the SFPUC prior to implementation, and the SFPUC would conduct periodic inspections to ensure compliance with the erosion and sediment control plan.

For projects not subject to NPDES or Article 4.1 requirements, SFPUC Construction Measure #3 (onsite air and water quality measures during construction) would require preparation and implementation of an erosion control plan for each facility site. The plan would provide both interim and permanent erosion control measures and requirements for secondary containment and berming of the diesel storage area or any chemical storage areas to contain a potential release and to prevent any such release from reaching an adjacent waterway or stormwater collection system.

In addition, WSIP projects in the Sunol Valley Region would be located within the Alameda watershed (and subject to the Alameda WMP), while some of the WSIP projects in the Peninsula Region would be located within the Peninsula watershed (and subject to the Peninsula WMP). Since these WSIP projects would be required to implement all pertinent WMP policies and actions, this analysis assumes the following actions pertaining to erosion and sedimentation would be implemented as part of the WSIP projects. (In the actions listed below, if two numbers are listed, the first number refers to the Alameda plan, and the second number refers to the Peninsula plan):

- *Action aqu1*. Prior to undertaking or constructing any non-water dependent facility or watershed activity, conduct site-specific review in conjunction with the review process for proposed plans and projects to ensure that the facility or activity is not located within a High Water Quality Vulnerability Zone. If feasible, relocate the activity or facility to an alternative upland site. If no feasible site exists, follow BMPs as set forth in Appendix C-6 of the Watershed Management Plan and minimize stream crossings.

- *Action aqu5*. Rehabilitate shoreline areas using structural shoreline protection practices in areas where erosion and sedimentation cannot be adequately controlled by land use restrictions.

- *Action veg4*. Prior to the initiation of any construction project involving grading, a grading plan shall be prepared by the project proponent and approved by appropriate SFPUC staff. Revegetation of all graded areas shall be required to the maximum extent practicable.

- *Action veg7/veg 9*. When conducting operations, maintenance, and construction activities, follow erosion control BMPs to ensure protection of wetlands, streams, and shoreline areas. BMPs provided in Appendix C-6 of the watershed management plan to be employed in the vicinity of wetlands and riparian areas shall be coordinated with the requirements of the CDFG Streambed Alteration Agreement and Clean Water Act Section 404 permit from the Army Corps of Engineers.

- *Action veg13/veg 17*. Encourage other agencies with interest in watershed lands to minimize the disturbance of serpentine bedrock or soils to prevent the erosion of asbestos fibers into the water supply.

Pipelines and Infiltration Galleries. The installation of pipelines would generally require excavation of a trench ranging from 5 to 8 feet deep and 2 to 5 feet wide for smaller pipe diameters, to as large as 15 feet deep and 12 feet wide where trenches are shored in congested areas. In open areas where the trenches would be constructed with sloped sides, the trench could be as wide as 50 feet at the surface. Pipelines would cross creek channels using cut-and-cover or open-cut methods for seasonal creeks during the dry season only, or jack-and-bore or microtunneling methods for perennial creeks. Rehabilitation of the infiltration galleries that could be conducted for the Alameda Creek Fishery project (SV-1) could also require excavation of substantial amounts of soil adjacent to Alameda Creek.

In addition to the NPDES requirements described above, the SFPUC or its contractor(s) would be subject to an encroachment permit from the local flood control district or other appropriate local agency. They must also comply with CDFG and U.S. Army Corps of Engineers (Corps) requirements pertaining to wetlands or streambeds, including associated water quality protection requirements of the applicable RWQCB.

Tunnels. Erosion and sedimentation during tunnel construction (and the resulting potential to degrade water bodies) would primarily be an issue at tunnel entry and exit shafts or portals where construction staging occurs, including the handling and removal of excavated materials (shaft/portal and tunnel spoils), and would depend on the extent of land disturbance and proximity to nearby water bodies. Construction activities at the tunnel portals would be subject to the NPDES Construction General Permit if more than one acre of land would be disturbed. Although a tunnel may pass beneath one or more water bodies, tunneling beneath water bodies would not result in increased sedimentation or erosion.

Other Facilities. Where feasible, WSIP facilities would be sited to avoid construction across creeks or other water bodies. The area of land disturbance required for construction would vary by project, and the potential for water quality effects related to construction activities would depend on a project's proximity to nearby water bodies and the size of the disturbed area. The applicable NPDES or erosion control requirements for construction activities would depend on the size and location of the project.

San Joaquin Region

Impact 4.5-1: Degradation of water bodies as a result of erosion and sedimentation or a hazardous materials release during construction		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	LS
Tesla Portal Disinfection	SJ-5	LS

The Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) projects would each disturb more than one acre of soil. These facilities are located adjacent to vegetated swales, and runoff from these sites would not directly enter a waterway. Pipeline construction associated with the SJPL System project (SJ-3) could disturb 400 or more acres of land and would cross the Delta-Mendota Aqueduct and California Aqueduct. The amount of land disturbance for the Lawrence Livermore (SJ-2) and SJPL Rehabilitation (SJ-4) projects has not been determined. However, with implementation of SFPUC Construction Measure #3 (onsite air and water quality measures during construction) and implementation of control measures in compliance with NPDES permit requirements for projects disturbing more than one acre of land, impacts related to the degradation of water bodies as a result of erosion and sedimentation during construction would be *less than significant* for all projects in this region. The SJPL System project would also be required to comply with encroachment permitting requirements and the requirements of other regulatory agencies, as described above.

Sunol Valley Region

Impact 4.5-1:	**Degradation of water bodies as a result of erosion and sedimentation or a hazardous materials release during construction**	
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	LS
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	LS

Erosion and sedimentation from the Sunol Valley Region projects could affect water quality in Alameda Creek, Calaveras Creek, Arroyo Hondo, San Antonio Creek, and several unnamed drainages. The Calaveras Dam (SV-2), 40-mgd Treated Water (SV-3), New Irvington Tunnel (SV-4), and Treated Water Reservoirs (SV-5) projects would each disturb more than one acre of land, with the Calaveras Dam project disturbing over 600 acres and the New Irvington Tunnel project disturbing an estimated 120 acres. The area of disturbance has not been determined for the Alameda Creek Fishery (SV-1) and SABUP (SV-6) projects. However, with implementation of SFPUC Construction Measure #3 (onsite air and water quality measures during construction) and implementation of control measures in compliance with NPDES permit requirements for projects disturbing more than one acre of land, impacts related to the degradation of water bodies as a result of erosion and sedimentation during construction would be *less than significant* for all projects in this region. The Alameda Creek Fishery, 40-mgd Treated Water, and SABUP projects would also involve creek or stream crossings and would be required to implement control measures to comply with encroachment permitting requirements and the requirements of other regulatory agencies, as described above. Projects in this region would also be required to implement policies and actions of the Alameda WMP regarding erosion control, also described above.

Bay Division Region

Impact 4.5-1:	**Degradation of water bodies as a result of erosion and sedimentation or a hazardous materials release during construction**	
BDPL Reliability Upgrade	BD-1	LS
BDPL 3 and 4 Crossovers	BD-2	LS
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	LS

Erosion and sedimentation from Bay Division Region projects could affect water quality in a number of water bodies. The BDPL Reliability Upgrade project (BD-1) would involve disturbance of more than 150 acres of land and would cross Newark Slough, Mission Creek, Agua Caliente Creek, Ojo de Agua Creek, and Cordilleras Creek as well as unnamed creeks, drainages, and flood control channels. The area of land disturbance has not been determined for the BDPL 3 and 4 Crossovers (BD-2) or BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) projects. However, with implementation of SFPUC Construction Measure #3 (onsite air and water quality measures during construction) and implementation of control measures in compliance with NPDES permit requirements for projects disturbing more than one acre of land, impacts related to degradation of water bodies as a result of erosion and sedimentation during construction would be *less than significant* for all projects in this region. Implementation of additional control measures in compliance with encroachment permitting requirements and the requirements of other regulatory agencies, as described above, would also be required for the BDPL Reliability Upgrade project.

Peninsula Region

Impact 4.5-1: Degradation of water bodies as a result of erosion and sedimentation or a hazardous materials release during construction		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS

Construction of the Lower Crystal Springs Dam project (PN-4) would involve land disturbance of approximately six acres. The amount of land disturbance has not been determined for the CS/SA Transmission (PN-2), HTWTP Long-Term (PN-3), and Pulgas Balancing Reservoir (PN-5) projects. Valve lot improvements under the Baden and San Pedro Valve Lots project (PN-1) would likely involve land disturbance of less than one acre at each construction site. However, with implementation of SFPUC Construction Measure #3 (onsite air and water quality measures during construction) and implementation of control measures in compliance with NPDES permit requirements for projects disturbing more than one acre of land, impacts related to degradation of water bodies as a result of erosion and sedimentation during construction would be *less than significant* for all projects in this region.

The Lower Crystal Springs Dam project (PN-4) would involve work in San Mateo Creek, and the Pulgas Balancing Reservoir project (PN-5) would enlarge Pulgas Channel. Encroachment permits and implementation of control measures in compliance with the requirements of other regulatory agencies could also be required for the Lower Crystal Springs Dam and Pulgas Balancing Reservoir projects.

Because they are located in the Peninsula watershed, the CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4), and Pulgas Balancing Reservoir (PN-5) projects as well as portions of the Baden and San Pedro Valve Lots project (PN-1) would also be required to implement policies and actions of the Peninsula WMP regarding erosion control, as described above.

San Francisco Region

Impact 4.5-1: Degradation of water bodies as a result of erosion and sedimentation or a hazardous materials release during construction		
SAPL 3 Installation	SF-1	LS
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	LS

As discussed in the Setting, most creeks within San Francisco were contained in underground culverts during urbanization of the city; most of the city is served by a combined sewer system that collects both sanitary sewage and stormwater and transports this combined flow to wastewater treatment plants. Discharges to the combined sewer system are treated and discharged to the bay or ocean in compliance with the City’s NPDES permit and must be in conformance with requirements of the Clean Water Act, Combined Sewer Overflow Control Policy, and the associated state requirements in San Francisco’s Basin Plan.

The SAPL 3 Installation project (SF-1) would be located partially within San Francisco and San Mateo Counties. The portions of this project located in San Francisco are served by the combined sewer system. The portions of the pipelines located in San Mateo County would be served by a separate sewer. However, with implementation of SFPUC Construction Measure #3 (onsite air and water quality measures during construction), implementation of control measures in compliance with NPDES permit requirements for those portions of the project disturbing more than one acre of land outside of San Francisco, and implementation of control measures in compliance with Article 4.1 of the San Francisco Public Works Code for those portions of the project within San Francisco, impacts related to the degradation of water bodies as a result of erosion and sedimentation during construction would be *less than significant* for the SAPL 3 Installation project.

Final locations for the Groundwater Projects (SF-2) have not been selected, but the local projects would be located in San Francisco and the regional projects would be located in San Mateo County. Final locations for the Recycled Water Projects (SF-3) have not been determined, but these projects would generally be located in San Francisco. With implementation of SFPUC Construction Measure #3 (onsite air and water quality measures during construction), implementation of control measures in compliance with NPDES permit requirements for projects disturbing more than one acre of land outside of San Francisco, and implementation of control measures in compliance with Article 4.1 of the San Francisco Public Works Code for projects within San Francisco, impacts related to the degradation of water bodies as a result of erosion and sedimentation during construction would be *less than significant* for these two projects.

Impact 4.5-2: Depletion of groundwater resources.

Construction Dewatering. Dewatering for construction of most facilities (except for tunnels, as discussed below) could temporarily affect groundwater levels in the shallow groundwater zones where WSIP facilities are located. As a result, water levels in shallow wells located near construction sites could be lowered temporarily. However, groundwater extracted from shallow sources tends to be of poor quality and unsuitable for human consumption; as a result, there would not likely be many domestic wells tapping the shallow groundwater zone near WSIP project facilities. Furthermore, any effects related to lowering the water table would be temporary. Therefore, groundwater dewatering would not be expected to substantially deplete shallow groundwater resources, and impacts related to the depletion of shallow groundwater resources are considered less than significant for all WSIP projects that would require dewatering.

Tunnels. Groundwater for domestic and other uses is commonly obtained from deeper groundwater-bearing zones that contain water of sufficient quality for the intended use. Groundwater dewatering, required for tunnel projects could affect water levels in the deeper groundwater-bearing zones by stopping or reducing the flow to springs or lowering groundwater levels in nearby wells, thus reducing the capacity of the wells or rendering them inoperable in the short or long term.

The use of a water-tight lining system and backfilling of the annular space between the pipe and the tunnel shaft would reduce the rate of groundwater infiltration and related groundwater dewatering requirements along much of the tunnel alignment. However, greater amounts of groundwater dewatering could be required for shaft or portal construction. After tunnel construction, the shafts or portals would be backfilled, and there would be no long-term groundwater infiltration into the shafts, portals, or tunnel.

San Joaquin Region

Impact 4.5-2: Depletion of groundwater resources		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	N/A
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	LS
Tesla Portal Disinfection	SJ-5	LS

Temporary groundwater dewatering could be required during construction of the Advanced Disinfection (SJ-1), SJPL System (SJ-3), SJPL Rehabilitation (SJ-4), and Tesla Portal Disinfection (SJ-5) projects. However, only shallow groundwater resources would be affected. Therefore, impacts related to the depletion of groundwater resources would be *less than significant* for these projects.

The Lawrence Livermore project (SJ-2) would not require construction dewatering or involve tunneling. Therefore, impacts related to the depletion of groundwater resources would *not apply* to this project.

Sunol Valley Region

Impact 4.5-2: Depletion of groundwater resources		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	N/A
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	N/A
SABUP	SV-6	LS

Springs located in the vicinity of the proposed alignment of the New Irvington Tunnel project (SV-4) indicate a groundwater level of at least 683 feet (more than 300 feet above the planned elevation of the tunnel bore), so considerable hydrostatic pressure can be expected at tunnel grade, and dewatering would be required during construction of the tunnel (Water Infrastructure Partners, 2005). Dewatering for construction of the existing Irvington Tunnel in the 1930s produced an average of about 250 gallons per minute (gpm) of groundwater and maximum sustained groundwater flows of about 1,000 gpm. This dewatering stopped or decreased flows in several local springs and caused groundwater levels to fall in some nearby wells. Under the New Irvington Tunnel project, groundwater dewatering would be conducted at rates of up to 2,000 gpm over a period of two years. Although many of the 104 wells noted in the vicinity of the Irvington Tunnel in the 1930s (described in the Setting) may have since been abandoned or may no longer be in use, construction of the tunnel and associated dewatering under the New Irvington Tunnel project could stop or decrease spring flow or lower groundwater levels in nearby wells, thus reducing the capacity of the wells or rendering them inoperable.

The effects of this dewatering on nearby springs and wells cannot be estimated without conducting an inventory of the existing springs and wells within the affected groundwater zone and performing additional site-specific analysis of the area’s geology and groundwater occurrence as well as dewatering requirements for the project. Therefore, impacts related to the depletion of groundwater resources are considered *potentially significant* for the New Irvington Tunnel project (SV-4), but would likely be reduced to a less-than-significant level though implementation of site-specific analysis and identified measures (as outlined in Measure 4.5-2). These impacts would be evaluated in greater detail as part of separate, project-level CEQA review for this project.

Temporary groundwater dewatering could be required during construction of the Alameda Creek Fishery (SV-1), Calaveras Dam (SV-2), and SABUP (SV-6) projects. However, only shallow groundwater resources would be affected. Therefore, impacts related to the depletion of groundwater resources would be *less than significant* for these projects. The 40-mgd Treated Water (SV-3) and Treated Water Reservoirs (SV-5) projects would not require construction dewatering or involve tunneling. Therefore, impacts related to the depletion of groundwater resources would *not apply* to these projects.

Bay Division Region

Impact 4.5-2: Depletion of groundwater resources		
BDPL Reliability Upgrade	BD-1	LS
BDPL 3 and 4 Crossovers	BD-2	LS
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	LS

The BDPL Reliability Upgrade project (BD-1) would involve construction dewatering along the portions of the alignment where pipeline would be installed using cut-and-cover methods. However, only shallow groundwater resources would be affected. The tunnel shafts for this project would be constructed using a slurry panel wall or secant pile method, which would prevent water from entering the work shaft. Although limited dewatering could be required at the base of the Ravenswood tunnel shaft to reduce uplift, dewatering would not be allowed at the Newark tunnel shaft, where there is groundwater contamination. Therefore, impacts related to the depletion of shallow and deep groundwater resources would be *less than significant* for this project.

Both the BDPL 3 and 4 Crossovers (BD-2) and BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) projects would require construction dewatering. However, only shallow groundwater resources would be affected. Therefore, impacts related to the depletion of groundwater resources would be *less than significant* for these projects.

Peninsula Region

Impact 4.5-2: Depletion of groundwater resources		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS

All of the Peninsula Region projects (Baden and San Pedro Valve Lots, PN-1; CS/SA Transmission, PN-2; HTWTP Long-Term, PN-3; Lower Crystal Springs Dam, PN-4; and Pulgas Balancing Reservoir, PN-5) could require construction dewatering. However, only shallow groundwater resources would be affected. Therefore, impacts related to the depletion of groundwater resources would be *less than significant* for these projects.

San Francisco Region

Impact 4.5-2: Depletion of groundwater resources		
SAPL 3 Installation	SF-1	LS
Groundwater Projects	SF-2	N/A
Recycled Water Projects	SF-3	LS

Both the SAPL 3 Installation (SF-1) and Recycled Water Projects (SF-3) could require construction dewatering. However, only shallow groundwater resources would be affected. Therefore, impacts related to the depletion of groundwater resources would be *less than significant* for these projects. The Groundwater Projects (SF-2) would not require construction dewatering. Therefore, impacts related to the depletion of groundwater resources would *not apply* to this project. (Potential depletion of groundwater resources resulting from operation of the groundwater projects is addressed in Chapter 5, Section 5.6.)

Impact 4.5-3: Construction dewatering discharges to surface waters and construction-related discharges of treated water.

Dewatering would be necessary for construction of facilities where excavation is required below the groundwater table; for pipeline projects where there is a shallow groundwater table and at stream crossings; and for all tunnel projects. Water produced during construction dewatering could contain sediments and contaminants that could degrade water quality if the water were discharged directly to surface water or if it infiltrated to groundwater. Water from dewatering during tunnel construction is expected to contain sediment, oils, and grout. Water quality impacts and permitting requirements related to these discharges are discussed below and analyzed by region in Impact 4.5-3a.

Construction-related discharges of treated water would also be required for construction of some WSIP facilities. These discharges could contain chlorine or chloramines and could degrade water quality and affect aquatic organisms. Depending on the rate of discharge, either type of discharge could also result in erosion in the receiving water or cause downstream flooding. Water quality impacts and permitting requirements related to these discharges are discussed below and analyzed by region in Impact 4.5-3b.

For projects that are subject to the Construction General Permit (described in Impact 4.5-1, above), the discharges could possibly be made in accordance with this permit, provided it could be demonstrated that the water is uncontaminated. In the San Joaquin Region, the groundwater could possibly be discharged to surface water under the General Order for Dewatering and Other Low Threat Discharges to Surface Waters, as described in the Setting, although in all regions an individual NPDES permit, or waiver, might be required. In agricultural areas or other areas where the groundwater would be discharged to land, the discharges could possibly be made under the Statewide General Waste Discharge Requirements for Discharges to Land with Low Threat to Water Quality, although individual waste discharge requirements, or a waiver, could be required. If discharges were made to lands not owned, controlled, or leased by the CCSF, then the CCSF would enter into agreements with landowners for the discharge. Discharges to a local sanitary sewer system would comply with the requirements of the local permitting agency. Other General Permits in the San Francisco Region under which dewatered groundwater may be discharged include the following General NPDES Permits:

- General NPDES Permit for VOC Cleanups (Order No. R2-2004-0055)
- General NPDES Permit for Fuel Cleanups (Order No. R2-2006-0075)
- General NPDES Permit for Groundwater Dewatering (Order No. R2-2006-0075)

Before discharging under any general permit, the SFPUC must submit a completed Notice of Intent that includes a dewatering plan with appropriate treatment and monitoring specifications. The SFPUC should also allow at least 60 days for the RWQCB review and acceptance of the Notice of Intent and dewatering plans.

For projects located in San Francisco, the construction contractor(s) would obtain approval from the SFPUC and comply with all NPDES permit requirements for the discharge of treated water to the combined sewer system, subject to the provisions of Article 4.1 of the San Francisco Public Works Code.

In accordance with the requirements of these permits or waivers, the contractor(s) would be required to implement control measures to ensure adequate quality of the discharged water, conduct the appropriate sampling to demonstrate permit compliance, and regulate flow rates to prevent erosion or downstream flooding in the receiving water. A groundwater treatment unit would be used, as needed, to comply with discharge requirements.

The contractor(s) would also be required to obtain the necessary permit from the local flood control district or any appropriate local agencies. For any discharge facilities affecting areas immediately adjacent to or within creeks and rivers, permits would be obtained from the Corps, CDFG, and RWQCB if needed. Depending on the location, the SFPUC would consult with and/or obtain approval from the U.S. Fish and Wildlife Service and/or National Marine Fisheries Service if sensitive aquatic species or habitat could be affected. If required, permits would include provisions for energy dissipation of discharges and regulation of flow rates to prevent downstream flooding.

Implementation of control measures in compliance with the permitting requirements described above would ensure that construction-related dewatering discharges would not degrade water quality or violate any water quality standards or waste discharge requirements. In addition, all WSIP projects would be required to implement SFPUC Construction Measure #4 (groundwater), which requires the preparation of a dewatering plan to ensure groundwater discharges to the storm sewer system comply with applicable local standards and discharge permit requirements.

In addition, WSIP projects in the Sunol Valley Region would be located within the Alameda watershed (and subject to the Alameda WMP), while some of the WSIP projects in the Peninsula Region would be located within the Peninsula watershed (and subject to the Peninsula WMP). Since these WSIP projects would be required to implement all pertinent watershed management plan policies and actions, this analysis assumes the following action pertaining to dechlorination of water prior to discharge would be implemented as part of the WSIP projects:

- *Action fis6*. Identify and adopt alternative nontoxic management practices for the protection of aquatic resources in coordination with the Integrated Pest Management program. Guidelines include:
  - Dechlorinate water before it is discharged to streams and reservoirs
  - Minimize the use of copper sulfate in the treatment of algal blooms in reservoirs
  - Limit the use of chemical fire retardants and Class A foams (except protein-based foams) in or near aquatic zones

Construction dewatering and construction-related discharges of clear water are evaluated separately below.

Degradation of Water Quality Due to Construction Dewatering Discharges

San Joaquin Region

Impact 4.5-3a: Degradation of water quality due to construction dewatering discharges		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	N/A
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	LS
Tesla Portal Disinfection	SJ-5	LS

The Advanced Disinfection (SJ-1), SJPL System (SJ-3), SJPL Rehabilitation (SJ-4), and Tesla Portal Disinfection (SJ-5) projects could involve construction dewatering, with potential discharges to a surface water body, storm sewer system, sanitary sewer system, or land. However, potential water quality impacts related to these construction discharges would be *less than significant* for all projects in this region with implementation of control measures in compliance with NPDES permitting, waste discharge requirements, or local agency permitting requirements (described above). SFPUC Construction Measure #4 (groundwater) would also require preparation of a dewatering plan for discharges to the storm sewer system.

The Lawrence Livermore project (SJ-2) would not likely involve dewatering; therefore, this impact would *not apply* to this project.

Sunol Valley Region

Impact 4.5-3a: Degradation of water quality due to construction dewatering discharges		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	N/A
New Irvington Tunnel	SV-4	LS
Treated Water Reservoirs	SV-5	N/A
SABUP	SV-6	LS

The Alameda Creek Fishery (SV-1), Calaveras Dam (SV-2), New Irvington Tunnel (SV-4), and SABUP (SV-6) projects could each involve construction dewatering, with potential discharges to a surface water body or storm sewer system. However, potential water quality impacts related to these construction discharges would be *less than significant* for all projects in this region with implementation of control measures in compliance with NPDES permitting requirements for these discharges (described above). SFPUC Construction Measure #4 (groundwater) would also require preparation of a dewatering plan for discharges to the storm sewer system.

The 40-mgd Treated Water (SV-3) and Treated Water Reservoirs (SV-5) projects would not likely involve dewatering; therefore, this impact would *not apply* to these projects.

Bay Division Region

Impact 4.5-3a: Degradation of water quality due to construction dewatering discharges		
BDPL Reliability Upgrade	BD-1	LS
BDPL 3 and 4 Crossovers	BD-2	LS
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	LS

All WSIP projects in this region (BDPL Reliability Upgrade, BD-1; BDPL 3 and 4 Crossovers, BD-2; and BDPL 3 and 4 Seismic Upgrade at Hayward Fault, BD-3) could involve construction dewatering, with potential discharges to a surface water body, storm sewer system, or sanitary sewer system. However, potential water quality impacts related to these construction discharges would be *less than significant* for all projects in this region with implementation of control measures in compliance with NPDES and local agency permitting requirements for these discharges (described above). SFPUC Construction Measure #4 (groundwater) would also require preparation of a dewatering plan for discharges to the storm sewer system.

Peninsula Region

Impact 4.5-3a: Degradation of water quality due to construction dewatering discharges		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS

All WSIP projects in this region (Baden and San Pedro Valve Lots, PN-1; CS/SA Transmission, PN-2; HTWTP Long-Term, PN-3; Lower Crystal Springs Dam, PN-4; and Pulgas Balancing Reservoir, PN-5) could involve construction dewatering, with potential discharges to a surface water body, storm sewer system, or sanitary sewer system. However, potential water quality impacts related to these construction discharges would be *less than significant* for all projects in this region with implementation of control measures in compliance with NPDES and local agency permitting requirements (described above). SFPUC Construction Measure #4 (groundwater) would also require preparation of a dewatering plan for discharges to the storm sewer system.

San Francisco Region

Impact 4.5-3a: Degradation of water quality due to construction dewatering discharges to surface water		
SAPL 3 Installation	SF-1	LS
Groundwater Projects	SF-2	N/A
Recycled Water Projects	SF-3	LS

The SAPL 3 Installation (SF-1) and Recycled Water Projects (SF-3) could involve construction dewatering, with potential discharges to a surface water body, storm sewer system, or sanitary sewer system. However, potential water quality impacts related to these construction discharges would be *less than significant* for each project with implementation of control measures in compliance with NPDES and local agency permitting requirements for those projects or portions of a project outside of San Francisco (described above), and compliance with Article 4.1 of the San Francisco Public Works Code for those projects or portions of a project within San Francisco. SFPUC Construction Measure #4 (groundwater) would also require preparation of a dewatering plan for discharges to the storm sewer system.

The Groundwater Projects (SF-2) would not likely involve dewatering; therefore, this impact would *not apply* to this project.

Degradation of Water Quality Due to Construction-Related Discharges of Treated Water

San Joaquin Region

Impact 4.5-3b: Degradation of water quality due to construction-related discharges of treated water		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	LS
Tesla Portal Disinfection	SJ-5	LS

Construction of the proposed crossover facilities and construction of valving and connections for the SJPL System project (SJ-3) and rehabilitation of pipelines under the SJPL Rehabilitation project (SJ-4) would require the discharge of water from the pipeline system during construction. This portion of the pipeline system contains raw water that has not been chlorinated or chloraminated; thus, dechlorination would not be required. Small discharges of chlorinated water could be required during construction of the Advanced Disinfection (SJ-1), Lawrence Livermore (SJ-2), and Tesla Portal Disinfection (SJ-5) projects. However, impacts related to construction discharges of raw and treated water from these facilities would be *less than significant* with implementation of control measures in compliance with NPDES permit or waste discharge requirements and the requirements of other regulatory agencies, as described above.

Sunol Valley Region

Impact 4.5-3b: Degradation of water quality due to construction-related discharges of treated water		
Alameda Creek Fishery	SV-1	N/A
Calaveras Dam	SV-2	N/A
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	LS
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	LS

Small discharges of chloraminated water could be required during construction of improvements to the Sunol Valley WTP for the 40-mgd Treated Water (SV-3) and Treated Water Reservoirs (SV-5) projects. However, these discharges would be managed in compliance with the Regionwide General NPDES Permit for Discharges from Surface Water Treatment Facilities for Potable Supply, as described in the Setting. Therefore, water quality impacts related to these discharges would be *less than significant* with implementation of control measures in compliance with existing regulations.

The SABUP project (SV-6) would likely require the discharge of chloraminated water for construction of valving and connections, and the New Irvington Tunnel project (SV-4) could require dewatering of the existing tunnel. However, water quality impacts related to these construction discharges of treated water would be *less than significant* with implementation of control measures in compliance with NPDES permit requirements and the requirements of other regulatory agencies, as described above. Implementation of Alameda WMP Action fis6 regarding the discharge of chlorinated water would also be required for all projects in the Sunol Valley Region.

No construction discharges of treated water are expected with the remaining Sunol Valley Region projects (Alameda Creek Fishery, SV-1, and Calaveras Dam, SV-2). Therefore, this impact would *not apply* to these projects.

Bay Division Region

Impact 4.5-3b: Degradation of water quality due to construction-related discharges of treated water		
BDPL Reliability Upgrade	BD-1	LS
BDPL 3 and 4 Crossovers	BD-2	LS
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	LS

Construction-related discharges of chloraminated water would be required for all WSIP projects in this region (BDPL Reliability Upgrade, BD-1; BDPL 3 and 4 Crossovers, BD-2; and BDPL 3 and 4 Seismic Upgrade at Hayward Fault, BD-3). However, water quality impacts related to these construction discharges of treated water would be *less than significant* with implementation of control measures in compliance with NPDES permit requirements and the requirements of other regulatory agencies, as described above.

Peninsula Region

Impact 4.5-3b: Degradation of water quality due to construction-related discharges of treated water		
Baden and San Pedro Valve Lots	PN-1	N/A
CS/SA Transmission	PN-2	N/A
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	N/A
Pulgas Balancing Reservoir	PN-5	LS

Small discharges of chloraminated water could be required during construction of treatment plan improvements under the HTWTP Long-Term project (PN-3). However, these discharges would be managed in compliance with the Regionwide General NPDES Permit for Discharges from Surface Water Treatment Facilities for Potable Supply; therefore, water quality impacts related to these chloraminated water discharges would be *less than significant* with implementation of control measures in compliance with these regulations.

Discharges of chloraminated water could also be required for construction of the Pulgas Balancing Reservoir (PN-5) project. However, water quality impacts related to these construction discharges would be *less than significant* with implementation of control measures in compliance with NPDES permit requirements and the requirements of other regulatory agencies. Because the Pulgas Balancing Reservoir project would be located within the Peninsula watershed, implementation of Peninsula WMP Action fis6 regarding the discharge of chlorinated water would also be required.

The Baden and San Pedro Valve Lots (PN-1), CS/SA Transmission (PN-2), and Lower Crystal Springs Dam (PN-4) projects are not expected to require construction-related discharges of chloraminated water. Therefore, this impact would *not apply* to these projects.

San Francisco Region

Impact 4.5-3b: Degradation of water quality due to construction-related discharges of treated water		
SAPL 3 Installation	SF-1	LS
Groundwater Projects	SF-2	N/A
Recycled Water Projects	SF-3	N/A

Small discharges of chloraminated water could be required for the SAPL 3 Installation project (SF-1). However, water quality impacts related to these construction discharges would be *less than significant* with implementation of control measures in compliance with NPDES permit requirements and the requirements of other regulatory agencies for discharges to surface waters or separate storm sewer systems outside of San Francisco, as well as implementation of control measures in compliance with Article 4.1 of the San Francisco Municipal Code for discharges to the combined sewer system in San Francisco.

The Groundwater Projects (SF-2) and Recycled Water Projects (SF-3) are not expected to involve construction-related discharges of chlorinated or chloraminated water. Therefore, this impact would *not apply* to these projects.

Impact 4.5-4: Flooding and water quality impacts associated with impeding or redirecting flood flows.

Construction of WSIP facilities within an existing flood zone could impede or redirect flood flows.

Pipelines and Tunnels. Pipelines and tunnels would be constructed beneath the land surface and therefore would not impede or redirect flood flows once constructed. However, construction activities within FEMA-designated 100-year flood zones could impede flood flows or cause the discharge of sediments and pollutants to flood flows if a flood occurred during construction. Hazardous materials and debris could also be released into flood flows if construction diesel tanks, hazardous materials, or other construction materials were stored in a flood zone. Associated structures would be designed to withstand flood flows and pass the floodwaters without significant impedance or erosion.

Dams. Dams constructed within a creek could increase flooding impacts if located in a flood zone or could cause flooding if located in an area not already subject to flooding. The degree of impact would depend on the design, placement, and operation of the dam.

Other Facilities. Except for groundwater wells proposed under the Alameda Creek Fishery project (SV-1) and proposed crossover facilities located at Barron Creek and Guadalupe River under the BDPL 3 and 4 Crossovers project (BD-2), discussed below under the Bay Division Region projects, no other facilities would be constructed within 100-year flood zones; therefore, flooding impacts are not applicable to these facilities. Outlet structures for crossover facilities could include construction of permanent facilities within a stream channel, which could potentially impede or redirect stream flows and contribute to flooding. However, compliance with permitting requirements would ensure that these facilities are designed such that they do not impede or redirect stream flows.

San Joaquin Region

Impact 4.5-4: Flooding and water quality impacts associated with impeding or redirecting flood flows		
Advanced Disinfection	SJ-1	N/A
Lawrence Livermore	SJ-2	N/A
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	N/A

As discussed in the Setting, the existing San Joaquin Pipelines cross an approximate 3.6-mile-wide section of the 100-year flood zone of the San Joaquin River. None of the new pipeline segments proposed under the SJPL System project (SJ-3) would be located within this flood zone, although the western crossover facility with an aboveground power supply could potentially be located within this zone. Power supply facilities for the SJPL System project would be designed to withstand flood flows and pass the floodwaters without substantial impedance or erosion. Although this facility would not redirect or impede flood flows, impacts related to flooding are considered *potentially significant* for this project, because construction of this facility could still contribute sediment or contaminants to flood flows. Rehabilitation activities under the SJPL Rehabilitation project (SJ-4) could occur anywhere along the existing San Joaquin Pipelines, including within the flood zone. Therefore, impacts related to the diversion of flood flows or contribution of sediment or contaminants to flood flows during construction are also considered *potentially significant* for this project. However, incorporation and implementation of flood flow protection measures (Measure 4.5-4a) in the erosion control measures or SWPPP prepared for the SJPL System and SJPL Rehabilitation projects would reduce this impact to a less-than-significant level.

None of the components of other San Joaquin Region projects (Advanced Disinfection, SJ-1; Lawrence Livermore, SJ-2; and Tesla Portal Disinfection, SJ-5) would be located within a 100-year floodplain. Therefore, flooding impacts would *not apply* to these projects.

Sunol Valley Region

Impact 4.5-4: Flooding and water quality impacts associated with impeding or redirecting flood flows		
Alameda Creek Fishery	SV-1	PSM
Calaveras Dam	SV-2	N/A
40-mgd Treated Water	SV-3	N/A
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	N/A
SABUP	SV-6	PSM

The Alameda Creek Fishery project (SV-1) could construct new facilities such as groundwater extraction wells, pipelines, or pump stations within the 100-year floodplain of Alameda Creek. The SABUP project (SV-6) would install a new outfall energy dissipation structure within this flood zone (FEMA, 1981). Any groundwater extraction wells constructed under the Alameda Creek Fishery project would be located primarily below ground with, at most, small aboveground structures. The SABUP project would construct an outfall energy dissipation structure within the channel of Alameda Creek and a new outfall structure in San Antonio Creek, but these structures would be designed so they do not substantially impede flow in the creek. Although these structures would not substantially impede flood flows, impacts related to flooding are considered *potentially significant* for these projects, because construction activities could contribute sediment or contaminants to flood flows. However, incorporation and implementation of flood flow protection measures (Measure 4.5-4a) in the SWPPP prepared for these projects would reduce this impact to a less-than-significant level.

It is possible that a diversion dam or concrete weir could be constructed under the Alameda Creek Fishery project (SV-1). If the diversion dam or weir were located south of the Alameda Siphons, it would be outside of the 100-year floodplain of Alameda Creek. However, if the diversion dam or weir were located north of the Alameda Siphons, it could be constructed within the flood zone. In addition, small earthen dams could be constructed within the 100-year flood zone of Alameda Creek during high stream flows if infiltration galleries are used as part of this project. If located outside of the flood zone, these structures could alter the drainage of surface flows in Alameda Creek, causing flooding or siltation. If located within the flood zone, the dams could exacerbate flooding issues and also contribute to siltation. These effects cannot be estimated without information on stream flows as well as the planned operation of the project. Therefore, impacts related to the impedance or redirection of flood flows would be *potentially significant* for this project. However, implementation of a site-specific flooding analysis and identified measures (Measure 4.5-4b) would be expected to reduce this impact to a less-than-significant level.

Although the primary components of the New Irvington Tunnel project (SV-4) are outside the 100-year floodplain, the proposed permanent access road and bridges, as well as the spoils area, under this project might require placement of fill in the 100-year floodplain area. The potential flooding impacts would be *potentially significant* for this project. However, implementation of flood flow protection measures (Measure 4.5-4a) and a site-specific flooding analysis and identified measures (Measure 4.5-4b) would be expected to reduce this impact to a less-than-significant level.

The Calaveras Dam (SV-2), 40-mgd Treated Water (SV-3), and Treated Water Reservoirs (SV-5) projects would not be located within a mapped 100-year floodplain. Therefore, flooding impacts would *not apply* to these projects.

Bay Division Region

Impact 4.5-4: Flooding and water quality impacts associated with impeding or redirecting flood flows		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	PSM
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	N/A

The BDPL Reliability Upgrade project (BD-1) would cross 100-year floodplains and areas designated as Zone B[2] (associated with Mission Creek and Lake Elizabeth) and would pass beneath several flood control channels on the east side of San Francisco Bay (FEMA, 1983, 2000a). Flood flows are expected to be contained within each flood control channel. On

[2] Zone B is an area between the limits of the 100-year flood and the 500-year flood; or certain areas subject to 100-year flooding with average depths less than 1 foot or where the contributing drainage area is less than one square mile; or areas protected by levees from the base flood.

the west side of the bay, much of the alignment between the intersection of Ivy and Hollyburne Avenues and the Ravenswood Valve House is located within a broad 100-year flood zone associated with the west bay margin (FEMA, 1999a, 1999b, 1999c, 1999e). The west tunnel shaft would be constructed within this zone. The alignment would also cross a 100-year flood zone at the Bayshore Freeway (FEMA, 1999c) and the 500-year floodplains of Redwood Creek and Jefferson Creek (FEMA, 1982). Facilities constructed within these flood zones would be designed to withstand flood flows and pass the floodwaters without substantial impedance or erosion.

The Barron Creek crossover facility associated with the BDPL 3 and 4 Crossovers project (BD-2) could be located within or near a small 100-year floodplain associated with Barron Creek (FEMA, 1999d). In addition, the existing Bay Division Pipelines Nos. 3 and 4 cross a broad 100-year floodplain between Coyote Creek and the Guadalupe River (FEMA, 1988). The floodplain is located entirely to the east of the river. If the Guadalupe River crossover facility associated with this project were located to the east of the river, it would be located within the 100-year floodplain. If it were located to the west of the river, it would be located in Zone B, where flooding impacts would be less than significant. Outlet structures constructed at each crossover facility under the BDPL 3 and 4 Crossovers project would be designed so they do not substantially impede flood flows in a creek or redirect flood flows.

Even though BDPL Reliability Upgrade (BD-1) and BDPL 3 and 4 Crossovers (BD-2) facilities that would be located within identified 100-year floodplains would be designed so they do not substantially impede flood flows, impacts related to flooding are considered *potentially significant* for these projects, because construction activities could contribute sediment or contaminants to flood flows. However, incorporation and implementation of flood flow protection measures (Measure 4.5-4a) in the SWPPP prepared for these projects would reduce this impact to a less-than-significant level.

The Bear Gulch crossover facility constructed under the BDPL 3 and 4 Crossovers project (BD-2) and the BDPL 3 and 4 Seismic Upgrade at Hayward Fault project (BD-3) would not be located within a 100-year flood zone. Therefore, impacts related to the diversion of flood flows and contribution of sediments and contaminants to flood flows would *not apply* to the Bear Gulch crossover facility (under BD-2) or to the BDPL 3 and 4 Seismic Upgrade at Hayward Fault project.

Peninsula Region

Impact 4.5-4: Flooding and water quality impacts associated with impeding or redirecting flood flows		
Baden and San Pedro Valve Lots	PN-1	N/A
CS/SA Transmission	PN-2	N/A
HTWTP Long-Term	PN-3	N/A
Lower Crystal Springs Dam	PN-4	N/A
Pulgas Balancing Reservoir	PN-5	N/A

The Baden Valve Lot (under PN-1) and the CS/SA Transmission (PN-2), HTWTP Long-Term (PN-3), Lower Crystal Springs Dam (PN-4), and Pulgas Balancing Reservoir (PN-5) projects are not located within a 100-year floodplain. FEMA maps do not cover Daly City, where the San Pedro Valve Lot (under PN-1) is located. However, none of these sites is near a surface water feature and would not likely be subject to flooding. Therefore, flooding impacts would *not apply* to projects in this region.

San Francisco Region

Impact 4.5-4: Flooding and water quality impacts associated with impeding or redirecting flood flows		
SAPL 3 Installation	SF-1	N/A
Groundwater Projects	SF-2	PSM
Recycled Water Projects	SF-3	N/A

San Francisco is not presently mapped by FEMA, but localized flooding does occur during periods of intense precipitation, especially in low-lying areas where storm drains become clogged with debris. Because major flooding would not be expected in San Francisco, flooding impacts are not applicable to San Francisco Region projects within San Francisco. In addition, FEMA has not produced flood maps for Daly City, where the southern portion of the SAPL 3 Installation project (SF-1) would be located. Therefore, impacts related to the diversion of flood flows or contribution of sediment or contaminants to flood flows during construction would *not apply* to the SAPL 3 Installation which is located in San Francisco and Daly City and Recycled Water Projects (SF-3) which is located in San Francisco.

Some facilities under the Groundwater Projects (SF-2) would be constructed in San Mateo County, but their locations have not been determined. These facilities would be designed so they do not substantially impede flood flows, but if the facilities were constructed in a flood zone, impacts related to flooding would be *potentially significant* for these facilities, because construction activities could contribute sediment or contaminants to flood flows. However, incorporation and implementation of flood flow protection measures (Measure 4.5-4a) in the SWPPP prepared for this project would reduce this impact to a less-than-significant level.

Operational Impacts

Impact 4.5-5: Degradation of water quality and increased flows due to discharges to surface water during operation.

Various facilities would require the discharge of treated water to local surface waters during operation of proposed improvements, resulting in potential impacts related to water quality, aquatic organisms, and/or downstream flooding. Chemicals present in treated (chlorinated or chloraminated) water could affect aquatic organisms, as could temperature differences between the discharge and receiving waters. In addition, depending on the volume, timing, and location of the discharge, discharges could result in increased flows and related increases in erosion in surface waters and downstream flooding. Nutrients present in recycled water or treated stormwater could also cause eutrophication[3] of Lake Merced. The potential water quality effects, the types of discharges that would occur from each facility type, and the expected operational discharges within each region are described below.

[3] Eutrophication is the over-enrichment of a water body with nutrients, resulting in the excessive growth of organisms and depletion of dissolved oxygen.

Water Quality Effects of Discharges

Toxicity Effects. While both chlorine and chloramine are effective disinfectants for potable water, the discharge of chlorinated and chloraminated water into natural waters can be detrimental due to the toxicity of chlorine, ammonia, and chloramine to aquatic organisms. Chlorine residuals (both free and combined) are acutely toxic to aquatic organisms at low concentrations and are persistent due to their stability. The San Francisco Bay Basin Plan standard for residual chlorine is 0.0 milligrams per liter and the Central Valley Region General Order for Dewatering and Other Low Threat Discharges to Surface Waters standard for residual chlorine is 0.02 milligrams per liter; thus, dechlorination of any discharges would be required in order to remove all residual chlorine prior to discharge to surface waters, and to assure compliance with RWQCB requirements. There would be a potential for discharges of chlorinated water during operation of WSIP projects located downstream of chlorination (Tesla Disinfection Facility) and chloramination (Alameda Disinfection Facility) processes in the regional system.

Ammonia, which is contained in chloraminated water, exists in two forms in water: un-ionized and ionized. The un-ionized form of ammonia is toxic, while the ionized form is relatively harmless. In the temperature and pH range of natural waters, ammonia exists predominately in its nontoxic form. In general, ammonia in chloraminated discharges would be diluted or degraded to a nontoxic form fairly rapidly. Therefore, the potential for ammonia toxicity as a result of chloraminated water discharges would be less than significant.

Chloramine is regulated in the Basin Plan as a form of chlorine. Like chlorine and ammonia, chloramine is toxic to aquatic life due to its reactive nature. In general, removal of the chlorine portion of chloramine is required to eliminate toxicity before water is discharged to surface waters. Dechlorination of discharges would therefore reduce potential impacts on surface water quality and aquatic organisms to a less-than-significant level.

Temperature Effects. The sensitivity of aquatic organisms to water temperature depends on numerous factors, including the species, the stage in its life cycle, and the surrounding conditions. In particular, discharges to surface waters during the dry, summer months can result in thermal shock to aquatic organisms when a large volume of cool water enters a natural stream with relatively warm water.

Eutrophication. Increased aquatic plant growth (such as an increase in algae), known as eutrophication, can result from the addition of nutrients to a water body. Although algal blooms usually pose no direct health effects for humans, some species of algae flourish in highly eutrophic waters and can develop noxious blooms that cause offensive tastes and odors. Excessive algal growth may also deplete dissolved oxygen and cause toxic conditions for fish.

Erosional and Flooding Effects. Depending on such factors as the location, timing, and volume, discharges could result in erosional effects on surface water bodies and increase the potential for downstream flooding. Effects could include scouring of banks or vegetation, particularly in smaller creeks. In general, the larger watercourses and static water bodies would be less sensitive to discharges. Sites with stabilized banks and channels would also be less sensitive than natural banks and channels. Where large volumes of water would be discharged to creeks, the installation of energy dissipation structures and stream bank improvements would minimize scouring, and flows would be regulated to prevent downstream flooding. Energy dissipation structures could be permanently placed in the stream channel, or could be temporarily placed when dewatering occurs.

For any discharge facilities affecting areas immediately adjacent to or within creeks and rivers, permits would likely be required from the Corps, CDFG, and RWQCB; and, depending on the location, consultation/approval with the U.S. Fish and Wildlife Service and/or National Marine Fisheries Service could be necessary if sensitive species or habitat would be affected. If required, permits would include provisions for energy dissipation of discharges and regulation of discharge rates to prevent downstream flooding.

General Discussion of Discharges During Operation

Water Treatment Facilities. During operation, water treatment facilities would be expected to require miscellaneous discharges related to maintenance or emergencies at the facility. These discharges would be dechlorinated or dechloraminated and would occur at a rate that would not cause erosion or downstream flooding. Within the jurisdiction of the San Francisco Bay RWQCB, these discharges would be subject to the Regionwide General NPDES Permit for Discharges from Surface Water Treatment Facilities for Potable Supply, and within the jurisdiction of the Central Valley RWQCB, these discharges would be subject to the General Order for Dewatering and Other Low Threat Discharges to Surface Waters. These permits (described in the Setting) would include provisions to protect water quality and aquatic organisms.

Crossover Facilities and Pipelines. Crossover facilities consist of valves and related equipment that enable operators to isolate and shut down discrete segments of pipelines along the regional system, either for maintenance or emergencies. In either event, shutting down a segment of pipeline could require draining that portion of the pipeline to a local surface water body. This discharge could be treated or raw water of various volumes. Discharges from crossover facilities and pipelines could result in toxicity, temperature, and erosional effects; however, as described above, discharges would be dechlorinated or dechloraminated and would occur at a rate that would not cause erosion or downstream flooding.

In areas under jurisdiction of the Central Valley RWQCB, these discharges could possibly be discharged to surface water under the General Order for Dewatering and Other Low Threat Discharges to Surface Waters, although in all regions, an individual NPDES permit, or waiver, might be required. In agricultural areas or other areas where the water would be discharged to land, the discharges could possibly be made under the Statewide General Waste Discharge Requirements for Discharges to Land with Low Threat to Water Quality, although individual waste discharge requirements, or a waiver, could be required. If discharges were made to lands not owned, controlled, or leased by the CCSF, the CCSF would enter into agreements with landowners for the discharge. Compliance with Corps and CDFG requirements could also be required for these discharges. Permit requirements for any discharges to surface water bodies would include provisions to protect water quality and aquatic organisms.

For projects located in San Francisco, the construction contractor(s) would obtain approval from the SFPUC and comply with all permit requirements for the discharge of treated water to the combined sewer system, subject to the provisions of Article 4.1 of the San Francisco Public Works Code.

Other Facilities. Routine and non-routine discharges of treated water from tunnels, vaults, valve lots, and pump stations would not be required during operation of these facilities.

Use of Recycled Water for Irrigation. The SFPUC would produce and distribute recycled water in San Francisco in compliance with the RWQCB General Water Reuse Order described in the Setting. All recycled water for irrigation purposes would be treated to disinfected tertiary standards specified in Title 22 of the California Code of Regulations, and recycled water would be applied in a manner that is protective of surface and groundwater quality. In addition, the recycled water "users" would comply with San Francisco's Reclaimed Water Ordinance and would be required to obtain a reclaimed water use certificate from the SFPUC in accordance with the ordinance (also described in the Setting). Adherence to these regulatory requirements would ensure that high-quality recycled water is consistently produced, monitored, and carefully applied, and that public health and surface and groundwater quality are protected.

Because recycled water typically has elevated levels of salts (as measured by total dissolved solids, or TDS), the infiltration of recycled water used in irrigation could cause salts to accumulate in the groundwater. However, the potential for salt buildup would be low in San Francisco, since the recycled water would be derived from high-quality SFPUC system water originating primarily from Hetch Hetchy Reservoir. Because SFPUC system water (which is the source of the recycled wastewater) is naturally very low in TDS, the recycled water is also expected to be low in TDS. The RWQCB may determine that irrigation with recycled water could result in salt buildup in the groundwater and may require preparation of a salt management plan in accordance with the General Water Reuse Order.

Lake Augmentation. Augmentation of water levels in Lake Merced using SFPUC system water, recycled water, or treated stormwater could potentially degrade Lake Merced water quality as well as groundwater quality in the shallow groundwater aquifer (the relationship of Lake Merced and the shallow groundwater aquifer is discussed in Section 5.6). Mechanisms that could affect water quality include: eutrophication of surface water resulting from the addition of nutrients in recycled water or stormwater; introduction of chlorine or chloramines in SFPUC system water or recycled water to surface or groundwater, resulting in the toxicity effects noted above; and degradation of surface or groundwater quality by contaminants that could be present in stormwater.

Degradation of Lake Merced water quality could affect the lake's beneficial uses, including cold and warm freshwater habitat, wildlife habitat, fish spawning, and recreational purposes as well as its potential use as an emergency water supply. Degradation of groundwater quality could affect use of the North Westside Groundwater Basin (described in Section 5.6) as a municipal water supply. However, use of any water to augment Lake Merced water levels would be subject to an NPDES permit, which would establish water quality goals and criteria that are protective of the lake's beneficial uses.

Watershed Management Plan Actions

In addition, WSIP projects in the Sunol Valley Region would be located within the Alameda watershed (and subject to the Alameda WMP), while some of the WSIP projects in the Peninsula Region would be located within the Peninsula watershed (and subject to the Peninsula WMP). Since these WSIP projects would be required to follow all pertinent watershed management plan policies and actions, this analysis assumes the following action pertaining to the dechlorination of water prior to discharge would be implemented as part of the WSIP projects.

- *Action fis6*. Identify and adopt alternative nontoxic management practices for the protection of aquatic resources in coordination with the Integrated Pest Management program. Guidelines include:
  - Minimize the use of copper sulfate in the treatment of algal blooms in reservoirs
  - Dechlorinate water before it is discharged to streams and reservoirs
  - Limit the use of chemical fire retardants and Class A foams (except protein-based foams) in or near aquatic zones

San Joaquin Region

Impact 4.5-5: Degradation of water quality and increased flows due to discharges to surface water during operation		
Advanced Disinfection	SJ-1	N/A
Lawrence Livermore	SJ-2	N/A
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	N/A
Tesla Portal Disinfection	SJ-5	N/A

Operation of the SJPL System project (SJ-3) could result in minor discharges of raw water from the crossover facilities for pipeline maintenance or repairs. However, water quality impacts related to these discharges during operation would be *less than significant* with implementation of control measures in compliance with NPDES permit or waste discharge requirements and the requirements of other regulatory agencies, as described above.

No new discharges would be expected during operation of the Advanced Disinfection (SJ-1), SJPL Rehabilitation (SJ-4), and Tesla Portal Disinfection (SJ-5) projects, and discharges would not be expected during operation of the Lawrence Livermore project (SJ-2). Therefore, this impact would *not apply* to these projects.

Sunol Valley Region

Impact 4.5-5: Degradation of water quality and increased flows due to discharges to surface water during operation		
Alameda Creek Fishery	SV-1	N/A
Calaveras Dam	SV-2	N/A
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	N/A
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	LS

The 40-mgd Treated Water (SV-3) and Treated Water Reservoirs (SV-5) projects at the Sunol Valley WTP would not likely result in new discharges of chloraminated water during operation, although intermittent discharges could be required for maintenance. Water quality impacts related to these intermittent discharges would be *less than significant* with implementation of control measures in compliance with the Regionwide General NPDES Permit for Discharges from Surface Water Treatment Facilities for Potable Supply.

Under the SABUP project (SV-6), chloraminated water would be dechlorinated using the existing dechlorination train and discharged to San Antonio Creek using the San Antonio Pipeline. Under this project, new discharge facilities consisting of a cone valve and stilling basin would be installed as energy dissipation devices to reduce erosion in San Antonio Creek, and the creekbeds at the discharge point would be armored to prevent scouring. Vent overflows from the Alameda East Portal would also be discharged to Alameda Creek and would be dechlorinated using the existing chlorination trains. An energy dissipation structure and creekbed armoring would be installed at the point of discharge to prevent erosion of Alameda Creek. Water quality impacts related to these discharges would be *less than significant* with implementation of control measures in compliance with NPDES permit requirements and the requirements of other regulatory agencies, as described above.

The SFPUC would also implement Alameda WMP Action fis6, as described above, as it applies to discharges from the 40-mgd Treated Water (SV-3), Treated Water Reservoirs (SV-5), and SABUP (SV-6) projects.

No discharges of treated water would be expected during operation of the remaining Sunol Valley Region projects (Alameda Creek Fishery, SV-1; Calaveras Dam SV-2; and New Irvington Tunnel, SV-4). Therefore, this impact would *not apply* to these projects.

Bay Division Region

Impact 4.5-5: Degradation of water quality and increased flows due to discharges to surface water during operation		
BDPL Reliability Upgrade	BD-1	LS
BDPL 3 and 4 Crossovers	BD-2	LS
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	N/A

Infrequent discharges of chloraminated water would be required for maintenance during operation of the BDPL Reliability Upgrade (BD-1) and BDPL 3 and 4 Crossovers (BD-2) projects. However, water quality impacts related to these discharges would be *less than significant* with implementation of control measures in compliance with NPDES permit requirements and the requirements of other regulatory agencies, as described above.

No discharges of treated water would be associated with operation the BDPL 3 and 4 Seismic Upgrade at Hayward Fault project (BD-3). Therefore, this impact would *not apply* to this project.

Peninsula Region

Impact 4.5-5: Degradation of water quality and increased flows due to discharges to surface water during operation		
Baden and San Pedro Valve Lots	PN-1	N/A
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	N/A
Pulgas Balancing Reservoir	PN-5	LS

The HTWTP Long-Term project (PN-3) would not likely result in new discharges of chloraminated water during operation, although intermittent discharges could be required for maintenance. However, water quality impacts related to these discharges would be *less than significant* with implementation of control measures in compliance with the Regionwide General NPDES Permit for Discharges from Surface Water Treatment Facilities for Potable Supply.

Current discharges of treated water at Pulgas Balancing Reservoir occur in accordance with a permit from the RWQCB, and these discharges would continue following implementation of proposed improvements at this reservoir under PN-5. These discharges flow down an unnamed drainage south of the Pulgas Water Temple public parking lot and eventually flow to Upper Crystal Springs Reservoir. Proposed improvements under the Pulgas Balancing Reservoir project would include modifications to the dechlorination system so that treated discharges would be reliably dechlorinated prior to flowing to Crystal Springs Reservoir. With construction of these improvements and implementation of control measures in compliance with NPDES and other agency permitting requirements, water quality impacts associated with this discharge would be *less than significant*. Operational discharges of treated water could also occur as a result of construction of the CS/SA Transmission project (PN-2); however, water quality impacts associated with these discharges would be *less than significant* with compliance with NPDES discharge requirements and the requirements of other regulatory agencies, as described above. The SFPUC would also implement Peninsula WMP Action fis6 as it applies to these discharges.

The Baden and San Pedro Valve Lots (PN-1) and Lower Crystal Springs Dam (PN-4) projects would not result in discharges of treated water during operation. Therefore, this impact would *not apply* to these projects.

San Francisco Region

Impact 4.5-5: Degradation of water quality and increased flows due to discharges to surface water during operation		
SAPL 3 Installation	SF-1	N/A
Groundwater Projects	SF-2	PSM
Recycled Water Projects	SF-3	LS

Augmentation of Lake Merced. Under the Local Groundwater Projects (SF-2), SFPUC system water, treated stormwater, or recycled water would be added to Lake Merced to augment lake levels (restoration of lake levels and potential effects on groundwater resources are discussed in Section 5.6). If recycled water were used, it would be produced under the Recycled Water Projects (SF-3). Addition of SFPUC system water, treated stormwater, or recycled water could degrade water quality in Lake Merced, potentially causing eutrophication or otherwise affecting beneficial uses of the lake. Degradation of shallow groundwater quality could also occur, because the lake recharges the shallow groundwater system, as discussed in Section 5.6.

Although water added to Lake Merced to maintain water levels would be dechlorinated to meet Basin Plan standards and would be conducted under an NPDES permit from the RWQCB, studies in support of the Recycled Water Projects (SF-3) have shown that it may also be necessary to remove nutrients from the recycled water to avoid eutrophication of Lake Merced (RMC, 2006). Because advanced treatment is proposed under the Recycled Water Projects, impacts related to eutrophication of Lake Merced would be less than significant if recycled water were used to augment water levels. However, because of the potential for nutrients in treated stormwater, eutrophication could occur if stormwater were used to augment Lake Merced water levels.

Eutrophication would result in an increase algal growth in the lake, potentially lowering dissolved oxygen levels in the lake and affecting aquatic organisms.

The use of treated stormwater for groundwater recharge could affect groundwater quality if the bacterial standards for the source water were less stringent than those for drinking water. Therefore, water quality impacts related to the addition of treated stormwater to Lake Merced are considered *potentially significant* for the Groundwater Projects (SF-2), but would be reduced to a less-than-significant level with treatment to remove nutrients from stormwater and implementation of groundwater monitoring in the vicinity of Lake Merced (specified in Measure 4.5-5). Requirements for treatment are determined on a case-by-case basis and would be identified during separate, project-level CEQA review for the Local Groundwater Projects.

Ocean Outfall Discharges. If it became necessary to implement advanced tertiary treatment of wastewater under the Recycled Water Projects (SF-3) to avoid adverse water quality effects of recycled water use in Lake Merced, the treatment process could require discharges of reverse-osmosis concentrate, likely through the ocean outfall. Discharges from this outfall are regulated under the City of San Francisco's NPDES permit for the Oceanside Water Pollution Control Plant, and this permit would be modified as necessary to cover discharges of reverse-osmosis concentrate. With implementation of control measures in compliance with NPDES permitting requirements, water quality impacts related to this discharge would be *less than significant*.

Discharges to Surface Waters or Sewer Systems. Incidental discharges of chlorinated water to surface waters, a separate storm sewer system, or the combined sewer system could be required for maintenance purposes during operation of the Recycled Water Projects (SF-3). However, if any treated water were discharged directly to surface water or a separate storm sewer system as part of project operations, these discharges would need to comply with NPDES permit requirements and the requirements of other regulatory agencies, as described above. Discharges to the combined sewer system would need to comply with Article 4.1 of the San Francisco Public Works Code. With implementation of control measures in compliance with these regulatory requirements, water quality impacts associated with these maintenance discharges to surface water, the combined sewer, or a separate storm sewer system would be *less than significant*.

Irrigation Uses of Recycled Water. The Recycled Water Projects (SF-3) would include development of projects to provide recycled water treated to a disinfected tertiary level for irrigation at Golden Gate Park, Lincoln Park, Lincoln Park Golf Course, San Francisco Zoo, Sunset Boulevard medians, and San Francisco State University. The potential for the accumulation of salts in the groundwater would be low in San Francisco, because the recycled water would be derived from high-quality SFPUC system water originating primarily from the Hetch Hetchy Reservoir, which is naturally very low in TDS. Regardless, a salt management plan would be prepared in accordance with the General Water Reuse Order if the recycled water user or RWQCB determines that irrigation with recycled water could result in salt buildup in the groundwater. With implementation of this plan in accordance with RWQCB regulatory requirements, if needed, groundwater quality impacts related to the use of recycled water for irrigation under the Recycled Water projects would be *less than significant*. However, this program-level review would be further refined as part of the separate, project-level CEQA review for the Recycled Water Projects, which could result in a change in the significance determination.

The SAPL 3 Installation project (SF-1) would not require discharges of treated water. Therefore, this impact would be *not apply* to this project.

Impact 4.5-6: Degradation of water quality, including offsite erosion and flooding, as a result of alteration of drainage patterns or an increase in impervious surfaces.

Construction of the WSIP facilities could alter drainage patterns and would result in a minor increase in impervious surfaces associated with new structures and paved areas, potentially resulting in offsite erosion or flooding. Although the amount of impervious surfaces that would be added is negligible compared to the existing acreage of impervious surfaces throughout the program area, the WSIP's addition of impervious surfaces could result in an incremental increase in surface runoff and related stormwater pollutants.

However, implementation of SFPUC Construction Measure #10 (project site) would require the SFPUC or its contractor(s) to return project sites to the general condition that existed prior to construction, including regrading the site and revegetating disturbed areas, which would ensure that drainage patterns are not altered in a way that would cause offsite flooding, erosion, or sedimentation. In addition, projects in all regions would be required to implement permanent erosion control measures in accordance with SFPUC Construction Measure #3 (onsite air and water quality measures during construction) and to implement control measures in compliance with applicable water quality regulations, including Article 4.1 of the San Francisco Public Works Code for projects in San Francisco and NPDES stormwater permitting requirements for other projects. In accordance with these requirements, projects would incorporate BMPs for temporary and permanent erosion control and incorporate stormwater control measures to reduce the quantity and rate of stormwater runoff and related erosion and flooding effects, as well as the potential for pollutants in stormwater.

Tunnels and Pipelines. Where a pipeline is located in a public right-of-way, construction could result in the replacement of asphalt or other impervious surfaces. However, the replacement of paved surfaces within a public right-of-way is generally exempted from municipal stormwater permitting requirements related to impervious surfaces. Additionally, the installation of pipelines in unpaved areas and the construction of tunnels would generally not result in the creation or replacement of impervious surfaces, because these facilities are underground and would not be paved. Therefore, there would be no water quality impacts associated with increased impervious surfaces for tunnel and pipeline projects, unless new impervious surfaces would be constructed.

Installation of pipelines and tunnels in unpaved areas would not alter drainage patterns in a way that results in offsite flooding, erosion, or sedimentation because, in accordance with SFPUC Construction Measure #10 (project site), the contractor(s) would be required to return the project site to the general condition that existed prior to construction, including regrading the site and revegetating disturbed areas. These projects would also be required to implement BMPs for temporary and permanent erosion control in accordance with SFPUC Construction Measure #3 (onsite air and water quality measures during construction), Article 4.1 of the San Francisco Public Works Code for projects in San Francisco, and NPDES construction stormwater permitting requirements for other projects.

Other Projects. With the exception of San Francisco and San Joaquin County, the municipal stormwater permits for the counties within the WSIP study area require new development and redevelopment projects that involve the creation or replacement of impervious surfaces to incorporate treatment measures and other appropriate source control and site design features to reduce the pollutant load in stormwater discharges and to manage runoff flows; the applicability of countywide MS4 stormwater management controls to the WSIP will be determined on a project-by-project basis as part of project-level review of individual WSIP projects. In each county, projects subject to these controls that involve the creation or replacement of one or more acres of impervious surfaces were required to comply with the new development and redevelopment requirements as of February 15, 2005. Projects subject to countywide MS4 stormwater management controls that involve the creation or replacement of 10,000 square feet or more of impervious surfaces were required to comply with the requirements by August 15, 2006. These thresholds apply to individual projects and are not applied to a cumulative set of projects if the locations of the cumulative set of projects under a single program are noncontiguous and/or are not part of a single common plan of development. To the extent that projects subject to countywide MS4 stormwater management controls are part of a single common plan of development that cumulatively exceeds 10,000 square feet of new or replaced impervious surface, the smaller amount of impervious surface from each sub-project would require appropriately sized stormwater treatment BMPs.

In addition, projects subject to countywide MS4 stormwater management controls that involve land disturbance of more than one acre would be required to include post-construction erosion and sediment control BMPs in the SWPPP prepared for the project (Described in the Setting and in Impact 4.5-1). For projects subject to countywide MS4 stormwater management controls, the post-construction erosion and sediment control BMPs for projects located in Alameda, Santa Clara, and San Mateo Counties and creating or replacing more than one acre of impervious surface must also comply with requirements in the Hydrograph Modification Management Plans for those counties. Post-construction BMPs could include minimizing land disturbance or the amount of impervious surfaces; treating stormwater runoff using infiltration, detention/retention, or biofilters; using efficient irrigation systems; ensuring that interior drains are not connected to a storm sewer system; and using appropriately designed and constructed energy dissipation devices. These measures would be designed to ensure that drainage patterns are not changed in a way that results in offsite erosion or flooding, and must be consistent with all local post-construction stormwater management requirements, policies, and guidelines. Coverage under the General Construction Permit cannot be terminated until the site is in compliance with all local stormwater management requirements and a post-construction stormwater management plan is in place, as described in the SWPPP.

Projects located in San Francisco would not be subject to the new development and redevelopment guidelines described above because stormwater discharges to the combined sewer system are regulated under the City's NPDES permit, in conformance with the Combined Sewer Overflow Control Policy. However, an increase in impervious surfaces could result in an incremental increase in the number or volume of combined sewer discharges. Projects located in San Joaquin County would not be regulated under a municipal stormwater permit.

Alameda and Peninsula Watershed Plans Actions. WSIP projects located in the Alameda and Peninsula watersheds would also be required to implement the following watershed management plan action pertaining to onsite stormwater collection and drainage systems:

- *Action sto1*. Assess the onsite stormwater collection and drainage systems at SFPUC facilities, Sunol Water Temple, applicable East Bay Regional Park District facilities, the Sunol Valley Golf Course, quarries, and nurseries for adequate sizing and erosion. Remediate where necessary by establishing preventive maintenance programs, infiltration drainfields and trenches, or wet and dry detention basins to optimize the quality of stormwater which flows into reservoirs and tributaries.

San Joaquin Region

Impact 4.5-6: Degradation of water quality as a result of alteration of drainage patterns or an increase in impervious surfaces		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	PSM
SJPL System	SJ-3	LS
SJPL Rehabilitation	SJ-4	LS
Tesla Portal Disinfection	SJ-5	LS

The Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) projects would include construction of new disinfection facilities, most likely at Tesla Portal, and could involve the creation or replacement of impervious surfaces. Construction of two crossover facilities under the SJPL System project (SJ-3) would also create new impervious surfaces. These facilities would not be covered by a municipal stormwater permit. However, the construction contractor(s) would be required to comply with SFPUC Construction Measure #10 (project site); post-construction stormwater controls would be implemented and maintained, as specified in the SWPPP; and a post-construction stormwater management plan would be prepared for these projects. With implementation of SFPUC Construction Measure #10 (project site) and implementation of control measures in compliance with these legal requirements, impacts related to increases in surface runoff, stormwater pollutants, and the potential for offsite erosion and flooding would be *less than significant* for these projects.

The Lawrence Livermore project (SJ-2) would construct a new disinfection facility, most likely at Thomas Shaft, and would create new impervious surfaces. If this project involved less than one acre of land disturbance, it would not be covered by the General Construction Stormwater Permit. Therefore, NPDES permitting requirements would not apply, and impacts related to increases in surface runoff and stormwater pollutants as well as the potential for offsite erosion and flooding would be *potentially significant*, but would be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #10 (project site) and implementation of appropriate source control and site design measures (Measure 4.5-6).

The SJPL Rehabilitation project (SJ-4) would involve rehabilitation of pipelines in a public right-of-way and would not result in the creation of new impervious surfaces. Although ground disturbance would occur, impacts related to the potential to alter drainage patterns would be *less than significant* with implementation of SFPUC Construction Measure #10 (project site) and post-construction erosion and sediment control BMPs required by NPDES regulations.

Sunol Valley Region

Impact 4.5-6: Degradation of water quality as a result of alteration of drainage patterns or an increase in impervious surfaces		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	LS
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	LS

The Alameda Creek Fishery project (SV-1) could include the construction of a pump house, which would create new impervious surfaces. The 40-mgd Treated Water (SV-3) and Treated Water Reservoirs (SV-5) projects would include improvements to the Sunol Valley WTP to provide new and upgraded water treatment facilities and increased treated water storage and would therefore result in the creation or replacement of impervious surfaces. Construction of new tunnel portals for the New Irvington Tunnel project (SV-4) would involve the creation or replacement of impervious surfaces, and the Calaveras Dam project (SV-2) would involve construction of new access roads, which would create new impervious surfaces. Each of these projects would also include ground disturbance activities with the potential to alter drainage patterns, including excavation of the proposed borrow and disposal areas the under the Calaveras Dam project; this project would also inundate a portion of Alameda Creek downstream of the dam.

However, impacts related to increased surface runoff and stormwater pollutants, as well as the potential for offsite erosion and flooding resulting from alteration of drainage patterns, would be *less than significant* with implementation of SFPUC Construction Measure #10 (project site) and implementation of control measures in compliance with stormwater permitting requirements. Stormwater control measures to achieve compliance with permitting requirements would be specified in the SWPPP and the post-construction stormwater management plan prepared for these projects. These projects would also implement Alameda WMP Action sto1 regarding stormwater collection systems, as described above. Inundation of a portion of Alameda Creek due to construction of the Calaveras Dam project (SV-2) would not result in offsite flooding, erosion, or sedimentation because releases from the dam would be controlled to prevent these effects.

The SABUP project (SV-6) would not involve the creation or replacement of impervious surfaces. Although ground disturbance would occur, impacts related to the potential to alter drainage patterns would be *less than significant* with implementation of SFPUC Construction Measure #10 (project site) and post-construction erosion and sediment control BMPs required by NPDES regulations.

Bay Division Region

Impact 4.5-6: Degradation of water quality as a result of alteration of drainage patterns or an increase in impervious surfaces		
BDPL Reliability Upgrade	BD-1	LS
BDPL 3 and 4 Crossovers	BD-2	LS
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	LS

The BDPL Reliability Upgrade (BD-1), BDPL 3 and 4 Crossovers (BD-2), and BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) projects would include construction of new vaults, shafts, and other structures, which would result in a small increase in impervious surfaces. Depending on the alternative selected, the BDPL 3 and 4 Seismic Upgrade at Hayward Fault project could construct up to 128,000 square feet of impervious surface. Impacts related to increased surface runoff and stormwater pollutants, as well as the potential for erosion and flooding resulting from alteration of drainage patterns, would be *less than significant* with implementation of SFPUC Construction Measure #10 (project site) and implementation of control measures in compliance with stormwater permitting requirements. Stormwater control measures to achieve compliance with permitting requirements would be specified in the SWPPP and post-construction stormwater management plan prepared for these projects.

Peninsula Region

Impact 4.5-6:	**Degradation of water quality as a result of alteration of drainage patterns or an increase in impervious surfaces**	
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS

Impervious surfaces could be created or replaced under the Baden and San Pedro Valve Lots (PN-1), CS/SA Transmission (PN-2), HTWTP Long-Term (PN-3), Lower Crystal Springs Dam (PN-4), and Pulgas Balancing Reservoir (PN-5) projects. Impacts related to increased surface runoff and stormwater pollutants, as well as the potential for offsite erosion and flooding due to the alteration of drainage patterns, would be *less than significant* with implementation of SFPUC Construction Measure #10 (project site) and implementation of control measures in compliance with stormwater permitting requirements. Stormwater controls to achieve compliance with permitting requirements would be specified in the SWPPP and post-construction stormwater management plan prepared for these projects. The CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4), and Pulgas Balancing Reservoir (PN-5) projects and those portions of the Baden and San Pedro Valve Lots project within the Peninsula watershed would also be required to implement Peninsula WMP Action sto1, as described above.

San Francisco Region

Impact 4.5-6:	**Degradation of water quality as a result of alteration of drainage patterns or an increase in impervious surfaces**	
SAPL 3 Installation	SF-1	LS
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	LS

Impervious surfaces associated with San Francisco Region projects could increase stormwater flows to the combined sewer system, with an associated potential increase in the volume or frequency of combined sewer discharges. However, none of the projects within San Francisco are expected to increase stormwater flows or alter drainage patterns in a way that would result in offsite erosion or flooding, because these projects would replace existing impervious surfaces. If new impervious surfaces were created, the extent would be minimal and would not be expected to measurably affect the volume or frequency of combined sewer discharges. Furthermore, projects in San Francisco would be required to implement erosion control measures in accordance with SFPUC Construction Measure #3 (onsite air and water quality measures during construction) and Article 4.1 of the San Francisco Public Works Code.

Therefore, impacts related to the alteration of drainage patterns and an increase in stormwater flows due to increased impervious surfaces would be *less than significant* for all San Francisco Region projects located in San Francisco (portions of the SAPL 3 Installation, SF-1; portions of the Groundwater Projects, SF-2; and the Recycled Water Projects, SF-3).

The Regional Groundwater Projects (SF-2) constructed within San Mateo County could involve the creation or replacement of impervious surfaces. Impacts related to increased surface runoff and stormwater pollutants, as well as the potential for offsite erosion and flooding due to the alteration of drainage patterns, would be *less than significant* with implementation of SFPUC Construction Measure #10 (project site) and implementation of control measures in compliance with stormwater permitting requirements. Stormwater controls to achieve compliance with permitting requirements would be specified in the SWPPP and post-construction stormwater management plan prepared for this project.

The portions of SAPL 3 Installation (SF-1) located in San Mateo County would include underground pipeline construction, either in unpaved areas or within a public right-of-way, and would not result in the creation of new impervious surfaces. Although ground disturbance would occur, impacts related to the potential to alter drainage patterns would be *less than significant* with implementation of SFPUC Construction Measure #10 (project site) and post-construction erosion and sediment control BMPs required by NPDES regulations.

4.6 Biological Resources

4.6 Biological Resources

This section provides a program-level evaluation of the potential effects of constructing and operating the proposed WSIP facility improvement projects on terrestrial biological resources and aquatic resources. Chapter 5 deals separately with the effects of the proposed water supply and system operations, including effects on fisheries and other biological resources associated with the water supply sources.

This discussion of potential effects begins by providing a broad regional context and then focuses on those sensitive habitats and key special-status species that have the highest degree of ecological sensitivity and legal protection. "Key special-status species" include those that have been formally listed or designated under the California and Federal Endangered Species Acts or identified as having special sensitivity in the WSIP program area.[1] At the programmatic level, this PEIR describes the nature and magnitude of potential WSIP impacts on key special-status species and sensitive habitats and frames appropriate mitigation strategies where necessary. Separate, project-level CEQA review will be conducted as appropriate for the WSIP projects; this review will describe project impacts on the full range of biological resources more precisely and, where necessary, tailor the mitigation measures presented in Chapter 6 to site-specific project conditions.

4.6.1 Setting

For the purpose of this analysis, the WSIP study area has been defined as comprising the areas directly affected by proposed projects and their immediate surroundings. The WSIP projects would be within the San Joaquin and Bay Area Delta ecological regions, two of the 10 ecological regions identified in California as part of a program to conserve biodiversity.[2] The San Joaquin ecological region has the highest concentration of endangered plants and animals of the two ecological regions crossed by WSIP projects. However, this ecological region—originally a vast mosaic of marshes, lakes, rivers, and uplands—has been substantially altered — even the most common elements (such as perennial grasses) have been replaced by Mediterranean annuals. The Bay Area Delta ecological region, adjacent to the San Joaquin Valley at a zone of overlap in the distribution of Northern and Southern California plants and animals, is the second most important region.

1 Several species known or that may occur on or in the program area are accorded "key special status" because of their recognized rarity or vulnerability to various causes of habitat loss or population decline. Some of these species receive specific protection defined in federal or state endangered species legislation, but others have been designated as key special-status species on the basis of expertise of state resource agencies or other organizations.

2 In 1991, a Biodiversity Memorandum of Understanding was signed by major federal and state agencies, with the intent of promoting interagency cooperation in conserving biodiversity across administrative boundaries. As part of this conservation strategy, California was divided into 10 ecological regions that are defined mainly by physical features, such as soils, topography, and climate, and by the distribution patterns of plants and animals.

Vegetation mapping developed for the 2005 California Gap Analysis Project (GAP),[3] conducted by the US Geological Survey, was used to compile **Figure 4.6-1** for the WSIP study area (California Gap Analysis Project, 2007). Vegetation groupings are reported as Wildlife Habitat Relationship (WHR) types, or habitat types (Mayer and Laudenslayer, 1988). WHR types are more useful when evaluating plant and animal resources simultaneously.

The setting discussion for each region describes the WHR habitat types as well as the sensitive natural communities known to occur within the WSIP study area. A natural community is a subset of a habitat type, with more or less consistent plant species composition, structure, and physical conditions. Of the roughly 375 natural communities defined and described by Holland (1986), about 125 are considered "sensitive" by the California Natural Diversity Database (CNDDB) because of their rarity in California. Sensitive natural communities often support key special-status species and are therefore a useful filter for identifying sensitive biological resources at the program level of analysis. Separate, project-level CEQA review will present detailed discussions of sensitive natural communities based on further field investigation and more refined project descriptions for the WSIP projects.

This setting discussion also identifies species considered to be key special-status species. In addition to state- and federally listed species, four other species have been included based on input from state resource agencies or other organizations. Western burrowing owl (*Athene cunicularia hypugaea*) is included in this analysis because it has been the subject of two recent listing petitions. Foothill yellow-legged frog (*Rana boylii*), a California species of special concern,[4] has been identified by the CDFG as a species deserving special attention in the Alameda Creek watershed. Finally, the Alameda Creek watershed's population of rainbow trout (*Oncorhynchus mykiss*) is also considered.[5] Because there are impassable barriers to fish migration in lower Alameda Creek, the National Marine Fisheries Service (NMFS) considers the population in Alameda Creek to be rainbow trout rather than steelhead (Federal Register, 2005a). In general, the key special-status species discussed in this analysis occupy sensitive habitats, and many are associated with other species of concern.[6] Together with the sensitive natural communities, key special-status species are used in this PEIR as indicators of the nature and extent of impacts on sensitive biological resources.

[3] GAP provides regional assessments of the conservation status of native vertebrate species and natural land cover types and facilitates the application of this information to land management activities. GAP is conducted as state-level projects and is coordinated by the U.S. Geological Survey Biological Resources Division.

[4] "California species of special concern" is a list of animal species maintained by the California Department of Fish and Game to identify animal species whose populations have declined in California and whose breeding populations are at risk of extirpation (local extinction) in California. Species on this list have no legal protection under the California Endangered Species Act.

[5] Rainbow trout and steelhead are the same species of trout (*Oncorhynchus mykiss*). Rainbow trout spend their whole life in freshwater; steelhead spend much of their life in the ocean but return to freshwater to spawn. Alameda Creek historically supported a run of steelhead, but impassable barriers have prevented steelhead from returning to spawn.

[6] "Other species of concern," defined in this PEIR as U.S. Fish and Wildlife Service (USFWS) candidate species, California Department of Fish and Game (CDFG) species of special concern, and California Native Plant Society (CNPS) List 1A, 1B, and List 2 species, are too numerous and site-specific to identify at the program level; however, most of these additional species are associated with the sensitive habitats addressed in this section. "Other species of concern" are evaluated in Chapter 5 for those WSIP elements that would not receive further CEQA analysis.

Habitat Types in the WSIP Study Area

THIS PAGE INTENTIONALLY LEFT BLANK

As noted above, project-level environmental review will address the full suite of species that must be assessed under CEQA—that is, candidates for listing, rare and endangered plants, federal species of concern, California species of special concern, and California fully protected species. Special-status fish species that could be affected by construction of specific WSIP projects are described in this section, but are discussed in more detail in the fisheries sections of Chapter 5 (Sections 5.3.6, 5.4.5, and 5.5.5), which addresses WSIP impacts related to the proposed water supply and system operations.

San Joaquin Region

Habitats

This region includes the area crossed by the Hetch Hetchy Aqueduct between Oakdale Portal and the Telsa Portal. Over 50 percent of this corridor has been altered by human development; it includes 34 percent cropland,28 percent orchard and vineyard, and 6 percent urban uses. Prevalent or important natural habitats are discussed below.

Annual Grassland (23%)

Introduced annual grasses are the dominant plant species in this habitat. Annual grassland habitats are open grasslands composed primarily of annual plant species. Many of these species also occur as understory plants in valley oak woodland and other habitats. Structure in annual grassland depends largely on weather and livestock grazing patterns. Dramatic differences in plant growth, both among seasons and among years, are characteristic of this habitat. Fall rains lead to the germination of annual plant seeds. Plants grow slowly during the cool winter months, remaining low in stature until spring, when temperatures increase and stimulate more rapid growth (Mayer and Laudenslayer, 1988). Annual grasslands are found primarily in the eastern and western portion of the San Joaquin Region, on the foothills, lower terraces, and periphery of the valley floor. In areas with soils underlain by a slowly pervious hardpan or claypan, annual grasslands are often associated with vernal pools, a sensitive natural community. Remnant alkali meadows, also a sensitive natural community, are present on floodplains near the San Joaquin River. These resources are too small to map at the program level and thus are included in this habitat type.

Blue Oak Woodland (6%)

Generally, blue oak woodland has an overstory of scattered trees, although the canopy can be nearly closed on more fertile sites. The canopy is dominated by broad-leaved trees that are 16 to 50 feet tall, commonly forming open stands on dry ridges and gentle slopes. Blue oak (*Quercus douglasii*) is the dominant species, constituting 85 to 100 percent of the trees. Typical understory is similar to that of annual grassland (Mayer and Laudenslayer, 1988). In this region, blue oak woodland is found in rolling terrain on the Sierra Nevada and Coast Range foothills at elevations above annual grasslands and below chaparral, woodland, and forest habitats.

Valley Foothill Riparian, Freshwater Emergent Wetlands, and Aquatic Habitats (3%)

The canopy height of valley foothill riparian vegetation is approximately 100 feet in a mature riparian forest, with a canopy cover of 20 to 80 percent. Most trees are winter-deciduous. There is a subcanopy tree layer and an understory shrub layer. Herbaceous vegetation constitutes about 1 percent of the cover, except in openings where tall herbs and shade-tolerant grasses are present. Generally, the understory is impenetrable and includes fallen limbs and other debris. Dominant species in the canopy layer are Fremont cottonwood (*Populus fremontii*), California sycamore (*Platanus racemosa*), and valley oak (*Quercus lobata*). Subcanopy trees are white alder (*Alnus rhombifolia*), box-elder (*Acer negundo* var. *californica*), and Oregon ash (*Fraxinus latifolia*). Riparian vegetation occurs along perennial watercourses that drain the San Joaquin Region, such as the San Joaquin River and its tributaries. Riparian vegetation is also seen along canals and ditches, although its development is generally limited by maintenance practices. Riparian, wetland, and aquatic habitats are the most productive and diverse of California's habitats, although they have been largely eliminated due to agriculture and urbanization, especially in the San Joaquin Region. For example, less than 2 percent of valley foothill riparian habitats remain in the Central Valley of California (Smith, 1980).

Freshwater emergent wetlands are characterized by erect, perennial herbs and grass-like plants with special adaptations to permanent or seasonal flooding. The term "emergent wetland" refers to the vegetation growing out of flooded soils. The vegetation may vary in extent from a few square feet to vast areas covering several square miles. The acreage of freshwater emergent wetlands in California has decreased dramatically since the turn of the century, especially in this region, due to drainage and conversion to other uses, primarily agriculture (Mayer and Laudenslayer, 1988). Extremely small remnant examples of freshwater emergent vegetation are associated with the San Joaquin River and other waterways.

Aquatic habitat includes perennial and seasonal streams, seasonal wetlands, vernal pools, natural ponds and lakes, and reservoirs, including stock ponds. Aquatic habitat throughout the Central Valley, and especially in the San Joaquin River watershed, has been greatly modified since the arrival of Europeans. Formerly vast marshes and riparian areas were cleared, drained, and otherwise modified for increasingly intensive agricultural operations, urbanization, and water storage and distribution projects. The resulting changes in aquatic habitat and water quality conditions (e.g., reduced or lost summer flows in many areas, elevated temperatures, increased turbidity, altered sediment transport, and the runoff or discharge of water containing pesticides, fertilizers, and animal or human wastes) reduced the available habitat suitable for native aquatic species while improving conditions for non-native species, many of which were deliberately or inadvertently introduced to the system, often to the further detriment of native species. Seasonal wetlands, ephemeral or seasonal streams, vernal pools, and stock ponds are located primarily in annual grasslands, mostly at the eastern and western sides of the San Joaquin Region.

Sensitive Natural Communities

Sensitive natural communities in the San Joaquin Region are found in areas of extensive natural habitat, such as the eastern and western foothills of the San Joaquin Valley, and near the San Joaquin River and its floodplain. The sensitive natural communities known to occur in this region and a brief description of known or potential distribution within the WSIP study area are provided below.

Valley needlegrass grassland and pine bluegrass grassland. Small areas dominated by purple needlegrass (*Nassella pulchra*) or pine bluegrass (*Poa secunda*) may occur in the lower Sierra Nevada foothills and Inner Coast Ranges, respectively, generally in areas with relatively thin soils, steep slopes, and historically limited livestock influence.

Northern hardpan vernal pool. This sensitive natural community is known to occur in the rolling grasslands and low terraces between Oakdale Portal and the irrigated pasture on the eastern valley floor.

Alkali meadow. This community is a native-dominated grassland found on alkaline-affected soils such as on the San Joaquin floodplain.

Coastal and valley freshwater marsh. A few natural examples of this formerly extensive community still remain, primarily in the vicinity of the San Joaquin River.

Great Valley cottonwood riparian forest, Great Valley mixed riparian forest, Great Valley valley oak riparian forest, Great Valley willow scrub, and Great Valley elderberry scrub. These riparian natural communities are associated with permanent water. The most extensive natural examples in the WSIP study area are along the San Joaquin and Tuolumne Rivers, although these communities may also be found along smaller perennial streams and along canals and other artificial waterways in the Central Valley.

Key Special-Status Species in the San Joaquin Region

Invertebrates

Vernal pool fairy shrimp (*Branchinecta lynchi*) is a federal threatened species typically found in vernal pools (winter rain pools formed over impervious or slowly permeable soils) and valley grassland drainage swales (areas where winter rain collects but does not stand as long as in vernal pools). This aquatic invertebrate is also found in unvegetated areas with pooled water. Of the listed vernal pool invertebrates, vernal pool fairy shrimp has the largest distributional range; it is found from southern Oregon to Southern California, but primarily in the Sacramento and San Joaquin Valleys.

Conservancy fairy shrimp (*Branchinecta conservatio*) is a federal endangered species found in large, turbid pools as well as in swales formed by old, braided alluvium that fill with winter rains. It ranges from the northern Sacramento Valley through the western San Joaquin Valley and into the South Coast of California.

Vernal pool tadpole shrimp (*Lepidurus packardi*) is a federal endangered species that shares the same habitat as vernal pool fairy shrimp. It ranges from the northern and central Sacramento Valley to the northern half of the San Joaquin Valley and the southern San Francisco Bay.

Valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*) is a federal threatened species. During the springtime, adult Valley elderberry longhorn beetles feed and lay eggs on blue elderberry (*Sambucus mexicana*) shrubs found within riparian habitat in the San Joaquin

Valley. It ranges from Red Bluff southward to Tulare or Kern County in the Central Valley, and from the valley floor to elevations as high as 2,200 feet (Barr, 1991). The only critical habitat designated for Valley elderberry longhorn beetle is in Sacramento County, along the Sacramento and American Rivers (Federal Register, 1980).

Program Area Occurrence. The best natural habitat along the Hetch Hetchy Aqueduct for the three key special-status crustaceans (vernal pool fairy shrimp, Conservancy fairy shrimp, and vernal pool tadpole shrimp) occurs in two areas: the low, rolling grasslands on the east side of the program area between Oakdale Portal and the irrigated pastures on the valley floor, and the alkaline grasslands near the San Joaquin River. There is critical habitat for vernal pool fairy shrimp (Unit 14A) in the alkaline grasslands of the San Joaquin River floodplain immediately south of the Hetch Hetchy Aqueduct (Federal Register, 2005b). Critical habitat for the Conservancy fairy shrimp in the San Joaquin Region (Unit 5) is located in the alkaline grasslands north of Highway 132 and west of Gates Road in Stanislaus County. Critical habitat for vernal pool tadpole shrimp in the San Joaquin Region (Unit 13) is situated at the lower edge of the rolling grasslands south of Claribel Road and adjacent to Tim Bell Road to the west of Oakdale Portal in Stanislaus County (Federal Register, 2005b).[7] Although their natural habitat is vernal pools and swales, these species could be found in the program area wherever water ponds for extended periods of time, including in manmade depressions. As a result, these species are considered potentially present throughout their range.

Valley elderberry longhorn beetle could be present anywhere that supports blue elderberry between Oakdale Portal and Tesla Portal, excluding leveled agricultural fields and developed areas.

Fishes

Chinook salmon (*Oncorhynchus tshawytscha*) is an anadromous[8] fish with populations that spawn at different times of year; the Central Valley fall- and late fall-run population is a federal species of concern (69 FR 73:19975). In the Central Valley, all designated critical habitat for the Chinook is in the Sacramento River watershed, not the San Joaquin River (CDFG, 2007). Chinook salmon spawn only once in their lifetime, and the resulting young swim to the ocean in their first months of life.

Central Valley Distinct Population Segment (DPS) steelhead (*Oncorhynchus mykiss*) is a federal threatened anadromous species historically known to occur within all of the major streams in the Central Valley. Steelhead Central Valley DPS critical habitat includes the San Joaquin River to the Tuolumne River, and the Tuolumne River to La Grange Dam (CDFG, 2007). Like Chinook salmon, steelhead live most of their lives in the ocean and return to freshwater to spawn.

---

7 From time to time, the USFWS revises the boundaries of critical habitats, and several such revisions were published for vernal pool invertebrates prior to 2007. As a result, the critical habitat boundaries described here may differ from current boundaries at the time of this reading, and may also differ slightly from those shown on Figure 4.6-2, which was prepared at a later time. This information should be considered as guidance for resource analysis; definitive analysis would be performed during preparation of project-level CEQA review.

8 Anadromous fish hatch (rear) in freshwater, migrate to the ocean (saltwater) to grow and mature, and migrate back to freshwater to reproduce.

Unlike Chinook salmon, steelhead are capable of spawning more than once. Young steelhead live in freshwater for their first year or more before migrating to the ocean.

Rainbow trout (*Oncorhynchus mykiss*) is the resident, stream-dwelling form of steelhead. When present in landlocked streams, rainbow trout are considered a distinct population segment (DPS). Currently, they are not part of the Central Valley DPS and thus have no federal or state protection status in the program area (NMFS, 2006).

Green sturgeon (*Acipenser medirostris*) is a bottom-feeding fish that lives in marine and estuarine waters but spawns in freshwater. It is a large, olive-green, bony-plated fish. Water flow is one of the key determinants of larval survival. Juveniles migrate downstream to estuaries, where they live and grow for some time before migrating to the ocean. The Southern DPS is federally listed as threatened (Federal Register, 2006a).

Program Area Occurrence. A wild run of Chinook salmon still exists in the Tuolumne River, but the steelhead run has dwindled, in part due to its requirement for year-round suitable conditions in the river. Efforts are underway to restore both runs, and are focused on the Chinook run in particular. The San Joaquin River and the Tuolumne River up to La Grange Dam are critical habitat for the steelhead Central Valley DPS (CDFG, 2007a; Federal Register, 2006a; CDFG, 2007).Green sturgeon is assumed to have used the main stem of the San Joaquin River for spawning as far south as the confluence with the Tuolumne River. No critical habitat is present in the program area for green sturgeon or Chinook salmon.

Amphibians and Reptiles

California red-legged frog (*Rana aurora draytonii*) is a federal threatened species known or expected to occur in association with stream crossings. Preferred habitat is permanent water (ponded water or slow-moving streams) with densely vegetated shorelines.

California tiger salamander (*Ambystoma californiense*), an inhabitant of annual grasslands, breeds and lays eggs in vernal pools and other temporary ponds (Zeiner et al., 1988). Recently listed as threatened at the federal level and a California species of special concern, California tiger salamander can be found seeking refuge in grassland burrows during most of the year. In the rainy season, tiger salamanders migrate to and breed in temporary ponds. Their summer retreats may be up to one-quarter mile from their winter breeding pools.

Program Area Occurrence. The most likely range for California red-legged frog is west of the California Aqueduct. No critical habitat has been designated for this species in the San Joaquin Region (Federal Register, 2006b). The historical range for California tiger salamander covers the entire San Joaquin Region, from Oakdale Portal to Tesla Portal. The species is now known to occur primarily in the eastern grasslands in the San Joaquin Region, where it breeds in vernal pools and stock ponds. Historical records indicate that this species was known to be present within the Tuolumne River floodplain as well as the rolling grasslands to the north and south. Critical habitat for California tiger salamander has been designated in Stanislaus County just north of the Stanislaus River near Oakdale (Unit 7) and south of Highway 132 in Stanislaus

County (Unit 8). The highest quality natural habitat for this species is natural grasslands that contain large vernal pools, such as those found in the eastern grasslands; however, populations may persist in irrigated pasture and orchards where there is sufficient ponded water for breeding.

Birds

Swainson's hawk (*Buteo swainsoni*), a state threatened species, hunts for small mammals and insects in the grasslands of the San Joaquin Valley. Mature trees (such as oaks) surrounded by large open areas provide nesting habitat. Swainson's hawk nests in the valley are frequently found in riparian areas adjacent to grasslands, grazing lands, and some croplands. Breeding occurs from late March through late August.

Western burrowing owl (*Athene cunicularia hypugaea*), a federal species of concern and California species of special concern, inhabits grasslands as well as disturbed or bermed areas. Burrowing owl is included in this analysis because recent evaluations of its status suggest the species may be a candidate for state or federal listing in the near future. These owls utilize the burrows of ground-dwelling mammals, in particular California ground squirrel (*Spermophilus beecheyi*). Breeding occurs from February through August, with a peak in April and May.

Least Bell's vireo (*Vireo belli pusillus*) is listed as endangered at both the state and federal levels. It inhabits riparian brush, where it feeds on insects and nests in dense vegetation within a meter of the ground. This species winters in Baja California and migrates to central and coastal California to breed. Least Bell's vireo was formerly widespread in riparian habitats in the Central Valley; the species has been considered extinct from the valley until recent years, but anecdotal reports suggest it may have returned. Least Bell's vireo has high site fidelity (i.e., individuals return to nest in the same territory and often in the same shrub). Nesting can extend from late March to August.

Program Area Occurrence. Swainson's hawk is opportunistic in its foraging and could be found virtually anywhere. Nesting is more restricted, but could occur anywhere along the Hetch Hetchy Aqueduct where large trees are present. Swainson's hawks can nest in riparian forest or in isolated trees near agricultural fields. This species has been reported as nesting in large trees in some of the older sections of large San Joaquin Valley cities. Western burrowing owl is also opportunistic in its foraging habits and can be found in agricultural fields as well as grasslands throughout the program area. The species can persist at the edges of plowed fields and along the banks of canals. Since the USFWS has not listed these two species, no critical habitat has been designated for them. A recent sighting of Least Bell's vireo at the San Joaquin River National Wildlife Refuge has confirmed its presence in the Central Valley.

Mammals

San Joaquin kit fox (*Vulpes macrotis mutica*), a federal endangered and state threatened species, primarily inhabits annual grassland habitat on flat terrain. San Joaquin kit foxes usually construct dens in loose soils, often enlarging the dens or burrows of other species. Evidence of den use includes the presence of scat, prey remains, tracks, or matted vegetation at the entrance. However, evidence of den use is not always readily apparent. Kit foxes are born in late February or early March and will venture from the dens by late March. Young of the year generally disperse by October, when family groups begin to split up.

The **riparian, or San Joaquin, woodrat** (*Neotoma fuscipes riparia*) is a federal endangered species closely associated with large rivers in the San Joaquin Valley. Its habitat is dense riparian vegetation with a mix of brush and trees, with trees, snags, and logs for nesting. Riparian woodrats live in loosely cooperative societies, building large stick houses in dense brush such as willow thickets. They are mostly nocturnal and feed on plant material such as flower buds, young shoots, nuts, and fungi.

Program Area Occurrence. Currently, San Joaquin kit fox is primarily present in the remaining native valley and foothill grasslands and saltbush scrub communities of the valley floor and surrounding foothills (Endangered Species Recovery Program, 2007). The only potentially suitable habitat for riparian woodrat in the program area is along the San Joaquin River. No critical habitat has been designated for either San Joaquin kit fox or the riparian woodrat.

Vernal Pool Plants

Vernal pools are seasonal wetlands formed in gently undulating or rolling topography where the soil is underlain by a slowly permeable subsoil layer. The extreme conditions of ponding in the winter and complete drying in the summer have given rise to many species that are adapted to these conditions, and further new species have evolved in response to specific conditions of soil texture, chemistry, and length of inundation. Many of the key special-status vernal pool plants are closely associated with specific soil types. The physical conditions necessary for vernal pools are permanently altered when the subsoil layer is disturbed, so vernal pools persist mainly on the uncultivated terrace soils peripheral to the valley floor.

Succulent owl's-clover (*Castilleja campestris* ssp. *succulenta*), a federal endangered, state endangered, and CNPS List 1B plant species, occurs on somewhat acid, gravelly loams such as Pentz and Redding soils. **Hoover's spurge** (*Chamaesyce hooveri*), a federal threatened and CNPS List 1B species, occurs on large and relatively deep, clay-lined vernal pools. Four related grass species, **Colusa grass** (*Neostapfia colusana*), **San Joaquin Valley Orcutt grass** (*Orcuttia inaequalis*), **hairy Orcutt grass** (*Orcuttia pilosa*), and **Greene's tuctoria** (*Tuctoria greenei*), are CNPS List 1B and both federally and state-listed species. These species are typically found in the larger and deeper vernal pools on the terrace soils on the east side of the San Joaquin Valley.

Program Area Occurrence. The grasslands in the eastern portion of the valley contain vernal pools on the somewhat acid soils of the Keyes-Pentz-Peters association—habitat consistent with that of several key special-status vernal pool plants. The largest and deepest vernal pools are the most likely to support rare vernal pool plants. Critical habitat has been designated for all six of these plants. Critical habitat units for five of the species are located at or near the Hetch Hetchy Aqueduct, primarily in Stanislaus County. Unit 2A for succulent owl's-clover extends from Highway 132 north to Rock River Road and Warnerville Road, just south of the aqueduct. Unit 4A for Hoover's spurge also occupies a large area of rolling grasslands from Highway 132 north to Rock River Road and Warnerville Road. Unit 4A for Colusa grass extends both to the north and south of Willms Road near the Tuolumne-Stanislaus County line; Unit 4B lies to the south of Claribel Road, south of the aqueduct, and Units 4D and 4E occupy the large area of rolling grasslands from Highway 132 north to Warnerville Road. Units 4A and 4B for hairy Orcutt grass are located south of Highway 132 and the Tuolumne River. Unit 6D for Greene's tuctoria is located in eastern Stanislaus County south of Rock River Road, and Unit 6E is located on the western edge of Tuolumne County on both sides of Highway 120 (Federal Register, 2005b).

Grassland Plants

Large-flowered fiddleneck (*Amsinckia grandiflora*), a state endangered, federal endangered, and CNPS List 1B annual plant, grows in grasslands on deep loamy soils, typically on northern slopes of the Inner Coast Ranges. Its historical distribution was from Antioch to northern San Joaquin County, but the species is currently restricted to three natural populations in Corral Hollow and one introduced population at Black Diamond Mines Regional Park.

Program Area Occurrence. In Corral Hollow, there are two natural populations of large-flowered fiddleneck at Lawrence Livermore National Laboratory's Site 300 and one on private land. The population on private land is the largest and the most recently discovered, suggesting that additional populations could exist in the area. The Lawrence Livermore project (SJ-2), at the Thomas and Mocho Shafts and their access roads, is located in an area that could be suitable habitat for this species. Although not strictly located within the San Joaquin Region, large-flowered fiddleneck is included in this discussion because of its close association with Tesla Portal. Critical habitat has been designated for large-flowered fiddleneck and consists of 160 acres at Lawrence Livermore Laboratory's Site 300 in Corral Hollow (Federal Register, 1985).

Riparian Plants

Delta button-celery (*Eryngium racemosum*), a state endangered, CNPS List 1B plant, grows in clay depressions in riparian scrub. It is geographically restricted to the floodplains of large rivers in the area from San Joaquin County to Merced County.

Program Area Occurrence. There are two CNDDB records for Delta button-celery at Caswell State Park and one in the city of San Joaquin, about three miles north of the Hetch Hetchy Aqueduct as it crosses the San Joaquin River. If any suitable habitat is present, it would be near the San Joaquin River. No critical habitat is designated for this species.

Sunol Valley, Bay Division, Peninsula, and San Francisco Regions

Habitats

The Sunol Valley, Bay Division, Peninsula, and San Francisco Regions support some of the same habitats already described for the San Joaquin Region, including annual grassland (15 percent) and blue oak woodland (5 percent). In addition, these regions contain coastal oak woodland (6 percent), valley oak woodland (2 percent), coastal scrub (1 percent), riparian and aquatic habitats (less than 1 percent), and saline emergent wetland (1 percent). Blue oak woodland was described in the preceding section; its occurrence in these regions is limited to the Inner Coast Ranges, primarily east of the Sunol Valley. The other habitat types are described below. Many occurrences of habitat types are interspersed, but are too small to map at the program level. Due to the large number of key special-status species known to occur in the Bay Area, and the extent of habitat conversion to urban and agricultural land uses that has taken place, even small areas of natural habitat may have high ecological importance.

Annual Grassland (15%)

As noted in the preceding section, annual grasslands are non-native-dominated but support a variety of native annual and perennial grasses and broadleaf plants. Under some harsh site conditions, such as very dry, steep, or infertile soils, native species still predominate. Examples of these habitats are serpentine grasslands, valley needlegrass grassland, and wildflower fields, all of which are considered sensitive natural communities (see discussion under Sensitive Natural Communities, below). Most remnant examples of these communities are too small to map at the program level, but would be identified (and potential impacts addressed) at the project level. Some native grasslands, including purple needlegrass grassland and potential serpentine grassland, are located to the east, west, and north of Calaveras Reservoir in the Sunol Valley (SFPUC, 2001).

Coastal Oak Woodland (6%)

Coastal oak woodland is extremely variable. In the program area, this habitat type consists of an open- to closed-canopy overstory primary made up of evergreen hardwoods, such as coast live oak (*Quercus agrifolia*) and California bay (*Umbellularia californica*), that are 15 to 70 feet tall. The understory is also variable; it can consist of shrubs from adjacent scrub or chaparral, or shrubs scattered among and under trees. Where trees form a dense canopy, the understory can be a lush cover of shade-tolerant shrubs and herbs or a sparse cover with a thick layer of leaf litter (Mayer and Laudenslayer, 1988). Coastal oak woodland is found on moderate slopes and sometimes near watercourses in the Sunol Valley, Peninsula, and San Francisco Regions.

Valley Oak Woodland (2%)

Valley oak woodland varies from savanna-like to forest-like stands of trees with partially closed canopies, comprised mostly of winter-deciduous, broad-leaved species. Denser stands typically grow in valley soils along natural drainages. Similarly, the shrub layer is best developed on deep soils near drainages, becoming insignificant in the uplands with the sparser stands of trees. In these locations, the herbaceous understory resembles annual grassland. In most situations, the canopy of valley oak woodland consists almost exclusively of valley oaks. Mature trees with well-developed crowns range in height from 50 to 115 feet (Mayer and Laudenslayer, 1988). Because valley oak woodland is typically found on deep soils on gentle slopes, most has been urbanized. Narrow bands of valley oaks are often associated with watercourses in all three regions, but the Sunol Valley still supports extensive stands of valley oak woodland on the valley floor.

Coastal Scrub (1%)

The structure of coastal scrub ranges from low- to moderate-height shrubs with generally small leaves, flexible branches, semiwoody stems growing from a woody base, and a shallow root system. In the program area, mature coastal scrub consists of a nearly closed canopy of dense shrubs about 7 feet tall with a limited herbaceous layer growing in the openings. Bare zones about 3 feet wide may extend from stands dominated by coastal sage (*Artemisia californica*) into surrounding annual grasslands (Mayer and Laudenslayer, 1988). Most of the coastal scrub in the program area is located on steep, rocky slopes above the Sunol Valley, but some also occurs on steep, rocky slopes in the Peninsula and San Francisco Regions, such as in San Mateo Creek Canyon.

Valley Foothill Riparian and Aquatic Habitats (1%)

These habitat types are extremely rare and have been diminished in the Sunol Valley, Bay Division, Peninsula, and San Francisco Regions, but some of the best remaining examples in the Bay Area lie within the Sunol Valley Region. The Sunol Valley supports one of the largest remaining stands of sycamore alluvial woodland in the Bay Area—a widely spaced stand of sycamores in the broad floodplain of Alameda Creek. Well-developed examples of arroyo willow scrub and valley oak forest, and even small examples of alder forest, are found along Alameda Creek and its tributaries in the Sunol Valley as well as along the larger and more natural creeks in the Peninsula and San Francisco Regions, such as San Mateo Creek.

Aquatic habitats include perennial and seasonal streams, seasonal wetlands, vernal pools, natural ponds and lakes, and reservoirs, including stockponds. Stockponds are the main breeding sites for both California tiger salamanders and California red-legged frogs.

South San Francisco Bay is a shallow, mud-bottom estuary, with limited circulation and events of poor water quality during the dry season and following flood flows in the wet season. Numerous factors have greatly modified the ecology of the South Bay, including deposition of vast amounts of sediment, reclamation of tidal wetlands, unregulated harvest of native species, pollution, reduced input of freshwater, and rampant, continuing introductions of non-native species of plants, fish, and invertebrates. Nevertheless, the South Bay still serves as a migration corridor for anadromous fishes such as Chinook salmon and steelhead, and plans are underway to restore stream habitat where possible. One such example is the SFPUC's removal of the Sunol and Niles Dams on Alameda Creek in 2006. The Peninsula and San Francisco Regions represent the most highly altered aquatic habitats of all. Several of the larger streams occupy their natural channels in the Peninsula hills, and then enter culverts as they pass the low-lying areas before emptying into the bay. The SFPUC reservoirs—Upper and Lower Crystal Springs Reservoirs and San Andreas Reservoir—are the largest freshwater bodies. Lake Merced is a smaller lake in western San Francisco.

Saline Emergent Wetland (1%)

The South Bay supports a network of tidal sloughs and salt marshes, and efforts are underway to restore extensive areas of former marshes. Saline emergent wetlands are salt or brackish marshes consisting mostly of perennial herbs and grass-like plants, ranging in height from 0.7 to 7 feet or more, along with algal mats on moist soils and at the base of larger plants. These wetlands occur above sand and mud flats flooded for long periods with each cycle of the tide, and below upland communities that are not subject to tidal action; they provide food, cover, nesting, and roosting habitat for a variety of birds, mammals, reptiles, and amphibians. These include endemic subspecies of birds such as the endangered California clapper rail (*Rallus longirostris obsoletus*), and mammals such as the salt marsh harvest mouse (*Reithrodontomys raviventris*).

Sensitive Natural Communities

Sensitive natural communities in these regions are concentrated in areas of extensive natural habitat, such as the Sunol Valley, the Peninsula watershed, and various perennial watercourses. The sensitive natural communities known to occur in these regions and a brief description of known distribution within the WSIP study area are provided below. Other sensitive natural communities may also be present, especially in areas of extensive natural vegetation, such as along the margins of San Francisco Bay, the Alameda and Peninsula watersheds, and San Bruno Mountain.

Valley needlegrass grassland and serpentine grassland. Areas dominated by native bunchgrasses occur in grasslands in the Sunol Valley, especially to the north and east of Calaveras Reservoir, on the ridges to the east and west of Upper and Lower Crystal Springs Reservoirs, and on San Bruno Mountain. Those areas on serpentine soils are considered serpentine grassland, while others are simply native bunchgrass-dominated and are considered valley needlegrass grassland.

Alkali meadow. Native-dominated grasslands on alkaline-affected soils are found along the margins of the South Bay, such as at the Don Edwards San Francisco Bay National Wildlife Refuge in Fremont.

Northern coastal salt marsh. This tidal marsh, located around the periphery of San Francisco Bay, is dominated by pickleweed (*Salicornia* spp.). A large amount of this sensitive natural community has been lost to development, and much of the remaining areas have been modified by diking and draining. However, even somewhat degraded examples of northern coastal salt marsh provide habitat for a number of key special-status species that may be found in the vicinity of the Newark and Ravenswood Valve Houses, and in low-lying land near San Bruno Mountain.

Coastal and valley freshwater marsh and freshwater seep. Examples of these natural communities can be found along the perimeter of Calaveras Reservoir and Upper and Lower Crystal Springs Reservoirs, and in areas where there is permanent standing water, such as below Crystal Springs Dam. Freshwater seep communities can be found occasionally in the Peninsula and Alameda watersheds.

Central coast cottonwood-sycamore riparian forest, central coast live oak riparian forest, central coast arroyo willow riparian forest, sycamore alluvial woodland, white alder riparian forest, valley oak riparian forest, and central coast riparian scrub. These riparian natural communities are associated with permanent water. The most extensive natural examples in the WSIP study area are in the Sunol Valley along Alameda Creek and its tributaries, in the

Peninsula watershed along San Mateo Creek and its tributaries. Smaller examples are also found along other permanent streams such as the Guadalupe River and other creeks in the East Bay, South Bay, and Peninsula, although many of these have been highly altered through channelization, urbanization, and vegetation management for flood control.

Key Special-Status Species in the Sunol Valley, Bay Division, Peninsula, and San Francisco Regions

For species already described under the San Joaquin Region, the text below provides only "Program Area Occurrence" information.

Invertebrates

Vernal pool tadpole shrimp. See description in the San Joaquin Region section for status and ecology.

Bay checkerspot butterfly (*Euphydryas editha editha [=E. e. bayensis]*), a federal threatened species, is a medium-sized butterfly with a wingspan of 1 to 2 inches. The black bands along the veins on the upper wing surface contrast sharply with bright red and yellow spots. The black basal coloration gives a checkered appearance. Habitat consists of isolated patches of native grassland on shallow, serpentine-derived or similar soils that support growth of the butterfly's two larval foodplants, annual plantain (*Plantago erecta*) and annual owl's-clover (*Orthocarpus densiflorus*).

Callippe silverspot butterfly (*Speyeria callippe callippe*), a federal endangered species, is a small yellow-orange butterfly with dark markings. There are 16 subspecies of silverspot, of which two are found in the Bay Area. Only the Callippe silverspot subspecies is protected under the Federal Endangered Species Act. The Callippe silverspot larval foodplant is the Johnny-jump-up violet (*Viola pedunculata)*, which is generally found in native-dominated grasslands. The adults feed on nectar from several sources, including California buckeye (*Aesculus californica*), coyote mint (*Monardella villosa)*, and thistles such as *Cirsium* and *Silybum*.

Program Area Occurrence. Bay checkerspot butterfly is found on serpentine grasslands on San Bruno Mountain and on several ridges east of Upper and Lower Crystal Springs Reservoirs. Surveys for this species have been carried out in the native grasslands around Calaveras Reservoir, but none have been found (Arnold, 2005). Critical habitat for Bay checkerspot butterfly (see the Regulatory and Conservation Planning Framework section, below) is mapped on San Bruno Mountain in the San Francisco Region, extending to the eastern shoulder of the mountain, including a small segment of the Crystal Springs Pipeline No. 2. Another critical habitat unit is located in the Bay Division Region, extending from Edgewood County Park to the west side of Cañada Road, slightly south of the program area. A third unit is located at Stanford University's Jasper Ridge Ecological Reserve, to the southwest of the Bay Division Pipelines Nos. 3 and 4 (Federal Register, 2001).

Callippe silverspot butterfly is found on San Bruno Mountain and at Edgewood County Park. A population of silverspot butterfly similar to the endangered subspecies was observed on the Alameda watershed near Calaveras Reservoir in 2004 (Arnold, 2005). The Alameda watershed population exhibits characteristics somewhat intermediate between the Callippe silverspot and another subspecies, *S. callippe comstocki*; however, Arnold (2005) concluded that its attributes were sufficiently similar to the Callippe silverspot that it should be treated as such.

A review of the distribution of the vernal pool invertebrates and information from an SFPUC biologist (Stoltz, 2006) indicates that habitat in the Sunol Valley area is considered unsuitable for vernal pool fairy shrimp, vernal pool tadpole shrimp, and Conservancy fairy shrimp and is somewhat outside the known range for these species. Several recent records exist for vernal pool tadpole shrimp in the alkaline grasslands near the Don Edwards San Francisco Bay National Wildlife Refuge, so this species is considered to be potentially present in the Bay Division Region. Critical Habitat Units 16A and 16B for vernal pool tadpole shrimp are located west of Interstate 880 between Mowry Slough and Mud Slough in the Don Edwards San Francisco Bay National Wildlife Refuge (Federal Register, 2005b), some distance from both the Bay Division Pipelines Nos. 1 and 2 and Bay Division Pipelines Nos. 3 and 4.

Fishes

Chinook salmon. The California Coast DPS Chinook salmon is federally listed as threatened. Chinook salmon spawn only once, and their young migrate to the ocean during their first months of life. The designated critical habitat for this DPS extends only from Eureka to Santa Rosa, but the range of the population includes San Francisco Bay.

Central California Coast DPS steelhead (*Oncorhynchus mykiss*) is federally listed as threatened. Like the Central Valley DPS steelhead, this population segment spawns in streams, then swims to the ocean where it grows and matures, returning to spawn in its natal stream. This DPS is defined as steelhead originating in streams that drain directly into San Francisco and San Pablo Bays, or into the Pacific Ocean along the Central Coast.

Rainbow trout (*Oncorhynchus mykiss*) is the resident, stream-dwelling form of steelhead. When present in landlocked streams, rainbow trout are considered a distinct population segment and are not part of the Central California Coast DPS (NMFS, 2006).

Program Area Occurrence. Chinook salmon of the California Coast DPS have spawned in small numbers in accessible portions of the Guadalupe River in recent years, although this drainage has not been designated as critical habitat. In the Bay Division and Peninsula Regions, Central California Coast DPS steelhead have continued to spawn in accessible reaches of the larger creeks draining into San Francisco Bay as well as the major creeks along the coast that drain into the Pacific Ocean. Critical habitat for the Central California Coast DPS steelhead includes the Guadalupe River, Coyote Creek, and San Francisquito Creek and their tributaries (Federal Register, 2005a).

For many decades, impassible barriers along Alameda Creek have blocked steelhead from entering the upper Alameda Creek watershed in the Sunol Valley to spawn. In 2006, the SFPUC removed two upstream barriers, the Niles and Sunol Dams. However, other barriers, including the

BART weir downstream, continue to block anadromous fish passage. Thus, rainbow trout is the only form of *Oncorhynchus mykiss* present in Alameda Creek within the Sunol Valley Region.

On the coast side of the Peninsula watershed, Central California Coast DPS steelhead spawn in Pilarcitos and San Pedro Creeks, both of which are considered critical habitat for steelhead.

In the Bay Division and Peninsula Regions, Central California Coast DPS steelhead have continued to spawn in accessible reaches of Coyote Creek, Guadalupe River, San Francisquito Creek, Stevens Creek, San Mateo Creek, and smaller seasonal streams. Additionally, Chinook salmon of the California Coastal DPS have spawned in small numbers in accessible portions of the Guadalupe River in recent years.

Amphibians and Reptiles

Foothill yellow-legged frog (*Rana boylii*) is a California species of special concern. It lives in shallow, moving water with riffles and sunny banks. It is always found near water. Populations of this species have been nearly eliminated from the Bay Area. Foothill yellow-legged frog is subject to predation from introduced species, poorly timed fluctuations in water releases from upstream reservoirs, and unfavorable precipitation conditions, all of which have contributed to its ongoing decline in California.

California red-legged frog. See description in the San Joaquin Region section for status and ecology.

California tiger salamander. See description in the San Joaquin Region section for status and ecology.

San Francisco garter snake (*Thamnophis sirtalis tetrataenia)* is a federal and state endangered and California fully protected species most often found in the vicinity of standing water, mainly ponds, lakes, marshes, and sloughs.

Alameda whipsnake (*Mastcophis lateralis euryxanthus)* is a federal and state threatened species that occurs within coastal scrub, woodland, and grassland habitat in the eastern Bay Area. Home ranges are typically centered on areas of scrub habitats with open to partially open canopies, on south-, southeast-, east-, and southwest-facing slopes.

Program Area Occurrence. Healthy populations of foothill yellow-legged frogs are present in the Alameda watershed. California red-legged frog is well distributed in suitable habitat throughout the three regions. Critical Habitat Unit SNM-1A includes much of the Peninsula watershed north of Highway 92 (Federal Register, 2006b). Critical Habitat Unit STC-1A for California red-legged frog has also been designated in Santa Clara County south of Calaveras Reservoir (CDFG, 2007a). California tiger salamander has been reported to occur in pools in the Sunol Valley near the Alameda East and West Portals; however, in the Bay Area it has disappeared from almost all of the lower elevation areas, except for one small site at the Don Pedro San Francisco Bay Wildlife Refuge near Fremont (Goals Project, 2000) and a declining population at Lake Lagunitas at Stanford University. They may extend somewhat further north on the Peninsula. Critical

Habitat Unit 3 for California tiger salamander is located in the Calaveras Creek watershed, between Arroyo Hondo and Calaveras Reservoir.

The largest extant population of San Francisco garter snake is on SFPUC Peninsula watershed lands (USFWS, 1985), in and near most of the Peninsula region projects (PN-1, PN-2, PN-4 and PN-5) and the western terminus of the Bay Division pipeline (BD-1). No critical habitat is designated for this species. The Alameda whipsnake range is restricted to the Inner Coast Ranges in western and central Contra Costa and Alameda Counties (Federal Register, 2005c). Critical Habitat Unit 5B for Alameda whipsnake includes 18,214 acres in the Sunol Valley between Calaveras and San Antonio Reservoirs. This habitat unit therefore includes the southern but not northern part of the Sunol Valley (the New Irvington Tunnel project, SV-4, is outside the designated critical habitat).

Birds

Bald eagle *(Haliaeetus leucocephalus)* is a federal threatened species, but was proposed for delisting in 1999. It is state-listed as endangered and is a California fully protected species. Bald eagle nests in tall trees, often near water. It is an opportunistic forager, feeding on fish, waterfowl, and carrion. Breeding territory for bald eagle has been expanding in the past several decades, which prompted the proposal for federal delisting.

Western burrowing owl. See description in the San Joaquin Region section for status and ecology.

California clapper rail (*Rallus longirostris obsoletus*) is a federal and state endangered species and a California fully protected species. It is a secretive, hen-like bird that nests and forages in emergent wetlands with pickleweed (*Salicornia* spp.), cordgrass (*Spartina foliosa*), gumplant (*Grindelia stricta* var. *angustifolia*), and bulrush (*Scirpus* spp.). Clapper rails are non-migratory, but juveniles have been known to move as much as a half-mile when dispersing. This species feeds primarily on aquatic invertebrates (Goals Project, 2000).

California black rail (*Laterallus jamaicensis coturniculus*) is state-listed as threatened. It relies on tidally influenced, heavily vegetated, high-elevation marshlands. It is highly secretive and is observed mainly during high tides when forced out by high water. Its habitat requirements resemble those of the salt marsh harvest mouse but are more restrictive (Goals Project, 2000).

Western snowy plover (*Charadrius alexandrinus nivosus*) is a federal threatened species and a California species of special concern. It nests and forages on sandy beaches on marine and estuarine shores. It requires sandy, gravely, or friable soils for nesting.

Program Area Occurrence. Bald eagle has been frequently observed wintering near large lakes and reservoirs such as those in the Alameda Creek watershed, and in recent years may be breeding there as well. Western burrowing owl is well distributed in suitable habitat throughout the WSIP study area, especially in the South Bay. The largest populations of California clapper rail occur in the Dumbarton and Mowry Marshes in the East Bay, and the Palo Alto and Greco Marshes on the

Peninsula, both near the Hetch Hetchy Aqueduct. Nesting California black rail were historically known to occur in the South Bay, but the individuals recently observed there are juveniles and non-breeding adults. The majority of western snowy plover nest in salt evaporation ponds south of the San Mateo Bridge, predominantly on the eastern side of San Francisco Bay (using Guadalupe Slough as the division line) (Goals Project, 2000).

Mammals

San Joaquin kit fox. See description in the San Joaquin Region section for status and ecology.

Salt marsh harvest mouse (*Reithrodontomys raviventris*) is a small, native mouse that is both federal and state endangered and California fully protected. It is endemic to the salt marshes and adjacent diked wetlands of San Francisco Bay and is most abundant in the middle and upper portions of salt marshes in the thick perennial cover of pickleweed (Goals Project, 2000).

Program Area Occurrence. Two adult San Joaquin kit fox were sighted recently on another SFPUC project site in the Sunol Valley.[9] Despite this sighting of apparently a pair of transient animals, this species is not otherwise considered present in the Sunol Region. Salt marsh harvest mouse occurs most frequently in suitable habitat that lies generally south of a line between Redwood City and Hayward (Goals Project, 2000).

Plants

Fountain thistle (*Cirsium fontinale* var. *fontinale*) is both a state and federal endangered species. It grows in moist soils near springs and seeps on serpentine soils. It is restricted to just a few populations in the vicinity of Crystal Springs Reservoir and nearby uplands.

San Mateo woolly sunflower (*Eriophyllum latilobum*) is both a state and federal endangered species. It grows in shady openings in live oak woodlands, both on and off serpentine soils. San Mateo woolly sunflower is a highly restricted endemic whose distribution is limited to several hundred individuals in less than a dozen scattered subpopulations in the Crystal Springs area of San Mateo County. Many of the known populations occur on roadcuts along Crystal Springs Road in the San Mateo Creek canyon.

M**arin western flax** (*Hesperolinon congestum)* is both a state and federal threatened species. It grows on serpentine ridges covered with bunchgrass from Marin County to San Mateo County. There are now 20 known occurrences. Residential development and road and freeway construction have eliminated five of the historically known populations of Marin western flax.

Program Area Occurrence. Fountain thistle grows along the shores of Upper Crystal Springs Reservoir. San Mateo woolly sunflower is known to occur in several colonies along Crystal Springs Road, where it is highly vulnerable both to proposed WSIP project activities and to ordinary road maintenance activities. Marin western flax is known to occur in grasslands in the Crystal Springs and San Mateo Creek canyon area.

9 A single individual was observed during nighttime surveys associated with the SFPUC Sunol / Niles Dam Removal Project in 2006, performed by Environmental Science Associates.

Regulatory and Conservation Planning Framework

Key Special-Status Species and Other Species of Concern

Federal Endangered Species Act

Under the Federal Endangered Species Act (FESA), the Secretary of the Interior (represented by the USFWS) and the Secretary of Commerce (represented by the NMFS) have joint authority to list a species as threatened or endangered (16 United States Code [USC] 1533[c]). Pursuant to the requirements of FESA, an agency reviewing a proposed project within its jurisdiction must determine whether any federally listed threatened or endangered species may be present in the project area and determine whether the project will have a potentially significant impact on such species. In addition, the agency is required to determine whether the project is likely to jeopardize the continued existence of any species proposed for listing under FESA or result in the destruction or adverse modification of critical habitat proposed to be designated for such species (16 USC 1536[3], [4]). Project impacts on these species or their habitats are considered potentially significant in this PEIR. Before granting a permit, the U.S. Army Corps of Engineers will ask either or both the USFWS and NMFS to concur with its decision to issue the permit. If endangered species or endangered migratory fish protected under FESA are present in the project area, a consultation under Section 7 of the act may be required. Consultations may be either formal or informal. If a formal consultation is required, the project proponent prepares a Biological Assessment to evaluate the potential impacts of a particular project on listed species that are known or likely to occur in the project area. The agency with jurisdiction over the listed species (either the USFWS or NMFS) then reviews the Biological Assessment and issues a Biological Opinion (the agency's determination as to whether or not the proposed project will jeopardize the listed species), which includes the conditions under which the project may proceed; an incidental take permit is also issued, identifying the number of individuals of the listed species allowed to be harmed by project activities without violating the terms of the permit. If appropriate for certain listed species (e.g., California red-legged frog), the Corps may invoke a Programmatic Biological Opinion.[10]

FESA of 1973 was amended in 1982 under Section 10 of the act to permit the "taking" (i.e., killing, harassing, or disturbing the habitat of) federally listed species when such taking was incidental to an otherwise lawful activity (16 USC 1539). It was the intent of Congress to resolve the issues of onsite taking of listed species or critical habitat by creating the habitat conservation plan (HCP) process. An HCP accompanies a permit application to "take" a certain number of threatened and endangered species or acres of their habitat over a certain period of time, and demonstrates that the permit applicant will compensate for the taking so as to achieve "no net reduction" in the species' chances for survival. There is one adopted HCP in the WSIP study area—the *San Joaquin County Multi-species Habitat Conservation and Open Space Plan*. Several other HCPs are under preparation, including two by the SFPUC for operations on its Peninsula and Alameda watersheds and one by a multi-agency partnership that includes Santa Clara County, Santa Clara Valley Water District, the City of San Jose, the Santa Clara Valley Transit Authority,

[10] A Programmatic Biological Opinion is a general set of rules designed to protect the listed species; these rules must be followed during construction of certain types of projects that frequently recur within the range of the species (e.g., road or culvert repairs).

and the Cities of Gilroy and Morgan Hill. Section 4.2, Plans and Policies, describes HCP efforts underway by the SFPUC. The "Conservation Planning" section below also discusses HCP efforts in more detail.

The USFWS also publishes a list of candidate species for listing. Species on this list receive special attention from federal agencies during environmental review, although they are not otherwise protected under FESA. The candidate species are those for which the USFWS has sufficient biological information to support a proposal to list as endangered or threatened. Project impacts on such species may, on a case-by-case basis, be considered potentially significant in this PEIR.

California Endangered Species Act

Under the California Endangered Species Act (CESA), the CDFG has the responsibility for maintaining a list of threatened and endangered species (California Fish and Game Code Section 2070). The CDFG also maintains a list of candidate species, which are species that the CDFG has formally noticed as being under review for addition to either the list of endangered species or the list of threatened species. The CDFG also maintains lists of "species of special concern," which are animal species whose populations have diminished and may be considered for listing if declines continue. Pursuant to the requirements of CESA, an agency reviewing a proposed project within its jurisdiction must determine whether any state-listed endangered or threatened species may be present in the project area and determine whether the project will have a potentially significant impact on such species. In addition, the CDFG encourages informal consultation on any proposed project that could affect a candidate species.

Actions otherwise prohibited under CESA can be legalized under the state's Natural Community Conservation Planning Act (Fish and Game Code Sections 2800–2840), which is somewhat broader in its orientation and objectives than CESA or FESA. These laws are designed to identify and protect individual species that have already significantly declined in number. The primary objective of the program is to conserve natural communities at the ecosystem scale while accommodating compatible land uses. The program provides limited authorization to adversely affect habitat supporting special-status species.

For the potential taking of individual animals (as opposed to habitat) listed under CESA, there is a permit process somewhat similar to Section 10 of FESA, which allows the USFWS to issue take permits for federally listed species.[11] If the species is listed by California alone, and a proposed project would result in impacts, an incidental take permit pursuant to Section 2081 of the Fish and Game Code would be necessary. The CDFG will issue an incidental take permit only if:

- The authorized take is incidental to an otherwise lawful activity
- The impacts of the authorized take are minimized and fully mitigated

[11] If a landowner obtains a federal take permit for a species that is also state listed, CESA does not require an additional state permit, but CESA Section 2080.1(c) does require the CDFG to review the terms and conditions of the permit to ensure they meet CESA's requirements.

- The measures required to minimize and fully mitigate the impacts of the authorized take are roughly proportional in extent to the impact of the taking on the species; maintain the project applicant's objectives to the greatest extent possible; are capable of successful implementation; and adequate funding is provided to implement the required minimization and mitigation measures and to monitor compliance with, and the effectiveness of, the measures

California Fully Protected Species

California law (Fish and Game Code Sections 3511, 4700, 5050, and 5515) allows the designation of a species as fully protected. This is a greater level of protection than is afforded by CESA, since such a designation means the listed species cannot be taken at any time.

California Native Plant Protection Act

The California Native Plant Protection Act (Fish and Game Code Sections 1900–1913) and the Natural Communities Conservation Planning Act provide guidance on the preservation of plant resources; these two acts underlie the language and intent of Section 15380(d) of the CEQA Guidelines. Vascular plants listed as rare or endangered by the CNPS (2001), but which have no designated status or protection under federal or state endangered species legislation, are defined as follows:

- List 1A: Plants presumed extinct
- List 1B: Plants rare, threatened, or endangered in California and elsewhere
- List 2: Plants rare, threatened, or endangered in California, but more numerous elsewhere
- List 3: Plants about which more information is needed – a review list
- List 4: Plants of limited distribution – a watch list

In general, plants appearing on CNPS List 1A, 1B, or 2 are considered to meet the criteria of Section 15380 of the CEQA Guidelines. Additionally, plants listed on CNPS List 1A, 1B, or 2 also meet the definition of Section 1901, Chapter 10 (Native Plant Protection Act) and Sections 2062 and 2067 (CESA) of the California Fish and Game Code.

Other Statutes, Codes, and Policies Affording Limited Species Protection

The federal Migratory Bird Treaty Act (MBTA) (16 USC, Section 703, Supp. I, 1989) prohibits killing, possessing, or trading in migratory birds, except in accordance with regulations prescribed by the Secretary of the Interior. This act encompasses whole birds, parts of birds, and bird nests and eggs. For projects that would not result in the direct mortality of birds, the MBTA is generally interpreted in CEQA analyses as protecting active nests of all species of birds that are included in the "List of Migratory Birds" published in the Federal Register in 1995.

Independent of the MBTA, birds of prey are protected in California under the Fish and Game Code (Section 3503.5, 1992). Section 3503.5 states that it is "unlawful to take, possess, or destroy any birds in the order Falconiformes or Strigiformes (birds of prey) or to take, possess, or destroy the nest or eggs of any such bird except as otherwise provided by this code or any regulation adopted pursuant thereto." Construction disturbance during the breeding season could result in the incidental loss of fertile eggs or nestlings, or otherwise lead to nest abandonment. Disturbance that causes nest abandonment and/or loss of reproductive effort is considered taking by the CDFG. Any loss of fertile eggs, nesting raptors, or any activities resulting in nest abandonment would constitute a potentially significant impact. This approach would apply to red-tailed hawks, American kestrels, burrowing owls, and other birds of prey. Substantial adverse project impacts on these species are considered potentially significant in this PEIR if a species is known or has a high potential to nest on the site or rely on it for primary foraging.

The federal Bald Eagle Protection Act prohibits persons within the United States (or places subject to U.S. jurisdiction) from "possessing, selling, purchasing, offering to sell, transporting, exporting or importing any bald eagle or any golden eagle, alive or dead, or any part, nest, or egg thereof."

Sensitive Natural Communities and Critical Habitat

The CDFG has identified several natural communities within California (as distinct from the organisms they support) as rare and/or sensitive. These natural communities are of special significance because the present rate of loss indicates that acreage reductions or habitat degradation could threaten the viability of dependent plant and wildlife species and possibly hinder the long-term sustainability of the community or species dependent on the community. As natural communities diminish, the need to list dependent plant and wildlife species as rare, threatened, or endangered under the state or federal endangered species acts increases. The loss of some significant natural communities can diminish valued ecosystem functions, such as the roles of marshes in water filtration or of riparian woodlands in riverbank stabilization.

The primary types of sensitive habitat are wetlands, including riparian habitat types such as sycamore alluvial woodland and willow scrub. Almost all types of wetlands are highly biologically active, and almost all have suffered significant declines in California. Various laws and regulations protect wetlands, as described below. Other sensitive habitats that could occur in the program area but are too small to map at the GAP level of analysis include native grasslands, such as serpentine grassland, native bunchgrass grassland, and alkali meadow.

Officially designated critical habitat is also included in this category. Critical habitat is defined as specific areas that are essential to the conservation of a federally listed species, and which may require special management considerations or protection. Critical habitat is determined using the best available scientific information about the physical and biological needs of the species. These needs, or primary constituent elements, include: space for individual and population growth and for normal behavior; food, water, light, air, minerals, or other nutritional or physiological needs; cover or shelter; sites for breeding, reproduction, and rearing of offspring; habitat that is protected from disturbance or is representative of the historical geographic and ecological distribution of a species. Critical habitats are delineated on maps published in the Federal Register and are subject to modification from time to time. **Figure 4.6-2** displays those critical habitats in effect at the time of PEIR preparation.

THIS PAGE INTENTIONALLY LEFT BLANK

Federal and State Provisions Applying to Wetlands

In a jurisdictional sense, there are two definitions of a wetland, one adopted by federal agencies and another adopted by the State of California. Both definitions are presented below.

Federal Wetland Definition. Wetlands are a subset of "waters of the United States" and receive protection under Section 404 of the Clean Water Act. The term "waters of the United States,"[12] as defined in Code of Federal Regulations (33 CFR 328.3[a]; 40 CFR 230.3[s]), includes:

1. All waters which are currently used, were used in the past, or may be susceptible to use in interstate or foreign commerce, including all waters which are subject to the ebb and flow of the tide.

2. All interstate waters including interstate wetlands. (Wetlands are defined by the federal government [CFR, Section 328.3(b)] as those areas that are inundated or saturated by surface or ground water at a frequency and duration sufficient to support, and that under normal circumstances do support, a prevalence of vegetation typically adapted for life in saturated soil conditions.)

3. All other waters such as intrastate lakes, rivers, streams (including intermittent streams), mud flats, sand flats, wetlands, sloughs, prairie potholes, wet meadows, playa lakes, or natural ponds, the use, degradation, or destruction of which could affect interstate or foreign commerce including any such waters which are or could be used by interstate or foreign travelers for recreational or other purposes; or from which fish or shellfish are or could be taken and sold in interstate or foreign commerce; or which are used or could be used for industrial purposes by industries in interstate commerce.

4. All impoundments of waters otherwise defined as waters of the United States under the definition.

5. Tributaries of waters identified in paragraphs (1) through (4).

6. Territorial seas.

7. Wetlands adjacent to waters (other than waters that are themselves wetlands) identified in paragraphs (1) through (6).

8. Waters of the United States do not include prior converted cropland. Notwithstanding the determination of an area's status as prior converted cropland by any other federal agency, for the purposes of the Clean Water Act, the final authority regarding Clean Water Act jurisdiction remains with the U.S. Environmental Protection Agency.

[12] Based on the Supreme Court ruling in *Solid Waste Agency for Northern Cook County v. U.S. Army Corps of Engineers* (SWANCC) concerning the Clean Water Act jurisdiction over isolated waters (January 9, 2001), non-navigable, isolated, intrastate waters are no longer defined as waters of the United States based solely on their use by migratory birds. Jurisdiction of non-navigable, isolated, intrastate waters may be possible if their use, degradation, or destruction could affect other waters of the Unites States, or interstate or foreign commerce. Jurisdiction over such other waters should be analyzed on a case-by-case basis. Impoundments of waters, tributaries of waters, and wetlands adjacent to waters should be analyzed on a case-by-case basis. Further legal cases recently decided by the Court (e.g., *Rapanos* and *Carabel*) have not yet been interpreted in Corps regulations or definitions.

California Wetland Definition. California has adopted the Cowardin et al. (1979) classification system to define wetlands. For purposes of this classification, wetlands must have one or more of the following three attributes: (1) at least periodically, the land supports predominantly hydrophytes[13] (at least 50 percent of the aerial vegetative cover); (2) the substrate is predominantly undrained hydric soil; and (3) the substrate is nonsoil and is saturated with water or covered by shallow water at some time during the growing season of each year (Cowardin et al., 1979).

Under normal circumstances, the federal definition of wetlands requires all three wetland identification parameters to be met, whereas the Cowardin definition requires the presence of at least one of these parameters.

Regulation of Activities in Wetlands. The regulations and policies of various federal agencies (e.g., U.S. Army Corps of Engineers, U.S. EPA, USFWS, NMFS) mandate that the filling of wetlands be avoided unless it can be demonstrated that no practicable alternatives exist. The Corps has primary federal responsibility for administering regulations that concern waters and wetlands. In this regard, the Corps acts under two statutory authorities: the Rivers and Harbors Act (Sections 9 and 10), which governs specified activities in "navigable waters," and the Clean Water Act (Section 404), which governs specified activities in waters of the United States, including wetlands. The Corps requires that a permit be obtained if a project proposes to place structures within navigable waters and/or to alter waters of the United States below the ordinary high-water mark in nontidal waters. The U.S. EPA, USFWS, NMFS, and several other agencies may provide comment on Corps permit applications. The U.S. EPA has provided the primary criteria for evaluating the biological impacts of Corps permit actions in wetlands.

The state's authority to regulate activities in wetlands and water at the project sites resides primarily with the California Regional Water Quality Control Board (RWQCB), which regulates construction in waters of the United States and waters of the state, including activities in wetlands, under both the Clean Water Act and the State of California's Porter-Cologne Water Quality Control Act. The CDFG provides comment on Corps permit actions under the Fish and Wildlife Coordination Act. The CDFG is also authorized under the Fish and Game Code, Sections 1600–1607, to develop mitigation measures and enter into a streambed alteration agreement with applicants proposing a project that would obstruct the flow or alter the bed, channel, or bank of a river or stream in which there is a fish or wildlife resource, including intermittent streams and ephemeral streams (i.e., those flowing briefly during and immediately following storm events). The RWQCB must certify that a Corps permit action meets state water quality objectives (Section 401, Clean Water Act).

State Provisions and Policies Applying to Sensitive Habitats in both Wetlands and Uplands

In addition to the lists of special-status plants and animals, the CDFG maintains a classification of the state's natural communities (both terrestrial and aquatic). The natural community classification is used by a wide variety of government agencies, private conservation organizations, and private biological consultants to help identify and prioritize species preservation, acquisition, or designation activities.

[13] The USFWS has developed the following definition for hydrophytic vegetation: "plant life growing in water or on a substrate that is at least periodically deficient in oxygen as a result of excessive water content" (Cowardin et al., 1979).

Each community is ranked according to its rarity and threat of extinction on both global and statewide scales, regardless of its state or federal listing or management status.[14] By virtue of the rarity or sensitivity of such natural communities (as determined by the state authority responsible for resource protection), impacts on such a community may be considered significant under CEQA.

Local Laws, Regulations, and Policies Applying to Natural Resource Protection

The San Francisco Bay Conservation and Development Commission (BCDC) was formed in 1969 under the McAteer-Petris Act to regulate development in and around San Francisco Bay. BCDC developed the San Francisco Bay Plan to guide the wise use of the bay's water and shorelines. In reviewing permit applications for projects within its jurisdiction, BCDC relies on its Bay Plan policies to ensure the protection of habitats and biological resources, including fish, other aquatic organisms, and wildlife, and water quality; as well as policies on uses of the bay and shoreline.

City and county general plans usually contain provisions to maintain parks and open space, and to protect valued biological resources such as wetlands. Many of the resources protected by local policies and ordinances also are protected under state and federal laws and regulations; others, such as heritage trees, are not. **Table 4.6-1** lists vegetation ordinances (including tree protection ordinances) adopted by jurisdictions where WSIP projects are proposed. Consistency with the provisions of these ordinances (as well as the habitat conservation planning efforts described below) would be further evaluated during preparation of project-specific CEQA documentation.

Conservation Planning in the WSIP Study Area

SFPUC Watershed Management Plans

The SFPUC articulates its policies for the protection and management of key special-status species and other species of concern in its Alameda and Peninsula Watershed Management Plans (WMPs) (SFPUC, 2001, 2002). (See Section 4.2, Plans and Policies, for a more detailed description of this topic.) SFPUC policy is to preserve, protect, and enhance significant botanical and wildlife resources, including rare, threatened, endangered, and sensitive species and their habitat, and to preserve biodiversity and genetic diversity of wildlife populations where possible. The policy requires a site-specific analysis prior to implementing facility and infrastructure projects, operations and maintenance activities, and construction projects in order to determine the presence of sensitive vegetation and wildlife and the potential effects of the activity on these resources. Analyses must be conducted in accordance with applicable state and federal laws, statutes, and guidelines.

---

[14] Global and State Sensitivity Rankings are part of a system devised by the CDFG to provide information on the rarity of a species or community. For example, G1 is defined as: less than six viable element occurrences *or* less than 1,000 individuals *or* less than 2,000 acres.

Habitat Conservation Plans (HCPs)

Habitat conservation plans provide comprehensive, long-term conservation measures for species listed as threatened or endangered under the California and Federal Endangered Species Acts, or for species that could be listed in the future. Several conservation plans are described below, two of which have been adopted: the *San Joaquin County Multi-species Habitat Conservation and Open Space Plan* and the *San Joaquin River National Wildlife Refuge Comprehensive Conservation Plan*.

TABLE 4.6-1
PERTINENT LOCAL VEGETATION ORDINANCES

Jurisdiction and Code	Ordinances
San Joaquin County Ordinance Code (amended through July 27, 2004)	Title 10, Streets and Highways, Division 5, Miscellaneous Regulations, Chapter 2, Trees, Shrubs and Other Plants
Alameda County General Code (amended through March 2005)	Title 12, Public Roadways and Parks, Chapter 12.11, Regulation of Trees in County Right-of-Way
Santa Clara County Ordinance Code (amended through September 28, 2004)	Title C, Construction, Development and Land Use, Division C16, Tree Preservation and Removal
San Mateo County Ordinance Code (amended through June 7, 2005)	Title 3, Public Safety, Morals and Welfare, Chapter 3.92, Street Trees
Fremont Municipal Code (amended through May 24, 2005)	Title IV, Sanitation and Health, Chapter 5, Tree Preservation
	Title VI, Public Works and Public Utilities, Chapter 2, Street Trees
Newark Municipal Code (amended through February 2005)	Title 12, Streets, Sidewalks and Public Places, Chapter 12.28, Parkway Maintenance
	Title 8, Health and Safety, Chapter 8.16, Preservation of Trees on Private Property
Hayward Municipal Code	Chapter 10, Planning, Zoning and Subdivisions, Article 15, Tree Preservation
Milpitas Municipal Code (amended through July 2005)	Title X, Trees and Sidewalks, Chapter 2, Tree and Planting
San Jose Municipal Code	Chapter 13.28, Trees, Hedges and Shrubs
Santa Clara City Code (amended through June 28, 2005)	Title 12, Streets, Sidewalks and Public Places, Chapter 12.35, Trees and Shrubs
Mountain View Municipal Code	Chapter 32, Protection of the Urban Forest
Los Altos Municipal Code	Title 11, Chapter 11.08, Tree Protection Regulations
Palo Alto Municipal Code (amended through May 25, 2005)	Title 8, Trees and Vegetation, Chapter 8.04, Street Trees, Shrubs and Plants
	Title 8, Trees and Vegetation, Chapter 8.10, Tree Preservation and Management Regulations
East Palo Alto Municipal Code (amended through June 15, 2004)	Title 13, Public Services, Chapter 13.24, Water System, Section 13.24.410, Street Trees
Menlo Park Municipal Code (amended through March 2005)	Title 13, Streets, Sidewalks and Utilities, Chapter 13.24, Heritage Trees
	Title 13, Streets, Sidewalks and Utilities, Chapter 13.20, Street Trees, Shrubs and Plants
Atherton Municipal Code (amended through May 18, 2005)	Title 8, Health and Safety, Chapter 8.10, Removal of and Damage to Heritage Trees
Redwood City Municipal Code (amended through March 2005)	Chapter 18, Local Improvements and Planning, Article XIV, Local Development Standards, Section 18.241, Street Improvements – Street Trees
	Chapter 29, Streets, Sidewalks and Driveways, Article VI, Planting and Care of Trees and Other Vegetation on Public Streets
	Chapter 35, Tree Preservation
San Mateo Municipal Code	Title X, Peace, Safety and Morals, Chapter 10.52, Heritage Trees
Hillsborough Municipal Code (amended through February 14, 2005)	Title 14, Trees, Chapter 14.04, Tree Removal

TABLE 4.6-1 (Continued)
PERTINENT LOCAL VEGETATION ORDINANCES

Jurisdiction	Ordinances
Burlingame Municipal Code (amended through January 2004)	Title 11, Trees and Vegetation, Chapter 11.04, Street Trees
	Title 11, Trees and Vegetation, Chapter 11.06, Urban Reforestation and Tree Protection
	Title 11, Trees and Vegetation, Chapter 11.12, Obstructing View at Intersections
Millbrae Municipal Code (amended through June 14, 2005)	Title 8, Public Works, Chapter 8.60, City of Millbrae Tree Protection and Urban Forestry Program
San Bruno Municipal Code	Title 8, Streets, Sidewalks, and Rights-of-Way, Chapter 8.24, Street Trees and Other Plantings
	Title 8, Streets, Sidewalks, and Rights-of-Way, Chapter 8.25, Heritage Trees
South San Francisco Municipal Code (amended through June 2005)	Title 13, Public Improvements, Chapter 13.28, Street Trees
	Title 13, Public Improvements, Chapter 13.30, Tree Preservation
Brisbane Municipal Code (amended through April 2005)	Title 12, Streets, Sidewalks and Public Places, Chapter 12.12, Tree Regulations
Daly City Municipal Code (amended through April 2005)	Title 12, Streets, Sidewalks and Public Places, Chapter 12.40, Urban Forestry
San Francisco Public Works Code (amended through August 19, 2005)	Article 16, Urban Forestry Ordinance

San Joaquin County Multi-Species Habitat Conservation and Open Space Plan. The *San Joaquin County Multi-species Habitat Conservation Plan and Open Space Plan* provides a strategy for conserving open space while addressing the need to convert open space to non-open-space uses, protecting agricultural resources, preserving property rights, and providing for the long-term management of plant, fish, and wildlife species, especially special-status species. A Joint Powers Authority/Technical Advisory Committee implements the *Multi-species Habitat Conservation Plan and Open Space Plan* (SJMSCP JPA, 2001). The WSIP projects located in San Joaquin County are the Advanced Disinfection (SJ-1), Lawrence Livermore (SJ-2), SJPL System (SJ-3), SJPL Rehabilitation (SJ-4), and Tesla Portal Disinfection (SJ-5) projects.

Draft Santa Clara Valley Habitat Conservation Plan / Natural Communities Conservation Plan. The City of San Jose, Santa Clara County, Santa Clara Valley Transportation Authority, Santa Clara Valley Water District, City of Gilroy, and City of Morgan Hill have initiated a collaborative process to prepare and implement a habitat conservation plan/natural communities conservation plan (HCP/NCCP) for the Santa Clara Valley. The Draft Santa Clara Valley HCP/NCCP targets specifics areas of the county where land development activities and the continued survival of endangered, threatened, or other species of concern are in conflict. The goal of this plan is to provide the means for conservation of these species, thereby contributing to their recovery while allowing for compatible and appropriate development to occur. The HCP/NCCP and associated environmental documentation are scheduled for completion in 2009 (Santa Clara Valley HCP/NCCP, 2007).

SFPUC Habitat Conservation Plans. The SFPUC is also developing HCPs for its watershed lands as part of implementation of the Alameda and Peninsula WMPs. The Peninsula and Alameda Creek watershed HCPs are being prepared in compliance with federal and state regulations for endangered species protection. The HCPs will identify specific species to be covered, including steelhead, in consultation with federal and state resource agencies. The plans will also identify and describe SFPUC watershed operations and maintenance activities to be covered. The intent of the HCPs is to minimize and/or mitigate potential adverse effects on species addressed in the plans that could result from watershed operations and maintenance activities through implementation of conservation programs. The conservation programs will focus on providing long-term protection of covered species by protecting biological communities in the watersheds. The draft Alameda Creek watershed HCP is scheduled for public review in 2007, and the draft Peninsula watershed HCP is scheduled for public review in 2008. The plans are subject to environmental review by the San Francisco Planning Department before the SFPUC can consider adoption and begin implementation.

San Joaquin River National Wildlife Refuge Comprehensive Conservation Plan. The San Joaquin River National Wildlife Refuge (NWR) was established in 1987 as a unit of the San Luis NWR complex with its primary goal initially to protect habitat for the Aleutian Canada goose, then a federally listed endangered species. Its goals have since been expanded to include protection for other threatened and endangered species, and restoration of wetlands and floodplain habitat and the species that depend on them. The approved Refuge boundary encompasses 12,887 acres along the San Joaquin River both north and south of the confluence with the Tuolumne River (USFWS, 2007). About three miles of the Hetch Hetchy Aqueduct crosses the San Joaquin River NWR. The SJPL System (SJ-3) project could extend into the western portion of the NWR, primarily in cropland and recently established floodplain riparian habitat near the San Joaquin River. The SJPL Rehabilitation project (SJ-4) could involve repair and replacement of pipeline within the San Joaquin River NWR (generally within the pipelines right-of-way), including areas adjacent to floodplain, native grassland, cropland and irrigated pasture.

The USFWS has adopted a comprehensive conservation plan (CCP) that describes the goals, objectives, and management strategies of the CCP. The five primary goals of the San Joaquin River NWR CCP, as identified in the CCP/EA (USFWS, 2007), are summarized below:

- *Biological Diversity*. Conserve and protect the natural diversity of migratory birds, resident wildlife, fish, and plants through restoration and management of riparian, upland, and wetland habitats on refuge lands.
- *Threatened and Endangered Species*. Contribute to the recovery of threatened/endangered species, as well as the protection of populations of special-status wildlife and plant species and their habitats.
- *Aleutian Canada Goose*. Provide optimum wintering habitat for Aleutian Canada geese to ensure the continued recovery from threatened and endangered status.
- *Ecosystem Management*. Coordinate the natural resource management of the San Joaquin River NWR within the context of the larger Central Valley/San Francisco Ecoregion.

- *Public Use of the Refuge*. Provide the public with opportunities for compatible, wildlife-dependent visitor serves to enhance understanding, appreciation, and enjoyment of natural resources at the San Joaquin River NWR (USFWS, 2007).

4.6.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to biological resources, but generally considers that implementation of the proposed program would have a significant biological impact if it were to:

- Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS (Evaluated in this section)

- Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations or by the CDFG or USFWS (Evaluated in this section)

- Have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act and as protected under the Porter-Cologne Water Quality Control Act (including but not limited to marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means (Evaluated in this section)

- Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites (Evaluated in this section)

- Have the potential to degrade the quality of the environment, substantially reduce the habitat of a fish or wildlife species, cause a fish or wildlife population to drop below self-sustaining levels, threaten to eliminate a plant or animal community, or substantially reduce the number or restrict the range of an endangered, rare or threatened species (Evaluated in this section)

- Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance (Evaluated in this section)

- Conflict with the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, or state habitat conservation plan (Evaluated in this section)

Approach to Analysis

The potential for key special-status species occurrence in the WSIP study area was determined based on CNDDB records (CDFG, 2007b), CDFG and USFWS lists of species (CDFG, 2007a; Federal Register, 2006b), CNPS data (CNPS, 2005), and GAP analysis maps, species ranges, and habitat suitability information from such sources as Mayer and Laudenslayer (1988). Other documents prepared for the SFPUC supplied additional information (e.g., ESA, 1999); however, no site-specific surveys were conducted for this programmatic analysis. This process resulted in the selection of the key special-status species described above in the Setting. These species are evaluated in terms of their reasonably predictable responses to proposed facility construction and operation (based on such factors as the size of the project footprint and proximity to known occupied habitat). While some sensitive natural communities could be identified at this program level of analysis, others are evaluated based on a reasonable probability of occurrence and impact. More detailed analyses would be performed during separate, project level CEQA review of the WSIP projects.

"Rare" and "endangered" are analogous terms defined in CEQA Guidelines Sections 15380(a) and 15380(d) and provide additional regulatory guidance. Program impacts on species listed as endangered or threatened under CESA or FESA are considered potentially significant in this PEIR. Impacts on other species of special concern are considered significant under certain circumstances. However, a detailed analysis of potential impacts on these species at the program level is not feasible because of the large number of other species of special concern, each with its own ecological characteristics, and because many aspects of the projects have not yet been defined. Impacts on many of these species would be similar to those on the sensitive natural communities, upon which most of these species depend.

For the purposes of this PEIR, the definition of the word "substantial" (as used in the significance criteria) has three principal components:

- Magnitude and duration of the impact (e.g., substantial/not substantial)
- Uniqueness of the affected resource (rarity)
- Susceptibility of the affected resource to disturbance

The evaluation of significance must also consider the interrelationship of these three components. For example, a relatively small-magnitude impact on a state or federally listed species would be considered significant because the species is rare and is believed to be very susceptible to disturbance. Conversely, a natural community such as California annual grassland is not necessarily rare or sensitive to disturbance, and thus a much larger magnitude of impact would be required to result in a significant impact. Impacts on biological resources are considered significant when project-related habitat modifications (e.g., development, introduction of non-native plant and animal species, increased human intrusion, barriers to movement, or landscape management) could reduce species populations to the extent that they become locally less numerous; impacts on habitats are considered significant when the habitats could not continue to support viable populations of associated plant and animal species as a result of project implementation.

Before identifying ways to lessen or mitigate these impacts, the PEIR preparers reviewed the Alameda and Peninsula WMPs (SFPUC, 2001, 2002) for guidance on actions that would routinely be applied to projects on SFPUC lands and for consistency between the WMPs and mitigation identified in this PEIR. For example, Policy V15 (for the Alameda watershed) requires a site-specific analysis prior to implementing facility and infrastructure projects, operations and maintenance activities, and construction projects to determine the presence of sensitive vegetation resources and the potential effects of the activity on the resource. Policy W6 (for the Peninsula watershed) stipulates that the integrity of the watershed creeks must be maintained to preserve their value as riparian ecosystems and wildlife corridors. Policy V15 ensures that the WSIP projects would be subject to a site-specific analysis independent of CEQA mitigation requirements and would be consistent with SFPUC Construction Measure #8 for biological resources, and Policy W6 sets a significance standard, based on local policy, which makes loss of riparian integrity a significant impact.

This PEIR evaluates the potential for impacts of the facility improvement projects at a program level and does not address project-specific aspects that require design details, such as the size and location of borrow and spoils areas; site-specific locality information, such as the location of key special-status species; and information typically developed at the project level, such as local hydrology. Project-specific information would be needed to determine the nature and extent of impacts more precisely and would be developed during the separate CEQA review of individual WSIP projects.

This analysis also proposes general, programmatic mitigation measures that could reduce identified program-level impacts to a less-than-significant level where adequate information is known; in some cases, additional analysis at the project level would be needed to identify project-specific mitigation measures to reduce impacts to a less-than-significant level. Mitigating the impacts of infrastructure projects is not a new regulatory or applied ecological endeavor in California. The natural history of most of the species involved is well enough understood, and there have been sufficient opportunities to test mitigation measures based on this understanding. Therefore, reliance on precedent and standard practice is justifiable for most projects. For example, burrowing owl impact analysis and mitigation was the subject of a CDFG staff report in 1995 (California Burrowing Owl Consortium, 1995); the USFWS developed guidance for California red-legged frog 1997, and programmatic avoidance measures/mitigations for San Joaquin kit fox and red-legged frog in 1997 and 1999, respectively (USFWS, 1997, 1999). For this reason, this PEIR is able to recommend standard programmatic mitigation measures for constructing project facilities based on accepted protocols.

[Additional discussion on the appropriate level of detail for analysis of biological resources was prepared in response to comments on the Draft PEIR. Please refer to Section 14.4, Master Response on PEIR Appropriate Level of Analysis (Vol. 7, Chapter 14).]

Impact Summary by Region

Table 4.6-2 presents a summary of impacts of the WSIP projects by region. While implementation of various WSIP projects would result in potentially significant impacts on biological resources, all impacts identified herein are determined to be less than significant with mitigation. **Table 4.6-3** summarizes the natural habitats and key special-status species with the potential to occur at each WSIP facility site. Table 6-1 in Chapter 6 summarizes the mitigation measures that might be required at each WSIP facility site if these habitats and species are found, and Table 6-2 defines the mitigation measures in detail.[15]

[15] The measures in Table 6-2 are not applicable at every site and could be modified for individual projects.

Notes: Project-specific CEQA documents would review recent special-status species lists relevant to the habitats present. The information presented here is for guidance only, and project design and site-specific assessment is needed to definitively determine the presence of habitats and key special-status species for each project.

Vernal pool invertebrates:
- Vernal pool fairy shrimp
- Conservancy fairy shrimp
- Vernal pool tadpole shrimp

Salt marsh species:
- Western snowy plover
- California clapper rail
- California black rail
- Salt marsh harvest mouse

Fishes:
- Green sturgeon (San Joaquin Valley only)
- Chinook salmon
- Central Valley DPS steelhead
- Central California Coast DPS steelhead
- Rainbow trout (Alameda Creek)

Vernal pool plants:
- Succulent owl's-clover
- Hoover's spurge
- Colusa grass
- San Joaquin Valley Orcutt grass
- Hairy Orcutt grass
- Greene's tuctoria

Riparian and Reservoir species:
- Least Bell's vireo (San Joaquin)
- Valley elderberry longhorn beetle (San Joaquin)
- Riparian woodrat (San Joaquin)
- Delta button-celery (San Joaquin)
- Bald eagle (Sunol Valley)
- Foothill yellow-legged frog

Native grassland species:
- Bay checkerspot butterfly (Peninsula)
- Callippe silverspot butterfly
- Fountain thistle (Peninsula)
- Marin dwarf flax (Peninsula)
- San Mateo woolly sunflower (Peninsula)

Impact 4.6-1: Impacts on wetlands and aquatic resources.

Many of the WSIP projects would affect streams or wetlands that fall under state or federal jurisdiction. Most impacts would be associated with construction activities and thus would be temporary. Projects crossing streams and rivers could require dredging or filling, potentially causing erosion, siltation, and the loss of riparian habitat. In addition, aquatic plants and animals could be stranded by dewatering, exposed to predation, and trampled or crushed. Aquatic resources could also be affected by siltation or degradation of water quality from spills during construction. Hazardous materials, including hydrocarbons such as fuel and lubricants, could enter waterways during construction and contaminate the soil and water, causing direct and indirect impacts on wetlands and aquatic resources (see Sections 4.5, Water Quality, and 4.14, Hazards). Some types of wetlands, such as vernal pools, are permanently affected by changes in soil permeability or drainage. The extent of wetlands affected by a project is usually small compared with the total project footprint, but highly dependent on the final project design. Since final designs have not been prepared for most WSIP projects, the acreage of affected wetlands is not specified in this analysis, but would be determined during project-level CEQA review. The majority of WSIP projects also have the potential to affect seasonal wetlands under state or federal jurisdiction. In addition, pending the outcome of recent cases in federal court, some man-made depressions where water collects for long periods of time may be considered jurisdictional and, in addition, may have the potential to support key special-status invertebrates. Permanent freshwater and saline wetlands could be affected by those projects located in salt marsh or freshwater habitats, but few projects are near these relatively rare habitats. Vernal pools would be permanently affected by excavation or substantial alteration of the soil surface. Even with subsequent compaction, such activity would alter the slow soil permeability upon which vernal pool hydrology depends.

Because wetlands, especially small seasonal wetlands, could occur on almost any facility site, impacts on wetlands are assumed to occur for all WSIP projects that involve surface disturbance. For those projects restricted to sites that are already surfaced, drained, landscaped, or maintained free of vegetation, the potential for impacts on wetlands is low but cannot be entirely ruled out. Once the WSIP projects have undergone preliminary design and biological surveys have been conducted, some of these projects could be determined to have no impact on wetland resources, in which case no mitigation would be required. If impacts on wetlands would occur, further analysis and permitting would be required. Potential impacts on wetlands, by facility type, are described below.

Pipelines. The standard pipeline installation method proposed for the WSIP projects is the open-cut trench method. In environmentally sensitive areas such as creeks, “trenchless” construction techniques such as jack-and-bore or microtunneling could be utilized. Where pipeline installation or replacement is not required, sliplining might be possible. For the open-cut trench method, the construction area would extend for the length of the pipeline and would have a width dependent on the size of the pipe. For trenchless pipeline construction and sliplining, vehicle access and a work area would be required for each pit or entry point. Some land would be temporarily used for construction or staging areas, while a small amount would be permanently committed to accessways, valves, and other control structures. Wetlands would be temporarily affected in construction and staging areas, and permanently affected where habitat is lost. Vernal pools are a special example, because breaking up the impervious or slowly pervious subsoil permanently alters the hydrology of the pool; if this occurred, the vernal pool habitat would be deemed lost, even though post-construction restoration might be able to restore some vernal pool functions and values.

Tunnels. Impacts on wetlands could occur at portals and shaft openings. The construction area at the entry portal would be the largest, as it must accommodate the portal/shaft entry, vehicles, spoils, equipment, and materials storage. Construction areas at exit portals and shaft openings would require vehicle access and a smaller work area. Dewatering of the tunnel during construction sometimes affects the groundwater, resulting in impacts on surface water features such as springs, seeps, and even creeks. Assessment of this impact would require site-specific information on hydrology and project design, which would be developed as part of project-level CEQA review. Tunnels require spoils disposal sites and access from the portal or shaft openings to the disposal site. The spoils disposal site, as well as a portion of the work area at both portals and shafts, would be permanently committed to access, control, and maintenance structures; permanent loss of wetlands could occur in these areas.

Valves, Valve Lots, and Crossovers. Valves, valve lots, and crossovers are located along existing pipelines and already have developed vehicular access. WSIP projects sited in developed areas that are drained and maintained free of vegetation would not affect wetlands. Projects in undeveloped areas could affect seasonal wetlands. Crossover facilities must be sited near creeks so they can discharge large volumes of water into the watercourse during regular maintenance and during emergency situations. The discharge of water from crossover facilities could cause erosion, temporary out-of-season flooding of the stream channel, loss of wetland and riparian vegetation, and mortality of aquatic organisms dislodged by the high flows.

Pump Stations. New pump stations that would replace existing pump stations (on sites that are surfaced, drained, and maintained free of vegetation) would not affect wetlands. However, if the surfaces at existing pump stations collect soil and standing water, the potential exists for species that live in temporary ponds to establish themselves. New stations on natural habitat could result in temporary and permanent habitat loss, particularly of seasonal wetlands.

Treatment Facilities. WSIP treatment facility projects in developed areas (on sites that are surfaced, drained, and maintained free of vegetation) would not affect wetlands. If natural habitat were affected, impacts on seasonal wetlands could occur (temporary impacts in the work area and permanent impacts where buildings, surfacing, or other facilities are constructed). If it were necessary to install pipelines to connect treatment facilities to the rest of the Hetch Hetchy system, the same type of impacts discussed above in the pipeline section could occur.

Storage Facilities. WSIP storage facility projects would involve the construction or improvement of storage reservoirs and dams. Improvements to below-grade storage reservoirs would require extensive grading and structural work, and it could be necessary to haul material offsite for disposal. Construction activity in areas of natural vegetation could result in impacts on seasonal wetlands. Dam improvements would involve extensive earthmoving activities around the dam as well as the development of borrow areas, disposal areas, and access roads. These projects would result in temporary construction impacts on the impounded stream and its associated riparian vegetation, and permanent loss of riparian habitat where facilities and access roads are sited. Also, raising or lowering reservoir water levels could inundate existing wetlands or allow them to dry out. This impact of WSIP operations is discussed in Chapter 5.

San Joaquin Region

Impact 4.6-1: Impacts on wetlands and aquatic resources		
Advanced Disinfection	SJ-1	PSM
Lawrence Livermore	SJ-2	PSM
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	PSM

All five of the projects in this region have the potential to affect at least small areas of seasonal wetlands. The Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) projects would be located in the vicinity of Tesla Portal in largely developed area. Only a small portion of this project site could support seasonal wetlands. However, both projects would generate spoils requiring offsite disposal. The location and area required for spoils disposal have not been determined, so impacts on wetlands are conservatively considered to be *potentially significant*. The Lawrence Livermore (SJ-2) project could also affect small seasonal wetlands or watercourses at the facility sites or along access roads if they required improvements, resulting in *potentially significant* impacts.

The SJPL System (SJ-3) project would construct approximately 16 miles of pipeline and two crossovers, while the SJPL Rehabilitation (SJ-4) project would rehabilitate the existing pipelines at discrete locations. The pipeline construction area for both projects would be partially located on previously disturbed areas and partially on undisturbed areas of the right-of-way, because the work area must be located to the side of the existing pipelines. As a result, vernal pools in the eastern grasslands, alkaline meadows in the floodplains of the San Joaquin River, and other small seasonal wetlands throughout the pipeline route could be temporarily or permanently lost due to construction. Such impacts would be *potentially significant* for the SJPL System and SJPL Rehabilitation projects due to the presence of vernal pools and riparian areas within the project rights-of-way. However, pipeline rehabilitation work under the SJPL Rehabilitation project would occur primarily on previously disturbed lands, and the potential for impacts on vernal pools, small seasonal wetlands, or riparian habitats would be less than under the SJPL System project. In addition, these projects could adversely affect wetlands associated with the San Joaquin River and several other watercourses and their corresponding wetland, riparian, and aquatic life. Potential impacts on riparian areas would be greatly reduced through the proposed use of trenchless construction methods across permanent creeks and creeks with riparian vegetation. Crossovers associated with the SJPL System project may be located at watercourses, and construction could affect wetlands in these areas.

Taken as a whole, the San Joaquin Region projects would result in surface disturbance of 100 to 400 acres in construction areas (99 percent attributable to the SJPL System project, SJ-3, although the extent of construction under SJPL Rehabilitation project, SJ-4, is unknown); these projects would generate approximately 357,000 cubic yards of spoils (99 to 100 percent attributable to the

SJPL System project, and not including the SJPL Rehabilitation project). The location and extent of spoils disposal has not been determined, so the potential impacts on wetlands cannot be analyzed at the program level. Tunneling where feasible would minimize impacts on river and creek resources.

SFPUC Construction Measure #8 (biological screening survey) would be implemented for all projects to determine whether any wetlands could be affected by proposed development. Measures 4.6-1a and 4.6-1b call for assessment, avoidance, restoration, and, in the case of permanent impacts, compensatory creation or enhancement to ensure no net loss of wetlands. Implementation of Measures 4.6-1a and 4.6-1b could reduce *potentially significant* impacts to a less-than-significant level for the Advanced Disinfection (SJ-1), Lawrence Livermore (SJ-2), and Tesla Portal Disinfection (SJ-5) projects.

Substantial wetland resource impacts could occur under the SJPL System project (SJ-3) and the SJPL Rehabilitation project (SJ-4). For projects that could not avoid impacts on wetlands, compensation would be implemented as appropriate to ensure no net loss. An example of a mechanism for compensating wetland loss is the proposed Habitat Reserve Program (HRP), described in Chapter 3 as a related activity under the WSIP. The HRP proposes a variety of means to identify, protect, restore, and manage wetland resources as compensation for WSIP impacts.[16] Implementation of SFPUC Construction Measure #8 and Measures 4.6-1a and 4.6-1b would reduce potential impacts from all San Joaquin Region projects to a less-than-significant level. Potential impacts on wetlands will be evaluated in more detail as part of separate, project-level CEQA review.

Sunol Valley Region

Impact 4.6-1: Impacts on wetlands and aquatic resources		
Alameda Creek Fishery	SV-1	PSM
Calaveras Dam	SV-2	PSM
40-mgd Treated Water	SV-3	PSM
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	PSM
SABUP	SV-6	PSM

All of the projects in this region have the potential to affect small areas of seasonal wetlands. The Alameda Creek Fishery project (SV-1) would likely involve construction of pipeline, pumps, collection wells, control structures, and a recapture facility in and near Alameda Creek, downstream from Calaveras Dam. Since it would be situated in and near Alameda Creek, this project could result in *potentially significant* impacts on wetlands and associated vegetation. The volume of spoils generated by this project has not been determined, and the location and area required for spoils disposal have not been identified. The design and nature of the facilities would determine the extent of impacts on wetland and aquatic resources and whether a nationwide or individual Corps permit would be required.

16 The proposed HRP is one of a number of options for achieving the same mitigation goal, and in the absence of the HRP, project-level CEQA review would be required to identify and provide for distinct, project-specific mitigation actions.

The Calaveras Dam project (SV-2) would affect about 100 acres of habitat in the construction area, including portions of Calaveras Creek downstream from the existing dam and portions of Alameda Creek in the vicinity of the Alameda Creek Diversion Dam. Approximately 220 acres of land would be disturbed during the acquisition of borrow material and for spoils disposal. Surface disturbance and alteration of natural surface contours at the construction area would cause impacts on seasonal or permanent wetlands such as freshwater marsh, freshwater seeps, and perennial and seasonal streams, including several hundred linear feet of Calaveras Creek below the existing dam. This project would result in the temporary loss of wetlands and associated aquatic and riparian habitat in the construction area. Riparian and aquatic habitat loss would be permanent at the dam and associated facility sites and in borrow and spoils disposal areas. In addition, seasonal and permanent wetlands that have developed in the area between the existing and proposed reservoir elevations could become more or less permanently inundated (see Section 5.4.6 for a discussion of impacts related to Calaveras Dam operations). The impact of constructing the Calaveras Dam project on wetland resources would be *potentially significant*, but could be minimized through project siting, avoidance of sensitive resources to the extent possible, revegetation of temporarily disturbed areas, and compensatory habitat creation or enhancement in the case of permanent impacts (also see Section 5.4.6 for an analysis of system operations impacts on wetlands and other sensitive habitats).

The 40-mgd Treated Water project (SV-3) would have a construction footprint of 1.5 acres and a final footprint of about 1 acre. This facility would be situated on or near the Sunol Valley Water Treatment Plant (WTP) site, primarily on previously disturbed grasslands. Seasonal wetlands could be present in this area, but they would be man-made and very limited in extent. This project would generate an estimated 100,000 cubic yards of spoils. The location and area required for spoils disposal have not been determined, but could result in impacts on wetlands. Construction grading, erosion, and sedimentation could potentially affect the wetlands and riparian vegetation along adjacent areas of Alameda Creek. The proposed two miles of pipeline to the Alameda Siphons or New Irvington Tunnel as part of this project could affect wetland and aquatic resources along several ephemeral streams. Siting the 40-mgd Treated Water project to avoid the wetland and riparian resources at Alameda Creek could avoid significant impacts on wetlands. However, the two-mile pipeline must either cross steep terrain and several ephemeral tributaries of Alameda Creek, or be situated in the floodplain of Alameda Creek. Either location could cause a *potentially significant* impact on wetland resources.

Under the New Irvington Tunnel project (SV-4), construction of facilities at the proposed tunnel portals south of the Alameda West and Irvington Portals, as well as land required for access roads, shafts, control structures, and a spoils disposal area, could permanently affect seasonal and permanent wetlands. In addition, seasonal wetlands could be temporarily affected in the construction area. The construction footprint at the proposed tunnel portal in the Sunol Valley would be located primarily in uplands; however, impacts could extend to seasonal or permanent wetland or riparian resources near Alameda Creek. The construction area required for this project is estimated at 127 acres, with most spoils to be disposed of onsite. The location of any offsite spoils disposal areas and associated access routes have not been determined. Taken together, the impacts on wetlands would be *potentially significant* for this project.

The Treated Water Reservoirs project (SV-5) would require installation of a 0.3-mile pipeline, including a pipe bridge across Alameda Creek; it would have a construction footprint of 10.5 acres and a final footprint of 3.2 acres. This project would generate a spoils volume of 300,000 cubic yards, although the location and extent of land required for spoils disposal have not been identified for this WSIP. The Treated Water Reservoirs project would result in *potentially significant* temporary and permanent losses of wetland and aquatic habitat in and near Alameda Creek near the Sunol Valley WTP and elsewhere, depending on the location of spoils disposal.

The SABUP project (SV-6) would closely parallel (but would not cross) San Antonio Creek. This project would install 2.3 miles of backup pipeline and would include a new discharge structure in San Antonio Creek and about 1,000 feet of pipeline from Alameda East Portal to Alameda Creek, ending with an energy dissipation structure in Alameda Creek. The construction and permanent placement of such structures would affect these watercourses, and the installation of pipeline could affect ephemeral watercourses and small seasonal wetlands along the proposed alignment. As indicated previously, construction in riparian areas would cause temporary impacts, and the placement of facilities within wetland or aquatic habitat would cause permanent impacts. Siting the SABUP project along existing graded access roads would reduce impacts on wetlands. This project would also generate an estimated net 37,000 cubic yards of spoils. The location and extent of the area required for spoils disposal have not been determined, but could result in a *potentially significant* impact on wetlands and aquatic resources.

Since all WSIP PEIR projects in this region could have a significant impact on wetlands, SFPUC Construction Measure #8 (biological screening survey) would be required to determine the presence and potential impact on wetlands. For projects on SFPUC watershed lands, Construction Measure #8 would ensure consistency with the Alameda WMP. Impacts on permanent creeks and creeks with riparian vegetation would be minimized through the use of trenchless construction methods, which are proposed for crossing such creeks. As mentioned above, these projects are subject to separate, project-level CEQA review, which will evaluate potential impacts in more detail and determine appropriate mitigation measures based on the presence of sensitive biological resources. A wetlands assessment and implementation of avoidance, protection, restoration, and compensation (Measures 4.6-1a and 4.6-1b), would be implemented as appropriate. Taken together, SFPUC Construction Measure #8 and Measures 4.6-1a and 4.6-1b would reduce these potentially significant impacts to a less-than-significant level.

Bay Division Region

Impact 4.6-1: Impacts on wetlands and aquatic resources		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	PSM
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSM

Of the three projects in this region, the BDPL Reliability Upgrade project (BD-1) has the greatest potential to affect small seasonal wetlands. This project would consist of about 16 miles of pipeline and 5 miles of tunnel. The pipeline segment would cross several modified creek channels and artificial flood control channels between the Irvington Portal and Newark Valve House. This pipeline could affect degraded saline emergent wetland habitat near the valve houses at the edge of San Francisco Bay, especially at the Newark Valve House where the staging area would be located for the tunnel segment of the pipeline. West of the bay, the pipeline would cross two urbanized flood control channels and one natural stream course. Depending on the extent of pipeline requiring upgrades, construction for this project would affect from 82 to 164 acres. In addition, spoils generated by this project are estimated at 614,000 cubic yards. Some of the spoils from the tunnel could be placed in one or more former salt evaporation ponds that are being restored. While there might be temporary impacts on wetlands associated with placing the spoils, the spoils could be used as part of the restoration effort and could therefore have a long-term beneficial impact. Other spoils might be disposed of at other locations, but the extent of any disposal areas has not been determined. The typical construction scenario for pipelines (presented in Chapter 3, Section 3.10.1) indicates that trenchless construction methods would be used to cross beneath streams and avoid sensitive habitats such as salt marsh, and that unpaved affected areas would be graded and revegetated following construction. The proposed use of trenchless construction methods across permanent creeks and creeks with riparian vegetation would reduce potential impacts, but impacts on riparian vegetation could still occur due to construction activity at the tunneling sites. Therefore, the BDPL Reliability Upgrade project would have a *potentially significant* impact on wetlands and aquatic resources.

The BDPL 3 and 4 Crossovers project (BD-2) would affect a minimum of 0.4 acre and could affect wetlands and aquatic resources associated with the Guadalupe River, Barron Creek, and Bear Gulch Reservoir during construction. The effect on wetlands would be temporary, except for the permanent loss of habitat associated with the small vaults and discharge pipes installed at each of the crossovers to enable discharge for maintenance or emergencies. Although small, these impacts would be *potentially significant*.

The BDPL 3 and 4 Seismic Upgrade at the Hayward Fault (BD-3) would involve construction or replacement of up to three miles of pipeline in the vicinity of I-680 and Mission Boulevard in Fremont. The extent of the construction area and spoils disposal sites has not been determined. The proposed use of trenchless methods for creek crossings would reduce the potential impact on these aquatic resources. Although the wetland resources in this area have been highly modified, impacts are considered *potentially significant* pending further analysis.

SFPUC Construction Measure #8 (biological screening survey) would be implemented for all WSIP projects to determine the extent of impacts on wetlands and aquatic resources. Impacts on permanent creeks and creeks with riparian vegetation would be minimized through the proposed use of trenchless construction methods across such creeks. Where wetland resources are present, Measure 4.6-1a calls for a wetland assessment, and Measure 4.6-1b would provide for identifying, preserving, creating, enhancing, and managing compensation lands, as appropriate to fully compensate for temporary and permanent loss of wetlands. Taken together, these measures would reduce impacts on wetlands to a less-than-significant level.

Peninsula Region

Impact 4.6-1: Impacts on wetlands and aquatic resources		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	PSM
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	PSM
Pulgas Balancing Reservoir	PN-5	PSM

Most of the projects in this region have the potential to affect small seasonal wetlands. It should be noted that the acreage of potentially affected area has not been determined for any of these projects.

The Baden and San Pedro Valve Lots project (PN-1) is located primarily on maintained, surfaced land, with some access areas on well-sloped, disturbed land that cannot support wetlands. The HTWTP Long-Term project (PN-3) would be located entirely on maintained, surfaced land. Therefore, impacts on wetlands under these two projects would be *less than significant* if all activity is limited to graded, paved, and drained sites that are maintained free of vegetation, or areas that do not contain wetland characteristics.

The CS/SA Transmission project (PN-2) would consist of repairing or replacing 4.5 miles of pipeline and 0.5 mile of tunnel between the Lower Crystal Springs and San Andreas Reservoirs. This project would cause *potentially significant* temporary impacts on wetlands, including freshwater emergent wetlands, and on riparian resources at stream crossings where existing facilities would be replaced, such as the culverts connecting Upper and Lower Crystal Springs Reservoirs and outlet structures and tunnels at Crystal Springs Dam. In addition, impacts on riparian wetlands could occur where the pipeline crosses streams. The acreage of required construction area and the location and extent of borrow or spoils areas have not been determined, and impacts on wetlands will be analyzed in more detail as part of separate, project-level CEQA review for this project.

The Lower Crystal Springs Dam project (PN-4) could adversely affect creek and riparian resources along San Mateo Creek if work areas are needed at the base of the dam. If the stilling basin area at the base of the dam is reconstructed, the freshwater marsh habitat would be lost, a *potentially significant* impact. This project would generate 21,000 cubic yards of spoils; disposal of this volume could affect wetlands if any watercourses or wetlands are located at the spoils disposal site. Operationally, this project would allow Upper and Lower Crystal Springs Reservoirs to be maintained at historical levels, which are higher than the prevailing reservoir levels. This impact of WSIP operations is discussed in Section 5.5.6.

The Pulgas Balancing Reservoir project (PN-5) would affect streams at pipeline crossings and could affect limited freshwater emergent wetland habitat, a *potentially significant* impact. Potential impacts on wetlands and aquatic resources would be evaluated in more detail as part of separate, project-level CEQA review for these projects. Impacts on permanent creeks and creeks with riparian vegetation would be minimized through the proposed use of trenchless construction methods across such creeks.

Implementation of SFPUC Construction Measure #8 (biological screening survey) calls for an initial screening of all project sites for sensitive wetland and aquatic resources. If wetland resources were present, performance of wetlands assessment and avoidance, protection, restoration, and compensation for the lost wetlands and aquatic resources would be required (Measures 4.6-1a and 4.6-1b). Taken together, these measures would reduce wetlands impacts for all Peninsula Region projects to a less-than-significant level.

San Francisco Region

Impact 4.6-1: Impacts on wetlands and aquatic resources		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	PSM
Recycled Water Projects	SF-3	PSM

All three projects in this region have the potential to affect small seasonal wetlands, either directly in construction areas or in spoils disposal areas, a *potentially significant* impact. The SAPL 3 Installation project (SF-1) consists of about four miles of pipeline through predominantly urban and developed areas, but would generate an estimated 44,000 cubic yards of spoils. The location and extent of spoils disposal areas have not been determined. The Groundwater Projects (SF-2) would affect Lake Merced by raising its water level, a potentially beneficial impact. It could also affect wetlands and stream crossings at undetermined locations, totaling 0.6 acre in western San Francisco and northern San Mateo County. The Recycled Water Projects (SF-3) would install 20 miles of pipeline; it would require an estimated five to seven acres for construction and would generate an estimated 47,200 cubic yards of spoils. The location and extent of the construction areas and spoils disposal areas have not been determined. This project could affect larger wetlands, depending on the locations of proposed pipeline, treatment, and storage facilities.

Impacts on any identified permanent creeks and creeks with riparian vegetation would be reduced through the proposed use of trenchless construction methods to cross such creeks. The potential impacts associated with the SAPL 3 Installation project (SF-1), Groundwater Projects (SF-2), and Recycled Water Projects (SF-3) would be evaluated as part of separate, project-level CEQA review. SFPUC Construction Measure #8 (biological screening survey) would be implemented for all WSIP projects to determine whether biological resources could be affected, including wetland and aquatic resources. If jurisdictional wetlands were identified at any of these sites, performance of a wetlands assessment and avoidance, protection, restoration, and compensation for the loss of wetlands would be required (Measures 4.6-1a and 4.6-1b). Taken together, SFPUC Construction Measure #8 and Measures 4.6-1a and 4.61b would reduce wetlands impacts for all three WSIP projects in this region to a less-than-significant level.

Impact 4.6-2: Impacts on sensitive habitats,[17] common habitats, and heritage trees.

For the purpose of this analysis, sensitive habitats include sensitive natural communities, as defined by Holland (1986), and USFWS-defined critical habitats for listed species. Many of the sensitive habitats that could be affected by WSIP implementation are wetlands or are associated with wetlands, such as vernal pools, riparian habitats, and alkali meadows; wetland-related impacts are discussed above under Impact 4.6-1. Impact 4.6-2 addresses non-wetland-related sensitive habitats, such as native grasslands, and also applies to the full extent of the sensitive habitat (e.g., the outer canopy of riparian trees and shrubs).

More common or widespread habitats would also be affected, such as ruderal (or weedy) areas and non-native grassland. As discussed above, impacts on common habitats must be extensive to be considered significant. To determine the level of impact, the estimated amounts of total ground disturbance displayed in Table 4.6-3 were used as a general guide to conclude that impacts on common habitats would not be significant if the extent of the construction area and expected volume of borrow and spoils were small. These numbers would be refined and partitioned among habitat types as part of separate, project-level CEQA review for the individual WSIP projects. Impacts on sensitive habitats also include the disturbance or removal of large, old, or historically important trees. For example, Alameda County protects heritage trees, and the CCSF has specific prohibitions against the removal of street trees and landmark trees. These trees are collectively referred to in this section as heritage trees. Also included in the loss of sensitive habitats are impacts on critical habitat for listed species, as described above and mapped in Figure 4.6-2. Impacts and mitigations do not vary by region, except with respect to the species associated with critical habitats. Potential impacts on sensitive habitats, by facility type, are described below.

Project- and site-specific impacts would be analyzed when more detailed project design information is developed, especially with regard to access, construction and staging areas, location and extent of borrow areas, and spoils disposal areas. Such impacts would be analyzed as part of separate, project-level CEQA review for those projects that could result in potentially significant impacts on sensitive natural communities and habitats.

Pipelines. Pipelines could affect sensitive habitats through temporary and permanent disturbance as well as loss of rare natural communities and critical habitat. As linear features, pipelines cannot avoid these sensitive resources entirely. Where pipelines are constructed using the open-trench method, the trench, work area, spoils pile, and vehicle lanes must be cleared. In addition to the direct loss of heritage trees and other sensitive habitat along the pipeline route, nearby trees could be killed due to root damage. Trenching and stockpiling soil could have an adverse impact on nearby trees if the roots were cut or the drainage altered. If trenching occurred within the dripline of a tree, large roots would likely be damaged. Other construction activity, such as vehicle traffic, under the dripline of trees could compact the soil and damage the roots. Piling soil against tree trunks could also alter the drainage around trees, potentially resulting in disease or death. The right-of-way would be maintained as annual vegetation, so heritage trees or sensitive habitat supporting trees or shrubs could be permanently affected. Trenching, clearing, and soil

[17] Sensitive habitats include critical habitat for listed species.

compaction associated with open-trench construction can permanently alter the soil structure, causing vernal pools and alkali meadows to be permanently lost. With trenchless methods, a larger work area would be developed at the openings of tunnels or jack-and-bore pits, but sensitive habitats would not be affected between these work areas. Trenchless methods would be used where sensitive habitats must be avoided.

Tunnels. Impacts on sensitive habitats or heritage trees could occur at portals, shaft openings and accessways, associated staging areas, and spoils disposal sites. Sensitive habitats in the construction area would be temporarily affected, while sensitive habitats at the tunnel openings used for operational activity would be permanently affected. Impacts on areas that are maintained as access roads to shafts would also be permanent. Compacting or disturbing soil within the dripline of a tree or piling soil against the trunk of a tree could affect the tree, potentially resulting in disease or death.

Valves, Valve Lots, and Crossovers. Valves, valve lots, and crossovers could remove sensitive habitats and heritage trees; however, projects located at existing developed sites would have little impact on adjacent resources, except for potential root damage to nearby large trees, as described for pipelines and tunnels. Valves and crossovers located at watercourse crossings could require the removal of trees and other sensitive riparian vegetation.

Pump Stations. The proposed replacement of pump stations at developed sites would generally not affect sensitive habitats or heritage trees, except for potential root damage to nearby trees. New pump stations could result in temporary and permanent loss of sensitive habitats, similar to impacts described above for pipelines and tunnels.

Treatment Facilities. In general, proposed treatment facility projects would be located in developed areas that are surfaced, drained, and maintained free of vegetation and would not affect sensitive habitats or heritage trees, except for potential root damage to nearby large trees. Treatment facilities sited in areas of natural vegetation could affect heritage trees and sensitive habitats, as discussed above. Some treatment facility projects would require pipelines; if pipelines are located outside of developed areas, these projects could affect sensitive habitats.

Storage Facilities. Construction or improvement of storage reservoirs and dams could affect nearby sensitive habitats through direct temporary and permanent loss of habitat and heritage trees. Improvements to below-grade storage reservoirs could affect large ornamental trees (which in San Francisco could meet the requirements for protection under city ordinance), and construction activities could harm the roots of nearby trees. Construction of new storage reservoirs and dams, depending on their location, could cause extensive impacts on sensitive habitats and heritage trees. Sensitive habitats would be permanently lost within the zone of inundation and in the area required for the impoundment, control structures, and accessways. Permanent loss of sensitive habitat could also occur in borrow and spoils disposal areas as well as their associated accessways. Restoration of certain types of sensitive habitats, such as riparian vegetation, might be possible in some construction, borrow, and spoils disposal areas. Storage facilities are often located in bottomlands, which contain such sensitive habitat types as sycamore alluvial woodland and riparian forest and scrub communities. Impacts on sensitive habitats during operation of the WSIP projects are discussed in Chapter 5.

San Joaquin Region

Impact 4.6-2: Impacts on sensitive habitats, common habitats, and heritage trees		
Advanced Disinfection	SJ-1	PSM
Lawrence Livermore	SJ-2	PSM
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	PSM

There is a limited potential for sensitive habitat impacts under the Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) projects because of their location in previously developed and non-native-dominated areas with few native trees. However, the Lawrence Livermore project (SJ-2) could affect small areas of sensitive valley needlegrass grassland and pine bluegrass grassland natural communities in the hills west of Tesla Portal. Also, the Advanced Disinfection and Tesla Portal Disinfection projects would generate significant volumes of spoils requiring offsite disposal. The location of spoils disposal has not been determined, so this impact on sensitive habitats is conservatively considered to be *potentially significant*. This impact will be evaluated in more detail as part of separate, project-level CEQA review for these projects.

The eastern portion of the SJPL System project (SJ-3) would affect potentially large areas of non-native grassland and oak woodland, and smaller areas of the sensitive natural communities northern hardpan vernal pool and valley needlegrass grassland. If the pipeline crosses the San Joaquin River and floodplain in the central section of the valley, it could affect relatively small areas of sensitive natural communities, including alkaline meadow, coastal and valley freshwater marsh, Great Valley cottonwood forest, Great Valley mixed riparian forest, Great Valley oak riparian forest, Great Valley willow scrub, and elderberry savanna. The extent of potential impacts in this area would depend on the project design and methods for crossing the river. Where open-trench construction is used, a portion of the construction area would be located on previously undisturbed habitat. Because of their dependence on natural soil conditions, northern hardpan vernal pool and alkaline meadow communities in these areas could be permanently affected by any soil disturbance. Valley needlegrass grassland and riparian natural communities could be temporarily affected by pipeline construction and work/staging areas and could be permanently affected by roads and control structures. Although the potentially affected areas would be fairly small, the remaining acreage of these communities is so limited in extent that the impact would be *potentially significant*. Stanislaus County has no heritage tree protection ordinance, so the loss of large trees such as isolated blue oaks or valley oaks would not be considered significant. This project would pass through critical habitat for Colusa grass in the eastern rolling foothills, and critical habitat for the Conservancy fairy shrimp in the alkaline grasslands near the San Joaquin River. The area required for spoils disposal could affect sensitive habitats or heritage trees.

The SJPL Rehabilitation project (SJ-4) could affect areas where pipeline repair or replacement is needed. Since this project encompasses the entire San Joaquin portion of the Hetch Hetchy Aqueduct, impacts could occur on any of the sensitive natural communities described for the SJPL System project (SJ-3), including riparian forests and scrubs, vernal pools, and grasslands, as well as the established critical habitat units for Colusa grass and Conservancy fairy shrimp. The area required for spoils disposal could affect sensitive habitats or heritage trees. The impact of this project on sensitive habitats is *potentially significant*.

Implementation of SFPUC Construction Measure #8 (biological screening survey) would ensure that all potentially affected areas would be surveyed for biological resources, including heritage trees, sensitive natural communities, and critical habitats. If sensitive habitats were present, onsite avoidance, protection, and restoration for impacts would be required, including compensation for heritage trees, as appropriate (Measure 4.6-2). As described above under Impact 4.6-1, in Measure 4.6-1b the WSIP HRP or similar offsite compensation would provide a mechanism for identifying, preserving, creating, enhancing, and managing compensation lands, as appropriate, although mitigation actions would be implemented on a project-by-project basis. Taken together, SFPUC Construction Measure #8, Measure 4.6-1b, and Measure 4.6-2 would reduce potential impacts on sensitive habitats to a less-than-significant level.

Sunol Valley Region

Impact 4.6-2: Impacts on sensitive habitats, common habitats, and heritage trees		
Alameda Creek Fishery	SV-1	PSM
Calaveras Dam	SV-2	PSM
40-mgd Treated Water	SV-3	PSM
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	PSM
SABUP	SV-6	PSM

Most of the projects in the Sunol Valley Region have the potential to affect one or more sensitive riparian habitats and to result in the loss of large native trees. All of the Sunol Valley Region projects are situated in critical habitat for one or more listed species. Some of the projects would also affect large areas of relatively common habitats.

The Alameda Creek Fishery (SV-1) and Calaveras Dam (SV-2) projects would affect relatively large areas of sensitive riparian natural communities, including central coast cottonwood sycamore riparian forest, central coast arroyo willow riparian forest, central coast riparian scrub, and sycamore alluvial woodland. Areas of serpentine grassland below Calaveras Dam and east of Calaveras Reservoir could be affected during dam reconstruction. Relatively small areas of these sensitive natural communities would be committed to permanent facilities and accessways for the Alameda Creek Fishery project, and most project impacts on these communities are assumed to be temporary construction impacts. The Calaveras Dam project would result in the permanent loss of sensitive riparian natural communities in the vicinity of the new dam and associated facilities and accessways, as well as the temporary loss of these communities in construction and staging areas. Although the borrow and spoils disposal areas have not been identified, riparian communities (such as coast live oak riparian forest, central coast arroyo willow riparian forest, or central coast riparian scrub) could be permanently lost to accommodate them. Established critical habitat in the Sunol Valley includes the area between Arroyo Hondo and Calaveras Reservoir (for California tiger salamander) and the area between the Alameda Creek Diversion Dam, Calaveras Reservoir and San Antonio Reservoir (for Alameda whipsnake). Critical habitat for California tiger salamander could be affected by the construction, borrow, or spoils disposal areas associated with the Calaveras Dam project. Alameda whipsnake critical habitat encompasses all of the Sunol Valley Region projects. Relatively large areas of common habitats, such as non-native annual grassland, oak woodland,

and coastal scrub, could also be affected by the Calaveras Dam construction, borrow, and spoils disposal areas. The Alameda Creek Fishery project could result in impacts on smaller areas of these common habitats.

The remaining WSIP projects in this region (40-mgd Treated Water, SV-3; New Irvington Tunnel, SV-4; Treated Water Reservoirs, SV-5; and SABUP, SV-6) would affect riparian forest and alluvial woodland, including coast live oak riparian forest, central coast arroyo willow forest, and sycamore alluvial woodland where the project facilities would cross Alameda Creek or its floodplain and tributaries. These sensitive natural communities would be permanently lost to storage facilities, control buildings, accessways, pipelines, outfalls, and, in the case of the New Irvington Tunnel, spoils disposal. Temporary loss of sensitive riparian and alluvial natural communities would occur in construction and staging areas. Critical habitat for the Alameda whipsnake could be lost under any of these projects. Common habitats such as non-native annual grassland, oak woodland, and coastal scrub could also be affected by these projects, especially the New Irvington Tunnel, which would have a project footprint estimated at 127 acres. Impacts on sensitive habitats would be *potentially significant* for each WSIP project in this region due to the presence of critical habitat, sensitive riparian and serpentine grassland habitats, and the size of the project footprints, including spoils disposal.

Implementation of SFPUC Construction Measure #8 (biological screening survey) would be required for all WSIP projects to determine the presence of sensitive habitats. If the survey identified sensitive habitats, heritage trees, or critical habitat, further mitigation would be required. Measure 4.6-2 would ensure onsite avoidance, minimization of the impact area, protection, restoration of habitats, and replacement of lost trees, including heritage trees, as appropriate. In Measure 4.6-1b, the WSIP HRP or similar program would provide a mechanism for offsite identification, protection, restoration, and management of compensation land (although not necessarily outside of lands already managed by the SFPUC). Mitigation actions could be implemented on a project-by-project basis or on a more comprehensive basis. Taken together, these measures would reduce impacts to a less-than-significant level.

Bay Division Region

Impact 4.6-2: Impacts on sensitive habitats, common habitats, and heritage trees		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	PSM
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSM

The largest project in this region, the BDPL Reliability Upgrade project (BD-1), would cross several natural watercourses and could affect the associated riparian communities, which could include central coast riparian scrub or central coast arroyo willow forest. This project could also affect somewhat disturbed examples of northern coastal salt marsh and coastal and valley freshwater marsh in the vicinity of the Newark and Ravenswood Valve Houses. Most if not all of the salt marsh would be avoided, however, due to the use of a tunnel under San Francisco Bay. Spoils disposal could affect sensitive habitats, although some of the spoils could be used to enhance San Francisco Bay wetland habitat. Some heritage trees could also be lost as a result of pipeline construction. The BDPL Reliability Upgrade project would cross critical habitat for Central California DPS steelhead in the Guadalupe River, Coyote Creek, and San Francisquito Creek. Although not identified as critical habitat for steelhead, Stevens Creek, San Mateo Creek, and several smaller streams still support populations of this species. The Guadalupe River also supports a small run of Chinook salmon. Common habitats that could be significantly affected include non-native grassland and oak woodland. The impact of this project would be *potentially significant*.

The BDPL 3 and 4 Crossovers project (BD-2) would cause limited impacts on maintained coast and valley freshwater marsh and central coast riparian scrub (or a similar natural riparian vegetation community) within the Guadalupe River floodplain. Construction could remove a small number of native oaks at Barron Creek and Bear Gulch Reservoir, some of which could meet criteria for heritage trees. Since this project involves construction at the Guadalupe River, impacts on steelhead critical habitat and Chinook salmon sensitive habitat could occur, such as erosion and sedimentation at the discharge outfall; therefore, the impact of this project would be *potentially significant*.

The BDPL 3 and 4 Seismic Upgrade at Hayward Fault project (BD-3) would cross one or more highly modified creek channels and flood control channels that support limited riparian vegetation and few trees, so the potential impact of this project on sensitive habitats in the construction area would be small. The volume of spoils has not been determined for this project, so the impact of this project on sensitive habitats is conservatively considered to be *potentially significant*.

SFPUC Construction Measure #8 (biological screening survey) would be required for all WSIP projects to determine whether sensitive habitats were present. If so, additional mitigation would be required to ensure avoidance, protection, restoration, and replacement of heritage trees (Measure 4.6-2). In Measure 4.6-1b, additional compensation would be implemented through the WSIP HRP or similar mechanism to provide for the identification, protection, restoration, and management of compensation lands, although mitigation actions would be implemented on a project-by-project basis. Taken together, SFPUC Construction Measure #8, Measure 4.6-1b, and Measure 4.6-2 would reduce potential impacts on sensitive habitats resulting from Bay Division Region projects to a less-than-significant level.

Peninsula Region

Impact 4.6-2: Impacts on sensitive habitats, common habitats, and heritage trees		
Baden and San Pedro Valve Lots	PN-1	PSM
CS/SA Transmission	PN-2	PSM
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	PSM
Pulgas Balancing Reservoir	PN-5	PSM

The HTWTP Long-Term project (PN-3) would be sited within a surfaced, drained site that is landscaped or maintained free of vegetation. Therefore, this project is not expected to affect sensitive habitats and would have a limited potential to affect nearby heritage trees. Implementation of SFPUC Construction Measure #8 would be adequate to ensure impacts on sensitive resources are *less than significant*.

The Baden and San Pedro Valve Lots project (PN-1) is located primarily on graded, drained, and surfaced sites, but also includes some small elements in more or less natural habitat where heritage trees could be affected, a *potentially significant* impact. The CS/SA Transmission project (PN-2) would affect coastal and valley freshwater marsh at Upper and Lower Crystal Springs Reservoirs at the culverts between the reservoirs and at several outlet sites, as well as potentially at the base of Crystal Springs Dam where freshwater marsh vegetation has grown around old, existing structures. In addition, repair and replacement of segments of the Crystal Springs/San Andreas Pipeline could affect one or more types of sensitive natural communities, such as central coast riparian forest at watercourse crossings and along the trace of San Mateo Creek between San Andreas and Lower Crystal Springs Reservoirs. The location and extent of spoils disposal have not been determined, but could affect sensitive habitats, including heritage trees. The extent of this impact would be analyzed in more detail following the pipeline assessment and completion of project-level CEQA review. Impacts of the CS/SA Transmission project are also considered *potentially significant.*

The Lower Crystal Springs Dam project (PN-4) would affect coastal and valley freshwater marsh and potentially central coast riparian forest at the stilling basin at the base of the dam. Areas of serpentine grassland could be affected by construction of this project. The construction area and staging areas have not been identified, but depending on their size and location could cause impacts on heritage trees. This project could affect critical habitat for California red-legged frog. Common habitats would also be affected by these projects, including non-native grassland, coastal scrub, and oak woodland. Impacts of the Lower Crystal Springs Dam project would be *potentially significant.* (The impacts of project operation, including the impact of raising water levels at Upper and Lower Crystal Springs Reservoirs, are discussed in Chapter 5.)

The Pulgas Balancing Reservoir project (PN-5) would require the removal of trees that could meet heritage tree criteria and could affect sensitive natural communities such as central coast riparian forest and willow riparian forest along the smaller ephemeral watercourses where the pipeline to the Pulgas Water Temple is proposed. Areas of oak woodland and non-native grassland could also be affected, although much of the route traversed by this project would pass through maintained, landscaped areas around the Pulgas Water Temple. The impact of this project would be *potentially significant.*

SFPUC Measure #8 would be implemented for all projects in this region to screen for sensitive resources; if sensitive habitats were present, additional mitigation would be required to ensure that identified resources would be avoided, protected, and restored to the extent possible. Measure 4.6-2 would ensure that onsite sensitive habitats were avoided, protected, and restored to the extent possible, and also would provide compensation for the loss of heritage trees. If further compensation were required, Measure 4.6-1b specifies the WSIP HRP or similar program as a mechanism for habitat compensation, although mitigation actions would be implemented on a project-by-project basis. Taken together, SFPUC Construction Measure #8, Measure 4.6-1b, and Measure 4.6-2 would reduce the potentially significant impacts from Peninsula Region projects to a less-than-significant level.

San Francisco Region

Impact 4.6-2: Impacts on sensitive habitats, common habitats, and heritage trees		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	PSM
Recycled Water Projects	SF-3	PSM

All projects in this region (SAPL 3 Installation, SF-1; Groundwater Projects, SF-2; and Recycled Water Projects, SF-3) could affect heritage trees, a *potentially significant* impact. The location of spoils disposal for the SAPL 3 Installation project could affect sensitive habitats. The locations of facilities, construction areas, and spoils disposal areas, as needed, have not been determined for the Groundwater and Recycled Water Projects. Implementation of SFPUC Construction Measure #8 would ensure that all project sites are screened for the occurrence of sensitive habitats, including heritage trees. If sensitive habitats were present, additional mitigation would be required, including onsite habitat restoration/tree replacement measures, avoidance of sensitive resources, and protection, as appropriate (Measure 4.6-2). If additional compensation were required, Measure 4.6-1b specifies the WSIP HRP as one potential mechanism to provide for the identification, protection, restoration, and management of compensation land, as appropriate. Taken together, SFPUC Construction Measure #8, Measure 4.6-1b, and Measure 4.6-2 would reduce impacts from San Francisco Region projects to a less-than-significant level.

Impact 4.6-3: Impacts on key special-status species – direct mortality and/or habitat effects.

Most of the WSIP projects would affect natural habitats (such as grasslands, seasonal or permanent wetlands and watercourses, and oak woodland) or disturbed habitat that could support one or more key special-status species. As a result, all projects would be evaluated to determine their potential to affect these resources. Some projects are likely to be sited largely or entirely on surfaced, drained areas that are maintained free of vegetation, in which case these projects could have no impact or a less-than-significant impact on sensitive species. However, not all WSIP project designs have been finalized. Potential impacts on key special-status species, by facility type, are described below.

For projects where key special-status species or their habitat would be affected, avoidance is the foremost impact minimization measure. Avoidance would consist of siting the project to avoid habitat, to the extent possible; fencing or other measures to limit the construction footprint and reduce interaction between construction activity and individual animals; timing construction to avoid interrupting the reproductive season; and monitoring to ensure no take of species during construction. Where loss of habitat is inevitable, mitigation measures include actively or passively relocating animals and salvaging key special-status plants. The loss of key special-status species and their habitat would require compensatory measures, such as restoring habitat in the construction footprint, restoring degraded or lost habitat outside the construction area, and protecting existing, high-quality habitat elsewhere, which could be accomplished through acquisition, management agreement, conservation easement, or other measures. The WSIP HRP outlines a potential programmatic approach to habitat compensation.

Consultation with the USFWS, NMFS, and CDFG, as appropriate, would be initiated on a project-by-project basis for those WSIP projects that could affect listed species.

It should be noted that there would be effects not only on key special-status species discussed herein, but also on other species of concern (see the introduction to this section), such as California species of special concern, federal candidate species, CNPS List 1 plants (rare and endangered), and List 2 plants (rare but not endangered). Many of these species would also benefit from mitigation measures developed for listed species, although the impact on each species and appropriate mitigation must be analyzed at the project level during separate CEQA review.

Pipelines. Trenching and other soil disturbance has the potential to cause direct mortality of key special-status plants and their seed accumulated in the soil. Key special-status animals could be killed by vehicles and equipment, their burrows or other retreats could be crushed, or they could be killed if they fall into trenches or pits and cannot escape. Trenching and other surface-disturbing activity could dry out the streams, wetlands, or seasonal ponds in which aquatic animals live, or the pools in which the larval stages of amphibians develop. Sediment or other pollutants could cause mortality to aquatic animals in streams at and below the construction areas. Fish could be stranded as a result of dewatering (leading to suffocation or exposure to birds, raccoons, and other predators attracted to dewatered areas), or they could be trampled or crushed by humans, vehicles, or other equipment. The noise, dust, and traffic caused by construction activity could also cause breeding animals to abandon their nests or their young. The loss of habitat would be temporary in construction areas that could be fully restored to their original vegetation. The loss of habitat would be permanent in areas permanently committed to project facilities, or when the habitat could not be fully restored, such as vernal pools. During operation of the WSIP projects, wildlife could be affected by ongoing vehicle activity along pipeline accessways, and by erosion, sedimentation, or other pollution of waterways; reptiles and amphibians would be especially vulnerable.

Tunnels. As with pipelines, direct mortality of individual key special-status species could result from interactions with vehicles and equipment or the removal of individual plants and their seed in the soil during construction. The area of surface disturbance for tunnels would be more restricted than for pipelines and would be limited to tunnel shafts or portals. However, dewatering during tunnel construction could alter the hydrology of nearby surface features, such as ponds, seeps, springs, and creeks on which certain key special-status animal species depend. Vehicle activity to and from spoils disposal sites presents a high risk of mortality to key special-status animals, particularly reptiles and amphibians. Also, noise would occur 24 hours per day at tunnel entry shafts/portals, potentially causing more intensive disturbance to key special-status wildlife species. Temporary and permanent loss of habitat would occur as discussed above for pipelines. Temporary and permanent impacts could result from habitat loss due to spoils disposal. During operation, ongoing vehicle activity could be a cause of mortality, especially for reptiles and amphibians. Nesting birds are unlikely to be affected by vehicle activity and noise, as they would become accustomed to the activity.

Valves, Valve Lots, and Crossovers. Valves and valve lot projects could be sited in existing maintenance yards that are surfaced, drained, and maintained free of vegetation. These projects could affect key special-status species if the construction area were expanded into natural vegetation. Crossover facilities must be sited near creeks, so they would have a high potential to cause direct mortality to animals and plants that depend on aquatic habitats. Dispersing animals could move across valve lots and crossovers from nearby natural habitat, even if little or no cover were present, resulting in direct mortality to animals in the construction area. Temporary and permanent loss of habitat would occur as discussed above for pipelines. During project operation, releases from crossovers into watercourses could cause scouring and result in thermal shock for sensitive species that depend on aquatic habitats.

Pump Stations. New pump stations sited at existing developed pump station sites that are surfaced, drained, and maintained free of vegetation would not affect key special-status species unless construction activity were extended into areas of natural vegetation, or if key special-status animals moved into the construction area from nearby natural habitat. If new pump stations were located within natural habitat, project activities could result in direct mortality of key special-status species and temporary and permanent loss of habitat, as discussed above for pipelines. Impacts during project operation on key special-status wildlife species are expected to be insignificant, because wildlife would become accustomed to pump station operations and activity.

Treatment Facilities. Proposed treatment facility projects sited in developed areas that are surfaced, drained, and maintained free of vegetation would have a low potential to affect key special-status species unless construction were extended into areas of natural vegetation. However, some treatment facilities are situated near extensive areas of natural, high-quality habitat, such as the Sunol Valley and the Peninsula watershed. Animals could move into the construction area from nearby habitat and could be killed by moving vehicles and equipment, by falling into trenches or pits, or by dewatering of aquatic habitat on which the species depend. Noise could result in the abandonment of nests or other breeding areas used by key special-status animals. Locating treatment facilities in natural, undisturbed habitats would have a greater risk of causing direct mortality to key special-status species. Temporary and permanent loss of habitat would occur as discussed above for pipelines. Operationally, vehicle activity at treatment facilities could result in roadkills, especially of slow-moving reptiles and amphibians.

Storage Facilities. Storage reservoirs requiring extensive grading could cause direct mortality of key special-status animals due to moving vehicles and equipment, animals falling into pits or trenches, and dewatering of aquatic habitat. Construction of facilities in areas surrounded by extensive urban development would have a low potential to affect key special-status species. Dam improvements involving extensive earthmoving activities near streams and associated riparian vegetation have a high potential to cause mortality of key special-status species that depend on these habitats. Temporary and permanent loss of habitat would occur as discussed above for pipelines.

San Joaquin Region

Impact 4.6-3: Impacts on key special-status species – direct mortality and/or habitat effects		
Advanced Disinfection	SJ-1	PSM
Lawrence Livermore	SJ-2	PSM
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	PSM

All five projects in this region (Advanced Disinfection, SJ-1; Lawrence Livermore, SJ-2; SJPL System, SJ-3; SJPL Rehabilitation, SJ-4; and Tesla Portal Disinfection, SJ-5) would be located within the habitat and range of the following key special-status species: San Joaquin kit fox, vernal pool crustaceans, Swainson's hawk, burrowing owl, California red-legged frog, and California tiger salamander. Impacts on key special-status species would be *potentially significant* for all of the projects in this region.

Construction activity at Tesla Portal for the Advanced Disinfection and Tesla Portal Disinfection projects and associated spoils disposal activity could cause direct mortality of these species, as described above. The Lawrence Livermore project would be located within the range of large-flowered fiddleneck. Construction in natural grassland habitat, such as improving access roads or installing control facilities, could result in direct mortality and permanent loss of habitat for these species.

The SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects could affect the suite of vernal pool plants in the grasslands west of Oakdale Portal, as well as riparian key special-status species such as Valley elderberry longhorn beetle, riparian woodrat, least Bell's vireo, and Delta button-celery. These projects are located within the habitat and range of Central Valley DPS steelhead, green sturgeon, and Chinook salmon, and impacts on these species and their habitat could occur at the San Joaquin River pipeline crossing. Temporary loss of habitat would occur in all construction areas containing habitat for key special-status species. Permanent loss of habitat would occur where new project facilities are sited on habitat for key special-status species and where that habitat is permanently altered, such as vernal pools in the trenching construction area and in spoils disposal areas.

SFPUC Construction Measure #8 (biological screening survey) would be required for all WSIP projects in this region to identify potentially occurring key special-status species and their habitat. If the screening survey identified the potential for key special-status species to be affected, then additional surveys would be carried out to determine the presence and extent of key special-status species, the extent of project impacts, and measures to avoid or reduce these potential impacts as much as possible (Measure 4.6-3a, first bullet). If impacts would occur, applicable standard programmatic measures (Measure 4.6-3b, as modified for each project) would be implemented to compensate for these impacts. If additional compensation were required, Measure 4.6-1b provides for identifying, preserving, creating, enhancing, and managing compensation lands, as appropriate. Taken together, these measures would reduce impacts to a less-than-significant level for key special-status species for all projects in this region.

In addition, SFPUC Construction Measure #8, Measure 4.6-1b, and Measures 4.6-3a and 4.6-3b and project-specific CEQA analysis would identify all other species of concern (such as

California species of special concern, federal candidate species, and CNPS List 1 and 2 plants) that could be affected by a specific project, as well as determine project impacts on these species and establish appropriate avoidance, protection, minimization, and compensation measures.

Sunol Valley Region

Impact 4.6-3: Impacts on key special-status species – direct mortality and/or habitat effects		
Alameda Creek Fishery	SV-1	PSM
Calaveras Dam	SV-2	PSM
40-mgd Treated Water	SV-3	PSM
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	PSM
SABUP	SV-6	PSM

Because the Sunol Valley Region projects are located in an area of extensive high-quality habitat for rainbow trout, California red-legged frog, foothill yellow-legged frog, California tiger salamander, Alameda whipsnake, and burrowing owl, construction activity of all projects in this region could cause direct mortality of these species. Temporary loss of habitat could occur in all construction areas. Habitat degradation (such as erosion or sedimentation within aquatic habitats) could result in mortality of individuals and degradation of breeding habitat for aquatic-dependent species. Permanent loss of habitat for key special-status species would occur where new project facilities are sited and where habitat is permanently altered. Impacts on key special-status species would be *potentially significant* for each project in this region (Alameda Creek Fishery, SV-1; Calaveras Dam, SV-2; 40-mgd Treated Water, SV-3; New Irvington Tunnel, SV-4; Treated Water Reservoirs, SV-5; and SABUP, SV-6).

Construction of the Alameda Creek Fishery project (SV-1) would cause a temporary loss of habitat and potential mortality of rainbow trout and other water-dependent species such as California tiger salamander, foothill yellow-legged frog, and California red-legged frog during facility construction. Upland habitat for Alameda whipsnake and burrowing owl could also be lost, and mortality could result from vehicle activity and animals becoming trapped in trenches.

Construction of the Calaveras Dam project (SV-2) would affect riparian and wetland areas, potentially resulting in mortality of individuals and affecting breeding habitat for foothill yellow-legged frog, California red-legged frog, California tiger salamander, and rainbow trout. The project could affect grassland species such as the Callippe silverspot butterfly, which is known to occur near the dam, reservoir, access roads, and borrow and spoils disposal areas. The loss of upland habitats, such as non-native grassland, oak woodland, and coastal scrub, could result in mortality of Alameda whipsnake, burrowing owl, California red-legged frog, and California tiger salamander, species that depend on these upland habitats for portions of their life cycle. Construction activity and noise in and around Calaveras Reservoir could disturb nesting or foraging bald eagles. Construction impacts are usually considered temporary, but habitat loss would be considered permanent unless the habitat could be fully restored. The location of the 220-acre borrow areas have not been identified, but construction activity could affect ponds, non-native grassland, coastal scrub, oak woodlands, and riparian habitat, and thus could result in habitat loss and direct mortality of any of these key special-status species. Impacts related to Calaveras Dam operations are discussed in Section 5.4.6.

Construction of the 40-mgd Treated Water project (SV-3) could temporarily affect habitat for California red-legged frog, foothill yellow-legged frog, California tiger salamander, Alameda whipsnake, burrowing owl, and rainbow trout, since this project would be located adjacent to riparian habitat; the pipeline for this project would cross several small watercourses and would also affect upland habitat supporting non-native grasslands, oak woodland, and coastal scrub. Depending on the final project footprint, a portion of the water treatment facilities and the associated pipeline could result in permanent habitat loss for these species. These facilities would have a minimal additional impact on the movements and dispersal of tiger salamanders, red-legged frogs, yellow-legged frogs, and burrowing owls, because the footprint of the fenced area at the Sunol Valley WTP is expected to be about the same as at present. Construction activity could cause direct mortality of these key special-status species.

The New Irvington Tunnel (SV-4) and SABUP (SV-6) projects would cause a temporary loss of habitats in the construction zone and a permanent loss of habitats where facilities are sited (including accessways and spoils disposal areas), as well as the permanent conversion of forest and woodland habitat for pipelines. These projects could affect foraging habitat for the Callippe silverspot butterfly, breeding and estivation habitat for California red-legged frog and California tiger salamander, breeding and foraging habitat for burrowing owl, and movement corridors for Alameda whipsnake; they could also cause erosion and sedimentation in Alameda Creek and its tributaries, which could affect foothill yellow-legged frog and resident rainbow trout. Dewatering during tunnel construction could alter surface water features such as ponds, seeps, springs, and streams, with potential impacts on associated key special-status species such as California red-legged frog and California tiger salamander.

The Treated Water Reservoirs project (SV-5) would result in about three acres of permanent habitat loss for the new storage and contact basins. This project could temporarily affect habitat in nearby Alameda Creek due to construction of a pipe bridge across the creek, and permanently affect disturbed grassland and oak woodland near the existing Sunol Valley WTP, resulting in habitat loss for California red-legged frog, foothill yellow-legged frog, California tiger salamander, burrowing owl, and Alameda whipsnake. Fencing around the facility would alter movement corridors between uplands and Alameda Creek for California red-legged frogs and California tiger salamanders, a permanent impact. Temporary impacts on rainbow trout habitat in Alameda Creek could occur during construction. Mortality of individual animals, especially red-legged frogs, yellow-legged frogs, and tiger salamanders could occur, both during construction and operation.

SFPUC Construction Measure #8 (biological screening survey) would be required for all WSIP projects in this region to identify potential habitat for key special-status species. Measures 4.6-3a and 4.6-3b call for surveys to verify the presence or absence of key special-status species, a worker awareness program, environmental inspections, protection measures to avoid mortality to individuals during construction and operation of the projects, and restoration of temporary use areas. Measure 4.6-1b would provide a mechanism for identifying, preserving, creating, enhancing, and managing compensation lands, as appropriate to fully compensate for temporary and permanent loss of habitat. Taken together, these measures would reduce impacts on key special-status species to a less-than-significant level for all projects in this region.

In addition, SFPUC Construction Measure #8 and project-specific CEQA analysis would identify all other species of concern (such as California species of special concern, federal candidate species, and CNPS List 1 and 2 plants) that could be affected by a specific project, as well as determine project impacts on these species and appropriate avoidance, protection, minimization, and compensation measures.

Bay Division Region

Impact 4.6-3: Impacts on key special-status species – direct mortality and/or habitat effects		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	PSM
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSM

All of the projects in this region have the potential to affect key special-status species. The BDPL Reliability Upgrade project (BD-1) could affect salt-marsh-dependent key special-status species near San Francisco Bay (such as western snowy plover, California clapper rail, and salt marsh harvest mouse) through roadkills, loss of habitat, and mortality due to dewatering, trenching, and disturbance. Although these impacts could be significant, they would be limited to previously disturbed salt marshes near the Newark and Ravenswood Valve Houses; the Bay Tunnel section of this project would avoid most of the habitat supporting these species. Some of the spoils from the tunnel could be placed in a restoration area at a former salt evaporation pond, and thus could result in a beneficial impact on salt-marsh-dependent sensitive species. Impacts on California red-legged frog, California tiger salamander, and burrowing owl could occur at the stream crossings and in disturbed grasslands, although this habitat is much degraded and fragmented along the pipeline route. The potential for direct mortality during construction is therefore relatively low. Some temporary habitat loss of riparian and grassland habitat would occur during construction. This project could cause sedimentation or other reduction in water quality in the bay and in tributary streams used by spawning anadromous fishes such as the Chinook salmon and Central Coast DPS steelhead. Replacement of Bay Division Pipelines Nos. 3 and 4 could affect vernal pool tadpole shrimp, known to be present in the vicinity of Milpitas, resulting in the loss of habitat and potential mortality of individuals. The western terminus of the Bay Division Pipelines at the entrance to the Pulgas Tunnel is also within the range of the San Francisco garter snake. Therefore, the BDPL Reliability Upgrade project would result in *potentially significant* impacts on key special-status species in this region.

The BDPL 3 and 4 Crossovers project (BD-2) could temporarily affect migration or spawning habitat for Central Coast DPS steelhead in the Guadalupe River due to erosion and sedimentation within the river levees during construction. Temporary habitat loss for California red-legged frog and California tiger salamander could occur at Barron Creek and Bear Creek Reservoir. Although these projects are small in extent, habitat loss and potential mortality of individuals is *potentially significant.* Operationally, large volumes of water are released from the crossover valves for brief periods during maintenance and emergencies. This potential impact on listed species is expected to be less than significant because the increased flows would be short in duration.

The BDPL 3 and 4 Seismic Upgrade at Hayward Fault project (BD-3) could affect California red-legged frog, California tiger salamander, and burrowing owl through loss of habitat as well as mortality due to construction vehicle activity, dewatering, sedimentation, water quality degradation, trenching, and disturbance. However, the watercourses in this portion of the East Bay are highly modified and support little or no habitat for red-legged frog and tiger salamander. There could be marginal habitat for burrowing owl on the levee banks and disturbed grasslands, so temporary loss of habitat could occur for this species, a *potentially significant* impact.

SFPUC Construction Measure #8 (biological screening survey) would be required for all WSIP projects in this region to identify potential habitat for key special-status species. If the screening survey identified the potential for key special-status species to be affected, then additional measures would be required to avoid, minimize, and compensate for potential impacts. Measure 4.6-3a calls for surveys to determine the presence and extent of key special-status species, the extent of project impacts, and measures to avoid or reduce these potential impacts as much as possible (Measure 4.6-3a, first bullet); it would also require a worker awareness program, environmental inspections, project planning to minimize direct impacts, and onsite restoration. If impacts could occur, applicable standard programmatic measures (Measure 4.6-3b, as modified for each project) would be implemented to compensate for these impacts. If additional compensation were required outside the construction footprint, Measure 4.6-1b would provide for identifying, preserving, creating, enhancing, and managing compensation lands, as appropriate to fully compensate for temporary and permanent loss of habitat. Taken together, these measures would reduce impacts to a less-than-significant level for these projects.

In addition, SFPUC Construction Measure #8 and project-specific CEQA analysis would identify all other sensitive species (such as California species of special concern, federal candidate species, and CNPS List 1 and 2 plants) that could be affected by a specific project, as well as determine impacts on these species from the project and appropriate avoidance, protection, minimization, and compensation measures.

Peninsula Region

Impact 4.6-3: Impacts on key special-status species – direct mortality and/or habitat effects		
Baden and San Pedro Valve Lots	PN-1	PSM
CS/SA Transmission	PN-2	PSM
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	PSM
Pulgas Balancing Reservoir	PN-5	PSM

Although the Baden and San Pedro Valve Lots (PN-1) are located on developed sites, some improvements that are part of this project would take place within known habitat for California red-legged frog and San Francisco garter snake, and potential habitat for California tiger salamander. Therefore, the impact from this project would be *potentially significant*.

The CS/SA Transmission project (PN-2) would pass through areas of known habitat for the San Francisco garter snake and California red-legged frog. Although unlikely, potential habitat for California tiger salamander may be present. Construction activity, including staging areas, could temporarily affect aquatic and nearby upland habitat on which these species depend. Direct mortality of individuals from roadkills and heavy equipment activity could occur during construction, both at the culvert repair site at Highway 92 and along the pipeline itself. It is expected that all construction and staging impacts would be temporary for the garter snake and red-legged frog, since the upland and wetland habitats along Upper and Lower Crystal Springs Reservoirs can be restored. The impact of this project would be *potentially significant*.

The HTWTP Long-Term project (PN-3) would occur entirely on graded, surfaced, or maintained sites, and therefore is not expected to affect key special-status species (*less than significant*).

The Lower Crystal Springs Dam project (PN-4) could affect California red-legged frog and its habitat in the pools and wetlands at the base of the dam, as well as any populations in and around the parapet. Depending on the design of improvements, some of the impacts on this habitat would be permanent and some temporary. Since the area below the dam is potential habitat for San Francisco garter snake, these species also could be impacted by construction activity in and around the stilling basin. Construction or staging areas in San Mateo Creek canyon could result in habitat loss and direct mortality of two key special-status plant species: San Mateo woolly sunflower and Marin western flax. Potential habitat for California tiger salamander may also be present. Disturbance associated with spoils disposal and vehicle activity could result in direct mortality and loss of habitat for any of these key special-status species. Unless restoration can be demonstrated, any impacts would be considered permanent. Any project activity or staging areas at the top of the dam could potentially affect San Francisco garter snake, especially if activity is in or near emergent wetland vegetation along the reservoir margins. Erosion or sedimentation in San Mateo Creek downstream from the dam could result in habitat degradation or mortality of Central Coast DPS steelhead. The impact of the Lower Crystal Springs Dam project would be *potentially significant*. Operation of the project, which would involve raising the reservoir water level to historical elevations, would affect California red-legged frog, San Francisco garter snake, and fountain thistle (which grows at the perimeter of the reservoir). These impacts are discussed in Chapter 5.

Construction of the Pulgas Balancing Reservoir project (PN-5) could affect California red-legged frog, California tiger salamander, and San Francisco garter snake and their habitat. Construction and operation at the existing reservoir site would occur within potential dispersal habitat for California red-legged frog, but this site does not support foraging or breeding habitat for any key special-status species. However, this project also includes improvements to the discharge channel from Pulgas Water Temple to Upper Crystal Springs Reservoir. Construction activity could result in the temporary loss of habitat for California red-legged frog and San Francisco garter snake as well as direct mortality of individuals. Permanent loss of habitat would occur where new project facilities are sited on natural habitat. Direct mortality and loss of habitat could occur as a result of spoils disposal vehicle activity and habitat disturbance. The impact of the Pulgas Balancing Reservoir project would be *potentially significant*.

SFPUC Construction Measure #8 (biological screening survey) would be required for all WSIP projects in this region to determine the presence of habitat for key special-status species. If the screening survey identifies the potential for key special-status species to be affected, then additional surveys would be carried out to determine the presence and extent of suitable habitat, the extent of project impacts, and measures to avoid or reduce these potential impacts as much as possible (Measure 4.6-3a, first bullet). If impacts would occur, applicable standard programmatic measures (Measure 4.6-3b, as modified for each project) would be implemented to compensate for these impacts. These measures include a worker environmental awareness program, environmental inspections, and minimizing and restoring temporary use areas. If additional compensation were required, Measure 4.6-1b calls for identifying, preserving, creating, enhancing, and managing compensation lands, as appropriate. Taken together, these measures would reduce impacts on key special-status species to a less-than-significant level.

In addition, SFPUC Construction Measure #8 and project-specific CEQA analysis would identify all other sensitive species (such as California species of special concern, federal candidate species, and CNPS List 1 and 2 plants) that could be affected by a specific project, as well as determine impacts on these species from the project and appropriate avoidance, protection, minimization, and compensation measures.

San Francisco Region

Impact 4.6-3: Impacts on key special-status species – direct mortality and/or habitat effects		
SAPL 3 Installation	SF-1	LS
Groundwater Projects	SF-2	LS
Recycled Water Projects	SF-3	LS

The SAPL 3 Installation project (SF-1) consists of about 4.2 miles of pipeline. It is located in urban and developed land. There are no recent records for any listed species in this area, and therefore impacts are expected to be *less than significant*. However, a number of species of concern could be affected by this project, and potential impacts on these species will be analyzed in detail as part of separate, project-level CEQA review for this project.

The Local Groundwater Projects (SF-2) would raise the level of Lake Merced and would involve construction of wells, pumps, and control facilities at various locations in San Francisco. The Regional Groundwater Projects (SF-2) would involve construction of up to 10 wells and 0.5 mile of pipeline to connect the wells with the existing water conveyance system. These facilities would be located in San Mateo County. All project facilities are assumed to be located in previously disturbed areas that do not support key-special-status species. No listed species are known to be present in the area proposed for project facilities, and therefore potential impacts on key special-status species would be *less than significant*, although impacts on other species of concern would be addressed as part of separate, project-level CEQA review for this project.

The Recycled Water Projects (SF-3) would affect five to seven acres and would involve 20 miles of pipeline. All project facilities are assumed to be located in previously disturbed areas that do not support key-special-status species. No listed species are known to be present in the area proposed for project facilities, and therefore potential impacts on key special-status species would be *less than significant*, although impacts on other species of concern would be addressed as part of separate, project-level CEQA review for this project.

SFPUC Construction Measure #8 (biological screening survey) would be required for all WSIP projects in this region to determine the presence of habitat for key special-status species.

Impact 4.6-4: Water discharge effects on riparian and/or aquatic resources.

Construction and operation of many of the WSIP projects would involve discharges of system water to surface waters. These discharges would have the potential to affect riparian and aquatic resources, depending on the water quality, volume, timing, frequency, and location of the discharge. Under the WSIP projects, there could be controlled, uncontrolled, and accidental discharges of chlorinated or chloraminated water into natural water bodies at any of the streams and reservoirs that are integral to or crossed by regional water system facilities. General water quality impacts related to chlorine, chloramine, and ammonia toxicity and to nitrogen loading and algal stimulation are discussed in detail in Section 4.5, Hydrology and Water Quality, Impacts 4.5-3 and 4.5-5 (degradation of surface water quality during construction and operation, respectively).

During construction, discharges of treated water would be required for construction of some WSIP facilities, including discharges of large volumes of water in the existing pipelines or tunnels in order for construction to proceed; these discharges would be required to include control measures to prevent erosion and to protect water quality in accordance with Regional Water Quality Control Board waste discharge requirements or National Pollutant Discharge Elimination System (NPDES) permit (see Section 4.5, Impact 4.5-3b).

Similarly, during operation, the SFPUC would periodically discharge treated water from some facilities (such as treatment plants and crossover facilities), primarily for maintenance or emergency purposes. Aquatic organisms can experience mortality from thermal shock when large quantities of cold water are released into a stream with much warmer water, especially in summer under low-flow conditions. Aquatic organisms also can experience mortality when large quantities of chlorinated or chloraminated water are released into water bodies. During scheduled maintenance, discharges would be dechlorinated or dechloraminated as needed, and would also be required to include control measures to prevent erosion and to protect water quality in accordance with NPDES permits, as described in Section 4.5 under Impact 4.5-5. Thus, the greatest potential for impact would be under emergency conditions when releases are unscheduled and the water may not be fully dechlorinated or dechloraminated. In cases where the discharge would be to rivers, creeks, or other natural water bodies and where sensitive habitat or species could be affected, impacts on biological resources could be avoided or reduced through avoidance, protection, restoration, and compensation for loss of wetlands.

During construction, discharges of untreated surface or groundwater (that is, non-system water) may be required in projects that require dewatering. These project discharges would be subject to NPDES permitting requirements.

In addition, WSIP projects in the Sunol Valley Region would be located in the Alameda Creek watershed (and subject to the Alameda WMP), and some of the WSIP projects in the Peninsula Region would be located in the Peninsula watershed (and subject to the Peninsula WMP). Since these WSIP projects would be required to implement all pertinent watershed management plan policies and actions, this analysis assumes the following action pertaining to dechlorination of water prior to discharge would be implemented as part of the WSIP projects:

- *Action fis6*. Identify and adopt alternative nontoxic management practices for the protection of aquatic resources in coordination with the Integrated Pest Management program. Guidelines include:
  - Dechlorinate water before it is discharged to streams and reservoirs
  - Minimize the use of copper sulfate in the treatment of algal blooms in reservoirs
  - Limit the use of chemical fire retardants and Class A foams (except protein-based foams) in or near aquatic zones

San Joaquin Region

Impact 4.6-4: Water discharge effects on riparian and/or aquatic resources		
Advanced Disinfection	SJ-1	LS
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	LS

Construction and operation of the SJPL System project (SJ-3) and construction for rehabilitation of pipelines under the SJPL Rehabilitation project (SJ-4) would require the discharge of water from the regional system. This portion of the pipeline system contains raw water that has not been chlorinated or chloraminated; thus, removal of chlorine or chloramine would not be required. Discharges to water bodies may also be required as part of dewatering during construction. Depending on their magnitude, frequency, and location, construction and operational discharges under these two projects could result in *potentially significant* impacts on riparian or aquatic resources, particularly in the vicinity of the San Joaquin River. These impacts could be avoided or reduced to a less-than-significant level by discharging to drainage systems where feasible, applying control measures required as conditions of NPDES and other regulatory permits, or by implementing Measure 4.6-4 and controlling the nature and timing of discharges to minimize effects on biological resources.

Small discharges of chlorinated water could be required during construction of the Advanced Disinfection (SJ-1), Lawrence Livermore (SJ-2), and Tesla Portal Disinfection (SJ-5) projects, and no new discharges would be expected during operation of these three facilities. Impacts related to construction discharges of raw and treated water from these facilities would be *less than significant* with implementation of control measures, in compliance with NPDES permits or waste discharge requirements, and adherence to the requirements of other regulatory agencies, as described in Section 4.5 for fishery resources.

Sunol Valley Region

Impact 4.6-4: Water discharge effects on riparian and/or aquatic resources		
Alameda Creek Fishery	SV-1	LS
Calaveras Dam	SV-2	LS
40-mgd Treated Water	SV-3	LS
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	LS
SABUP	SV-6	LS

Construction of the Alameda Creek Fishery (SV-1) would involve dewatering of Alameda Creek, and return of this water to the creek under best management practices. There would be no discharge of system water during construction or operation and therefore, this impact would be *less than significant*.

Construction of the Calaveras Dam (SV-2) project would involve large amounts of discharge into surface waters from dewatering during construction, and would occur over a long construction period spanning the winter high-flow months. These discharges would be raw, untreated surface water. However, because of the potential for sedimentation during winter storm events, the discharges could contain large amounts of sediments. With implementation of control measures in compliance with NPDES permitting requirements for these discharges, potential impacts to riparian habitat associated with erosion would be *less than significant* (see Section 4.5, Hydrology and Water Quality, Impact 4.5-3a, for more discussion). Impacts related to discharges or releases of water during operation of these facilities are analyzed in Chapter 5, Section 5.4.6.

Small discharges of chloraminated water could be required during construction and operation of improvements to the Sunol Valley WTP for the 40-mgd Treated Water (SV-3) and Treated Water Reservoirs (SV-5) projects. However, these discharges would be managed in compliance with the required water quality permits, as described in Section 4.5, and continuation of existing SFPUC protective measures as well as secondary containment and other design provisions included in the proposed WSIP project designs would ensure that impacts on aquatic habitat associated with discharges or accidental spills would be *less than significant* for these two projects.

Dewatering of the existing tunnel under the New Irvington Tunnel project (SV-4) would require discharges to Alameda Creek, and periodic maintenance during operations might also require discharging system water to the creek. Depending on their magnitude, frequency, and location, these discharges could result in *potentially significant* impacts on riparian or aquatic resources in Alameda Creek, including sensitive habitats and special-status species. These impacts could be avoided or reduced to a less-than-significant level by discharging to drainage systems where feasible, applying control measures required as conditions of NPDES and other regulatory permits, or by implementing Measure 4.6-4, which involves controlling the nature and timing of discharges to minimize effects on biological resources.

The SABUP project (SV-6) would likely require the discharge of chlorinated or chloraminated water during construction, although implementation of control measures in compliance with NPDES permit requirements and the requirements of other regulatory agencies, as described in Section 4.5, would reduce impacts on biological resources. During operation, the SABUP project would include periodic discharges of system water to San Antonio and Alameda Creeks, but this project includes energy dissipation devices to minimize impacts of these discharges on habitat. Since the nature of the operational discharges would be essentially the same as under existing conditions, this impact would be *less than significant*.

Implementation of Alameda WMP Action fis6 regarding the discharge of chlorinated water would also be required for all projects in the Sunol Valley Region. Implementation of this measure, as well as Measure 4.6-4 where appropriate, would reduce impacts to a less-than-significant level.

Bay Division Region

Impact 4.6-4: Water discharge effects on riparian and/or aquatic resources		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	PSM
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	LS

Construction-related discharges of chloraminated water would be required for all WSIP projects in this region (BDPL Reliability Upgrade, BD-1; BDPL 3 and 4 Crossovers, BD-2; and BDPL 3 and 4 Seismic Upgrade at Hayward Fault, BD-3). Depending on the magnitude and location, these discharges could affect riparian and/or aquatic resources if discharges are directed to creeks, rivers, or other natural water bodies. Implementation of construction control measures in compliance with NPDES and other regulatory permits, including avoidance of discharges to sensitive habitats where feasible, would ensure that construction-related impacts on biological resources are less than significant.

However, the BDPL Reliability Upgrade (BD-1) and BDPL 3 and 4 Crossovers (BD-2) projects would include periodic operational discharges of chloraminated water, generally for maintenance purposes. In particular, the design of the BDPL 3 and 4 Crossovers calls for operational discharges of large volumes of water to an adjacent creek, river, or other water body. Depending on their magnitude, frequency, and location, these discharges could result in *potentially significant* impacts on riparian or aquatic resources, including sensitive habitats and special-status species. Potential adverse impacts include erosion, scouring, and rapid temperature changes in the receiving water body. These impacts could be avoided or reduced to a less-than-significant level by discharging to drainage systems where feasible, implementing of control measures required as conditions of NPDES and other regulatory permits, or by implementing Measure 4.6-4 and controlling the nature and timing of discharges to minimize effects on biological resources. Site-specific mitigation measures would be developed as part of project-level CEQA review on these projects.

The BDPL 3 and 4 Seismic Upgrade at Hayward Fault project (BD-3) would require only construction-related discharges and no operational discharges. As discussed above, this construction-related impact would be *less than significant*.

Peninsula Region

Impact 4.6-4: Water discharge effects on riparian and/or aquatic resources		
Baden and San Pedro Valve Lots	PN-1	LS
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	LS
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	LS

Small discharges of chloraminated water could be required during construction and operation of treatment plant improvements under the Baden and San Pedro Valve Lots (PN-1) and HTWTP Long-Term (PN-3) projects. However, standard control measures for protecting riparian and aquatic resources as well as required water quality control measures would be incorporated into construction and operational procedures. In addition, secondary containment and other design provisions included in these two projects would ensure that impacts on aquatic habitat associated with accidental spills would be less than significant. Therefore, impacts on biological resources due water discharges from these two projects would be *less than significant*.

The CS/SA Transmission (PN-2) and Lower Crystal Springs Dam (PN-4) projects are not expected to require construction or operational discharges of chloraminated water. However, they may require extensive dewatering for long construction periods and are located in areas of sensitive wetlands. With implementation of control measures required as conditions of NPDES and other regulatory permits and the Peninsula WMP Action fis6 regarding the discharge of chlorinated water, this impact would be *less than significant* for these two projects. Impacts related to discharges or releases of water during operation of the Lower Crystal Springs Dam are analyzed in Chapter 5, Section 5.5.6.

The Pulgas Balancing Reservoir project (PN-5) includes improvements to the Pulgas Discharge Channel. This area has already experienced erosion due to ongoing discharge flows into Upper Crystal Springs Reservoir without sufficient energy dissipation. Changes in discharge flow patterns under the WSIP could incrementally increase erosion at the discharge point and this area contains sensitive habitats and species. With implementation of control measures required as conditions of NPDES and other regulatory permits, potential impacts associated with erosion would be *less than significant* (see Section 4.5, Hydrology and Water Quality, Impact 4.5-5, for more discussion). Potential impacts associated with construction or operational discharges of chloraminated water would be less than significant since this project, located within the Peninsula watershed, would be required to implement Peninsula WMP Action fis6 regarding the discharge of chlorinated water.

San Francisco Region

Impact 4.6-4: Water discharge effects on riparian and/or aquatic resources		
SAPL 3 Installation	SF-1	N/A
Groundwater Projects	SF-2	N/A
Recycled Water Projects	SF-3	N/A

No construction or operational discharges of system water would be expected under the SAPL 3 Installation project (SF-1), Groundwater Projects (SF-2), and Recycled Water Projects (SF-3). Therefore, this impact would *not apply* to these projects.

Impact 4.6-5: Conflicts with the provisions of adopted conservation plans or other approved biological resources plans.

The adopted conservation plans described in the Regulatory Framework section were reviewed to determine whether the WSIP would conflict with the plans' provisions. The adopted plans include *San Joaquin River National Wildlife Refuge Comprehensive Conservation Plan* and the *San Joaquin County Multi-Species Habitat Conservation and Open Space Plan*. Two WSIP projects, the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) could have *potentially significant* impacts on resources within the San Joaquin River NWR planning area, including impacts on riparian restoration areas, native perennial grasslands, and seasonal wetlands. SFPUC Construction Measure #8 (biological screening survey) and avoidance, minimization and compensation measures for biological resources as discussed in Measures 4.6-1a, 4.6-1b, 4.6-2, 4.6-3a, and 4.6-3b would be implemented to reduce impacts on biological resources to a less-than-significant level. SFPUC would negotiate with the refuge owner, USFWS, to determine specific actions to fully compensate for impacts within the San Joaquin NWR to ensure no net loss of extent or function of biological resources. Implementation of this agreement would ensure that project implementation would occur in a manner consistent with the provisions of the NWR Comprehensive Conservation Plan. Regarding the *San Joaquin County Multi-Species Habitat Conservation and Open Space Plan,* CCSF is not a signatory to the plan, so the WSIP would not be covered under the plan's incidental take permit or compensation mechanism. From a county-wide perspective, impacts from the WSIP within the plan area (San Joaquin County) are sufficiently small that they would not preclude implementation of the plan or protection of the covered species.

All six of the projects in the Sunol Valley Region and four of the five project in the Peninsula Region (PN-1, 2, 4, and 5) are situated within the SFPUC's Alameda and Peninsula Watershed Management Plan areas. These plans specifically provide for Hetch Hetchy system-wide improvements, and also identify avoidance, protection and compensation measures for biological resources. Therefore, impacts from these projects on biological resources would be consistent with these plans and the impacts would be *less than significant*.

There are no other adopted plans that affect the other WSIP projects, thus this impact is *not applicable* for the other 10 WSIP facility improvement projects. The CCSF will, as part of preparing project-specific CEQA documentation, evaluate project consistency with the provisions of any other relevant HCPs adopted subsequent to publication of the PEIR.

4.7 Cultural Resources

4.7 Cultural Resources

Cultural resources include paleontological resources, archaeological resources, historical resources, and human remains. This section provides a program-level assessment of potential WSIP impacts on historical, paleontological, or archaeological resources that might be present in the vicinity of the WSIP projects and/or historic water system facilities. Programmatic mitigation measures to reduce or eliminate potentially significant impacts on these cultural resources are identified in this section and presented in detail in Chapter 6. This analysis does not identify specific cultural resources at each of the 22 WSIP facility project sites, although some previously identified cultural resources are located at or near those project sites. Site-specific analysis will be conducted as part of separate, project-level CEQA review for individual WSIP projects.

4.7.1 Setting and Resource Types

Paleontological Setting

Paleontological resources within the WSIP study area consist of the fossilized remains of plants and animals, including vertebrates (animals with backbones) and invertebrates (e.g., starfish, clams, ammonites, and coral marine). Fossils of microscopic plants and animals, or microfossils, are also considered in this analysis. The age and abundance of fossils depend on the location, topographic setting, and particular geologic formation in which they are found. The geologic formations containing the majority of fossils in the WSIP study area are considered geologically young; the oldest fossil-bearing formation dates to the Paleocene epoch (65 million years old). Most of the fossil-bearing geologic units in the WSIP study area were formed in ancient marine environments such as inland embayments, coastal areas, and extensive inland seas. However, in the eastern portion of the study area, some vertebrate fossils have been found in non-marine formations consisting of sand, gravel, and mudflow deposits.

San Joaquin Region

Paleontological resources in the San Joaquin Region are most prevalent in geologic formations located along the western margin of the San Joaquin Valley. These formations include the marine sandstone, mudstone, siltstone, and shale of the San Pablo Formation (including units of the Neroly Sandstone, Cierbo Sandstone, and Briones Sandstone); various undivided conglomerate, sandstone, and siltstone units (including the Carbona and Oro Loma Formations); and the Moreno Formation. The Moreno Formation, which is present along the western margin of the Great Valley as an elongated and continuous, northwest-trending unit, consists of shale, sandstone, and siltstone that were once deposited in a deep-marine environment. The Moreno Formation contains abundant fossils, including a variety of marine reptiles, fish skeletons, and various marine invertebrates; plant remains such as wood, leaves, and needles; and the remains of dinosaurs (USFWS/CDFG, 2006). Dinosaurs are rarely found in California, but many of the plesiosaurs and mosasaurs found in the state come from the Moreno Formation (USFWS/CDFG, 2006).

The University of California Museum of Paleontology Collections Database lists 81 fossil localities in San Joaquin County; the majority of these sites are along the western boundary of the San Joaquin Valley. Several fossil localities are grouped in the San Pablo and Moreno Formations west of Vernalis near the Tesla Portal of the Hetch Hetchy Aqueduct (UCMP, 2006). These fossils include an extinct horse, mammoth, and boney fish dating to the Pleistocene epoch, about 1.8 million years ago. The Collections Database includes a fossil locality at the Hetch Hetchy Tunnel (Locality No. 3315), which is listed as a discovery site for a prehistoric camel (up to 1.8 million years old). Only a few fossil localities have been identified in the younger alluvial deposits throughout the central portion of the San Joaquin Valley. Fossil localities appear again on the east side of the San Joaquin Valley near Oakdale, where the Hetch Hetchy Aqueduct extends through the Mehrton Formation, a non-marine formation ranging in age from 24 to 5 million years old (Miocene). Fossils found at sites in the Mehrten Formation near Oakdale include early (Miocene age) turtles, tortoises, kangaroo rats, single-hoofed horses, and mammoths.

Sunol Valley and Bay Division Regions

Many fossil localities in the Sunol Valley and Bay Division Regions occur in marine and non-marine deposits ranging in age from 10,000 to 5.3 million years old.[1] These geologic formations include non-marine sediments of the Santa Clara Formation, Livermore Gravels, and Irvington Gravels. Marine fossil-bearing geologic deposits include the Cierbo Sandstone found in the San Pablo, Monterey, Santa Margarita, and Panoche Formations, and in the older (55 to 34 million years old) Domengine Formation. The majority of the fossils found in the Sunol Valley and Bay Division Regions are vertebrate fossils, including extinct bison, camels, boney fish, mammoths, and horses, although some localities contain marine invertebrate fossils such as bivalves (clams). A fossil of a mastodon from the Pleistocene epoch was discovered in Sunol (Locality No. 6535), while an unidentified vertebrate fossil was discovered in the vicinity of Calaveras Dam (Locality No. 3937) (UCMP, 2006).

The distribution of fossil localities and the location of corresponding geologic units indicate that most of the paleontological resources in the Sunol Valley Region are east and south of Interstate 680 in the upland foothills of the Diablo Range. Fossil localities diminish west of Interstate 680, towards the Santa Clara Valley and the central portion of the Bay Division Region, because the Santa Clara Valley and the south San Francisco Bay margin is underlain by much younger alluvial and basin deposits that do not contain abundant fossil remains. There are 280 fossil localities in Alameda County, but only 36 in Santa Clara County (UCMP, 2006). Some of the fossil localities in Santa Clara County contain vertebrate fossils, including a bison and another mammal that appears to be an ancient descendant of an elephant or sea cow.

1 The age range of these deposits is referred to as the Plio-Pleistocene, which is the period of time that spans the Pliocene epoch (5.3 to 1.8 million years ago) and the Pleistocene epoch (1.8 million to 10,000 years ago).

Peninsula and San Francisco Regions

There are few fossil localities in the Peninsula and San Francisco Regions. Most fossils are found along the Pacific Coast in the younger (Pliocene, 5.3 to 1.8 million years ago) marine units, such as the Purisima Formation, Monterey Formation, Butano Formation, Colma Formation, and Merced Formation, and in locations within the outcropping marine units in the Santa Cruz Mountains, west of the WSIP regions. Fossils found along the coast include vertebrates (e.g., extinct camels, horses, and sea mammals) and invertebrates (e.g., clams and corals). Fossil localities diminish along the eastern flank of the Santa Cruz Mountains, likely due to the presence of chaotically mixed and severely fractured Franciscan Complex bedrock and geologically younger alluvial deposits in the upland foothills.[2] No fossil localities were identified in the Crystal Springs Reservoir or San Andreas Reservoir areas. The lack of fossil localities is partly due to the Franciscan Complex bedrock surrounding the reservoirs and the degree of fracturing in this bedrock unit caused by the San Andreas Rift Zone. The closest fossil locality south of the WSIP study area is an extinct sea mammal, an ancestor of the sea lion (UCMP, 2006). To the north, the closest fossil locality to the study area is an extinct horse from the Pleistocene epoch (1.8 million to 10,000 years ago).

Archaeological / Prehistoric-Period Setting

Both prehistoric and historic resources are considered archaeological resources. This discussion of prehistoric archaeology addresses cultural patterns in the WSIP study area through the time of European contact. Historic archaeological resources, starting with the Mission era, are discussed below under "Historic-Period Setting."

Numerous prehistoric archaeological sites have been identified in a variety of environments within the WSIP study area. In many cases, these sites are buried by alluvial deposits at or near former or existing wetland boundaries, along seasonal and perennial watercourses and other sources of fresh water such as springs, at the base of foothills, or at or near vegetation ecotones (i.e., a region between two neighboring but dissimilar plant communities). Many of the sites are deposits of stone tools, while others are large habitation sites that represent years of layered subsurface material or residues that chronicle the behavior of the inhabitants.

Efforts to reconstruct the prehistoric period into broad cultural stages (e.g., the Windmiller, Berkeley, and Augustine Patterns, as discussed below) allow researchers to describe a wide variety of sites with similar cultural patterns during a given period of time, thereby creating a regional chronology. In some cases, regional patterns in material culture are reflected in areas that are broader than the WSIP regions. For example, the greater San Francisco Bay Area is often discussed as a single region in terms of archaeological sequences (Moratto, 1984). As a result, a broad discussion of the region that encompasses the Bay Area would include the Bay Division, Peninsula, and San Francisco Regions, in addition to elements of the Sunol Valley Region,

2 Fossils are rarely found in the Franciscan Complex bedrock of the Coast Range Province; any fossil remains originally present in the rock would not likely remain because the Franciscan Complex in this area is a chaotically mixed and fragmented mass of rock in a sheared matrix.

although some Central Valley regional patterns can be associated with the Sunol Valley and inland Alameda County in general.

San Joaquin Region

Although the Sacramento and San Joaquin Valleys were likely inhabited by humans as early as 10,000 years ago, any evidence of this time period is buried by alluvial deposits that have accumulated during the last several thousand years. Later periods are better understood because there is more representation in the archaeological record. Central California archaeology has been described as a series of patterns. Fredrickson (1973) defines these patterns as general modes of living shared by people within a given geographic region. Three such patterns, which overlap somewhat in adjoining areas, are recognized for central California: the Windmiller, Berkeley, and Augustine Patterns.

The Windmiller Pattern, which may represent the advent of early Penutian-speaking populations, extends from about 4,500 to 3,000 years ago. This pattern primarily encompasses the lower Central Valley and Delta regions and reflects the influence of a lacustrine or marsh adaptation (i.e., adaptation to settlement near lakes and marshes). This pattern may have pre-adapted the Windmiller people to the environment of the lower Sacramento–San Joaquin Valley and Delta; it is possible that these people entered the region with this adaptation more or less fully developed.

The Berkeley Pattern extends roughly from 3,000 to 1,500 years ago and became more widespread, or at least more archaeologically visible, than the previous pattern. The Berkeley Pattern places a greater emphasis on the exploitation of the acorn as a staple. The Berkeley Pattern may represent the spread of proto-Miwok and Costanoans, collectively known as Utians, from their hypothesized lower Sacramento Valley/Delta homeland.

The last complex in this sequence, the Augustine Pattern, extended from about 1,500 years ago to the time of European contact. The Augustine Pattern initially appears to be an outgrowth of the Berkeley Pattern, but may have become a blend of Berkeley traits with those carried into California during the migration of Wintuan populations from the north (Moratto, 1984).

Sunol Valley Region

The Sunol Valley Region was a favorable setting for prehistoric and early settlement. The diverse habitats and numerous creeks within Alameda watershed lands and surrounding areas support an abundance of animal and plant resources that would have encouraged permanent and seasonal habitation. There is evidence of settlement in this region from about 2,300 years ago, with numerous documented sites, including sites in Pleasanton and the Sunol Regional Wilderness. The Sunol Regional Wilderness Area Site (CA-Ala-428H) consists of a midden (i.e., refuse) deposit and associated bedrock mortars. Site occupation is dated from approximately 2,349 to 276 years ago (343 BC to AD 1730) (Leventhal et al., 1989; as cited in Chavez, 1994).

When Europeans first came to the general area, in about 1769, the land was inhabited by the Ohlone people (also known as the Costanoans). The tribe controlled the present-day East Bay, from Richmond to San Jose, and the Livermore Valley to the east. It is estimated that approximately 2,000 people inhabited this area at the time of European contact. Near the Alameda watershed lands, villages would have been situated adjacent to major and minor creeks and the prehistoric marsh located in the Pleasanton area, with both permanent villages and temporary camps for seasonal resources. Within the Alameda watershed lands, at least one prehistoric village, El Molino, located near the present-day Sunol Water Temple, is known to have existed (San Francisco Planning Department, 2000a).

Bay Division Region

Toward the end of the Pleistocene epoch (2 million to 10,000 years ago), the present-day San Francisco Bay region and central California coast experienced gradual shifts in coastal environmental conditions as sea levels rose in response to a general warming trend in climate (Fagan, 2003). Slowly, as human settlements began coping with the changing climate and landscape, the marshland biotic communities[3] along the edges of bays and channels, in contrast to earlier vegetal food sources, became the principal source for subsistence in the bay region.

Many of the original surveys of archaeological sites in the San Francisco Bay region, including the East Bay, were conducted between 1906 and 1908; these surveys yielded the initial documentation of nearly 425 “earth mounds and shell heaps” along the bay shoreline (Nelson, 1909). The most notable of these sites were excavated, such as the Emeryville shellmound (CA-Ala-309), the Ellis Landing site (CA-CCo-295) in Richmond, the Fernandez site (CA-CCo-259) in Rodeo Valley, and the West Berkeley site (CA-Ala-307) (Morrato, 1984). These dense midden sites, such as CA-Ala-309, have been carbon-14 dated to be 2,310 (±220 years) old, but other evidence from around the bay suggests that human occupation in the region dates back farther, to about 7,000 years ago (Davis and Treganza, 1959). Many of the earliest sites suggest less emphasis on shellfish than on hunting and vegetal food processing. These sites provide the basis for understanding cultural chronologies and evolution in the Bay Area.

Another site of equal importance, the West Berkeley site (CA-Ala-307)—occupied from 4,000 to 1,700 years ago (2000 BC to AD 300)—reflected a change in socioeconomic and technological complexity and settlement patterns from the Windmiller Central Valley influence to the more uniquely local Berkeley Pattern (Wallace and Lathrap, 1975; Fredrickson, 1973). This artifact pattern is characterized by minimally shaped cobble mortar and pestle, dart and atlatl,[4] and bone industry. Given the size of these settlements, it is probable that the populations were denser and more sedentary yet continued to exploit a diverse resource base, from woodland, grassland, and marshland to bay-shore resources throughout the San Francisco Bay region (Bickel, 1978; King, 1974).

While the bay shellmounds tend to dominate East Bay archaeology, a number of important sites have been investigated in the interior valleys of Alameda County. For example, the Santa Rita Village site (CA-Ala-413) in Pleasanton yielded numerous artifacts, burials, and plant and animal

3 A large ecosystem that supports a particular assemblage of plants and animals.
4 An Aztec term for spear thrower; a wooden device with a handle at one end and a hook or spur at the other that fits to the end of a dart or projectile.

remains. The site contains two stratigraphic components indicating occupation from 2,400 to 2,000 years ago (400 BC to AD 100); the later component revealed evidence of technological influence derived from the Delta region (Chavez, 1994).

Peninsula Region

The Peninsula Region was intensively occupied during prehistoric times due to the variety and proximity of resources from San Francisco Bay, the interior foothills and valleys, and the Pacific Ocean as well as the relatively easy access to these areas. Creeks and springs in the area also provided drinking water and riparian resources. Evidence indicates that the area was inhabited as early as 5,400 years ago and was likely associated with a pre-Ohlone/Costanoan, and possibly Esselen, population. Archaeological sites are documented in coastal areas west of this region as well as along the bay in areas east of this region.

San Francisquito Creek, which flows through Palo Alto, represents one of the most densely occupied watersheds along the San Francisco Peninsula. Two or more Ohlone tribelets may have occupied this watershed and would have relied on a variety of local resources, from mammals to shellfish (Bocek, 1992). Of the approximate 170 site locations discovered on the southern peninsula, about 75 percent are located within 100 meters of a creek or former creek bed (Bocek, 1992). Given the attractiveness of the riparian corridor along San Francisquito Creek to prehistoric inhabitants, areas along this corridor—even in currently urbanized settings—are more likely to yield both known and previously unidentified historic resources or unique archaeological resources. The sites contain extensive artifacts, cultural materials, and evidence of human burials (which is considered a rare finding in San Mateo County) and may be of cultural importance to the local Native American community. There is a potential for additional prehistoric cultural resources to exist within this region, including areas submerged by the reservoirs (San Francisco Planning Department, 2001).

San Francisco Region

Many areas of what is now San Francisco presented favorable conditions for the settlement of Native Americans. Previous archaeological research in San Francisco suggests that prehistoric resources may be encountered in remarkably diverse conditions. Sites have been found along beachfront as well as inland areas of the city. Only a small percentage of the total prehistoric sites in San Francisco have been systematically recorded. It is probable that many sites were covered rather than destroyed. Recent archaeological work reveals that numerous, relatively intact prehistoric deposits throughout San Francisco appear to have been buried beneath the region's sand dunes long before the beginning of the historic era. These sites are generally buried deep enough below the present ground surface to have avoided being disturbed by development. (This information is summarized from the *San Francisco Draft Water Recycling Master Plan Cultural Resources Evaluation 92.371E,* January 13, 1993.)

Historic-Period Setting

For the purpose of this analysis, the historic period begins with the Mission era and extends through the Gold Rush for each region. The historical setting of each region is described below. The historical context of the water system (from 1856 to the present) is described after these regional descriptions of earlier history.

The sections below are organized into the various geographic regions that are addressed in this PEIR. The regions are presented geographically from east to west in the order they are physically crossed by the Hetch Hetchy pipelines. Chronologically, however, European settlement and development in these regions generally occurred in the opposite order, beginning around the San Francisco Bay and spreading eastward toward the Sierra Nevada.

San Joaquin Region

Native American groups known as the Yokuts and Miwoks originally inhabited the San Joaquin Region. Many individual tribes within the larger Yokut and Miwok groups were scattered throughout the region, living primarily near rivers and creeks. It was not until the late 1770s that European influence made its way inland to the San Joaquin Valley. The first European party to visit the area was a Spanish military expedition lead by Jose Joaquin Moraga in 1776. The party followed the San Joaquin River into Stanislaus County and the vicinity of present-day Modesto. A second expedition, lead by Moraga’s son Gabriel in 1806, made a foray into the area and traveled as far east as the location of Knight’s Ferry. Gabriel Moraga led another expedition into the area in 1810.

As Spanish missions began to be established, primarily in the coastal regions of California, the Yokuts of the inland San Joaquin Valley were relocated to the nearest missions, including Mission San Jose, Mission San Francisco, and San Juan Bautista. These missions undertook efforts to convert the local Native Americans to Catholicism and a European style of farming and labor. Many Native Americans were the victims of diseases brought by the Spanish, including those who managed to remain outside the mission system. The land that had previously been inhabited by the Yokuts and Miwoks was thus left in the hands of the Catholic Church, which owned vast tracts throughout California at the height of the Mission era.

With secularization, the lands in the San Joaquin Region were divided into privately owned ranchos, initially consisting of the Rancheria del Rio Estanislao, Rancho El Pescadero, Rancho del Puerto, Rancho Orestimba, and Thompson’s Rancho. These huge ranchos were later sold and resold in increasingly smaller parcels as people flocked to the region to mine gold in the mid-1800s, and later turned to farming once the Gold Rush had ended (Tatam, 1994).

Sunol Valley Region

In 1797, Spanish Franciscan missionaries established Mission San Jose in present-day Fremont. Native Americans, primarily of the Ohlone tribe, were brought to the mission, converted to Catholicism, and taught to farm. With the 1836 Secularization Act, many of the Native Americans left Mission San Jose and settled on a rancheria know as Alisal, near Castlewood. This site is still owned by the City and County of San Francisco (CCSF). Elsewhere, Mexican and European settlers filed land grants, and vast ranchos became established throughout the region. Rather than selling land near the mission to private parties after secularization, the Catholic Church held the land in stewardship for the missionized Native Americans, hoping they would continue the mission way of life. However, this land tended to attract squatters—particularly those journeying west from the United States—because of its uncertain ownership and the lack of recognition of the Indians' claim to the land. Despite their mission training, the Indians were not prepared for the responsibility of land ownership and often lost their holdings to these squatters through gambling and other fraud.

The population of the Sunol Valley Region grew once California was admitted to the United States, in 1848, and as the Gold Rush brought prospectors west during this period. Those who did not find their fortune often settled as farmers in rural areas of California, many of them close to the community that had developed around the former Mission San Jose. The squatters farmed and established businesses and settlements on the land. Mexican land grants were often disputed, and most of the rancho properties in the area were sold and redistributed to new settlers, both Anglo-American as well as Mexican landholders, who managed to retain portions of their original holdings. In 1858, the United States government returned the mission buildings and a small portion of adjacent land to the Catholic Church (Krell, 1979). Shortly thereafter, around 1867, the squatters obtained official title to the land on which they were living.

By the late 1800s, the prosperity of the area was further stimulated by the arrival of the Western Pacific and South Pacific Coast Railroads, which led to the establishment of towns and influenced the growth of many settlements. The railroads provided for easy transport of people and goods to the Sunol Valley and Niles Canyon from San Jose and other areas south of the bay. Because the area was such a large agricultural producer, railroads were critical to the transportation of produce from farms to consumers in the more metropolitan Bay Area cities. Grain and vegetables were the dominant crops in the area, but were replaced by vineyards and orchards later in the 19th century. This shift in agricultural trends met with opposition when blight and prohibition decreased both the productivity and demand for vineyard crops. Drought was also a problem in the early 20th century, and the Depression later limited the sale of crops. However, the existence of natural hot springs in the area attracted recreational travel to the region, and the area continued to gain popularity for vacationing and seasonal living until the years of World War II. The Sunol Valley continued on its agricultural path and experienced prosperity because of the significant demand on production created by the war. During the post-war decade, an increasing number of people permanently settled in the Fremont and Sunol areas because of housing shortages throughout the Bay Area, leading to a population boom that continues today.

Bay Division and Peninsula Regions

The areas referred to in the PEIR as the Peninsula Region, located south of San Francisco, and the Bay Division Region, located at the southern end of San Francisco Bay, were once inhabited by the Ohlone/Coastanoan people. Today the area comprises San Mateo and Santa Clara Counties and a portion of Alameda County. In 1776, Spanish missionaries established the Mission Santa Clara de Asis at the southern end of the bay along Guadalupe Creek, and a settlement of colonists from Mexico soon followed. The mission settlement and the colonists' pueblo grew into the neighboring cities of Santa Clara and San Jose. In 1793, an outpost of Mission Dolores in San Francisco was established in the area of present-day San Mateo, which allowed the Spanish missionaries to maintain better contact with the Native American converts of the region and oversee their herding and food-producing activities. The majority of the Native Americans in the region became converts at the mission and were subjects of the Catholic Church until secularization in 1836. At that time, the mission passed from the church's possession and, in 1851, the mission site was gifted to the Jesuit order for the establishment of a university, which is today Santa Clara University.

With secularization, the Mexican government seized former mission lands and divided the Peninsula Region into a number of large ranchos, including Rancho San Mateo, granted in 1846 to Cayetano Arenas, and Rancho de las Pulgas, granted in 1835 to Luis Antonio Arguello, a former governor of Alta California. Other lands in the Bay Division Region were granted to private owners, and many ranchos were established throughout the region.

The construction of railroads stimulated growth and development in the Bay Division and Peninsula Regions by connecting these areas to distant agricultural markets. The industries of agriculture, viticulture, lumber, and even oil drilling supported the economic growth of these regions in the latter half of the 19th century and the early 20th century. As in other areas, a building boom in the 1920s was followed by the Depression; however, the high demand for various products during the years of World War II led to another economic resurgence. These products included ships, many of which were produced in the ports at the southern end of San Francisco Bay.

San Francisco Region

The following information is summarized from the *San Francisco Draft Water Recycling Master Plan Cultural Resources Evaluation 92.371E,* January 13, 1993, unless otherwise noted.

The Spanish first explored Northern California during the latter part of the 18th century. The Spanish began colonizing California as early as the 1760s. It is estimated that, at the time of European contact, between 7,000 and 10,000 Native Americans inhabited the coastal area between Point Sur, in Monterey County, and San Francisco Bay. Native American shellmounds once dotted the shoreline of the bay. According to site records on file at the Northwest Information Center, Sonoma State University, about 35 prehistoric sites have been officially recorded within San Francisco; about one-third of these were found in the Hunters Point–Islais Creek area. Prehistoric sites have also been found in the South of Market/Civic Center area, and in and around Fort Mason and the Marina District (Archeo-Tec, 1995). These sites consist mostly of a variety of shellmounds, but some of the sites on the east side have included prehistoric human remains (burial sites) and midden deposits. Like the Bay Division and Peninsula Regions (see above), the San Francisco Region was inhabited by Native Americans of the Ohlone/Costanoan tribe.

As Spanish missions were established, primarily in the coastal regions of California, the Native Americans were relocated to the nearest missions. In 1776, Mission Dolores (also known as Mission San Francisco de Asis) was founded along with the Presidio, in present-day San Francisco. At the missions, Native Americans were converted to Catholicism and introduced to a European style of farming and labor, which were much different from their own hunting and gathering practices. However, Mission Dolores had a difficult time retaining its converts.

The 1836 Secularization Act, enacted by the presiding Mexican government, disbanded the mission system, granted church lands to private citizens, and allowed Native Americans to leave the missions and establish their own settlements. Now familiar with the areas around the missions, many Native Americans presumably stayed in those areas and did not return to their original lands. The influence of Mission Dolores declined rapidly after the land was granted to Jose Galinda in 1835; he established the Rancho Laguna de Merced, which was purchased by Francisco de Haro in 1837. During the 1830s, the pueblo of Yerba Buena Cove developed on the original waterfront of what is now downtown San Francisco. DeHaro became the first *alcalde*, or mayor, of Yerba Buena in 1834 and served in that post again from 1838 to 1839 (Alexander and Heig, 2002).

In 1846, the United States Navy sailed into San Francisco Bay and took control of the pueblo of Yerba Buena, which was renamed San Francisco in 1847. California became part of the United States by conquest and treaty in 1848 and was admitted to the Union as a state in 1850. The Gold Rush brought hundreds of thousands of prospectors and other settlers from around the world to California during this period. During this time, the area surrounding the mission became a venue for gambling and taverns due to its distance from the pueblo. With the influx of gold miners after 1848, the city of San Francisco soon expanded to surround the mission and dominate the tip of the peninsula.

The population in San Francisco rose drastically in the years leading up to the Gold Rush. The small population of 500 in 1847 rose to 1,000 by early 1848 and doubled again by early 1849. In that year alone, the population soared to 20,000. The physical city grew quickly in response to this population explosion, and heavy demands were placed on its infrastructure. At least six major fires destroyed much of the city in the years immediately after the Gold Rush; these devastating fires—along with the general needs of such a rapidly growing population—served as an early indication of San Francisco's need for a reliable water supply.

San Francisco's population was as high as 50,000 in 1850 and, at the time of the 1906 earthquake, had reached 375,000. The earthquake became a major factor in reshaping San Francisco's future growth and unleashing an era of progressive municipal politics. Not only did the earthquake spark fires that decimated much of the city, it also broke the existing water delivery systems that may have made controlling the fires possible. Failure of the city's private water system gave impetus to the drive for a municipal water supply that would be drawn from distant Hetch Hetchy in Yosemite National Park.

San Francisco's downtown was largely rebuilt within three years of the disaster, and the city as a whole recovered within the following decade. The city's hosting of the 1915 Panama Pacific

International Exposition prompted further development on a grand scale leading up to the event. Though the earthquake and fire were devastating, they allowed the city a fresh start and an opportunity to grow beyond its previous size and complexity. By the time of the Exposition, the population of the city was approximately 500,000 people (Richards, 1997).

History of the SFPUC Regional Water System

The Need for a Water System

The transformation of San Francisco's water system from a local, private concern, to a regional private water company, to a municipally owned and operated system was part of a national trend that began before the Civil War on the east coast, and in major Midwestern and California cities in the later decades of the 19th century and early decades of the 20th century. For San Francisco, the resulting history can be seen as two major historical contexts that intersect: the history of the plans and developments of the Spring Valley Water Company; and later, the push for municipal control and development of the Hetch Hetchy system.[5]

The development of San Francisco's municipal water system in the history of urban water development has themes in common with many other major urban areas that made the same transformation:

- Gradual development of more distant and purer supplies, typically through systems relying on gravity for delivery
- Development of specific water supply and delivery plans, by both private and public entities, to assure supplies would continue to meet growing demand
- Transformation of private water companies into public entities
- Interrelationship of science, engineering, and political reform, and the role of trained engineers in developing water systems
- Transformation of municipal or other government agencies' ability to finance public works projects

Cities around the nation have, since the early decades of the 19th century, sought to improve their water supply systems, both in quality and quantity. Most rapidly growing cities soon found they were faced with a double—and related—dilemma: handling the vast amounts of waste produced in cities without sanitary sewer systems; and assuring their citizens ample supplies of water. The production of sewage and other waste had a direct impact on local supplies, because city wells and local streams flowing through urban areas were often fouled by animal waste, garbage, local privy pits, cesspools, and sewage vaults. While the direct connection between unsanitary waste handling and disease was not scientifically understood until late in the 19th century, the

5 The entire San Francisco water system is sometimes referred to in the press or other general publications as the Hetch Hetchy system. This usage is historically inaccurate and, in this chapter, references to and discussion of the "Hetch Hetchy system" or "Hetch Hetchy Project" refer specifically to the portion of San Francisco's water system directly related to the city's municipal development of delivering water from the Hetch Hetchy Valley to San Francisco that occurred in the 20th century.

relationship between pollution and disease, and the need for purer water, was generally recognized if not accurately attributed.

New York City was among the first to build a system to bring water to the city from an outside watershed. In 1842, it completed the Croton Project to supply additional water from the Croton River in Westchester County to the growing city. Water flowed into the city through what is now known as the Old Croton Aqueduct. Boston followed soon thereafter with its Long Pond / Lake Cochituate system, completed in October 1848.[6] In both instances, specific plans provided for local supplies to be replaced or augmented by water from more distant sources that were of higher quality, and in both cases private companies were replaced by city-owned systems. Historian Letty Anderson's study of New England systems also pointed out that the use of gravity to deliver water was a consistent goal of engineers establishing such systems, because it provided a constant flow at regular pressures, avoided the need to buy costly pumping equipment, and did not incur substantial and continuing operation and maintenance costs.[7]

Anderson's examination of urban water supplies also showed that in 1800, only 6.3 percent of water utilities in the United States were publicly owned. By 1850, that percentage had grown to 39.7 percent, and by 1897 reached 53.2 percent. Of course, the number of water utilities of all kinds had also grown, from only 16 in 1800, to 83 in 1850, to 3,196 in 1897.[8] In most California cities, the conversion of private water systems to public entities occurred later, often in the 20th century.

Nelson Blake, in his seminal history of urban water systems entitled *Water for the Cities* (1956), noted that by 1860, of the nation's 16 largest cities, 12 had municipal systems; only San Francisco, New Orleans, Buffalo, and Providence had privately owned systems. Private systems were characteristically located in smaller cities and towns; of the 136 water works in existence in 1860, noted Blake, 58 percent were privately owned. Water consumption on a per-capita basis was also increasing during this period, in large part due to the introduction of water closets, showers, and bathtubs connected to indoor plumbing. While such arrangements were not common in the last decades of the 19th century, their introduction over the decades had a profound effect. Blake reported that by the years just before World War II, per-capita use in major European cities averaged around 39 gallons a day; in the United States the rate was 155 gallons a day.[9]

---

6 The story of the Old Croton System is described on the New York Department of Environmental Protection's website, http://www.ci.nyc.ny.us/html/dep/html/history.html, accessed April 21, 2007. Other sources on the development of the New York system include Nelson Blake's *Water for the Cities: A History of the Urban Water Supply Problem in the United States* (Syracuse University Press, 1956). The history of Boston's fight for pure water, and the themes and factors leading to development of its system, is explored in Michael Rawson, "The Nature of Water: Reform and the Antebellum Crusade for Municipal Water in Boston." *Environmental History*, 2004, 9(3): 411-435.

7 Letty Anderson, "Hard Choices: Supplying Water to New England Towns." *Journal of Interdisciplinary History*, xv:2 (Autumn, 1984), 211-234. Anderson focused on New England's experience, but placed it in a national context.

9 Nelson M. Blake, *Water for the Cities: A History of the Urban Water Supply Problem in the United States*. (Syracuse University Press, 1956); see 267.

Blake also summarized the development of major urban systems in New York, Boston, Philadelphia, and Baltimore. Each followed the paradigm of an original private local system being integrated into a much larger set of public facilities, sequentially planned and constructed to meet demand, and that brought water to the urban area from distant supplies.

In New York, after completion of the Croton Aqueduct, the city quickly faced increased water use and a concomitant growth in demand that led to acquisition of additional sources of supply. It designed the Second Croton Aqueduct, completed in 1893, which brought water from 31 miles away through a system of tunnels. As New York expanded its boundaries to include Brooklyn, Queens, Richmond, and additional portions of the Bronx, it required new sources of supply to meet demand. In 1905, after an attempt to incorporate a private company's system, the city—with the approval of the state legislature—established the Board of Water Supply, which had "broad powers to plan and build new reservoirs and aqueducts." It was this board that planned and built the Catskill Aqueduct between 1907 and 1917, which brought water from Ashokan Reservoir in the Catskills 120 miles to the city. Some of the construction involved substantial engineering skills. "Picturesque arched bridges across rivers and valleys were now a thing of the past," Blake observed. "Instead, the aqueduct was carried through pressure tunnels bored deep in the solid rock. Thus the water was conveyed under the Hudson River near Storm King Mountain by the Roundout Siphon, 1,114 feet below sea level. The main artery of the city distributing system was a pressure tunnel from 200 to 750 feet below the street level." This system was again enlarged in 1927, and from 1921 through 1964 the Board of Water Supply planned and constructed a system to tap the Delaware River.[10]

Boston's system underwent a similar transformation. By 1869, it had become clear that the Cochituate system was inadequate, so the city added a 17-mile-long aqueduct to provide water from reservoirs on the Sudbury River. As the city annexed small towns on its periphery, the need for additional water grew, leading the city and state to organize the Metropolitan Water District. This body arranged for the construction of Wachusett Reservoir and Aqueduct, which fed the Sudbury system, in 1906. By 1922, the district recommended adding a connection to the Ware and Swift Rivers, requiring the construction of Quabbin Aqueduct and a later aqueduct to tap the two rivers. Later, the district built Quabbin Reservoir, which, Blake noted, was "designed to impound the entire flow from a watershed of 186 square miles," and nearly tripled the district's safe yield. The new works also allowed for the old Cochituate system to be retired in 1931, because development in its watershed had the potential to compromise its purity. Similarly, during the last decades of the 19th century, and well into the 20th century, both Baltimore and Philadelphia made similar improvements to their water supplies. In both cases the cities tapped distant supplies, building large storage dams and aqueducts to deliver the stored water. These series of projects were also developed through a set of specific plans. Both cities' systems utilized pressure tunnels; for example, Philadelphia's diversion of the Delaware River used a gravity-fed pressure tunnel some 80 miles long.[11]

[11] Blake, *Water for the Cities*, 272-276.

Analogues to these urban systems existed in California. For example, Los Angeles' private water company had appeared to reach its capacity in the last decade of the 19th century, and its superintendent, William Mulholland, with local businessmen, turned to the Owens Valley to tap the river for the city's use. The story of Los Angeles' acquisition of water rights and water, and construction of the Los Angeles Aqueduct, is an oft-told tale and will not be recounted here in detail.[12] By 1903, the city acquired the existing local private water company. Like New York, Boston, Baltimore, and Philadelphia, and at much the same time, Los Angeles acquired its enhanced supply from a distant watershed, and brought water through an aqueduct fed by gravity to its terminal reservoir. Moreover, after its initial completion in 1913, the city's Department of Water and Power later made extensions to enhance its supply by designing separate projects, like the Mono Basin extension, to bring more water to the system. In addition, in 1928, the southern California region, including Los Angeles, formed the Metropolitan Water District. Its aim was to tap another distant source, the Colorado River, and transport the water 242 miles through an aqueduct to Lake Matthews, its terminal reservoir. The Colorado River Aqueduct was completed in 1941.[13]

The cities of the East Bay also sought a larger supply of better quality water after the turn of the 20th century. By 1910, the small reservoirs were seen as insufficient to keep up with demand, and by 1915 it had become apparent to the area's citizens that new sources of water were needed. Dissatisfaction with private water companies, particularly the East Bay Water Company, was led by the Progressives in the East Bay, who focused their anger on private utilities as inefficient and often the sources of graft and corruption of local officials. This led at first to the passage of the Municipal Water District Act of 1911, followed by the Public Utilities Act, which put private utilities under the jurisdiction of the California Railroad Commission (later the Public Utilities Commission). It also led to a movement in the East Bay to establish a municipal utility district, a special district provided for by the Municipal Utility District Act in 1921. The act provided for districts that could straddle county lines and include incorporated cities and unincorporated areas; importantly, they could also issue revenue bonds to fund construction and development. The district was seen as a victory for regionalism over parochial local development that would allow for more efficient and comprehensive development. The East Bay Municipal Utility District was the first such district formed under the act, through an election in May 1923.[14]

Upon formation, the district immediately hired staff and engineers, including Arthur P. Davis (who had for many years been an engineer for the U.S. Bureau of Reclamation) as chief engineer, and established an advisory consultant team of George W. Goethals (chief engineer of the

14 Susan S. Elkind, *Bay Cities and Water Politics: The Battle for Resources in Boston and Oakland* (Lawrence, Kansas: University Press of Kansas, 1998); East Bay Municipal Utility District, *The Story of Water: A Brief History of the East Bay Municipal Utility District* (EBMUD, 1931?), 1-7; John H. Plumb, "Summary of the History of Municipal Utility Districts in California and of the Municipal Utility District Act," November 13, 1974. MS, WRCA, G4084/K4-4.

Panama Canal) and William Mulholland of Los Angeles. The district initially considered asking to join with San Francisco in its Hetch Hetchy Project, but soon decided to seek an independent supply. After considering a number of sources, the district settled on the Mokelumne River, and over the next years planned a system that stored water behind Pardee Dam and delivered it to the district through 93 miles of pipe and tunnels. The district noted, "by taking the water out through the tunnel 170 feet above the bottom of the dam it is possible to operate the pipe line to its entire capacity by gravity as far as Walnut Creek and even to carry over forty million gallons a day by gravity all the way into the District." The district described its aqueduct as "one of the great pipe lines of the world," which began deliveries in June 1929. Water flowing through the system replenished the nearly-empty reservoirs built by the original private water company that had been acquired by the district.[15]

The ability to fund such systems with municipal bonds was a key to their development. In the years following the massive bank failures associated with the Panic of 1873, the majority of municipalities around the nation could not go into debt to pay for municipal systems, and thus relied on private capital and private enterprise to build enlarged systems, usually under an exclusive franchise. Historian Anderson noted, "a city typically had two major problems with a private water company: rates and service." Rates were often well above those charged in municipally owned systems, and private companies often concentrated on profitable areas in their service area to the exclusion of poor or outlying areas.[16] Mechanisms such as the Municipal Water District Act or the Municipal Utility District Act, or other bonding provisions created by changes to other state laws, allowed for cities to take on debt to build their own systems.

Interestingly, these themes worked their way down to smaller cities and towns during the early decades of the 20th century; many underwent similar transformations from private to public ownership, and set about acquiring water from more distant sources. In addition, technological advances made by engineers working in the larger cities, such as in pumps, pipes, engineering, purification systems, and so on, worked their way down to the smaller cities and towns.[17] An example of this process within the Bay Area can be found in the story of the Marin Municipal Water District. Areas within Marin County had been served since the 1870s by private water companies such as the Marin Water Company (later called the Marin Water and Power Company), North Coast Water Company, and other, smaller enterprises. These companies built a number of reservoirs, large and small, to serve their customers, and added reservoirs as demand grew. However, by the first decades of the 20th century, poor service led to public acquisition of the systems by Marin Municipal Water District, formation of which was made possible by the passage of the Municipal Water District Act of 1911. This act, made during a period of Progressive reform in the state, allowed for the formation of municipal water districts. Between 1914 and 1918, the new district acquired the private companies within its boundaries. Soon

thereafter it began improving the acquired systems and planning for new construction to meet growing demand.[18]

An important related factor in the construction of major systems, whether public or private, was the role of professional engineers in their planning, construction, and development, and the fact that many of the most prominent and influential engineers worked on projects around the nation. Particularly after the last decades of the 19th century, trained and experienced engineers not only brought technical skills to their work, but also an ethos of disinterested neutrality and rationalism. Historians Stanley K. Schultz and Clay McShane noted that city engineers "contributed to the rationalization of fiscal techniques," and labeled themselves "neutral experts" who "professed to work above the din of local politics. Usually they tried to isolate themselves from partisan wrangles, and often succeeded." More than that, they were often typified by long tenure of position and were praised as "models of efficient bureaucrats." They were also prone to employing consultants, experts who moved around the country working on major projects. Schuyltz and McShane stated:

> As an emerging 'strategic elite,' in sociologist Suzanne Keller's telling phrase, engineers secured job tenure through professionalization. At a time when few if any clearinghouses for the exchange of ideas and practices benefited cities nationwide, the engineers built up a remarkable communications network among themselves. Their common training, whether in the relatively few engineering schools of the period or in shared apprenticeships, usually on the major railroads, bound them together. The practice of review by outside consultants reinforced these connections. Engineers belonged to the same national organizations. The majority held membership in the American Society of Civil Engineers that frequently published papers on municipal engineering with appended comments from experts throughout the nation. They also belonged to local professional clubs that corresponded with one another, publishing and exchanging reports about conditions in their individual cities.

These engineers contributed to debate and discussion in professional journals and discussed legal and administrative issues faced by their group. They also disseminated information about how similar problems were solved in other cities around the world.[19] Many of the engineers who worked on water supply systems in eastern cities, such as John R. Freeman, or had experience in California systems, like William Mulholland, or worked on federal irrigation systems, like A.P. Davis, also worked on Bay Area systems. Thus, it is not surprising that obstacles confronted by engineers might be surmounted through similar means in different projects, or that knowledge regarding the benefits and efficacy of certain designs might be widely distributed.

In all these cases, from New York to Boston, the East Bay, Marin County, and Los Angeles, the conversion from private to public entities resulted in the absorption of existing local private facilities into larger public systems. Historian Susan Elkind noted that this was a common process, if not always the most efficient. "But regional networks also retained the characteristics

of their municipal and private antecedents because regional officials saved enormous amounts of time and money simply by grafting bigger sewer mains and water supplies onto existing service networks," she reported. "The adaptation of existing infrastructure physically locked regional officials into established water supply and sewerage practices."[20]

San Francisco's water system followed this paradigm. The Spring Valley Water Company system grew organically within the city to provide local service, and then reached out to ever more distant sources through a series of specific plans to enhance and increase supply, the execution of which provided the means to keep up with demand and assure a growing supply. These plans were developed by expert engineers with wide experience. Finally, over the years, public dissatisfaction with this private system increased, and reform-minded citizens led the demand for conversion from a private to public water supply.[21]

The San Francisco Water System

The history of the SFPUC water system starts with a driving need for water in an area that is often described as a semi-arid peninsula. Though surrounded by the salt water of the ocean and bay, San Francisco had very little fresh water. The few creeks and springs that existed were sufficient to support early settlements, but as the area developed the need for water became critical. The Gold Rush of the mid-1800s brought the need for a water system to the forefront. As the population of San Francisco boomed with the influx of fortune seekers, the existing water supply proved to be inadequate. At that time, water was transported in barrels, sometimes from the other side of the bay, and sold at exorbitant prices to San Franciscans, who had little choice but to pay for it.

Before the establishment of an official water company in 1856 (as described below), one company attempted to provide San Francisco with an adequate water supply. In 1851, the Mountain Lake Water Company formed to distribute water from Mountain Lake in the Presidio, but its methods were inadequate and its finances shaky. It was granted a few time extensions to bring its business up to caliber, but it eventually folded in 1865.

The early history of the City Distribution System / Spring Valley Water Company, and the Peninsula and Alameda Systems are described below. The CCSF attempted to buy the Spring Valley Water Company during the 1870s, and eventually purchased it in 1930 (as further described under "Hetch Hetchy System").

---

[20] Elkind, *Bay Cities and Water Politics*: 164.

[21] The history of the transformation of San Francisco's water system from the control of a private corporation to a public entity is the subject of a recent dissertation by David R. Long, "The Flume Wildcatters: San Francisco, Private Waterworks, and Urban Development in the American West's Hydraulic Society, 1850-1930," (University of North Carolina, Chapel Hill, 2004).

City Distribution System / Spring Valley Water Company (1856–1877)

The San Francisco Water Works was formed in 1856 by an official city order and spearheaded by engineer Alexei Waldemar von Schmidt. The first water system was formed by a dam on Lobos Creek, a system of flumes and tunnels, a pumping station, and the Francisco and Lombard Reservoirs. The company was one of several, such as the Islais and Salinas Water Company and the Bensley Water Company, which competed within the city and supplied water to various service areas. San Francisco's private companies underwent a period of consolidation that mirrored similar experiences in other urban areas.

Soon, the San Francisco Water Works met with competition from the Spring Valley Water Company, founded by George H. Ensign in 1860, which used a spring at Mason and Washington Streets as its initial water source. It was this spring that gave the company its name. Though its beginnings were small, the Spring Valley Water Company soon came to dominate the city's water distribution. It began to consolidate its position, and bought out the Islais and Salinas Water Company and incorporated water from Islais Creek into the Spring Valley system, using a reservoir on Potrero Hill to hold the water. It also took over the competing Bensley Company's supply from Lobos Creek. The Spring Valley Water Company was especially successful because of the help of Von Schmidt, who, after a dispute with the San Francisco Water Works, gave his allegiance to the opposition in 1860. The resulting failure of the San Francisco Water Works left Spring Valley in a strong position. In 1864, the Spring Valley Water Company hired an engineer named Hermann Schussler, who in 1866 made his mark by raising Pilarcitos Dam. Schussler stayed with the company well into the 20th century and designed some of its most important components.

By 1868, Spring Valley had commenced negotiations to purchase Lake Merced from another local competitor—the Lake Merced and Clear Lake Water Company—and by 1877 integrated this spring-fed, natural reservoir into its system. Spring Valley dammed the outflow of Lake Merced, which had originally flowed northwest to the ocean. The company constructed Laguna Honda Reservoir in 1865 and incorporated it into the supply system; the north basin of University Mound Reservoir was constructed in 1885 and improved in 1924. These improvements are discussed below.

Peninsula System (1861–1898)

The Pilarcitos development, started in 1861, completed in 1863, and raised in 1866, was the first of a succession of large-scale projects planned and constructed by the Spring Valley Water Company. It was designed by company engineer Alexis von Schmidt. Pilarcitos Creek was the first source outside of San Francisco to be tapped as a water supply, and it proved to be the most productive of the dams and reservoirs on the Peninsula owing to high local rainfall. Pilarcitos Dam was a rolled earth dam with a puddle core and, at 70 feet high, was a large dam for the period. Its associated Tunnel No. 1 through Cahill Ridge to San Mateo Creek was a major construction project in its own right. The subsequent Pilarcitos Reservoir supplied water, via a gravity-fed system, to Laguna Honda Reservoir, which was constructed in San Francisco in 1865. Von Schmidt left Spring Valley in 1864 and was replaced by Hermann Schussler, a Swiss engineer trained at the Universities of Karlsruhe and Zurich. Schussler's long career as an engineer with Spring Valley was typified by a succession of plans, each of which served to increase the company's supply.

Schussler identified the San Andreas Valley as a prime reservoir site for the company's next plan of development. In 1868, he relocated the Pilarcitos pipeline and began constructing a dam to flood the valley. San Andreas Dam was a straight-crest gravity dam of earthen construction and was larger than Pilarcitos Dam, which used the same construction method. A tunnel through Buri Buri Ridge carried water from San Andreas Reservoir to Millbrae and then into San Francisco's network of mains and pipes through a gravity-flow system. By 1870, these facilities were supplying water to the city and had increased the amount sixfold. The dam was raised in 1874, and again in 1928, to a final height of 105 feet. It contributed up to 80 or 90 percent of San Francisco's water supply from the Peninsula system, greatly reducing the strain on sources within the city.

Stone Dam and Reservoir was the company's next system on the Peninsula. Relatively small, it collected the excess water from Pilarcitos Creek that was not impounded by Pilarcitos Reservoir and carried it by flume to San Andreas Reservoir. Stone Dam was also the receiving point for water from Lock's Creek flume, which brought water from Nuff Creek, Corinda Los Trancos, Apanolia Creek, Frenchman's Creek, and Lock's Creek through a tunnel to the reservoir. Stone Dam, built in 1871, was an engineering achievement despite its small size. It was the first dam of its type, and Schussler designed it of rubble masonry, blocks of local granite, and a herring-bone brick coping in a thin-arch configuration. The dam impounded nearly 5 million gallons of water.

The continuing increase in demand led Spring Valley Water Company to design and build its next system in Crystal Springs Canyon. From 1873 to 1877, the company installed an earthen dam with a puddle clay core across Laguna Creek. The water impounded behind it became Upper Crystal Springs Reservoir, the outlet of which consisted of a brick-lined, horseshoe-shaped tunnel. Upper Crystal Springs Dam was raised in 1891 to increase the capacity of its corresponding reservoir.

Spring Valley built Lower Crystal Springs Dam in 1890; the dam, credited to Schussler's design and plan, was an engineering achievement and, when completed, was the largest concrete dam in the world. The gravity-arch dam, made of poured-in-place interlocking blocks and reaching 150 feet high, dammed San Mateo Creek and created Lower Crystal Springs Reservoir. The dam was raised in 1890 and again in 1911. In 1976, the American Society of Civil Engineers listed Lower Crystal Springs Dam as a California Historic Civil Engineering Landmark, in part for Schussler's development of a number of innovative construction techniques that included washing the aggregate, machine-mixing the concrete, roughening the existing surfaces to ensure adhesion, curing the concrete by covering and wetting, and staggering the joints between the concrete blocks. An 1880s pump station designed by Willis Polk raised water to San Andreas Reservoir when Lower Crystal Springs Reservoir was experiencing low water levels.

During the Peninsula system era, Spring Valley also constructed the north basin of University Mound Reservoir in San Francisco to receive and store the new supplies of water coming into the city from the various dams and reservoirs. Development and construction of the Peninsula system continued after construction of the Crystal Springs dams. In 1898, Spring Valley built San Mateo Creek Dams Nos. 1 and 2 to collect more water for San Andreas Reservoir. Davis Tunnel also diverted water from San Mateo Creek into San Andreas Reservoir. This reservoir was fed with water from the Crystal Springs Reservoirs via the Crystal Springs/San Andreas Pipeline, which was constructed in portions in 1898 and 1932. This pipeline incorporates the Crystal Springs Pump Station, originally constructed in 1933, which is necessary to raise the water between the reservoirs.

Alameda Creek System (1875–1925)

At the same time that the company had dams under construction on the Peninsula, it also looked eastward across the bay to seek additional water, turning to sources in Alameda County. The company acquired land in the Calaveras Valley and a dam and mill property near Niles. In 1874, a report prepared by engineer T.R. Scowden recommended the Calaveras Valley as a source of water for a potential San Francisco municipal utility. The Spring Valley Water Company bought Calaveras Valley from the Alameda Water Company in 1875, ensuring its control of this source until the 1930s.

Niles Dam was the diversion point for a 1840s water right used to grind flour at the mill of Jose de Jesus Vallejo. The first project undertaken by Spring Valley on Alameda Creek, in 1887 and 1888, raised and adapted the Niles Dam system to divert water from the creek to San Francisco via the transbay pipelines at Dumbarton. The transbay pipelines carried the creek's water that was pumped from Dumbarton at the Belmont Pump Station into San Francisco.

In 1900, Spring Valley completed construction of the Sunol Filter Beds, Dam, and Aqueduct on Alameda Creek in the Sunol Valley area. Another Schussler plan, Sunol Dam did not form a reservoir, but rather backed shallow groundwater into the gravels upstream for diversion into the filter galleries. The water then passed into the greater water system through large concrete pipes and the Niles Canyon Aqueduct. These filter gallery diversions, plus withdrawals at Pleasanton, enabled the Spring Valley Water Company to divert in excess of 21.5 million gallons per day (mgd) to San Francisco from the Alameda Creek watershed. Additional transbay pipelines were added in 1903. As it had with Crystal Springs Dam, the American Society of Civil Engineers identified this system as an engineering landmark in 1976.

More groundwater was collected from artesian wells in the Livermore Valley, where the company created the Pleasanton Well Field. Under this plan, the company had a series of trenches dug in Pleasanton to feed artesian water into Arroyo de la Laguna; as water levels dropped, additional lines of deeper wells were dug and pumped for export. The 30-inch-diameter Pleasanton-Sunol Pipeline, constructed in 1909 and feeding into the Sunol Water Temple, eventually replaced Arroyo de la Laguna as the diversion method. The wells were regularly used from 1898 to 1930, at which time the CCSF purchased Spring Valley Water Company and stopped exporting water from the Livermore Valley. The system had become unnecessary because of the availability of water from Hetch Hetchy Reservoir. The CCSF used the wells again for a brief period during the 1949 drought. In the interim, water levels in Pleasanton returned to the artesian flows of earlier years. The Sunol Filter Beds are now operated intermittently as one of the sources supplying San Antonio Reservoir, and the Pleasanton Wells are operated to supply the Castlewood community south of Pleasanton.

The only substantial groundwater supplies in the Alameda Creek watershed above Niles were in the Livermore Valley. Shallow groundwater in the Sunol Valley was highly influenced by flood flows from Alameda Creek and was used during the rainy season, after which the Pleasanton Wells could pick up the slack and keep the transbay pipelines full over the summer months.

The Sunol Water Temple is a monument of high architecture that stands at the convergence of the three water sources within the Alameda Creek system: the creek itself, the Sunol Filter Beds, and the Pleasanton Wells. The temple, designed by Willis Polk in 1910, exhibits a Classical style. Consisting of a circle of Corinthian columns that support a wide entablature and conical roof of red tile, the temple shelters an oculus that allows viewers to see water flowing through the tunnel beneath it.

The other element of the Alameda Creek system is Calaveras Dam and Reservoir. The dam, located upstream of the Sunol Valley, effectively collected water from a number of sources, including Arroyo Hondo. Schussler retired from the company in 1909 and was replaced in 1911 by Fred C. Herrman. Spring Valley began construction of Calaveras Dam in 1913; after a structural failure in March of 1918, the dam was completed in 1925. A 1918 engineering study indicated that the dam had not been properly compacted, which left voids in the structure and caused the upstream face to collapse and the water gate tower to be destroyed. Although he was not part of the project, San Francisco's city engineer, Michael O'Shaughnessy, who at the time was playing an integral role in the Hetch Hetchy water system's construction, monitored the project with the forethought that it would someday be part of the larger municipal water system (CCSF, 2007).

Calaveras Dam incorporated hydraulic fill in its lower portions and was topped with rolled clay and rubble fill. When it was completed in 1925, it stood 215 feet tall and was reputedly the tallest dam the world (although it was only slightly taller than Upper San Leandro Dam, a 190-foot hydraulic-fill dam, built in 1926; Lake Arrowhead's 190-foot hydraulic-fill dam, built in 1922; or the City of Los Angeles' Stone Canyon Dam, a 185-foot earthen dam, built in 1925). These dams were soon surpassed by structures such as San Gabriel No. 1, an earth and rock dam built in 1938 to a height of 320 feet.

The corresponding Calaveras Reservoir was a major East Bay addition to the company's water system. It delivered water to San Francisco through the Niles Canyon Aqueduct and the city's Bay Division Pipeline No. 1, which was built in 1925 and ran across the southern end of San Francisco Bay. The CCSF built Bay Division Pipeline No. 1 as part of the Hetch Hetchy Project, but Spring Valley Water Company leased the pipeline for delivery of Calaveras water to Crystal Springs under a Railroad Commission order negotiated by San Francisco's engineers and attorneys. In order to convey the additional yield from Calaveras Reservoir to San Francisco, Spring Valley enlarged the Sunol Aqueduct in 1924 to carry 70 mgd, and also built Niles

Regulating Reservoir and Niles/Irvington Pipeline and Pump Station to boost Calaveras Dam and Sunol Filter Bed water into Bay Division Pipeline No. 1 (URS, 2004).

Hetch Hetchy System (1914–1934)

The CCSF's planning and development of the Hetch Hetchy system represents a second major context in which to understand the development of the regional water system. The Hetch Hetchy system was planned as a major part of the movement to wrest control of the water supply from Spring Valley Water Company; while parts of the systems overlap or were temporarily used by the Spring Valley Water Company (like Bay Division Pipeline No. 1), the overwhelming acceptance of the Hetch Hetchy system by the citizens of San Francisco represents a distinct break from the reliance on private water company developments to provide San Francisco with its municipal water supply.

The centerpieces of the Hetch Hetchy system—O'Shaughnessy Dam and Hetch Hetchy Reservoir—were hard won, and much controversy surrounded their construction. The effort began in 1890, when the Tuolumne River was surveyed as a potential water source for San Francisco and the Hetch Hetchy Valley as a potential reservoir site. The Sierra Club contested the damming of the Tuolumne River under the leadership of its first president, John Muir. Muir, one of the nation's best-known conservationists, first visited Hetch Hetchy Valley in 1871 and equated its damming to turning a cathedral into a water tank. He waged an eight-year campaign to thwart the valley's development, but was eventually defeated by a number of government decisions ending with the Raker Act in 1913.

Beginning in 1903, San Francisco sought permission from successive secretaries of the interior to build a dam in the Hetch Hetchy Valley and to use other federal lands in Yosemite National Park and Stanislaus National Forest to deliver the water to the Bay Area. Secretary of the Interior Ethan Allen Hitchcock denied the first request in 1903.

San Francisco's efforts to dam Hetch Hetchy gained momentum following the destructive fires associated with the 1906 San Francisco earthquake, during which there was limited water for firefighting because of breaks in water lines in the city and throughout the water distribution system. Two years after the 1906 earthquake and fire, Secretary of the Interior James R. Garfield granted San Francisco the so-called "Garfield Permit," many provisions of which anticipated the 1913 Raker Act. In 1909, the CCSF purchased much of the patented land in the Hetch Hetchy Valley from private owners. With the election of President William Howard Taft, new Secretary of the Interior R.A. Ballinger issued a 1910 "Order to Show Cause" directing San Francisco to establish why it required water from its proposed Hetch Hetchy Valley reservoir, as opposed to diverting water from Cherry and Eleanor Creeks. Also in 1910, the CCSF acquired competing rights to divert at Cherry and Eleanor Creeks from William Hammond Hall's Tuolumne Water Supply Company.

Ballinger asked the U.S. Army Corps of Engineers to prepare a report on other potential sources of supply available to San Francisco, including the Eel River, Mount Shasta, Clear Lake, Cosumnes River, and other sources. The Corps concluded that the Tuolumne River was the best available source for San Francisco for several reasons: it was comparatively free of conflicting claims to water rights; could be economically developed; could generate power as a valuable byproduct of water deliveries; could provide a pure water source that was unlikely to be compromised by future human activity because the watershed was protected in a national park; and had sufficient water to accommodate the future demands of the Bay Area. With another change of presidential administrations, former San Francisco City Attorney Franklin Lane became secretary of the interior under President Woodrow Wilson. To avoid the appearance of conflict, Secretary Lane did not approve the Hetch Hetchy permit, but rather recommended that the CCSF seek congressional approval. This move also avoided the potential for revocation of any permit by succeeding secretaries of the interior.

On President Taft's advice, the city needed to prove its need for more water. It hired influential consulting hydraulic engineer John R. Freeman to make the case for Hetch Hetchy before the Corps. His report was instrumental in pushing the project through to approval. An engineer from Rhode Island, Freeman was a consulting engineer on the early 20th century expansion of the municipal water supply of Boston and had consulted on the plan for the Los Angeles Aqueduct in 1906. He worked with California-based hydraulic engineers C.E. Grunsky and Marsden Manson, expanding on their initial concepts for the Hetch Hetchy Project.

Freeman's 1912 report called for the delivery of 160 mgd from Hetch Hetchy to San Francisco, with the prospect of increasing that amount to 400 mgd, an amount sufficient to serve the entire Bay Area. The plan also allowed for construction of powerhouses to supply electricity for the project and later, for the city. With this vast municipal water supply secured from the upper Tuolumne watershed, Freeman envisioned a booming metropolis developing around the bay. He treated the various parts of the upper drainage basin (those associated with Lake Eleanor, Hetch Hetchy Valley, and Cherry Valley) as part of the city's water system, adding them to the existing facilities of the Spring Valley Water Company. Promoting the "urban destiny" of the Bay Area, Freeman compared San Francisco's Hetch Hetchy development to the water systems that supported the industrial and population growth of other major metropolitan areas, including Boston, New York, London, and Oslo, Norway. Lastly, he argued that the reservoir created by damming Hetch Hetchy Valley would attract as many visitors, if not more, than if the valley were kept in its natural state. With a good network of mountain roads established by the construction project, Freeman envisioned Hetch Hetchy and the upper Tuolumne River watershed as a popular tourist destination high in the Sierra Nevada mountains. These various arguments favoring conservation and use of Hetch Hetchy eventually proved to be major contributing factors in the approval of the Hetch Hetchy Project.

The 1913 Raker Act succeeded in gaining the CCSF a congressional grant of right-of-way, construction, and use privileges in Hetch Hetchy Valley, which ultimately allowed the Tuolumne River to be dammed and the valley flooded. The act passed despite determined opposition from those in favor of preserving the valley, and from individual landowners in the Turlock and Modesto Irrigation Districts (TID and MID) who disagreed with the district boards' decisions to support San Francisco. Congress supported the act as an example of "conservation for use," believing it served a public need that outweighed any detriment to the natural environment.

(Readers interested in the Hetch Hetchy controversy, and the Raker Act's legislative history and passage through Congress, can find a large number of articles and books on the subject, some of which are included in this report's bibliography.)

Opposition to construction of the Hetch Hetchy project came from a variety of interests. Understandably, the Spring Valley Water Company opposed this project, which effectively ended the company's role as the utility company supplying San Francisco with its municipal and domestic water.[21a] The Hetch Hetchy project was designed to transmit electrical power to San Francisco from a power plant at Moccasin. A politically charged conflict over this electric power and associated revenue pitted public power advocates against the privately financed electric power industry. Opposition came from electrical power generating companies like Pacific Gas and Electric Company (PG&E) and Great Western Power Company (GWP), two utilities that served San Francisco and the Bay Area. These private power companies opposed the competing generation and sale of electricity by public agencies, which was a provision of the Raker Act. The CCSF planned to acquire PG&E and GWP's distribution systems within its service area, but between 1927 and 1941 the public consistently rejected bond issues required to fund their acquisition; allegedly, this opposition to the bond measures was largely funded by PG&E.[21b] The CCSF's agreements to have PG&E (which had acquired GWP in the 1930s) wheel its power through the company's existing transmission and distribution systems for delivery to San Francisco agencies, and its purchase of city power for resale, caused a longstanding controversy between the federal government, public power advocates, and the CCSF.[21c]

Perhaps the most prominent name associated with development of the Hetch Hetchy water and power system was that of Michael O'Shaughnessy, San Francisco's city engineer (1912–1934) and ex-officio city planner. Working under the direction of Mayor James Rolph, O'Shaughnessy had many of the state's best engineers in his work force. The rebuilding efforts following the 1906 earthquake had brought many skilled engineers and construction laborers to the area, and they were eager for more work, especially under the leadership of the well-respected O'Shaughnessy.

As the congressional act required, development of the gigantic Hetch Hetchy undertaking began in earnest after passage of the Raker Act in 1913. In 1918, Lower Cherry Diversion Dam and Aqueduct, the first major facilities in the system, were completed, enabling the generation of power at Early Intake Powerhouse on the Tuolumne River. This network of facilities was critical to development of the rest of the Hetch Hetchy system, as it supplied electricity to power construction efforts. Lower Cherry Diversion Dam and Aqueduct are still in use and available to provide additional water during droughts. Early Intake Powerhouse was demolished in 1967.

The Hetch Hetchy system, in some elements of its concept and engineering design, mirrored similar developments made by other urban centers at much the same time. Part of the challenge of building the system was its remote location, which required construction of an array of supporting facilities in the vicinity of the project; these included a railroad for transporting materials and workers to the dam site, a sawmill to produce lumber, and a powerhouse to generate electricity for construction equipment.

Multi-purpose dam and water conveyance projects proliferated within river basins throughout America in the early decades of the 20th century. The projects were built for a variety of purposes: municipal water supplies, federal land reclamation, irrigation, and electric power generation. Thousands of workers contributed to this construction work, often under tight schedules and difficult, even dangerous, conditions. Hetch Hetchy water project contract workers and wage laborers consisted of a varied group of individuals stratified by skill, race, and ethnicity. The largest proportion was low-paid, unskilled laborers, both native-born and immigrants. Above them were the better-paid skilled workers and craftsmen, and at the top was a smaller group consisting of managers, supervisors, administrative personnel, and skilled professionals such as civil and electrical engineers, hydrographers, and surveyors. Over more than 25 years of construction activity, the Hetch Hetchy project provided employment to many thousands of workers in many fields of industrial labor; these workers built everything from mountain roads, railroads, labor camps, buildings, bridges, and trestles that served as project infrastructure, to dams, tunnels, pipelines, siphons, and penstocks that stored and conveyed municipal water. Many of the lesser-skilled construction laborers were highly migratory, non-unionized workers whose employment was seasonal, with peak employment coming during the summer and autumn and minimal opportunities in winter and spring.

While some workers were more sedentary and lived in towns or work camps with their families, the majority of the workers—who were predominantly unmarried, mobile, and male—resided in boardinghouses or labor camps near their work sites. The ethnic makeup of the workingmen's boarding houses was often quite diverse, according to 1920 census records. For example, one lumber camp near Groveland was operated by an American civil engineer whose wife kept house with the assistance of one cook. Twenty-five boarders lived there, including painters, carpenters, contractors, lumberjacks, millwrights, and the lumberyard foreman. While the nationality of the boarders was predominately native-born, there were also Hungarians, Poles, Swedes, Germans, and Italians represented among the lodgers. Similarly, a tunnel camp in Groveland Precinct in 1920 contained boarding houses operated by a Swedish immigrant and a Canadian-born mine superintendent. While the Swedish-run operation catered mostly to about 20 Swedish, Norwegian, and native-born tunnel workers, the Canadian establishment lodged a diverse clientele of 22 workers, including tunnel miners and laborers, blacksmiths, foremen, and electricians. They were a diverse lot by nationality, including Canadians, native-born Americans, Spanish, German, Swedish, Italian, Irish, and Austrian workers. This pattern of boarding house occupation by workers of various nationalities was borne out at other tunnel camps and dam construction camps located outside the town of Groveland and at Lake Eleanor.[21d]

[21d] U.S. Census Bureau, MSS Population, Groveland Precinct, Tuolumne County, CA, 1920.

Unsafe working conditions and inadequate wages were issues that periodically contributed to labor strife and fostered efforts to unionize the rural industrial labor force assembled to construct the Hetch Hetchy project. During August of 1920, workers at some of the city's construction camps, particularly in the Mountain Tunnel Division, staged a general strike that lasted until May 1921. City officials, particularly O'Shaughnessy, had expressed general support for trade or craft unionism, but objected to "radicals" who organized the day laborers/construction workers hired by the CCSF and advocated worker solidarity, class conflict, and direct action (strikes) at the point of production. These radical labor leaders included representatives of the Industrial Workers of the World (I.W.W., or "Wobblies"), which variously functioned as an umbrella labor organization and revolutionary social movement, and the International Union of Mine, Mill & Smelter Workers, a labor union with militant roots in the copper, nickel, lead, and gold mines of the American West and British Columbia. During the 1920s and 1930s, Mine and Mill, as the union was known, made concerted efforts to organize unskilled national minorities such as Mexican-Americans and African-Americans in the American Southwest. City records indicated that Swedish/Finnish tunnel crews and Mexican laborers were among the more ardent supporters of the radical unionization effort.[21e]

Construction of Hetch Hetchy Dam, ancillary water storage structures, the city's extensive water conveyance system, and its power plant at Moccasin proceeded over several decades, from 1913 into the late 1930s. In 1925, in his report to the CCSF on Hetch Hetchy's progress, O'Shaughnessy made little mention of labor problems or strife over organizing, and no comments related to national groups and/or the ethnic composition of the workforce. He reported that the total number of "men" productively employed on the project between 1914 and mid-1925 ranged from over 500 at the end of 1914, less than a hundred at the beginning of 1915, and then a gradual increase (with ebbs and flows) to about 750 in 1919. Thereafter the numbers increased quickly, reaching over 2,000 in 1922, before dropping off again to less than 400 by mid-1925.[21f] After 1925, the bulk of the construction effort shifted to the Foothill and Coast Range Tunnels and installation of the San Joaquin Pipeline, leading eventually to the delivery of Hetch Hetchy water into the city in October 1934.[21g]

In the end, the Hetch Hetchy system included multiple dams and reservoirs, conduits, power plants, and 150 miles of aqueduct to transport water from high in the mountains down to the coastal city of San Francisco near sea level. Like other major urban systems on the East Coast, facilities within the system were sited to maintain a gravity flow of water from Hetch Hetchy Reservoir and O'Shaughnessy Dam to the various storage reservoirs and places of use in and near San Francisco. O'Shaughnessy Dam, named after the engineer who oversaw its construction, was of cyclopean concrete construction, consisting of large granite blocks embedded in concrete. It

had an arch-gravity configuration with a 101-foot-deep foundation. At 226.5 feet high, it was a major structure on the West Coast when it was completed in 1923. Its construction took four years and employed laborers around-the-clock, which was uncommon at that time. Utah Construction Company built the $17 million O'Shaughnessy Dam,[22] which was one of the company's early major dam projects. The company went on to become one of the major dam builders in the American West, being credited with construction of at least 58 large dams between 1916 and 1969, including the colossal Hoover Dam on the Colorado River.

[22] Founded in 1900, Utah Construction Company began as a railroad builder in the inter-mountain West. Among its projects was Western Pacific's Feather River Canyon Route (1911) on the Oakland to Salt Lake City line.

At the same time that O'Shaughnessy Dam was nearing completion, the city had another auxiliary dam and reservoir under construction. In 1923, Priest Dam and Regulating Reservoir was built to regulate the flow of water to the city's Moccasin Powerhouse. The following year, the city built Early Intake Diversion Structure, which was the major diversion point for the project. It took water spilled from Hetch Hetchy Reservoir and diverted it through Mountain Tunnel (1925). The tunnel traveled through solid granite and was a concrete-lined, horseshoe-shaped passage that conveyed water to Priest Reservoir and subsequently to the Moccasin facility. The water flowed through Moccasin Power Tunnel, down the penstock, and to Moccasin Powerhouse, where electricity was generated primarily during peak hours. In 1925, a switchyard, other facilities, and a small city-owned town, originally known as Moccasin Camp, sprang up around the powerhouse. The town and associated buildings, and the powerhouse, were designed in a uniform Mission Revival architectural style.

The Red Bar Mountain Siphon, a portion of Foothill Tunnel, was also constructed at this time to carry water across the Tuolumne River Canyon. Foothill Tunnel was constructed in 1928 and conducted water to the Central Valley, releasing it into the San Joaquin Pipelines.

In the San Joaquin Valley, Tesla Portal was added in 1928, providing a connection between the San Joaquin Pipelines (the first of which was constructed in 1932) and the Coast Range Tunnel (completed in 1934). In 1934, at the other end of the Coast Range Tunnel, the city constructed the first Alameda Siphon and Irvington Tunnel to carry water through to the Bay Division Pipelines. Alameda Creek Diversion Dam and Tunnel were begun in 1925 by Spring Valley Water Company and finished in 1931 by the CCSF. Located on Alameda Creek upstream of the Alameda Siphons, the dam diverted water from Alameda Creek through the diversion tunnel and into Calaveras Reservoir. The Alameda Creek Diversion Dam and Tunnel added 35 square miles of watershed area to the system (SFPUC, 2004).

O'Shaughnessy Dam was designed and built in a manner that would allow it to be raised. In the 1930s, President Franklin D. Roosevelt sought to provide America with a New Deal, a government-sponsored socioeconomic initiative that among its most prominent programs included dam construction projects as massive public works. Not long after Roosevelt's election (November 1932) and the start of the New Deal (after his inauguration in March 1933), the CCSF received a grant from the federal government covering 30 percent of the cost of labor and materials for raising O'Shaughnessy Dam. The money came from the National Recovery Administration, which was formed by the National Industrial Recovery Act of June 1933. The SFPUC reported that on November 7, 1933, the citizens of San Francisco passed a bond measure for $3.5 million to cover the city's portion of the cost of enlarging O'Shaughnessy Dam. The federal grant also stipulated that all available unemployed workers in Tuolumne County had to be put to work before unemployed people from San Francisco could be used. Soon thereafter, the state requested that the CCSF use 500 to 600 unemployed laborers it had available for "maintenance of municipal property" under the State Emergency Relief Act (SERA). By March 1934, the CCSF had erected seven SERA work camps capable of housing and feeding nearly 700 workers. Later, the state's SERA program for unemployment relief was absorbed into the federal

Works Progress Administration. The CCSF issued the contract for the Hetch Hetchy Dam enlargement project onApril 8, 1935 to the Transbay Construction Company, and the dam's raising was completed more than three years later, on July 1, 1938.[22a]

In 1926, Pulgas Tunnel was constructed to carry water from the Bay Division Pipelines to Upper Crystal Springs Reservoir. The Crystal Springs/San Andreas Pipeline, constructed in 1932, connected Crystal Springs Reservoirs to San Andreas Reservoir. In 1934, the arrival of Hetch Hetchy water at Crystal Springs was commemorated with construction of the Beaux Arts–style Pulgas Water Temple. The temple was designed by William Merchant, a San Francisco architect who trained under Bernard Maybeck, in a style sympathetic to the Sunol Water Temple. Completion of this pipeline allowed water to travel continuously by gravity flow from Hetch Hetchy Reservoir to the city of San Francisco, a total of over 170 miles.

During construction of the Hetch Hetchy system, the city finally completed the long process of acquiring Spring Valley Water Company. Citizens of the city had strongly supported the Hetch Hetchy system, regularly passing bond measures to fund its construction. Acquisition of the Spring Valley system proved more difficult. The city's board of supervisors put measures to acquire the system on the ballot five times between 1910 and 1928; it was only in 1928 that the voters finally approved its acquisition. While some of the elections nearly reached the required

[22a] San Francisco Public Utilities Commission (SFPUC), *San Francisco Water and Power,* pp. 59–60, June 1949; Ted Wurm, *Hetch Hetchy and its Dam Railroad*, Trans-Anglo Books, Glendale, CA, p. 251, 1973.

two-thirds majority, the 1928 vote in favor of purchase reached 82 percent.[23] The city then entered into negotiations to set a purchase price, and finally acquired the Spring Valley Water Company in 1930 for $39.96 million, at last converting the private utility into a public agency. This led to the creation of the San Francisco Water Department under the Department of Public Works. The first delivery of water from Hetch Hetchy to San Francisco occurred in 1934.

Expansion and Improvements (1934–1955)

Although San Francisco's water system was completed to its fullest geographic extent with the construction of Hetch Hetchy Reservoir, the city made later separate improvements and expansions to its municipal water system and undertook major maintenance projects to improve facilities already in use. Among the most notable of these improvement and expansion projects was raising O'Shaughnessy Dam by 85.5 feet in 1938.

In 1934, the city completed Moccasin Dam, forming Moccasin Reregulating Reservoir; the dam formed an afterbay that assisted in making the flow of water downstream from the Moccasin Power Plant facility more consistent, because the generators at the powerhouse operated in cycles and created varying water flow levels into the afterbay. That same year, the city installed the first of the Alameda Siphons to assist in carrying water under Alameda Creek, between the Coast Range Tunnel and Irvington Tunnel. Merced Manor Reservoir was constructed in 1936 in San Francisco to store water for the residential area surrounding it and to supply Central Pump Station, which pumps water to other reservoirs in the city. In addition, the south basin of University Mound Reservoir, constructed in 1937, and the north basin of Sunset Reservoir, constructed in 1938, greatly improved the capacity of city-based water storage facilities. The city constructed an additional Sunset Reservoir basin in the 1950s. The Sunset Wells in San Francisco were added to the system from 1930 to 1936, just after the city bought Spring Valley. The water department added and improved pipelines that enhanced the amount and dependability of the water supply. In 1936, the city constructed a second Bay Division Pipeline, parallel to the first, and in 1952, added a third Bay Division Pipeline. It skirted the southern end of the bay rather than crossing it. In addition, the city built a second San Joaquin Pipeline and a second Alameda Siphon in 1953.

Between 1953 and 1955, the city built Cherry Dam and created Lake Lloyd near Lake Eleanor Dam, high in the Sierras, adding to the facilities already associated with Cherry Creek. The city also constructed additional power tunnels and powerhouses in this portion of the system. Although Cherry Dam contributes to the system, it primarily provides water to TID and MID, as well as generating hydroelectric power for the city of San Francisco. Water comes into Lake Lloyd from Lake Eleanor via the Cherry-Eleanor Tunnel and Pump Facility. Water is transported out of Lake Lloyd via the Cherry Power Tunnel (1955), which conveys it to Holm Powerhouse (1960).

Modernization (post-1955)

Creative engineering aimed at solving specific problems sustained a later period of system development in the 1960s and 1970s, focused primarily on water quality issues. This period was typified by construction of Pulgas Pump Station and Balancing Reservoir, Pulgas Bypass Tunnel, Crystal Springs Bypass, San Andreas Treatment Plant, Sunol Valley Water Treatment Plant (WTP), and San Antonio Pump Station, Pipeline, and Reservoir, which were designed based on a specific set of plans to make the system more modern and efficient.

In the 1960s and 1970s, water quality issues became more of a concern on a national level, as well as statewide and local levels, than it had been in the early years of municipal water system development. Water quality became the focus of federal legislation in the 1970s; congress passed the landmark Clean Water Act in 1972, focusing primarily on the treatment of wastewater, and the Safe Drinking Water Act in 1974, which set standards for water quality around the nation. Accordingly, the city put into service facilities like the Sunol Valley WTP, serving Calaveras Reservoir, and the Harry Tracy WTP, serving San Andreas Reservoir. These facilities filter, disinfect, and introduce additives to the water before it is delivered to consumers.

In the mid-1960s, the city built Turner Dam and San Antonio Reservoir, the most recent of the major water system facilities. The dam and reservoir had been under consideration early in the system's history; in fact, these facilities were originally sited by the Spring Valley Water Company in 1875 and presented in the Freeman report of 1912, but were never built under any plan until the city did so. Finally completed in 1965, these facilities provided a needed water collection and storage point. In addition, the city had the upstream face of Pilarcitos Dam repaired in 1972, and strengthened Calaveras Dam in 1975.[24]

Many other mechanical facilities and stretches of pipeline have been constructed over the years. These various engineering facilities and structures, which were conceived, designed, and built during discrete periods and by separate plans, work together to unite the dispersed larger elements of the system, such as Peninsula, Alameda, and Tuolumne watershed dams and reservoirs, and make the SFPUC water system operate as an efficient whole.

Resource Types

The following discussion describes the types of cultural resources that might occur within the WSIP study region.

Paleontological Resource Types

Invertebrate fossils found in young marine sediments are usually not considered by paleontologists to be significant resources because they are often widespread, abundant, fairly well preserved, and present in predictable locations; the same or similar fossils can be located at

[24] During this time, TID and MID constructed New Don Pedro Dam (1967–1971). It replaced a smaller, 1923 dam in the same area and created Don Pedro Reservoir from the waters of the Tuolumne River. New Don Pedro Dam, while partially financed by the SFPUC (acting on behalf of the CCSF), is owned and operated by TID and MID as a part of their systems; it plays no direct role in the provision of water to San Francisco.

any number of sites throughout California. Most limestone deposits are prolific with invertebrate skeletal material; organic mudstones are also rich with invertebrate fossils. However, a new marine invertebrate fossil discovery that might provide a better understanding of a geologic unit or shed light on a new genus or species would be considered an important scientific discovery. Fossil remains of vertebrates are common in Pleistocene (1.8 million to 10,000 years ago) units throughout California, and units of alluvium, in particular, can contain diverse animal fossils that represent key evolutionarily significant specimens.

Archaeological Resource Types

Prehistoric Archaeological Resources

Prehistoric archaeological site types in the WSIP study areas include village sites, temporary campsites, milling sites, petroglyphs, stone or rock scatters, quarry sites, shell and ash middens, and burial sites. Prehistoric sites are more likely to be intact in areas that are not fully developed or farmed, or are beneath alluvial fans that have not been extensively plowed. Although buried deposits can occur in urbanized settings, substantial commercial and residential development has disturbed or destroyed many of these sites. For example, the Central Valley has undergone substantial change since prehistoric times due to its agricultural development, but it is possible to encounter paleontological resources when they become exposed due to soil erosion. Deeply buried prehistoric sites have also been found in San Francisco and the East Bay Hills; permanent settlements were common in the San Francisco Bay region, and prehistoric sites are likely to occur throughout much of the area.

Historic Archaeological Resources

Historic archaeological sites in the Central Valley are characterized by artifacts associated with mid-19th-century ranching and agricultural settlements, which may have also left behind farming landscapes, homesteads, corrals, fences, and canal and irrigation features. The historic archaeological resources in the San Francisco Bay Area include recreational sites, mining-related sites, early military sites, and refuse deposits, such as artifact-filled privies or wells. Of particular interest are those sites related to Mission-era activities, including dwellings or house depressions, cairns,[25] rock alignments, and household features such as hearths, pits, and fire-cracked rock. Throughout the WSIP study area, historic railroad properties remain, including railroad segments, campsites, berms, trestles, material dumps, and associated structural ruins (see Chapter 2, Existing Regional Water System, Table 2.1, for a listing of major SFPUC facilities).

Traditional Cultural Properties

Traditional Cultural Properties (TCPs), or sacred lands, are holy places, ceremonial sites, and other important places for Natives Americans. TCPs and other sacred lands may be eligible for listing in the National Register of Historic Places under the National Historic Preservation Act (Section 101[d][6][a]). TCPs may also be eligible for listing in the California Register of Historical Resources under Section 15064.5[a][3] of CEQA. In the WSIP study area, TCPs often consist of natural or geologic features that are traditionally considered sensitive or sacred. For

---

25 A rock pile, cache, or suspected burial.

example, Mount Diablo and Mount Tamalpais are landmarks considered to be TCPs for their religious and ceremonial significance to several Native American groups. However, not all TCPs are necessarily mountaintops or overt features of the landscape. The California Native American Heritage Commission maintains a database of known sacred lands and distributes information concerning these properties upon request.

Historic Architectural Resource Types

In a complicated hydraulic facility such as the SFPUC regional water system, each individual element contributes in some way to the overall function, which in this case is to capture, store, treat, and transport water from reservoirs to the city distribution system and ultimately to consumers. One useful document in identifying, assessing, and evaluating features of water conveyance systems, such as those in the regional water system, is *Water Conveyance Systems in California* (JRP Historical Consulting Services and Caltrans, 2000).

Some major facilities in water conveyance systems (such as certain dams and aqueducts) play more central roles and may have surmounted substantial engineering challenges through innovative solutions, warranting recognition as important examples of hydraulic engineering under the contexts of municipal water systems. Others (such as certain pumping plants, distribution reservoirs, and wells) perform more ancillary or subsidiary services and may be of well-known and common designs. Generally, these elements can be classified as either structures that physically manipulate the movement of water, or structures that house mechanisms or facilities for treating water.

Physically, each of the architectural resource types described below—as dictated by its function and period of construction—have distinct forms and materials. In addition, variations exist within each type according to the function it needed to fulfill, the preferences and skills of the designing engineers, and the technology and construction practices that were common when it was built. A number of resource types within the regional system may possess historical significance and still be active in the water system, while others are partially or no longer active. The following is a list of historic resource types, with variations described. Generally, these resource types take many diverse forms, not only among the resource types but also within those types. Therefore, resources must be assessed on an individual basis. The generalized descriptions given above provide a context for determining possible historic resources; however, the final determination is made based on the historical significance and historic integrity of the resource within a specific historical context, identified with a specific period of significance.

- <u>Dams</u>. A dam is a structure confining a body of water, or any barrier constructed across a waterway to control the flow or raise the level of water. Historic dams within the water system come in a number of configurations and materials, including: concrete buttressed arch dams, earth- and rock-fill dams, concrete gravity arch dams, earth and rock hydraulic fill dams, earth dams, masonry arch dams, and earth-fill clay core dams. Some of the dam designs may be considered innovative and pioneering for their eras of construction. Dams in the regional system range in height from 4 feet to 330 feet. While the size of a dam alone is not a sufficient measure of its potential historical significance, it can be a contributing attribute when combined with other design factors. The regional system dams of interest for the WSIP are those in the Sunol Valley and Peninsula Regions: the Calaveras, Turner, San Antonio, and Lower Crystal Springs Dams. Of those, only Calaveras and Lower Crystal Springs Dams would be directly affected by WSIP projects.

- *Reservoirs*. A reservoir is any natural or artificial pond or lake used for the storage and regulation of water. A reservoir is usually created by the installation of a dam, which forces water to collect behind it. Many reservoirs within the water system consist of natural depressions in the earth that are flooded with water from streams or creeks flowing into the valley. Historic reservoirs within the water system include flooded valleys, existing lakes, and man-made ponds. Reservoirs can be covered or uncovered. Smaller urban distribution reservoirs hold as little as 9.5 million gallons, while larger rural storage reservoirs hold as much as 117.4 million gallons. The proposed WSIP projects would affect the Calaveras, San Antonio, Lower Crystal Springs, and Pilarcitos Reservoirs.

- *Tunnels*. Tunnels are water-conveying structures that pass through topographic features or below the ground surface, and thus are surrounded by solid material like stone or soil. They can take the shape of a horseshoe, circle, or "U" and can be either unlined (the walls of the tunnel consisting of the surrounding material, typically stone) or lined with concrete, steel, or gunite. Historic tunnels in the regional system range from approximately 4 feet to 14.5 feet in diameter. Power tunnels are specific in their function only (i.e., delivering water to a powerhouse). The proposed WSIP projects would affect the Irvington Tunnel.

- *Aqueducts/Flumes*. An aqueduct (or, on a smaller scale, a flume) is an open channel designed to transport water, usually via gravity flow. The only operating historic aqueduct within the water system is the Lower Cherry Diversion Aqueduct, which is a concrete canal measuring 7.5 feet wide and 7.5 feet deep. Remnants of pre-1906 flumes built by the Spring Valley Water Company also remain near Crystal Springs Reservoir and Pilarcitos Reservoir. The WSIP would not affect the regional system's aqueducts or flumes.

- *Pipelines*. A pipeline is a conduit of pipe used to convey water. It can run above or below ground. Along with tunnels, aqueducts, and other conveyance arteries, pipelines connect reservoirs and other facilities within the water system. Pipelines from the historic period in this system consist of steel pipe, riveted steel pipe, wrought steel pipe, welded steel pipe, steel pipe that is cement-lined and coated, steel pipe that is cement-lined and coal-tar coated and wrapped, reinforced-concrete cylinder pipe, or prestressed concrete cylinder pipe. The pipelines in the regional system generally measure from 54 to 72 inches in diameter and can carry between 37 and 300 mgd of water. The proposed WSIP projects would affect the San Joaquin, Bay Division, and other pipelines.

- *Towers*. Towers have a variety of functions within the water system but have been grouped together as a single historic resource type. Surge towers are designed to reduce the damage to piping in the event of pump failure, which could cause water to surge backward from a pump station. Intake and outlet towers are located above the openings of reservoir intake and outlet pipes, and house controls that regulate the flow of water through the pipes. Intake/outlet towers are tall structures that are usually located in the water of a reservoir and are connected to shore by a catwalk. Within this system, the historic towers appear to be constructed primarily of poured concrete and have various shapes and detailing, some with notable architectural merit. The proposed WSIP projects would affect towers at Calaveras and Lower Crystal Springs Dams.

- *Powerhouses*. Powerhouses use water passing through them to generate electricity through the movement of a turbine. The water system's secondary function (after providing water to the city) is providing hydroelectric power. Powerhouses are typically large structures located below a reservoir or along the course of a waterway. The only extant historic powerhouse in the system is the Old Moccasin Powerhouse, which is a steel frame and concrete building measuring 225 by 98 feet and 67 feet high. It was built in the California Mission style with a tile roof, arcades, and other architectural details. The WSIP would not affect powerhouses in the regional water system.

- *Penstocks*. Also associated with powerhouses, penstocks are the pressure pipes that carry water from a forebay reservoir to the turbine. The Moccasin Penstocks are the only penstocks from the historic period. They are relatively small-diameter pipes that run parallel to one another over a distance of 5,625 feet and carry 800 mgd of water. The WSIP would not affect penstocks in the regional water system.

- *Switchyards*. Switchyards manage the electric power generated by the hydroelectric powerhouse. The Moccasin Switchyard is the only switchyard from the historic period. It contains various pieces of equipment, such as electrical transformers. The switchyards handle the maximum 102 kilowatts of electricity that the Moccasin facility can produce. The WSIP would not affect switchyards in the regional water system.

- *Siphons*. Siphons are pipelines used to convey water across a range of elevations (or topography) without the need for pumping. Siphons can be used when the starting elevation is higher than the final elevation, regardless of intervening changes in elevation, due to the force of water pressure; in this way, they are able to carry water across canyons or under riverbeds. Like pipelines, siphons can be located above or below ground. Essentially made of the same materials as pipelines, historic-period siphons in the SFPUC water system are made of riveted steel pipe, steel cylinder reinforced-concrete pipe, or steel plate with tar lining and coating and wrapped in felt. They range from 5.75 to 9.5 feet in diameter and generally convey from 70 to 150 mgd of water. The WSIP would affect the Alameda Siphons.

- *Portals*. Portals are the connecting points between pipelines and tunnels. The main feature of a portal is the tunnel mouth and connecting pipeline. Historically, portals typically consisted of a steel manifold that emerged from the tunnel mouth and connected to the pipeline(s) by way of multiple apertures. Portals often incorporate a small complex of facilities, including valve houses, storage tanks, equipment buildings, and caretaker residences. In some instances, these utility buildings and residences have some notable architectural merit. Valve houses are typically small, one-room structures made of concrete, and their number at each portal facility usually corresponds to the number of pipelines coming into or out of the associated portal. Most other utility buildings at portal facilities follow similar construction guidelines, being of modest size and made of utilitarian materials (typically concrete). In some instances, these buildings have some notable architectural merit, most typically in the Mission Revival style. The proposed WSIP projects would affect the Irvington, Alameda West, Alameda East, Tesla, and Oakdale Portals.

- *Pump Stations*. Pump stations function to pump water from a lower elevation to a higher elevation through mechanical means. The majority of the water system functions through gravity, with water flowing downward to facilities at progressively lower elevations; however, in some instances, when the water level is particularly low in any given reservoir or the topography rises along the water’s path, a pump station will raise it to the desired elevation. The only historic pump station in the system is the Crystal Springs Pump Station; this large building houses four pump mechanisms and has some notable architectural merit. A 60-inch pipe serves the pumping station, and the station pumps 80 mgd of water. The proposed WSIP projects would affect the Crystal Springs Pump Station.

- *Water Temples*. Water temples are unique structures with notable architectural merit that serve a primarily aesthetic function, though they also mark the confluence of certain water routes within the water system. Designed as circular temples in the Classical style, with fluted columns, wide entablatures, and expressive murals, they shelter an oculus that looks down into the tunnels that pass below them. The water temples are round, 60-foot tall structures surrounded by park-like open space. There are two water temples in the regional water system, Spring Valley's Sunol Water Temple and the SFPUC's Pulgas Water Temple. A proposed WSIP project would be adjacent to Pulgas Water Temple and could affect it.

- *Residences*. There are historic residences associated with water system facilities throughout the water system. Some portal facilities have caretaker cottages, while a notable neighborhood of employee residences, known as Moccasin Camp, is located near the Moccasin Powerhouse complex. This complex, typified by a unified architectural design, includes a historic administration building and powerhouse, as well as a core area of California Mission-style houses dating to the 1920s. It should be noted, however, that there are other residences in the town of Moccasin adjacent to this original core that were built in later decades. Historic houses within the water system are of various construction types and styles. Most are utilitarian in design, but some have notable architectural styling such as the residences at Moccasin Camp, which are in the California Mission style. Historic water system residences are typically modest in size. The proposed WSIP projects would affect residences, or former residences, at the Calaveras Dam and Tesla Portal sites. The residence at Calaveras Dam would be vacated during construction, but would not otherwise be affected.

- *Roads*. Roads are necessary to access facilities and water-conveying arteries throughout the system. Historic roads may still remain as accessways to historic resources, and can take the form of paved or unpaved roadways of varying lengths and widths built to fit the terrain and distance of resources from access points. Such roads are commonly subject to regular maintenance and improvement. The proposed WSIP projects would affect roads to the project sites.

4.7.2 Regulatory Framework

Federal, state, and local government laws and regulations protect significant cultural resources. As discussed below, the CEQA statute and guidelines include procedures for identifying, analyzing, and addressing potential impacts on cultural resources, and CEQA takes into account federal laws and regulations that pertain to paleontological, archaeological, and historic resources. CEQA also takes into account the laws and procedures of local California jurisdictions, such as the CCSF, that pertain to cultural resources.

The federal government, California state government, and local governments have published guidelines and standards for identifying and addressing archaeological and historical resources. Among these publications that would be useful for cultural resources studies related to the WSIP projects are the National Park Service's National Register Bulletins; the "Instructions for Recording Historical Resources" (Office of Historic Preservation, 1995); *Water Conveyance Systems in California* (JRP Historical Consulting Services and Caltrans, 2000); and "San Francisco Preservation Bulletin No. 16, CEQA Review Procedures for Historic Resources" (CCSF, 2004).

Federal

The Antiquities Act of 1906 (United States Code, Title 16, Sections 431–433) provides for fines or imprisonment of any person convicted of appropriating, excavating, injuring, or destroying any historic or prehistoric ruin or monument or other object of antiquity that falls under the jurisdiction of the federal government. According to the *Standard Environmental Reference of the California Department of Transportation* (Caltrans, 2007), the National Park Service, Bureau of Land Management, U.S. Forest Service, and other federal agencies have interpreted "objects of antiquity" to include fossils. The Antiquities Act provides for the issuance of permits to collect fossils on lands administered by federal agencies and requires projects involving federal lands to obtain permits for both paleontological resource evaluation and mitigation efforts.

Paleontological Resources Preservation Act

The federal Paleontological Resources Preservation Act of 2002 was enacted to codify the generally accepted practice of limiting the collection of vertebrate fossils and other rare and scientifically significant fossils to qualified researchers; these researchers must obtain a permit from the appropriate state or federal agency and agree to donate any materials recovered to recognized public institutions, where they will remain accessible to the public and to other researchers (USFWS/CDFG, 2006). The Paleontological Resources Preservation Act incorporates the following key findings of a recent report issued by the Secretary of the Interior, with input from staff of the Smithsonian Institute, U.S. Geological Survey, various federal land management agencies, paleontological experts, and the public (Society of Vertebrate Paleontology, 2003; as cited in USFWS/CDFG, 2006).

- Most vertebrate fossils and some fossils of other types (invertebrates, plants) represent a rare resource.
- Illegal collection and theft of fossil materials from public lands is a serious problem; penalties for fossil theft should be strengthened.
- Effective stewardship requires accurate information; federal fossil collections should be preserved and made available for research and educational use.
- Federal management of fossil resources should emphasize opportunities for public involvement.

National Register of Historic Places

The National Register of Historic Places is the official federal list of significant historic resources. The National Park Service administers the National Register in conjunction with the State Historic Preservation Officers. The National Register includes buildings, structures, sites, objects, and districts that possess historic, architectural, engineering, archaeological, or cultural significance at the national, state, or local level. The National Register criteria and associated definitions are presented in *National Register Bulletin Number 15: How to Apply the National Register Criteria for Evaluation*.

To qualify for the National Register, a property must meet at least one of the National Register criteria and retain sufficient historic integrity of convey its significance. A property that is significant under one or more of the National Register criteria must be associated with an important historical context *and* be significant within that historical context. Determining this significance is accomplished through physical examination of a property combined with thorough documentary research. National Register Bulletin 15 outlines the sequence for evaluating properties for eligibility to, and listing in, the National Register. A property must be classified as a specific property type (i.e., a building, structure, object, site, or district). Then one must identify the proper historical context (or prehistorical context) that the property represents, evaluate the property under the National Register criteria, conduct further evaluation (if necessary) for properties that are usually excluded from the National Register, and assess the historic integrity of the property.

The National Park Service uses specific definitions for property type categories. *Buildings* are used principally to shelter human activity. *Structures* are functional constructions, such as engineering features, for purposes other than creating human shelter. *Objects* are constructions that are artistic in nature, such as monuments or statuary, or simple features such as boundary markers. *Sites* are the locations of significant events that may or may not contain buildings, structures, objects, or archaeological resources. The resource boundaries of buildings, structures, and objects are limited to the resource itself, along with any setting that may contribute to its significance. *Districts* include more than one resource and "possess a significant concentration, linkage, or continuity of sites, buildings, structures, or objects united historically or aesthetically by plan or physical development."[26]

Historic districts derive their importance from being unified entities, and can include a few types of resources or a diverse set of resources. The unified quality of historic districts is a result of the interrelationships among resources, which often convey an overall visual sense of the historic environment to which the resources are associated. Districts can also be an arrangement of historically or functionally related properties, as well as a grouping of archaeological sites related by common components. Historic districts can include individually distinctive resources and/or resources that lack individual distinction but contribute to a significant or distinguishable entity or grouping of resources. This property type must be located in a definable geographic area that is distinguished from its surroundings, and these boundaries must be based on the shared relationship of the properties that constitute the district. A majority of resources in a historic district's boundaries must retain sufficient historic integrity to convey the district's significance as a whole.

Historic districts include contributors and non-contributors. A "contributor" is a building, site, structure, or object that adds to the historic associations or historic architectural qualities for which the district is significant. A "non-contributor" does not add to the historic associations or historic architectural qualities, as it was not present during the period of significance or has been altered in a manner that it no longer retains the historic integrity to convey the district's significance. Besides commercial areas and residential neighborhoods, historic districts can also

[26] National Register Bulletin 15, 5.

be located in industrial or rural locations as well as in areas with a concentration of resources that are significant within a specific context, such as may be identified in portions of the SFPUC regional water system. It is possible to have discontiguous historic districts that are united in historical significance but are located in more than one definable area and separated by non-significant areas. The use of discontiguous historic districts is limited to situations where, for example, the elements of the district are spatially discrete, the spaces between elements of the district are not related to its significance, and where visual continuity is not a factor in the significance. For example, a group of dams united in a water system by plan, design, and distinct period of significance, but spatially separated from one another, could be considered a discontiguous district.[27]

When evaluating a resource under National Register criteria, one must evaluate and clearly state the significance of that resource to American history, architecture, archaeology, engineering, or culture. In this process, one must identify the historical context, or facet of history, to which a resource is associated and identify whether that context is significant. Then one can identify the resource's relative importance within that context, assess how the resource illustrates that history, and identify whether the resource has the physical features necessary to convey the history to which it is associated.

According to National Register guidelines, a historic resource's "quality of significance in American history, architecture, archeology, engineering and culture" is determined based on whether it meets at least one of four main criteria. Resources may be significant at the local, state, or national level:

> Criterion A: Association with events or trends significant in the broad patterns of our history.
>
> Criterion B: Association with the lives of significant individuals.
>
> Criterion C: A property that embodies the distinctive characteristics of a type, period, or method of construction, represents the work of a master, or that possesses high artistic values.
>
> Criterion D: Has yielded or is likely to yield information important to history or prehistory.

A resource may be considered eligible for listing in the National Register if it meets one or more of the above-listed criteria for significance and it possesses historic integrity. Historic properties must retain sufficient historic integrity to convey their significance. The assessment of historic integrity must be grounded in an understanding of the resource's physical features and how they relate to its significance. The National Register recognizes seven aspects or qualities that define historic integrity. They are as follows:

- *Location*. The place where the historic property was constructed or the place where the historic event occurred.

[27] National Register Bulletin 15, 5-6.

- *Design*. The combination of elements that create the form, plan, space, structure, and style of a property.
- *Setting*. The physical environment of a historic property.
- *Materials*. The physical elements that were combined or deposited during a particular period of time and in a particular pattern or configuration to form a historic property.
- *Workmanship*. The physical evidence of the crafts of a particular culture or people during any given period in history or prehistory.
- *Feeling*. A property's expression of the aesthetic or historic sense of a particular period of time.
- *Association*. The direct link between an important historic event or person and a historic property.

Certain properties and resources are usually excluded from consideration for eligibility to or listing in the National Register, but can be considered if they meet special requirements in addition to meeting the regular criteria. The following are the seven Criteria Considerations that deal with properties usually excluded from listing in the National Register:[28]

Consideration A: Religious properties

Consideration B: Moved properties

Consideration C: Birthplaces and graves

Consideration D: Cemeteries

Consideration E: Reconstructed properties

Consideration F: Commemorative properties

Consideration G: Properties that have achieved significance within the past 50 years

The WSIP is unlikely to affect most of the types of properties or resources that are usually excluded from listing in the National Register. The two criteria considerations most likely to be applied to resources that could be affected by the WSIP are Criteria Consideration B, for moved properties, and Criteria Consideration G, for properties that have achieved significance within the past 50 years. The latter criteria consideration, as discussed below in Section 4.7.3, also frames the standard to which survey populations of known and potential historic resources are identified.

Resources moved after their period of significance are usually not eligible for listing in the National Register because they have lost the relationship with their original setting and the direct association with their original location. A moved resource could be eligible for listing in the National Register, under the standards of Criteria Consideration B, if its significance is primarily architectural or if it is the sole surviving resource associated with a historic person or event.

[28] USDI, National Park Service, "How to Apply the National Register Criteria for Evaluation," *National Register Bulletin 15*, 25, 41-43; USDI, National Park Service, "Guidelines for Evaluating and Nominating Properties that have Achieved Significance within the Last Fifty Years," *National Register Bulletin No. 22* (Washington, D.C.: Government Printing Officer, 1979, revised 1990 and 1996).

Resources that are less than 50 years old are usually not eligible for listing in the National Register, unless they can be shown, under the standards of Criteria Consideration G, to be of exceptional importance.[29]

The following properties, which are known to exist as part of or related to the SFPUC water system, are either listed, or have been determined to be eligible for listing, in the National Register:[29a]

- Delia Fleishhacker Memorial Building (listed in the National Register. This site is near one of the potential locations of a recycled water treatment facility under the Recycled Water Projects, SF-3, in San Francisco.)
- Lower Crystal Springs Dam (individually eligible for listing)
- Sunol Aqueduct (individually eligible for listing)
- Sunol Dam (individually eligible for listing)[30]
- Vallejo / Spring Valley Water Company's Niles Dam (individually eligible for listing)[31]
- Spring Valley Water Company's Alameda Creek System Historic District (eligible for listing)

National Historic Preservation Act

Federal involvement in a local project through permitting, approval, or funding requires project compliance with the Code of Federal Regulations (CFR), Section 36, Part 800, Protection of Historic Properties. Several WSIP projects would require a permit from the U.S. Army Corps of Engineers. Compliance with federal regulations regarding the protection of historic properties requires completion of cultural resource studies in compliance with Section 106 of the National Historic Preservation Act. Results of these studies would require concurrence from the State Historic Preservation Officer (SHPO) and would be supplied to the Corps. A federal lead agency may also enter into a Programmatic Agreement with the SHPO to address multiple projects within a program such as the WSIP.

As mentioned previously, TCPs may be eligible for listing in the National Register under the National Historic Preservation Act (Section 101[d][6][a]), which states that "Properties of traditional religious and cultural importance to an Indian tribe or Native Hawaiian organization may be determined to be eligible for inclusion on the National Register."

---

29 National Park Service, "How to Apply the National Register Criteria for Evaluation," *National Register Bulletin 15*, 25, 29-31, and 41-43; National Park Service, "Guidelines for Evaluating and Nominating Properties that have Achieved Significance within the Last Fifty Years," *National Register Bulletin No. 22* (Washington, D.C.: Government Printing Officer, 1979, revised 1990 and 1996).

29a These properties have been determined eligible for listing in the National Register through consensus between a federal agency and the State Historic Preservation Officer. Information regarding National Register eligibility was acquired through a records search conducted at the Northwest Information Center at Sonoma State University, which is one of regional offices of the California Historical Resources Information System established by the California Office of Historic Preservation.

30 This property was removed by the SFPUC in September 2006.

31 This property was removed by the SFPUC in September 2006.

State

California Public Resources Code

Several sections of the California Public Resources Code (PRC) protect paleontological resources. Section 5097.5 prohibits "knowing and willful" excavation, removal, destruction, injury, and defacement of any paleontologic feature on public lands (lands under state, county, city, district, or public authority jurisdiction, or the jurisdiction of a public corporation), except where the agency with jurisdiction has granted permission. Section 30244 requires reasonable mitigation for impacts on paleontological resources that occur as a result of development on public lands. The sections of the California Administrative Code pertaining to the State Division of Beaches and Parks afford protection to geological features and "paleontological materials," but grant the director of the state park system authority to issue permits for specific activities that may result in damage to such resources, if the activities are in the interest of the state park system and for state park purposes (California Administrative Code Sections 4307–4309; as cited in USFWS/CDFG, 2006).

The Public Resources Code also addresses archaeological resources. Archaeological resources that are not "historical resources" may be "unique archaeological resources" as defined in PRC Section 21083.2, which also generally provides that "non-unique archaeological resources" do not receive any protection under CEQA. PRC Section 21083.2 (g) defines "unique archaeological resource" as an archaeological artifact, object, or site that does not merely add to the current body of knowledge, but has a high probability of meeting any of the criteria identified in this section. If an archaeological resource is neither a unique archaeological nor a historical resource, the effects of the project on that resource will not be considered a significant effect on the environment. It is sufficient that the resource and the effects on it be noted in the EIR, but the resource need not be considered further in the CEQA process.

Additional sections of the Public Resources Code that are applicable to the proposed program are as follows:

- *Section 5097.5*. Provides that any unauthorized removal or destruction of archaeological or paleontological resources on sites located on public lands is a misdemeanor.
- *Section 5097.98*. Prohibits obtaining or possessing Native American artifacts or human remains taken from a grave or cairn, and sets penalties for such acts.
- *Section 5097.5*. Provides that any unauthorized removal of archaeological resources on sites located on public lands is a misdemeanor. As used in this section, "public lands" means lands owned by, or under the jurisdiction of, the state, or any city, county, district, authority, or public corporation, or any agency thereof.

California Register of Historical Resources

The California Register of Historical Resources is a statewide program of similar scope to the National Register. All resources listed in or formally determined eligible for the National Register are also eligible for listing in the California Register. In addition, properties designated under municipal or county ordinances are also eligible for the California Register. A historical resource must be significant at the local, state, or national level under one or more of the following criteria defined in the California Code of Regulations, Title 14, Chapter 11.5, Section 4850, identified as Criteria 1 through 4.

1. It is associated with events or patterns of events that have made a significant contribution to the broad patterns of local or regional history, or the cultural heritage of California or the United States; or

2. It is associated with the lives of persons important to local, California, or national history; or

3. It embodies the distinctive characteristics of a type, period, region, or method of construction, or represents the work of a master, or possesses high artistic values; or

4. It has yielded, or has the potential to yield, information important to the prehistory or history of the local area, California, or the nation.

The California Register definition of integrity and its special considerations for certain properties are slightly different than those for the National Register. Integrity is defined as "the authenticity of a historical resource's physical identity evidenced by the survival of characteristics that existed during the resource's period of significance." The California Register further states that eligible resources must "retain enough of their historic character or appearance to be recognizable as historical resources and to convey the reasons for their significance," and lists the same seven aspects of integrity used for evaluating properties under the National Register criteria. The California Register's special considerations for certain properties types are limited to: (1) moved buildings, structures, or objects; (2) historical resources achieving significance within the past 50 years; and (3) reconstructed buildings.

The following properties, which are known to exist as part of or related to the SFPUC water system, are either listed or have been determined to be eligible for listing in the California Register:

- *Delia Fleishhacker Memorial Building*. This building is listed in both the National and California Registers.
- *Sunol Aqueduct*. This facility is eligible for listing in both the National and California Registers.
- *Lower Crystal Springs Dam*. This dam is listed as a California Historic Civil Engineering Landmark and in the California Inventory of Historical Resources; it is eligible for listing in the California Register.
- *Hetch Hetchy Coast Range Tunnel*. This facility is listed as a California Historic Civil Engineering Landmark and appears to meet the criteria or listing in the National and California Register.
- *Stone Dam*. This dam is eligible for landmark status (San Francisco Department of Public Works, 1999) and is eligible for listing in the California Register.

Niles and Sunol Dams were removed in August and September 2006, respectively. Section 106 consultation was completed in August 2006 prior to the removal of Niles Dam. The EIR for this project concluded that the demolition created a significant unavoidable impact on these historical resources.

California Environmental Quality Act Statute and Guidelines

The CEQA Statute and Guidelines include procedures for identifying, analyzing, and disclosing potential adverse impacts on cultural resources, which include all resources listed in or formally determined eligible for the National Register, the California Register, or local registers.

CEQA requires the lead agency to consider the effects of a project on archaeological resources and to determine whether any identified archaeological resource is a historical resource (i.e., if the archaeological resource meets the criteria for listing in the California Register) (CEQA Guidelines Sections 15064.5[a][1] and [3] and [c][1] and [2]). An archaeological resource that qualifies as a historical resource under CEQA generally qualifies for listing under Criterion 4 of the California Register (CEQA Guidelines Section 15064.5[a][3][D]) (National Register Criterion D). An archaeological resource may qualify for listing under Criterion 4 when it can be demonstrated that the resource has the potential to significantly contribute to questions of scientific or historical importance. Archaeological resources that are not historical resources according to the above definitions may be "unique archaeological resources," as defined in PRC Section 21083.2, which generally provides that "non-unique archaeological resources" do not receive any protection under CEQA. If an archaeological resource is neither a unique archaeological resource nor a historical resource, the effects of a project on those resources are not considered significant.

CEQA defines a historical resource as a resource that meets any of the following criteria:

- A resource listed in, or determined to be eligible for listing in, the National Register or California Register.
- A resource included in a local register of historical resources, as defined in PRC Section 5020.1(k), unless the preponderance of evidence demonstrates that it is not historically or culturally significant.
- A resource identified as significant (e.g., rated 1 through 5) in a historical resource survey meeting the requirements of PRC Section 5024.1(g) (Department of Parks and Recreation Form 523), unless the preponderance of evidence demonstrates that it is not historically or culturally significant.
- Any object, building, structure, site, area, place, record, or manuscript which a lead agency determines to be historically significant or significant in the architectural, engineering, scientific, economic, agricultural, educational, social, political, military, or cultural annals of California, provided the determination is supported by substantial evidence in light of the whole record. Generally, a resource is considered "historically significant" if it meets the criteria for listing in the California Register (CEQA Guidelines Section 15064.5).
- A resource that is determined by a local agency to be historically or culturally significant even though it does not meet the other four criteria listed here (e.g., Article 10 and Article 11 of the San Francisco Planning Code).

According to the CEQA Guidelines (Section 15064.5[a][3]), a resource is generally considered historically significant if the resource meets the criteria for listing in the California Register (PRC Section 5024.1, California Code of Regulations, Title 14, Section 4852). A historical resource is defined as any site that:

1. Is listed in or determined to be eligible by the State Historical Resources Commission for listing in the California Register, or is determined to be significant in the architectural, engineering, scientific, economic, agricultural, educational, social, political, or cultural annals of California; and

2. Is eligible for listing in the California Register (criteria noted above); or

3. Is included in a local register of historical resources, as defined by PRC Section 5020.1(k), or identified as significant in a historical resource survey meeting the requirements of PRC Section 5024.l(g), is presumed to be historically or culturally significant.

Archaeological resources may be historical resources under CEQA. TCPs may also be eligible for the California Register under Section 15064.5[a][3]. CEQA Guidelines Section 15064.5 provides that, in general, a resource not listed in state or local registers of historical resources shall be considered by the lead agency to be historically significant if the resource meets the criteria for listing in the California Register. Section 15064.5(b) states that "a project with an effect that may cause a substantial adverse change in the significance of a historical resource is a project that may have a significant effect on the environment." This section also provides standards for determining what constitutes a "substantial adverse change" on archaeological or historical resources, including physical demolition, destruction, relocation, or alteration of the resource or its immediate surroundings such that the significance of the historical resource would be materially impaired (CEQA Guidelines Section 15064.5[b][1]). The significance of a historical resource is considered to be materially impaired when a project demolishes or materially alters in an adverse manner those characteristics that convey its historical significance and that justify its inclusion on a historical resource list (CEQA Guidelines 15064.5[b][2]).

California Health and Safety Code

The proposed program is also subject to the provisions of the California Health and Safety Code with respect to the discovery of human remains. Health and Safety Code Section 7050.5 states that "Every person who knowingly mutilates or disinters, wantonly disturbs, or willfully removes any human remains in or from any location other than a dedicated cemetery without authority of law is guilty of a misdemeanor, except as provided in Section 5097.99 of the Public Resources Code." PRC Section 5097.98, as amended by Assembly Bill 2641, states:

(a) Whenever the commission receives notification of a discovery of Native American human remains from a county coroner pursuant to subdivision (c) of Section 7050.5 of the Health and Safety Code, it shall immediately notify those persons it believes to be most likely descended from the deceased Native American. The descendents may, with the permission of the owner of the land, or his or her authorized representative, inspect the site of the discovery of the Native American human remains and may recommend to the owner or the person responsible for the excavation work means for treatment or disposition, with appropriate dignity, of the human remains and any associated grave goods. The descendents shall complete their inspection and make recommendations or preferences for treatment within 48 hours of being granted access to the site.

(b) Upon the discovery of Native American remains, the landowner shall ensure that the immediate vicinity, according to generally accepted cultural or archaeological standards or practices, where the Native American human remains are located, is not damaged or disturbed by further development activity until the landowner has discussed and conferred, as prescribed in this section, with the most likely descendents regarding their recommendations, if applicable, taking into account the possibility of multiple human remains. The landowner shall discuss and confer with the descendents on all reasonable options regarding the descendents' preferences for treatment.

City and County of San Francisco

Planning Code, Articles 10 and 11

The CCSF reviews the historic resources described under Articles 10 and 11 of the San Francisco Planning Code when it evaluates impacts on historic resources (see "Significance Criteria" below). Article 10 describes procedures regarding the preservation of sites and areas of special character or special historical, architectural, or aesthetic interest or value, such as officially designated city landmarks and buildings included within locally designated historic districts. Article 11 of the Planning Code designated six downtown conservation districts.

Historical Resources in the WSIP Study Area under Articles 10 and 11. There are no designated city landmarks or properties that contribute to designated historic districts in the WSIP study area.

Planning Department, CEQA Review Procedures for Historic Resources

The San Francisco Planning Department prepared the *CEQA Review Procedures for Historic Resources* (Final Draft, October 8, 2004, subject to change) (also referred to as San Francisco Preservation Bulletin No. 16) to determine whether a potential property or structure fits the definition of a historical resource as defined in the CEQA Statutes and Guidelines. Three categories of properties are defined.

- <u>*Category A*</u>. Category A has two sub-categories:
  - *Category A.1*. Resources listed in or formally determined to be eligible for the California Register.
  - *Category A.2*. Resources listed in adopted local registers, or properties that appear eligible, or may become eligible, for the California Register.
- <u>*Category B*</u>. Properties requiring further consultation and review.
- <u>*Category C*</u>. Properties determined not to be historical resources, or properties for which the city has no information indicating that the property is a historical resource.

Planning Department Citywide Survey (1976)

Between 1974 and 1976, the San Francisco Planning Department conducted a citywide inventory of the city's approximately 170,000 structures to determine their architectural importance. The physical appearance of both contemporary and older buildings was surveyed, but historical associations were not included in the study. An advisory review committee of architects and architectural historians determined that 10,000 of these buildings were eligible for inclusion in the survey based on various factors such as architectural design, urban design context, and overall environmental significance. These buildings represent roughly 10 percent of the city's entire building stock. Buildings included in the survey are rated from a low of 0 (least significant) to a high of 5 (most significant).

1976 Survey Properties in the WSIP Study Area. There are no WSIP facilities rated in the 1976 survey.

Other Cities and Counties

CEQA guidelines state that a resource does not need to be listed in or determined eligible for listing in the California Register for it to be considered a historical resource for the purposes of compliance under CEQA. Section 15064.5(a)(4) of the CEQA Guidelines provides for a lead agency to identify resources that are of historical significance and to categorize those resources as historical resources. This is usually accomplished with a city or county list of designated historic landmarks. In addition, some local governments identify historical resources to include previously recorded resources that were determined to have some measure of historical significance. Jurisdictions adjacent to the WSIP facility improvement projects, outside of San Francisco, may identify historical resources differently from one another.

Some WSIP projects have the potential to affect properties outside of the SFPUC right-of-way in areas outside of San Francisco. In locations where the study area of a WSIP project extends beyond the water system right-of-way in areas outside of San Francisco, CEQA compliance documentation related to historical resources should identify whether there are buildings, structures, objects, sites, or districts that the adjacent jurisdiction would consider to be historical resources. This effort would include verifying that resources other than SFPUC water system resources are neither local historical landmarks nor have been identified in some manner as potential historical resources. In addition to evaluating resources under National Register and California Register criteria, it may also be appropriate for WSIP project-level analyses to evaluate buildings, structures, objects, sites, and/or districts situated outside of the SFPUC right-of-way, in areas outside of San Francisco, under the historic landmarks and historical resources criteria of those adjacent jurisdictions.

4.7.3 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to cultural resources, but generally considers that implementation of the proposed program would have a significant impact on cultural resources if it were to:

- Cause a substantial adverse change in the significance of a historical resource as defined in CEQA Guidelines Section 15064.5, including those resources listed in Article 10 or Article 11 of the San Francisco Planning Code (Evaluated in this section)
- Cause a substantial adverse change in the significance of a unique archaeological resource pursuant to Section 15064.5 (Evaluated in this section)
- Directly or indirectly destroy a unique paleontological resource or site or unique geological feature (Evaluated in this section)
- Disturb any human remains, including those interred outside of formal cemeteries (Evaluated in this section)

Approach to Impact Analysis

The WSIP study area was screened at a programmatic level to determine the potential for WSIP projects to encounter historical resources as well as paleontological and archaeological resources. The evaluation of paleontological impacts (Impact 4.7-1) considered areas with known fossil localities and fossil-bearing geologic units. The evaluation of archaeological sensitivity (Impact 4.7-2) focused on areas favorable to human settlement.

The WSIP has the potential to cause substantial adverse changes in the historical significance of historical resources, as defined in CEQA Guidelines Section 15046.5. An analysis to assess whether the program would cause a substantial adverse change is only required for those resources that are or should be considered historical resources for the purposes of CEQA. Historical resources that could be affected by the WSIP include both individual resources and historic districts. There are three categories of impacts on historical resources, as follows:

- Impacts on a historic district or a contributor to a historic district (Impact 4.7-3)
- Impacts on individual resources that are part of the water system (Impact 4.7-4)
- Impacts on individual resources located adjacent to a WSIP facility improvement project (Impact 4.7-5)

These resources are assessed in this PEIR at a programmatic level. This review will be further refined, based on site-specific information, during separate project-level CEQA review of individual WSIP projects. The following text provides guidance in addressing the identification of historical resources that could be affected by the WSIP. This introduction is followed by a discussion of impacts on known or potential cultural resources, organized by WSIP region.

Table 4.7-1 lists potential impacts of the WSIP on paleontological, archaeological, and historical resources, divided into the three categories. Further identification of these resources will occur as part of the project-level analysis for individual WSIP projects. These project-level analyses will require identification of an appropriate study area and identification of known and potential historical resources that could be affected by the WSIP projects. Potential impacts could include direct, indirect, and cumulative impacts. In urban areas, it may be appropriate for the study area to include parcels or properties that are adjacent to a proposed facility improvement project. In rural areas, it would not likely be necessary for the study area to encompass entire large parcels if the WSIP project would only affect a portion of that property. Following standard cultural resources practices, which allow for time between environmental review and actual construction, resources that are more than 45 years old within the study area of a WSIP project will be considered part of the survey population of potential historical resources.[32] The inventory and evaluation process for project-level analyses will include the following tasks:

- Further refine the historical context(s) for the resources in the project study area
- Evaluate resources under National Register, California Register, CCSF historic landmarks, and other local landmarks criteria (if appropriate)
- Identify appropriate potential historical periods of significance for resources in a study area
- Identify character-defining features of individual properties and historic districts that should be considered historical resources for the purposes of CEQA compliance

Analysis regarding the potential impacts of a project on historical resources and the identification of mitigation measures to reduce the impacts depend on the identification of an appropriate period of significance, along with identification of the character-defining features that help convey the significance of the individual historical resources or historic districts. An appropriate historical context and period of significance for resources will be determined during the project-level CEQA analyses, based on an understanding of the history and importance of the components of the water-delivery system. This programmatic analysis lays the foundation for these project-level analyses.

Impact Summary by Region

Table 4.7-1 provides a summary of the cultural resources impacts associated with implementation of the WSIP.

[32] The California Office of Historic Preservation's guidelines for project review and planning call for the identification and evaluation of resources more than 45 years old to account for the passage of time between the period of project review and project completion. See Office of Historic Preservation, "Instructions for Recording Historical Resources," March 1995, 2.

TABLE 4.7-1
POTENTIAL IMPACTS AND SIGNIFICANCE – CULTURAL RESOURCES

Projects	Project Number	Impact 4.7-1: Impacts on paleontological resources	Impact 4.7-2: Impacts on archaeological resources	Impact 4.7-3: Impacts on historical significance of a historic district or a contributor to a historic district	Impact 4.7-4: Impacts on the historical significance of individual facilities resulting from demolition or alteration	Impact 4.7-5: Impacts on adjacent historic architectural resources

LS = Less than Significant impact, no mitigation required
PSM= Potentially Significant impact, can be mitigated to less than significant
PSU = Potentially Significant Unavoidable impact
SU = Significant Unavoidable impact
N/A = Not Applicable

Paleontological Resources

Impact 4.7-1: Impacts on paleontological resources.

This paleontological analysis identifies the potential to encounter paleontological resources (i.e., plant, animal, or invertebrate fossils or microfossils) in each WSIP region based on the following factors: the number of known fossil localities, the geologic formations (units) where these fossils occur, and the presence of fossil-bearing geologic units relative to WSIP facility locations. This analysis was conducted using local, available paleontology information provided through the University of California Museum of Paleontology Collections Database. The geological setting of the known fossil localities was determined using the geological map of the San Francisco–San Jose quadrangle prepared by the California Geological Survey (Wagner et al., 1991). By applying the fossil locality data and geological information from these sources, the distribution and abundance of fossil localities within fossil-bearing units in each WSIP region were determined. Based on this information, the paleontological sensitivity (or potential for discovery of paleontological resources during implementation) was determined for each WSIP project. The determination of whether a certain project has the potential to encounter a paleontological resource was based on the following criteria:

- The project is located in an area underlain by geologic materials known to contain fossils or microfossils of animals, invertebrates, or plants. In the WSIP study area, these geologic units are primarily marine sedimentary deposits ranging in age from 65 million years old (Paleocene epoch) to 10,000 years old (Pleistocene epoch).
- A fossil locality is within the project site, or the project site is in proximity to other fossil localities within the same or similar geologic unit.

These criteria were applied to the WSIP project information provided in Chapter 3, Program Description, and Appendix C to determine whether the WSIP projects would have the potential to disturb or destroy a paleontological resource and thus cause a significant impact. If the proposed project would be located in a fossil-bearing geologic unit or there are several nearby or regional fossil localities in the same geologic unit, the potential to encounter paleontological resources would be high. If the proposed project would be located in a geologic formation that is not typically fossil-bearing and no or very few recorded fossil localities exist in the geologic material, there would be a low potential to encounter paleontological resources. **Figure 4.7-1** generally indicates areas of paleontological sensitivity in the vicinity of WSIP facilities.

Paleontological resources could be disturbed during project excavation, deep grading, and tunneling. Destruction of a paleontological resource during construction of any of the WSIP projects would be considered a significant impact. **Table 4.7-2** indicates the geologic formation in which each WSIP project is located, whether fossils have been identified in the project area, the potential to encounter paleontological resources, and a determination of impact significance. As shown in this table, there is a high potential for the occurrence of paleontological resources in all five of the regions within the WSIP study area. Potential project impacts are discussed by region below. SFPUC Construction Measure #9 (cultural resources) requires that a qualified paleontologist or state-registered geologist conduct a preconstruction screening for paleontological resources, that impacts on identified cultural resources be avoided to the extent feasible, and that soil-disturbing construction work be immediately suspended if there is any indication of a paleontological resource. Table 4.7-2 describes the WSIP projects as having either a high potential or a low potential for impacts on paleontological resources. The preconstruction screenings required under Construction Measure #9 would analyze site-specific information, which would either confirm these program-level determinations or provide a basis to revise them.

For projects with a low potential to encounter paleontological resources, the implementation of SFPUC Construction Measure #9 (cultural resources) would ensure that impacts are less than significant.

For projects that would require subsurface disturbance in areas with a high potential to encounter paleontological resources, the impact would be potentially significant and would require additional mitigation to protect the resources. If a paleontological resource is encountered, it would be necessary to suspend work and have the site inspected by a qualified paleontologist (Measure 4.7-1), which would reduce this impact to a less-than-significant level.

San Joaquin Region

Impact 4.7-1: Impacts on paleontological resources		
Advanced Disinfection	SJ-1	PSM
Lawrence Livermore	SJ-2	LS
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	PSM

In the San Joaquin Region, the Advanced Disinfection (SJ-1), SJPL System (SJ-3), SJPL Rehabilitation (SJ-4), and Tesla Portal Disinfection (SJ-5) projects would have the highest potential for encountering and disturbing paleontological resources because they overlie fossil-bearing marine sedimentary rocks and are located in areas that have several existing recorded fossil localities. The Advanced Disinfection and Tesla Portal Disinfection project sites at Tesla Portal are underlain by geologic units that are known to contain fossil remains (in this case, possibly the San Pablo Group or other closely related fossil-bearing sandstone or siltstone deposits). A fossil locality has been identified (Locality No. 3315) at or very near the Advanced Disinfection project site. The proposed SJPL System and SJPL Rehabilitation projects would require excavation into the Mehrten Formation, a geologic unit that is known to contain fossil remains. Given the high likelihood that these projects could affect paleontological resources, this impact would be *potentially significant*, but could be reduced to a less-than-significant level by suspending work if a paleontological resource is identified and having the site inspected by a qualified paleontologist (Measure 4.7-1).

The proposed Lawrence Livermore project (SJ-2) is located in an area underlain by the Franciscan Complex, and fossil remains are not likely present. With implementation of SFPUC Construction Measure #9 (cultural resources), which includes a preconstruction paleontological screening and suspension of construction work if a paleontological resource is identified, impacts from the Lawrence Livermore project would be *less than significant*.

PN-5	Pulgas Balancing Reservoir Rehabilitation	Yes, marine deposits, possible Butano Formation and other marine sandstones and shale	Yes	High	PSM
San Francisco Region					
SF-1	San Andreas Pipeline No.3 Installation	Yes, marine sedimentary rocks	Yes	High	PSM
SF-2	Groundwater Projects	Yes, marine sedimentary rocks	Yes	High	PSM
SF-3	Recycled Water Projects	Yes, possible marine deposits	Yes	High	PSM

[a] Based on the information provided in Figure 4.7-1.
[b] Based on the information provided in Appendix C, Table C.4, all WSIP projects would either involve some level of excavation, or excavation is yet to be determined. For this analysis, a conservative assessment is made that excavation will occur and have an impact on paleontological resources.

Sunol Valley Region

Impact 4.7-1: Impacts on paleontological resources		
Alameda Creek Fishery	SV-1	PSM
Calaveras Dam	SV-2	PSM
40-mgd Treated Water	SV-3	PSM
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	PSM
SABUP	SV-6	PSM

Projects in the Sunol Valley Region would be located, for the most part, in an area underlain by marine sedimentary rocks, including the Panoche Formation, Monterey Formation, and other fossil-bearing, marine and non-marine sandstone, siltstone, or gravel deposits. Fossil localities have been identified in the Sunol Valley and surrounding area (UCMP, 2006).

Construction and excavation required for the Alameda Creek Fishery project (SV-1) could encounter paleontological resources in the Sunol Valley, an area where geologic conditions and recorded localities indicate the likely presence of fossils. Considering the amount of excavation and grading for the Calaveras Dam project (SV-2), and the discovery of a nearby fossil locality (Locality No. 3937), the potential to encounter paleontological resources during this project is considered high. The 40-mgd Treated Water (SV-3) and Treated Water Reservoirs (SV-5) sites are underlain by the sedimentary, fossil-bearing Monterey and Panoche Formations, so the potential for encountering paleontological resources is also considered high. The New Irvington Tunnel project (SV-4) would likely bore through sedimentary geologic formations, including the Panoche Formation, that contain fossil remains; therefore, this project is considered to have a high potential for encountering and disturbing paleontological resources. Construction and excavation work associated with the SABUP project (SV-6) would take place in marine sedimentary rocks at the southwest end of San Antonio Reservoir and could encounter paleontological resources.

Given the high likelihood that the projects in this region could affect paleontological resources, this impact would be *potentially significant*, but could be reduced to a less-than-significant level by suspending work if a paleontological resource is identified and having the site inspected by a qualified paleontologist (Measure 4.7-1).

Bay Division Region

Impact 4.7-1: Impacts on paleontological resources		
BDPL Reliability Upgrade	BD-1	LS
BDPL 3 and 4 Crossovers	BD-2	LS
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSM

Two WSIP projects in the Bay Division Region (BDPL Reliability Upgrade, BD-1, and BDPL 3 and 4 Crossovers, BD-2) would be located in areas of the Santa Clara Valley that are underlain by young alluvial deposits. The deposits include unconsolidated basin deposits containing geologically young gravel, sand, silts, and clays as well as intertidal deposits such as soft mud and peat. There is a low likelihood that notable paleontological resources would be encountered during excavation and grading for these projects because of the relatively young geologic age of these deposits. In Santa Clara County, the majority of fossil localities are in geologically older sandstones, siltstones, and shale found in the uplands surrounding the Santa Clara Valley, a considerable distance from these WSIP projects.

With implementation of SFPUC Construction Measure #9 (cultural resources), which includes a preconstruction paleontological screening and suspension of construction work if a paleontological resource is identified, potential impacts would be *less than significant* for these two projects.

Due to the relative complexity of the surrounding geology, the third WSIP project in this region, BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3), could be underlain by a fossil-bearing, non-marine formation (either the Santa Clara Formation or Livermore/Irvington Gravels) or a young valley alluvium that would be less likely to contain paleontological resources. Due to the presence of fossil-bearing, non-marine sedimentary deposits, there is a high potential to encounter paleontological resources at this project site. This determination, as with other WSIP projects, would be reevaluated based on site-specific information as part of separate, project-level CEQA review. Given the high likelihood that this project could affect paleontological resources, the impact would be *potentially significant*, but could be reduced to a less-than-significant level by suspending work if a paleontological resource is identified and having the site inspected by a qualified paleontologist (Measure 4.7-1).

Peninsula Region

Impact 4.7-1: Impacts on paleontological resources		
Baden and San Pedro Valve Lots	PN-1	PSM
CS/SA Transmission	PN-2	LS
HTWTP Long-Term	PN-3	PSM
Lower Crystal Springs Dam	PN-4	LS
Pulgas Balancing Reservoir	PN-5	PSM

Paleontological resources could be encountered during construction work for the Baden and San Pedro Valve Lots (PN-1), HTWTP Long-Term (PN-3), and Pulgas Balancing Reservoir (PN-5) projects. These project areas overlie marine sedimentary geologic units that have recorded fossil localities. The HTWTP Long-Term project overlies the Merced Formation, a marine sandstone, siltstone, claystone, and conglomerate deposit that contains numerous invertebrate fossil localities throughout the San Francisco Peninsula. The Pulgas Balancing Reservoir and Baden and San Pedro Valve Lots Improvements projects include construction at the southern end of Crystal Springs Reservoir, in areas underlain by Butano Formation sandstone/Whiskey Hill Formation[32a] and other fossil-bearing marine sandstones and shales. The Butano Formation/Whiskey Hill Formation contains numerous fossil localities throughout San Mateo County (UCMP, 2006). Given the high likelihood that these projects could affect paleontological resources, this impact would be *potentially significant*, but could be reduced to a less-than-significant level by suspending work if a paleontological resource is identified and having the site inspected by a qualified paleontologist (Measure 4.7-1).

[32a] The Whiskey Hill Formation was previously mapped as the Butano sandstone. However, in 1993 the USGS determined that the Butano sandstone was actually composed of two similar sandstones indistinguishable in lithology and age but separated by the San Andreas-Pilarcitos fault system and having different stratigraphic relations to other geologic units. As a result of this determination, the geologic unit in the vicinity of the southern end of Crystal Springs Reservoir is now identified as the Whiskey Hill Formation, but references prepared prior to 1993 (including the University of California Museum of Paleontology Collections Database) refer to the Butano sandstone instead of the Whiskey Hill Formation. For this reason, the formation is referred to as the Butano sandstone/Whiskey Hill Formation in this analysis.

The CS/SA Transmission (PN-2) and Lower Crystal Springs Dam (PN-4) projects would be located in areas underlain by the chaotically mixed Franciscan Complex rocks. There are few, if any, recorded fossil localities in this area of the Santa Cruz Mountains. Proposed construction excavation and grading work at these project sites would not likely encounter paleontological resources. With implementation of SFPUC Construction Measure #9 (cultural resources), which includes a preconstruction paleontological screening and suspension of construction work if a paleontological resource is identified, potential impacts would be *less than significant* for these two projects.

San Francisco Region

Impact 4.7-1: Impacts on paleontological resources		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	PSM
Recycled Water Projects	SF-3	PSM

All three projects in the San Francisco Region would be located in areas mapped as marine sedimentary deposits, including the Merced and Colma Formations. Several fossil localities have been recorded in the Merced Formation and, to a lesser degree, the Colma Formation. Excavation, grading, and well drilling work in these areas could encounter and disturb paleontological resources, such as invertebrate fossils and microfossils. The SAPL 3 Installation project (SF-1) would involve excavation to remove historic pipes and install pipes within new alignments, which could affect subsurface paleontological resources. Project-level studies would be conducted to evaluate the likelihood of buried sites along the alignment as part of separate, project-level CEQA review. The Groundwater Projects (SF-2) and Recycled Water Projects (SF-3) could also involve excavation. Given the high likelihood that these projects could affect paleontological resources, the impacts would be *potentially significant*, but could be reduced to a less-than-significant level by suspending work if a paleontological resource is identified and having the site inspected by a qualified paleontologist (Measure 4.7-1).

Archaeological Resources

Impact 4.7-2: Impacts on unknown and known prehistoric and historic archaeological resources.

This analysis provides a programmatic assessment of potential impacts on important archaeological resources that could result from the WSIP projects. Due to the geographic scale of the WSIP study area and the wide range of actions that fall within the scope of the WSIP, impacts on specific archaeological resources at each project site are not addressed in this PEIR, but would be assessed as part of separate, project-level CEQA review for each WSIP project. During these project-level reviews, cultural resource sites that have been previously identified and recorded would be reevaluated in accordance with Section 15064.5(a)(2)(3) of the CEQA Guidelines, if appropriate, using the criteria outlined in PRC Section 5024.1. Project-level reviews would also include communication with the Native American Heritage Commission. (This work must be performed on a project rather than program level, since the commission requires specific location information to effectively search its database of sacred lands.)

To identify areas within the WSIP study area where archaeological resources might be found, a predictive model was developed using a geographic information system (GIS). The purpose of a predictive model is to project known patterns and relationships into unknown areas. In the case of archaeological predictive modeling, the primary assumption is that archaeological sites tend to be found in areas favorable to human settlement. Although the focus of this model is to predict prehistoric settlements, the model might also be useful in studying younger historic resources, because areas favorable to settlement in the prehistoric era are likely to have continued as such during the historic period.

Given the size of the WSIP study area and the limitations on available datasets, only two dominate variables were considered for this model: distance-cost to water and slope percentage. In general, this model assumes that prehistoric people settled fairly close to water, as described previously under “Archaeological / Prehistoric-Period Setting,” and tended to live on relatively level ground. Other datasets were not useful as screening tools for determining archaeological sensitivity on a regional scale. For example, soil type was not considered due to the wide variability of soils in the study area. Consequently, the model is highly conservative in predicting whether sites would likely be located within a given geographic area. Figure 4.7-1 generally indicates the archaeological sensitivity of areas in the vicinity of WSIP facilities.

After areas of potential archaeological sensitivity were identified, the potential impacts from projects were evaluated. In general, projects that entail minor surface disturbance would likely result in less-than-significant impacts on archaeological resources. Projects on sites that are already surfaced, drained, or otherwise modified from native conditions also have a lower potential to affect archaeological resources. Projects that require the movement of large quantities of sediment would have the potential to cause more significant impacts. Any physical disturbance of significant historic and prehistoric archaeological resources could result in the permanent loss of scientific information that could contribute to our understanding of the past.

Potential impacts on archaeological resources are generally described below for the types of facilities and facility projects that would be implemented under the WSIP. Following this overview is a discussion of each WSIP project by region.

Pipelines. The standard pipeline installation method proposed for the WSIP projects is the open-cut trench method. With this method, the construction area would extend for the length of the pipeline and would have a width dependent on the size of the pipe. In archaeologically sensitive areas where known site locations would be directly affected, “trenchless” construction techniques such as jack-and-bore or microtunneling could be used to minimize impacts. Where pipeline installation or replacement is not required, sliplining might be possible. For trenchless pipeline construction and sliplining, vehicle access and a work area would be required for each pit or entry point. Some land would be temporarily used for construction or staging areas, while a small amount would be permanently committed to accessways, valves, and other control structures. In some cases, the disturbance of a surface area for staging activities could adversely affect archaeological deposits at the surface.

Tunnels. Impacts on archaeological resources could occur at portals and shaft openings. The construction area at the entry portal would be the largest, as it must accommodate the portal/shaft entry, vehicles, spoils, equipment, and materials storage. Construction areas at exit portals and shaft openings would require vehicle access and a smaller work area. A portion of the work area at both portals and shafts would be permanently committed to access, control, and maintenance structures, which could adversely affect archaeological resources if they were present within these project areas.

Valves, Valve Lots, and Crossovers. Valves, valve lots, and crossovers are located along existing pipelines and already have developed vehicular access. Projects sited in existing maintenance areas that are paved and graded are not likely to encounter intact, significant archaeological deposits. Moreover, these areas are less conducive to archaeological survey because the native surface has been modified or is obscured by concrete or asphalt. New crossover facilities must be sited near creeks so that water can be discharged into the watercourse during regular maintenance or emergency situations. Proximity to permanent or ephemeral water sources increases the probability that archaeological resources are present.

Pump Stations. New pump stations that would replace existing pump stations (on sites that are surfaced, drained, and maintained free of vegetation) would not likely affect archaeological resources. The construction of new stations on previously undeveloped, native topography could result in adverse effects on archaeological resources.

Treatment Facilities. WSIP treatment facility projects in developed areas (on sites that are surfaced and graded) would not likely affect intact, significant archaeological resources. If new buildings or facilities are constructed in previously undisturbed areas, the potential to encounter intact archaeological deposits is greater. If pipelines are required to connect treatment facilities to the rest of the Hetch Hetchy system, impacts on archaeological resources could result.

Storage Facilities. WSIP storage facility projects consist of the construction or improvement of storage reservoirs and dams. Improvements to below-grade storage reservoirs would require extensive grading and structural work, and it could be necessary to haul material offsite for disposal. Construction activity in natural topography could result in impacts on archaeological resources. Dam improvements would involve extensive earthmoving activities around the dam in addition to the development of borrow areas, disposal areas, and access roads. These project activities could cause adverse impacts on archaeological resources.

Table 4.7-3 indicates the potential for archaeological resources to be present at the WSIP project sites based on the distance to water and slope of the sites; each project site was evaluated as having a low, low-to-moderate, moderate, or high potential to affect known or unknown archaeological resources. Impacts from small, low-intensity, non-ground-disturbing project actions proposed in heavily disturbed settings are considered less than significant. Major construction operations that require substantial excavation pose a greater risk of impact on archaeological resources and would result in potentially significant impacts if they occur in areas of moderate to high potential for archaeological resources. SFPUC Construction Measure #9 (cultural resources) would require a qualified archaeologist to perform a preconstruction screening of each WSIP project site and its vicinity to determine whether archaeological resources could be affected by construction activities and to ensure that effects on cultural resources are avoided to the extent feasible. This measure also requires that construction be halted if an archaeological resource is discovered and, in the event that further investigation is necessary, would ensure that the SFPUC complies with all requirements for the investigation, analysis, and protection of cultural resources.

TABLE 4.7-3
POTENTIAL FOR ARCHAEOLOGICAL IMPACTS

Project No.	Project Name	Area of Archaeological Sensitivity?[a]	Potential for Impacts on Archaeological Resources?[b]	Impact Significance
SJ-1	Advanced Disinfection	Moderate	Yes	PSM
SJ-2	Lawrence Livermore Supply Improvements	Moderate	Yes	PSM
SJ-3	San Joaquin Pipeline System	Low to Moderate	Yes	PSM
SJ-4	Rehabilitation of Existing San Joaquin Pipelines	High	Yes	PSM
SJ-5	Tesla Portal Disinfection Station	Moderate	Yes	PSM
SV-1	Alameda Creek Fishery Enhancement	High	Yes	PSM
SV-2	Calaveras Dam Replacement	High	Yes	PSM
SV-3	Additional 40-mgd Treated Water Supply	Moderate to High	Yes	PSM
SV-4	New Irvington Tunnel	Low to Moderate	Yes	PSM
SV-5	SVWTP – Treated Water Reservoirs	Moderate to High	Yes	PSM
SV-6	San Antonio Backup Pipeline	High	Yes	PSM
BD-1	Bay Division Pipeline Reliability Upgrade	High	Yes	PSM
BD-2	BDPL Nos. 3 and 4 Crossovers	Low to Moderate	Yes	PSM
BD-3	Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault	Moderate	Yes	PSM
PN-1	Baden and San Pedro Valve Lots Improvements	Moderate	Yes	PSM
PN-2	Crystal Springs/San Andreas Transmission Upgrade	Moderate	Yes	PSM
PN-3	HTWTP Long-Term Improvements	Low to Moderate	Yes	PSM
PN-4	Lower Crystal Springs Dam Improvements	High	Yes	PSM
PN-5	Pulgas Balancing Reservoir Rehabilitation	High	Yes	PSM
SF-1	San Andreas Pipeline No. 3 Installation	Moderate	Yes	PSM
SF-2	Groundwater Projects	Low to Moderate	Yes	PSM
SF-3	Recycled Water Projects	Low to Moderate	Yes	PSM

[a] Based on the information provided in Figure 4.7-1.
[b] Based on the information provided in Appendix C, Table C.4, all WSIP projects would either involve some level of excavation, or excavation is yet to be determined. For this analysis, a conservative assessment is made that excavation will occur and have an impact on archaeological resources.

If any WSIP projects were located in areas with a low potential to encounter archaeological resources, implementation of SFPUC Construction Measure #9 (cultural resources) would ensure that impacts are less than significant. However, in this program-level evaluation, it does not appear that any of the WSIP projects would be located in areas of low archaeological sensitivity.

Table 4.7-3 identifies the WSIP projects as having a low-to-moderate, moderate, or high potential for archaeological sensitivity. The preconstruction screenings under Construction Measure #9 would analyze site-specific information, which would either confirm these program-level determinations or provide a basis to revise them.

Because projects in areas of low-to-moderate, moderate, or high archaeological sensitivity would have an increased likelihood to encounter archaeological resources during soil-disturbing activities, impacts on archaeological resources would be potentially significant and would require additional mitigation to protect these resources. In such cases, implementation of archaeological testing, monitoring, and treatment of human remains (Measure 4.7-2a) and accidental discovery measures (Measure 4.7-2b) would reduce impacts from the WSIP projects to a less-than-significant level.

San Joaquin Region

Impact 4.7-2: Impacts on unknown and known prehistoric and historic archaeological resources		
Advanced Disinfection	SJ-1	PSM
Lawrence Livermore	SJ-2	PSM
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	PSM

All five WSIP projects in this region would have the potential to adversely affect archaeological resources.

The SJPL System project (SJ-3) would install approximately 16 to 22 miles of new pipeline and construct two crossovers, while the SJPL Rehabilitation project (SJ-4) would rehabilitate the existing pipelines at discrete locations. These projects would be located in areas of low-to-moderate archaeological sensitivity. Some segments of both projects would be conducted in the vicinity of the San Joaquin River, an attractive location for prehistoric settlement and thus of greater sensitivity for archaeological resources. The pipeline construction area for both projects would be partially located in previously disturbed areas, but because the work area must be located to the side of existing pipelines, it could be partially located in undisturbed parts of the right-of-way. The SJPL System project would entail a greater degree of excavation—the primary construction activity that causes impacts on archaeological resources—than the SJPL Rehabilitation project.

The Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) projects would be located in the vicinity of Tesla Portal within largely developed areas of moderate archaeological sensitivity. The Lawrence Livermore project (SJ-2), which would also be located in an area of moderate archaeological sensitivity, could affect archaeological resources at the facility sites or along access roads if they required improvements. However, potential impacts associated with these three projects would be minimal due to the small areas involved (approximately two acres at the Tesla Portal facility for the Advanced Disinfection and Tesla Portal Disinfection projects).

All five projects in this region would be subject to separate, project-level CEQA review, which would evaluate potential impacts in more detail and determine appropriate mitigation measures based on the presence and type of archaeological resources identified. Given the likelihood that these projects could affect archaeological resources, impacts would be *potentially significant*, but could be reduced to a less-than-significant level with implementation of archaeological testing, monitoring, and treatment of human remains (Measure 4.7-2a) and accidental discovery measures (Measure 4.7-2b).

Sunol Valley Region

Impact 4.7-2: Impacts on unknown and known prehistoric and historic archaeological resources		
Alameda Creek Fishery	SV-1	PSM
Calaveras Dam	SV-2	PSM
40-mgd Treated Water	SV-3	PSM
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	PSM
SABUP	SV-6	PSM

All of the projects in this region would have the potential to affect archaeological resources. The Alameda Creek Fishery project (SV-1) would involve the construction of pipelines, pumps, collection wells, control structures, and a water recapture facility. This project would be situated in and near Alameda Creek and thus would have a greater potential to adversely affect archaeological resources.

The Calaveras Dam project (SV-2) would be located in an area of high archaeological sensitivity. The project would affect approximately 660 acres in the dam construction area, including portions of Alameda and Calaveras Creeks downstream from the existing dam, and the excavation of borrow areas could affect archaeological resources. Anecdotal evidence indicates that a number of burial sites were identified during construction of the Calaveras Dam (O'Shaughnessy, 1915), suggesting that the area surrounding the dam may be sensitive for significant archaeological resources. (If human remains are found at this or any WSIP project site, Measure 4.7-2a provides direction for the treatment of human remains and funerary objects.)

The 40-mgd Treated Water project (SV-3) would install approximately 1.5 to 2 miles of new pipeline. These pipelines would be situated on or near the Sunol Valley WTP and would be located primarily in previously disturbed grasslands. Thus, it is unlikely that this project would affect intact, significant archaeological deposits. However, the proposed two-mile pipeline to the Alameda Siphons or Irvington Tunnel as part of this project could affect archaeological resources along several ephemeral streams where there may have been prehistoric use for resource procurement. The archaeological sensitivity of this area is considered to be moderate to high.

The New Irvington Tunnel project (SV-4) could affect archaeological resources at permanent facilities proposed to be located at the new tunnel's portals in the Sunol Valley and Fremont. The project could also affect archaeological resources near Alameda Creek, where two new bridges would be built, and in the surrounding area required for access roads, shafts, control structures, and spoils disposal. The construction footprint at the tunnel's Sunol Valley portal (West Portal) would be located primarily on slopes, which would be less likely to yield archaeological resources; however, because the location of the spoils disposal area has not been designated, an impact assessment cannot be performed at this time. This project is in an area of low-to-moderate archaeological sensitivity.

The Treated Water Reservoirs project (SV-5) would have a construction footprint of approximately 10.5 acres and a pipeline alignment of approximately 0.3 mile. Depending on the location of the construction relative to identified archaeological resources, this project could have an adverse impact on these resources. The project is located in an area of moderate to high archaeological sensitivity.

The SABUP project (SV-6) would closely parallel San Antonio Creek but would not cross the creek itself. An outlet/energy dissipation structure would be located at the east channel of Alameda Creek, which could result in potential impacts on archaeological resources due to the project's proximity to a watercourse. The project is in an area of high archaeological sensitivity.

The projects in the Sunol Valley Region would be subject to separate, project-level CEQA review, which would evaluate potential impacts in more detail and determine appropriate mitigation measures based on the presence and type of archaeological resources identified. Given the likelihood that these projects could affect archaeological resources, the impacts would be *potentially significant*, but could be reduced to a less-than-significant level with implementation of archaeological testing, monitoring, and treatment of human remains (Measure 4.7-2a) and accidental discovery measures (Measure 4.7-2b).

Bay Division Region

Impact 4.7-2: Impacts on unknown and known prehistoric and historic archaeological resources		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	PSM
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSM

All of the projects in this region would have the potential to affect archaeological resources. The BDPL Reliability Upgrade project (BD-1) would install approximately 16 miles of pipeline and 5 miles of tunnel. The pipeline segment would cross several modified creek channels and artificial flood control channels between the Irvington Portal in Fremont and the Newark Valve House. While it appears that this construction activity would occur in previously disturbed areas, it is possible that intact, significant archaeological resources may exist in this area due to the project's proximity to bay and freshwater sources (i.e., in an area of high archaeological sensitivity).

The BDPL 3 and 4 Crossovers project (BD-2) is located in an area of low-to-moderate archaeological sensitivity near creeks, an attractive location for prehistoric settlement.

The BDPL 3 and 4 Seismic Upgrade at Hayward Fault project (BD-3) would provide for the planning, design, and construction of upgraded, seismically resistant sections of the Bay Division Pipelines Nos. 3 and 4 where they cross the Hayward fault. The replacement pipelines would be located between the two new crossover/isolation valves. This project is also in proximity to bay and freshwater sources, in an area of moderate archaeological sensitivity.

All three projects in this region would be subject to separate, project-level CEQA review, which would evaluate potential impacts in more detail and determine appropriate mitigation measures based on the presence and type of archaeological resources identified. Given the likelihood that these projects could affect archaeological resources, impacts would be *potentially significant*, but could be reduced to a less-than-significant level with implementation of archaeological testing, monitoring, and treatment of human remains (Measure 4.7-2a) and accidental discovery measures (Measure 4.7-2b).

Peninsula Region

Impact 4.7-2: Impacts on unknown and known prehistoric and historic archaeological resources		
Baden and San Pedro Valve Lots	PN-1	PSM
CS/SA Transmission	PN-2	PSM
HTWTP Long-Term	PN-3	PSM
Lower Crystal Springs Dam	PN-4	PSM
Pulgas Balancing Reservoir	PN-5	PSM

All of the projects in this region would have the potential to affect archaeological resources. The Lower Crystal Springs Dam project (PN-4) could adversely affect significant archaeological resources near San Mateo Creek if work areas are needed at the base of the dam. The Pulgas Balancing Reservoir project (PN-5) is located near the Pulgas Channel and Laguna Creek, which increases the potential for intact archaeological resources. These projects, both of which would be located in areas of high archaeological sensitivity, would be subject to separate, project-level CEQA review, which would further evaluate potential impacts on archaeological resources found during the cultural resources screening survey.

It is unlikely that the Baden and San Pedro Valve Lots (PN-1), CS/SA Transmission (PN-2), and HTWTP Long-Term (PN-3) projects would adversely affect significant archaeological resources, because the majority of the proposed activities would be conducted within existing facilities that have been previously disturbed, graded, or paved. Extant cultural resources are likely to be obscured or deeply buried beneath the native surface. However, because the Baden and San Pedro Valve Lots and CS/SA Transmission projects would be located in areas of moderate archaeological sensitivity, and the HTWTP Long-Term project would be located in an area of low-to-moderate sensitivity, the potential exists to adversely affect archaeological resources.

Given the likelihood that these projects could affect archaeological resources, the impacts would be *potentially significant*, but could be reduced to a less-than-significant level with implementation of archaeological testing, monitoring, and treatment of human remains (Measure 4.7-2a) and accidental discovery measures (Measure 4.7-2b).

San Francisco Region

Impact 4.7-2: Impacts on unknown and known prehistoric and historic archaeological resources		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	PSM
Recycled Water Projects	SF-3	PSM

All of the projects in this region would have the potential to affect archaeological resources. The SAPL 3 Installation project (SF-1) would remove historic pipes and lay pipes along new alignments, which could affect subsurface archaeological resources. Preliminary investigation indicates that the general area around the alignment was inhabited prehistorically; therefore, the area is considered to be of moderate archaeological sensitivity. Project-level studies would be conducted to evaluate the likelihood of buried cultural sites along the alignment.

The Groundwater Projects (SF-2) and Recycled Water Projects (SF-3) could affect Lake Merced by raising its water level, which could result in impacts on archaeological resources. The projects would be located in areas of low-to-moderate archaeological sensitivity. In addition, the Groundwater Projects would construct new wells and associated facilities, and the Recycled

Water Projects would construct approximately 20 miles of pipeline on five to seven acres. Depending on the amount of increase in the lake's water level and the locations of the new facilities, these projects could adversely affect archaeological resources.

The projects in this region would be subject to separate, project-level CEQA review, which would further evaluate potential impacts on archaeological resources found during the cultural resources screening survey. Given the likelihood that these projects could affect archaeological resources, impacts would be *potentially significant*, but could be reduced to a less-than-significant level with implementation of archaeological testing, monitoring, and treatment of human remains (Measure 4.7-2a) and accidental discovery measures (Measure 4.7-2b).

Historic Architectural Resources

As previously stated, this PEIR identifies three categories of potential impacts on historic architectural resources. These categories are as follows:

- Impacts on a historic district or a contributor to a historic district (Impact 4.7-3)
- Impacts on individual resources that are part of the water system (Impact 4.7-4)
- Impacts on individual resources located adjacent to a WSIP facility improvement project (Impact 4.7-5)

As noted above, identification of historical resources that could be affected by the WSIP will also be conducted during project-level CEQA review of the individual facility improvement projects. Assumptions were made for the purposes of this programmatic analysis regarding the potential for historical resources to be located in the study areas of specific WSIP facility improvement projects. The analysis presented in this section assumes that all water system facilities constructed during their period(s) of potential historical significance have retained historic integrity. Although this assumption has not been verified as part of this program-level analysis, it provides a conservative approach to evaluating potential impacts. Again, an appropriate historical context and period of significance for resources will be determined during the project-level CEQA analyses, based on an understanding of the water system's history and importance of the components of the water-delivery system. Table 4.7-1 summarizes the conclusions of this PEIR regarding the potential for WSIP facility improvement projects to affect historical resources. **Table 4.7-4** describes the potential impacts of the WSIP projects on historical resources in the regional water system.

This program-level analysis is based on information presented in Chapter 3, Program Description, and Appendix C, as well as on site visits to some of the SFPUC facilities. The site visits verified whether other buildings, structures, or objects are located at or near proposed WSIP facilities. It should be noted that this analysis is not a comprehensive evaluation of all historical resources in the WSIP study area. Detailed evaluations of historic architectural resources would be conducted as part of separate, project-level CEQA review, where warranted, to further define potential

TABLE 4.7-4
HISTORIC ARCHITECTURAL RESOURCES IMPACT POTENTIAL ON REGIONAL WATER SYSTEM FACILITIES

WSIP Facility Improvement Project	Construction Date of Potentially Affected Facilities	Would the project affect a potential historic district?	Significance determination for impacts on the historical significance of a potential historic district[a]	Would the project demolish or alter the historic fabric or function of a specific existing facility?	Significance determination for impacts on the historical significance of the individual facility[a]
SJ-1: Advanced Disinfection	Tesla Portal: 1928	Yes, the existing Tesla Portal could be a contributor to a potential historic district related to the implementation of John R. Freeman's plan for the development of the Hetch Hetchy system. The existing Tesla Portal would be modified as part of this project, which would result in a potentially significant impact on the potential historic district. This impact could likely be reduced to a less-than-significant level.	PSM	Yes, the existing Tesla Portal would be modified as part of this project. If the portal were considered to be an individual historical resource for the purposes of CEQA compliance, this project would result in a potentially significant impact on the potential historic facility. This impact could likely be reduced to a less-than-significant level.	PSM
SJ-2: Lawrence Livermore Supply Improvements	N/A (new construction)	No, new facilities would be added near non-historic facilities.	N/A	No, new facilities would be associated with non-historic facilities.	N/A
SJ-3: San Joaquin Pipeline System	Pipeline No. 1: 1932 Pipeline No. 2: 1953[b] Pipeline No. 3: 1968 Oakdale Portal: 1928	Yes, the proposed work on the existing pipelines and the modification of the existing Oakdale Portal could have a potentially significant impact on a potential historic district associated with the implementation of John R. Freeman's plan for the development of the Hetch Hetchy system. However, because the project would add new portions of pipelines and crossovers, and direct impacts on the existing pipelines and portal would be limited, it is likely that such impacts could be reduced to a less-than-significant level.	PSM	Yes, the existing Oakdale Portal would be modified as part of this project. If the portal were considered to be an individual historical resource for the purposes of CEQA compliance, this project would result in a potentially significant impact on the potential historic facility. This impact could likely be reduced to a less-than-significant level.	PSM
SJ-4: Rehabilitation of Existing San Joaquin Pipelines	Pipeline No. 1: 1932 Pipeline No. 2: 1953[b] Pipeline No. 3: 1968 Tesla Portal: 1928	Yes, the proposed work on the existing pipelines could have a potentially significant impact on a potential historic district associated with the implementation of John R. Freeman's plan for the development of the Hetch Hetchy system. However, because direct impacts on the existing pipelines would be limited, it is likely that such impacts could be reduced to a less-than-significant level.	PSM	Yes. Although the pipeline system would retain its historical function, the pipelines themselves could be altered enough to cause a substantial adverse change in their historical significance, if they were considered eligible. This would be a potentially significant impact. It is expected that the impact could be reduced to a less-than-significant level with mitigation.	PSM
SJ-5: Tesla Portal Disinfection Station	Approximately 1928	No, would replace and upgrade an existing non-historic disinfection facility.	N/A	No, would replace and upgrade an existing non-historic facility.	N/A

TABLE 4.7-4 (Continued)
HISTORICAL RESOURCES IMPACT POTENTIAL FOR WSIP PROJECTS

WSIP Facility Improvement Project	Construction Date of Potentially Affected Facilities	Would the project affect a potential historic district?	Significance determination for impacts on the historical significance of a potential historic district[a]	Would the project demolish or alter the historic fabric or function of a specific existing facility?	Significance determination for impacts on the historical significance of the individual facility[a]
SV-1: Alameda Creek Fishery Enhancement	N/A (new construction or nonstructural water recovery alternatives)	No. One alternative would construct a new water recapture facility near non-historic facilities. Other alternatives would not include construction.	N/A	No, new facility.	N/A
SV-2: Calaveras Dam Replacement	1925	Yes. Because the project requires demolition of Calaveras Dam and its associated structures, the project would have a potentially significant unavoidable impact on a historic district (if one exists) that may include Calaveras Dam and its associated structures.	PSU	Yes. Because the project requires demolition of Calaveras Dam and its associated structures, the project would have a potentially significant unavoidable impact on the complex as a historical resource.	PSU
SV-3: Additional 40-mgd Treated Water Supply	Sunol Valley Water Treatment Plant: 1966, upgraded 1976, 1990, 2001–2003	No, would upgrade an existing non-historic facility.	N/A	No, would upgrade an existing non-historic facility.	N/A
SV-4: New Irvington Tunnel	Irvington Tunnel: 1934 Irvington Portal: 1934 Alameda West Portal: 1934 Coast Range Tunnel: 1934	Yes, the existing Irvington Tunnel and the Irvington and Alameda West Portals could be contributors to a potential historic district related to the implementation of John R. Freeman's plan for the development of the Hetch Hetchy system. Because the existing Irvington Tunnel and Alameda West Portal would continue as originally designed, and the project would create a new component of the system (a new, redundant tunnel) rather than eliminate the existing tunnel, the impact on such a potential historic district would be less than significant. However, the existing Irvington Portal would be demolished as part of this project, which would result in a potentially significant impact on the potential historic district. This impact could likely be reduced to a less-than-significant level.	PSM	Yes, the project would demolish the unique spherical Irvington Portal (in Fremont) that was built in the 1930s. Since retaining the portal is not feasible due to safety concerns, the impact on the historic facility would be potentially significant and unavoidable, if the portal were determined to be a historical resource for the purposes of CEQA compliance.	PSU
SV-5: SVWTP – Treated Water Reservoirs	1966, upgraded 1976, 1990, 2001–2003	No, would upgrade an existing non-historic facility and construct new treated water reservoirs.	N/A	No, would upgrade an existing non-historic facility.	N/A

TABLE 4.7-4 (Continued)
HISTORICAL RESOURCES IMPACT POTENTIAL FOR WSIP PROJECTS

WSIP Facility Improvement Project	Construction Date of Potentially Affected Facilities	Would the project affect a potential historic district?	Significance determination for impacts on the historical significance of a potential historic district[a]	Would the project demolish or alter the historic fabric or function of a specific existing facility?	Significance determination for impacts on the historical significance of the individual facility[a]
SV-6: San Antonio Backup Pipeline	Alameda East Portal Vent Overflow Pipeline: 1934 Alameda East Portal: 1934 New pipelines to be built from San Antonio Reservoir (1965) to San Antonio Pump Station (1968)	Yes, the existing Alameda East Portal could be a contributor to a potential historic district related to the implementation of John R. Freeman's plan for the development of the Hetch Hetchy system. The existing Alameda East Portal would be modified as part of this project, which would result in a potentially significant impact on the potential historic district. This impact could likely be reduced to a less-than-significant level.	PSM	Yes, the existing Alameda East Portal would be modified as part of this project. If the portal were considered to be an individual historical resource for the purposes of CEQA compliance, this project would result in a potentially significant impact on the potential historic facility. This impact could likely be reduced to a less-than-significant level.	PSM
BD-1: Bay Division Pipeline Reliability Upgrade	Pipeline No. 1: 1925 Pipeline No. 2: 1935–1936 Pipeline No. 3: 1952[b] Pipeline No. 4: 1967–1973	Yes, one or more of the Bay Division Pipelines could be a contributor to a potential historic district related to the implementation of John R. Freeman's plan for the development of the Hetch Hetchy system. This project could have a significant impact on this potential historic district. The nature of the project and the fact that at least portions of the existing pipeline would remain following construction indicate that the impact could be reduced to a less-than-significant level.	PSM	Yes, impacts would be potentially significant if the pipelines were considered to be individual historical resources for the purposes of CEQA compliance. The impact on these resources is expected to be reduced to a less-than-significant level with mitigation.	PSM
BD-2: BDPL Nos. 3 and 4 Crossovers	Pipeline No. 3: 1952[b] Pipeline No. 4: 1967–1973	Yes, one or more of the Bay Division Pipelines could be a contributor to a potential historic district related to the implementation of John R. Freeman's plan for the development of the Hetch Hetchy system. This project could have a significant impact on this potential historic district. The nature of the project and the fact that at least portions of the existing pipeline would remain following construction indicate that the impact could be reduced to a less-than-significant level.	PSM	Yes, impacts would be potentially significant if the pipelines were considered to be individual historical resources for the purposes of CEQA compliance. The impact on these resources is expected to be reduced to a less-than-significant level.	PSM

**TABLE 4.7-4 (Continued)
HISTORICAL RESOURCES IMPACT POTENTIAL FOR WSIP PROJECTS**

WSIP Facility Improvement Project	Construction Date of Potentially Affected Facilities	Would the project affect a potential historic district?	Significance determination for impacts on the historical significance of a potential historic district[a]	Would the project demolish or alter the historic fabric or function of a specific existing facility?	Significance determination for impacts on the historical significance of the individual facility[a]
BD-3: Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault	Pipeline No. 3: 1952[b] Pipeline No. 4: 1967–1973	Yes, one or more of the Bay Division Pipelines could be a contributor to a potential historic district related to the implementation of John R. Freeman's plan for the development of the Hetch Hetchy system. This project could have a significant impact on this potential historic district. The nature of the project and the fact that the existing pipeline would remain following construction indicate that the impacts could be reduced to a less-than-significant level.	PSM	Yes, impacts would be potentially significant if the pipelines were considered to be individual historical resources for the purposes of CEQA compliance. The impact on these resources is expected to be reduced to a less-than-significant level.	PSM
PN-1: Baden and San Pedro Valve Lots Improvements	Non-historic	No, would upgrade existing non-historic facilities.	N/A	No, would upgrade existing non-historic facilities.	N/A
PN-2: Crystal Springs/San Andreas Transmission Upgrade	Upper Crystal Springs Dam: 1877 Lower Crystal Springs Dam: 1890 Crystal Springs Pump Station: 1933 Crystal Springs/San Andreas Pipeline: 1898–1932 San Andreas Reservoir: 1870	Yes, the pipeline and the pump station, and other associated structures that may be located near them, could be contributors to a potential historic district related to all or a portion of the Spring Valley Water Company's development of Crystal Springs Reservoir or San Andreas Reservoir. There could also be a historic district that includes the historical context related to San Francisco's incorporation of this portion of the former Spring Valley Water Company facilities into the municipal system.	PSU	Yes, the pipeline, and other associated structures that may be located near it, could be individually significant and considered to be historical resources for the purposes of CEQA. It is expected that many of the impacts could be reduced to a less-than-significant level, but impacts on the Crystal Springs Pump Station could be potentially significant and unavoidable.	PSU
PN-3: HTWTP Long-Term Improvements	1971, expansions in 1988, 1990	No, would alter and upgrade an existing non-historic facility, but would not affect its function or a nearby potential historic district.	N/A	No, would alter and upgrade an existing non-historic facility.	N/A

TABLE 4.7-4 (Continued)
HISTORICAL RESOURCES IMPACT POTENTIAL FOR WSIP PROJECTS

WSIP Facility Improvement Project	Construction Date of Potentially Affected Facilities	Would the project affect a potential historic district?	Significance determination for impacts on the historical significance of a potential historic district[a]	Would the project demolish or alter the historic fabric or function of a specific existing facility?	Significance determination for impacts on the historical significance of the individual facility[a]
PN-4: Lower Crystal Springs Dam Improvements	1890	Yes, this structure, and other associated structures, could be contributors to a potential historic district related to a portion of the Spring Valley Water Company's development of Crystal Springs Reservoir. Because the project would repair and upgrade portions of the historic dam rather than demolish or replace the dam, the impact could be reduced to a less-than-significant level.	PSM	Yes, could alter the historic fabric of the dam. Detailed project-level review may determine that effects could be mitigated, but until such determination, the impact is considered potentially significant and unavoidable.	PSU
PN-5: Pulgas Balancing Reservoir Rehabilitation	1975	No, would upgrade existing a non-historic facility.	N/A	No, would upgrade existing a non-historic facility.	N/A
SF-1: San Andreas Pipeline No. 3 Installation	Pipeline No. 1: 1870 (rebuilt in 1893 and taken out of service in 1983) Pipeline No. 2: 1927– 928 Pipeline No. 3: approx. 1928	Yes, the pipeline could be a contributor to a potential historic district associated with the development of a portion of the Spring Valley Water Company's system on the Peninsula or the SFPUC municipal water system. This project would remove and permanently decommission portions of the Baden-Merced Pipeline. This impact could be a potentially significant; however, it is expected that such an impact could be reduced to a less-than-significant level because portions of the original pipeline would remain following construction of the project.	PSM	Yes, because portions of the existing Baden-Merced Pipeline would be removed, this impact would be potentially significant if the pipeline were considered to be a historical resource for the purposes of CEQA compliance. The project's impact on these pipelines could be reduced to a less-than-significant level with mitigation.	PSM
SF-2: Groundwater Projects	N/A (new construction)	No, new facilities (including wells) would be added.	N/A	No, new facilities would be added to the system, but final facility locations have not yet been determined.	N/A
SF-3: Recycled Water Projects	N/A (new construction)	No, new facilities would be added.	N/A	No, new facilities would be added to the system, but final facility locations have not yet been determined.	N/A

[a] These are preliminary determinations that would be reviewed during project-level CEQA analysis.
[b] Detailed property evaluations of the facilities conducted during subsequent, project-level CEQA review would determine if these pipelines are historically significant facilities. If the pipelines are found to lack engineering merit or a strong association to historic events or people, they could be determined not historically significant. If so, that determination would not affect the potential historical significance of older pipelines in the same systems.

impacts on the water system and other cultural resources in the WSIP study area and to develop appropriate project-specific mitigation measures based on specific project design.

Implementation of SFPUC Construction Measure #9 (cultural resources) would ensure that a qualified historian conducts a preconstruction screening of each WSIP project site and its vicinity to determine whether historical resources could be affected by construction activities and to ensure that impacts on identified cultural resources are avoided to the extent feasible. This measure requires that soil-disturbing activities be immediately suspended if there is any indication of a cultural resource and, in the event that further investigation is necessary, would ensure that the SFPUC complies with all requirements for the investigation, analysis, and protection of cultural resources.

Impact 4.7-3: Impacts on the historical significance of a historic district or a contributor to a historic district.

As discussed in Section 4.7.2, a historic district is an area that "possesses a significant concentration, linkage or continuity of sites, buildings, structures, or objects, united historically or aesthetically by plan or physical development."[33] This analysis assesses impacts on potentially interrelated groups of facilities and resources, united by historic plan and function, which could be considered discrete historic districts. Historically significant historic districts that retain sufficient historic integrity to convey their significance are considered singular historical resources for the purposes of CEQA compliance and would include contributing and non-contributing elements. The WSIP would have an effect on potential historic districts within the water system if it were to remove or alter individual resources within a district in a manner that would diminish the district's historic integrity, and thus its ability to convey its significance, purpose, or original appearance.

Potential historic districts usually conform with the following standards:

- Resources in the district are physically located in relatively close proximity to one another as a cohesive unit.
- Approximately two-thirds of the resources should be contributors to a potential district in order for that district to be readily supportable.
- Boundaries of the district should encompass but not exceed the extent of the significant resources.
- Districts should not include buffer zones or "donut holes" of low-integrity, non-contributing resources, or empty acreage. (Non-contributing resources surrounded by a majority of contributing resources should be included within the district as non-contributors, or a discontiguous district should be specified when large areas lacking contributing resources intervene.)

[33] National Park Service, "National Register Bulletin #15: How to Apply the National Register Criteria for Evaluation," National Park Service: Washington DC, 1998.

- The majority of the district must retain historic integrity.
- Geographic, topographic, and historic boundaries should be considered when selecting district boundaries.

Historic districts may be identified as subsets of facilities within the regional water system. To qualify as a historic district, these facilities would also have to be united historically or aesthetically. These historic districts may be identified, for example, through common association with a specific and identifiable engineering plan implemented during a specific time in history.

A district could include water system facilities or a combination of system and non-system facilities, depending on the historical context of the resource. Resources within a potential district must be unified by historic plan and must work together to perform a specific function within the water system (acting as a subsystem, for instance). Resources within a potential district must share a historical timeframe that is specific to that district, during which facilities would have been built or modified. Groups of facilities might qualify as historic districts based on a specific aspect of their history, or, most importantly, through a plan of development that was designed and subsequently executed with a specific purpose in mind. Given the concentration of system facilities in the Sunol Valley and Peninsula Regions, there is greater potential for impacts on historic districts in these areas than in the other regions along the system (i.e., the San Joaquin, Bay Division, and San Francisco Regions), but the final determination will be made during project-level evaluation. For instance, the San Andreas Dam complex on the Peninsula, including its earthen dam, associated conveyance structures, and other structures and features, might be an example of a historic district, in which a collection of interrelated facilities represent a historical resource, in addition to the historical significance of some of the individual facilities.

As described in Section 4.7.1, facilities in various portions of the water system were built at different times: the Spring Valley Water Company's earliest facilities in the city were built between 1856 and 1877, the Peninsula facilities between 1861 and 1898, and the Alameda facilities between 1875 and 1925; the essential Hetch Hetchy system was built and became operative between 1914 and 1934. It is possible that there are historic districts with separate and distinct periods of significance within these areas and time periods that were united by plans of development or other direct historical associations. Alternatively, some resources may be individually eligible within their appropriate historical context, as discussed under Impact 4.7-4.

San Joaquin Region

Impact 4.7-3: Impacts on the historical significance of a historic district or a contributor to a historic district		
Advanced Disinfection	SJ-1	PSM
Lawrence Livermore	SJ-2	N/A
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	N/A

The SJPL System project (SJ-3) would add new pipes at the west and east ends of the pipelines and would modify Oakdale Portal. The SJPL Rehabilitation project (SJ-4) would repair or rehabilitate existing pipelines. The Advanced Disinfection project (SJ-1) would modify Tesla Portal. All three of these projects could affect one or more of the San Joaquin Pipelines and would modify the Oakdale and Tesla Portals; these facilities could be contributors to a potential historic district associated with the implementation of John R. Freeman's plan for the development of the Hetch Hetchy system. These three projects could have a *potentially significant* impact on a historic district, but because of the nature of the projects, impacts would be reduced to a less-than-significant level with implementation of Measure 4.7-3, which requires evaluation of historic districts, and Measures 4.7-4a through 4.7-4f, which require historical surveys (Measure 4.7-4d), evaluation of alternatives and materials salvage to the extent feasible (Measure 4.7-4a), documentation of historical resources (Measure 4.7-4b), project design consistent with the Secretary of the Interior's *Standards for the Treatment of Historic Properties* to the extent feasible (Measure 4.7-4c), resource protection during construction (Measure 4.7-4e), and consideration of vibration effects (Measure 4.7-4f).

The Lawrence Livermore project (SJ-2) would construct new facilities, while the Tesla Portal Disinfection project (SJ-5) would replace and upgrade an existing facility that is not from the historic period. Therefore, this impact would *not apply* to these projects.

Sunol Valley Region

Impact 4.7-3: Impacts on the historical significance of a historic district or a contributor to a historic district		
Alameda Creek Fishery	SV-1	N/A
Calaveras Dam	SV-2	PSU
40-mgd Treated Water	SV-3	N/A
New Irvington Tunnel	SV-4	PSM
Treated Water Reservoirs	SV-5	N/A
SABUP	SV-6	PSM

The Calaveras Dam project (SV-2) would replace the earth-fill dam (built in 1925) with a new earth-fill dam to meet the seismic and public safety requirements of the California Department of Water Resources, Division of Safety of Dams (DSOD). As described in Chapter 3, Program Description, the DSOD imposed operating restrictions on Calaveras Dam in 2001 that limit the reservoir to approximately 40 percent of its historical capacity, or 38,100 acre-feet. According to the *Calaveras Dam Replacement Project: Final Conceptual Engineering Report* (URS, 2005), the DSOD imposed this interim operating level to accommodate the SFPUC's water needs, with the understanding that the SFPUC would pursue an aggressive schedule to address the dam's safety issues. Under the project, a replacement dam would be built immediately downstream of the existing dam and would restore Calaveras Reservoir's capacity of 96,850 acre-feet.

The project would demolish the existing dam, including its intake and outlet towers and other related structures. The new reservoir would inundate the original dam's location. During construction of the project, the existing dam would be used as a cofferdam (i.e., a temporary structure to keep water away from the construction site). The existing dam would then be leveled off to an elevation approximately 50 feet below the water level of the refilled reservoir. The material removed from the existing dam would be placed between the original dam and the replacement dam.

The Spring Valley Water Company built Calaveras Dam and its complex of structures between the 1910s and 1940. The project could affect a potential historic district that includes the dam and its structures, which would be likely contributors. This potential historic district would be associated with the construction of Calaveras Dam, which was a distinct planned development that greatly expanded the delivery of water from the Alameda Creek portion of the Spring Valley system.

Unlike the other WSIP projects involving former Spring Valley facilities, the existing dam and all its appurtenant structures would be removed under this project. The Calaveras Dam project (SV-2) would have a *potentially significant unavoidable* impact on a historic district (if one exists) that could include Calaveras Dam and its associated structures. Total demolition of a historical resource, such a historic district or most of the contributors to a historic district, usually cannot be reduced to a less-than-significant level.

One mitigation option, however, would be to identify alternatives that eliminate or reduce the need for demolition (Measure 4.7-4a). A technical memorandum, *Development of Calaveras Dam Replacement Project* (URS, 2005), summarizes an evaluation of project alternatives. The alternatives considered were: remediating or replacing the dam for the same reservoir storage (96,850 acre-feet), remediating or replacing the dam for increased reservoir storage (up to 420,000 acre-feet), and remediating or replacing the dam for the same reservoir storage while retaining an option for future enlargement. The alternatives were evaluated for their environmental impacts, implementability, cost, dam safety approval, as well as operational flexibility, maintainability, and reliability. The alternative chosen as the preferred alternative at that stage of planning was to replace (instead of remediate) the existing dam with a new earth-fill dam to be located downstream of the existing dam and designed with an open-chute spillway. The DSOD wrote the SFPUC in July 2005 expressing its approval of the conceptual design for this alternative. The next stage of planning, to be conducted as part of the separate, project-level CEQA analysis, will further assess the feasibility of this mitigation.

Even with implementation of Measure 4.7-3 and Measures 4.7-4a through 4.7-4f, the Calaveras Dam project's impact on most, or all, of a historic district's resources and character-defining features that would contribute to a potential historic district in this project area would be significant and unavoidable. Impacts on the subsidiary structures associated with the dam, including its intake and outlet towers, could be reduced through implementation of Measures 4.7-4a through 4.7-4f, including consistency with the Secretary of the Interior's *Standards for the Treatment of Historic Properties* and project redesign (Measure 4.7-4c). Despite these mitigation actions, the impacts would remain significant.

The Irvington Tunnel was built in 1934 as a part of the Hetch Hetchy Project. Under the New Irvington Tunnel project (SV-4), a new tunnel would be built parallel to and just south of the existing Irvington Tunnel to convey water from the Hetch Hetchy system and the Sunol Valley WTP to the Bay Area. A new portal would be constructed at the east end adjacent to the existing Alameda West Portal in the Sunol Valley, with connections to the existing and proposed Alameda Siphons. A new portal would also be built at the west end adjacent to the existing Irvington Portal in Fremont, with connections to the existing Bay Division Pipelines as well as to pipelines installed under the BDPL Reliability Upgrade project (BD-1). The existing Irvington Tunnel and the Irvington and Alameda West Portals could be considered contributors to a potential historic district related to the implementation of John R. Freeman's plan for the development of the Hetch Hetchy system. Because use of the existing Irvington Tunnel would continue as originally designed, and the project would create a new component of the system (a new, redundant tunnel) rather than eliminate the existing tunnel, the impact on such a potential historic district would be less than significant. However, the existing Irvington Portal would be demolished as part of this project, which would result in a *potentially significant* impact on the potential historic district; however, because of the nature of the projects, the impact would be reduced to a less-than-significant level with implementation of Measure 4.7-3, which requires evaluation of historic districts, and Measures 4.7-4a and 4.7-4f, which require surveys and documentation of historic resources. The removal of Irvington Portal and the modification of the Alameda West Portal would not likely disqualify a potential Hetch Hetchy historic district from being considered a historical resource for the purposes of CEQA. However, the determination of impact significance would be made during project-level CEQA review of the New Irvington Tunnel project.

The SABUP project (SV-6) would construct three new facilities: the San Antonio Backup Pipeline, the San Antonio Creek Discharge Facilities, and the Alameda East Portal Vent Overflow Pipeline. This project also includes modifications to the existing Alameda East Portal, which was built in 1934. This structure could be a contributor to a potential historic district related to the implementation of John R. Freeman's plan for the development of the Hetch Hetchy system. The SABUP project would have a *potentially significant* impact on a historic district, but because the portal would continue to function, the impact would be reduced to a less-than-significant level with implementation of Measure 4.7-3, which requires evaluation of historic districts, and Measures 4.7-4b and 4.7-4d, which require documentation and surveys of historic resources. In addition, both projects would be carried out in a manner that is consistent with the Secretary of the Interior's *Standards for the Treatment of Historic Properties* (Measure 4.7-4c).

The Alameda Creek Fishery (SV-1), 40-mgd Treated Water (SV-3), and Treated Water Reservoirs (SV-5) projects would not affect historical resources because they would involve construction of new facilities or upgrades to non-historic facilities. Therefore, this impact would *not apply* to these projects.

Bay Division Region

Impact 4.7-3: Impacts on the historical significance of a historic district or a contributor to a historic district		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	PSM
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSM

The Bay Division Pipelines were completed between 1925 and 1952 (1925 for Pipeline No. 1; 1935–1936 for Pipeline No. 2; 1952 for Pipeline No. 3). Under the BDPL Reliability Upgrade project (BD-1), a new Bay Division Pipeline (No. 5) would be built from the Irvington Portal in Fremont to the Pulgas Tunnel near Redwood City. Portions of Pipeline No. 1 would be removed or decommissioned to repair the pipeline. Approximately 1.4 miles of pipeline between the Edgewood and Pulgas Valve Lots would be removed, and aboveground and submarine sections of Bay Division Pipelines Nos. 1 and 2 would be decommissioned. The BDPL 3 and 4 Crossovers project (BD-2) would construct three additional crossover facilities along the Bay Division Pipelines to provide operational flexibility for maintenance and emergencies. The BDPL 3 and 4 Seismic Upgrade at Hayward Fault project (BD-3) would replace portions of the Bay Division Pipelines Nos. 3 and 4 with seismically resistant sections.

One or more of the Bay Division Pipelines could be a contributor to a potential historic district related to the implementation of John R. Freeman's plan for the development of the Hetch Hetchy system. All three projects in this region could have a *potentially significant* impact on this potential historic district. However, because of the nature of the projects, this impact would be reduced to a less-than-significant level with implementation of Measure 4.7-3, which requires evaluation of historic districts, and Measures 4.7-4b and 4.7-4d, which include surveys and documentation of historic resources. In addition, all three projects must be carried out in a manner that is consistent with the Secretary of the Interior's *Standards for the Treatment of Historic Properties* (Measure 4.7-4c). It should be noted that portions of the existing pipelines would remain following construction.

Peninsula Region

Impact 4.7-3: Impacts on the historical significance of a historic district or a contributor to a historic district

Baden and San Pedro Valve Lots	PN-1	N/A
CS/SA Transmission	PN-2	PSU
HTWTP Long-Term	PN-3	N/A
Lower Crystal Springs Dam	PN-4	PSM
Pulgas Balancing Reservoir	PN-5	N/A

The Spring Valley Water Company built Upper Crystal Springs Dam in 1877 and Lower Crystal Springs Dam in 1890. Crystal Springs/San Andreas Pipeline was built between 1898 and 1932 and may include portions built by the Spring Valley Water Company and portions built by the City of San Francisco. The Crystal Springs Pump Station, built in 1933, is also located in this vicinity.

These structures, and other associated structures that may be located near them, could be contributors to a potential historic district. It is unclear at this time to what specific historical context and planned development each of these resources may be associated. There could be a historic district related to all or a portion of the Spring Valley Water Company's development of Crystal Springs Reservoir or San Andreas Reservoir. There could also be a historic district that includes the historical context related to San Francisco's incorporation of this portion of the former Spring Valley facilities into the municipal system.

The CS/SA Transmission project (PN-2) would seismically improve existing facilities, including replacing or refurbishing the existing Crystal Springs Pump Station. Although it has not been determined at this time whether a district in this area exists or whether modification of the Crystal Springs/San Antonio Pipeline and demolition of the Crystal Springs Pump Station would significantly affect the historic integrity of such a potential district, this PEIR conservatively considers this impact on a historic district (if one exists) to be a *potentially significant unavoidable*. Even with protection of historic districts (Measures 4.7-3) and implementation of Measures 4.7-4a through 4.7-4f, which include historical surveys and documentation prior to demolition as well as compliance with the Secretary of the Interior's *Standards for the Treatment of Historic Properties* (Measure 4.7-4c), the CS/SA Transmission project's impact on most, or all, of a historic district's resources and character-defining features that would contribute to a potential historic district in this project area could be significant.

Under the Lower Crystal Spring Dam project (PN-4), the existing dam would be repaired to comply with DSOD requirements, and the dam would continue to function as originally designed. This project could have a *potentially significant* impact on one or more historic districts. One of these historic districts may include the Lower Crystal Springs Dam, which is already listed in the National Register and would be considered an individual historical resource for the purposes of CEQA compliance. It is expected, however, that protection of historic districts (Measure 4.7-3), and implementation of Measures 4.7-4a through 4.7-4f, which include historical surveys, documentation, compliance with the Secretary of the Interior's *Standards for the Treatment of Historic Properties*, and project redesign, could reduce this impact to a less-than-significant level, especially since most of the existing dam would remain following construction.

The other WSIP projects in this region (Baden and San Pedro Valve Lots, PN-1; HTWTP Long-Term, PN-3; and Pulgas Balancing Reservoir, PN-5) would affect non-historic facilities. Therefore, this impact would *not apply* to these projects.

San Francisco Region

Impact 4.7-3: Impacts on the historical significance of a historic district or a contributor to a historic district		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	N/A
Recycled Water Projects	SF-3	N/A

The SAPL 3 Installation project (SF-1) would replace the existing Baden-Merced Pipeline, which was built in the late 1890s, and would construct a new pipeline extension of San Andreas Pipeline No. 3. Portions of the Baden-Merced Pipeline would be removed where its alignment merges with the San Andreas Pipeline No. 3 alignment.

It is unclear, at this time, to which planned development the Baden-Merced Pipeline is associated and to what potential historic district (if any) it could be a contributor. The structure could be a contributor to a potential historic district associated with the development of a portion of the Spring Valley Water Company's system on the Peninsula. The SAPL 3 Installation project (SF-1) would remove and permanently decommission portions of this pipeline, which would constitute a *potentially significant* impact. It is expected, however, that protection of historic districts (Measure 4.7-3), and implementation of Measures 4.7-4a through 4.7-4f, which include historical surveys, documentation, compliance with the Secretary of the Interior's *Standards for the Treatment of Historic Properties*, and project redesign, could reduce this impact to a less-than-significant level, especially since at least portions of the existing pipeline would remain following construction.

The Groundwater Projects (SF-2) and Recycled Water Projects (SF-3) would add new facilities to the system or upgrade existing non-historic facilities. Because these projects would not affect historic components of the regional system, this impact would *not apply* to these projects.

Impact 4.7-4: Impacts on the historical significance of individual facilities resulting from demolition or alteration.

Some of the WSIP projects have the potential to cause a substantial adverse change (i.e. an adverse impact) on the historical significance of individual facilities within the regional water system.

Implementation of the WSIP could result in two types of adverse impacts on the historical significance of individual facilities: demolition or alteration. The demolition or destruction of a facility with historical significance is considered a significant impact under CEQA. Development of alternatives to the project, such as relocating a proposed facility to avoid demolition (Measure 4.7-3), would reduce this significant impact to a less-than-significant level. However, if relocation were not feasible, this impact would likely be significant and unavoidable, even with historical documentation prior to demolition (Measure 4.7-4b).

Alteration of a historical resource includes directly modifying a facility with historical significance or making an alteration that physically connects new elements with a historic facility. Such effects are considered potentially significant, because the historic fabric of the facility could be altered. Implementation of SFPUC Construction Measure #9 (cultural resources evaluation) along with historical documentation (Measure 4.7-4b) and compliance with the Secretary of the Interior's *Standards for the Treatment of Historic Properties* (Measure 4.7-4c) would reduce potential impacts to a less-than-significant level.

Numerous WSIP projects would entail the replacement, repair, or alteration of water conveyance pipelines. Many of these facilities are old enough to be considered potential historical resources under CEQA. To be individually eligible, a pipeline would have to stand on its own merits as a resource that reaches the significance threshold under one or more National Register or California Register criteria. For example, for a pipeline to be considered under Criterion A / Criterion 1, it would have to be related to important events or processes beyond simply providing water to a city; water supply facilities are inherently important to the towns they serve, as are city streets, schools, hospitals, and other infrastructural elements. To avoid an overly broad characterization of water delivery pipelines as important historical resources, they must be demonstrably significant to our history beyond simply delivering water in support of urban growth. All municipal water systems possess this characteristic. Engineering structures and features are infrequently, if ever, found to be significant under Criterion B / Criterion 2. Important historic persons associated with engineering structures and features are usually involved with their design, thus making them significant under Criterion C / Criterion 3, as the "work of a master." Under Criterion C / Criterion 3, a pipeline would need to be significant in the context of municipal water system engineering as an innovative and important example of water conveyance or transfer technology within a distinct period of significance. Such a feature might also be significant as an important work of a master engineer or builder. Criterion D / Criterion 4 is rarely applied, as archival data are usually sufficient to provide information related to historic engineering features.

Historic resources are often aboveground and visible, and alteration of aboveground facilities, if sufficiently extensive, would be potentially significant. However, the SFPUC regional water system includes numerous underground pipelines. The report entitled *Water Conveyance Systems in California* (JRP Historical Consulting Services and Caltrans, 2000) indicates that to retain historic integrity, the "property's essential physical features, important elements that were present during the historic period, must be present and visible." However, for the purposes of this analysis, a conservative assumption has been made that impacts on all pipelines built during the historical period, whether visible or not, are potentially significant. The impact could be reduced to a less-than-significant level through implementation of Measures 4.7-4a through 4.7-4f. More detailed information about the historical significance of the individual facility, its integrity, and compliance with the Secretary of the Interior's *Standards for the Treatment of Historic Properties* would be provided during separate, project-level CEQA review for each of the WSIP projects.

Some projects might alter or indirectly affect a historic facility, but impacts cannot be determined because the design or location of the proposed facility is not yet known. For these projects, implementation of SFPUC Construction Measure #9 (cultural resources), which requires preconstruction screening and further investigation/protection as necessary, is expected to adequately reduce potential impacts to a less-than-significant level.

To summarize, for the purposes of analyzing the potential impacts on the historical significance of individual facilities, a project is considered to have a potentially significant impact if it would demolish or make significant alterations to a presumed historic facility. A project would have a less-than-significant impact if work would be done on a historic facility, but the work would have a minimal effect on the qualities or characteristics that make the resource significant. This impact would not apply to projects that would either construct a new facility or replace or upgrade a non-historic facility.

San Joaquin Region

Impact 4.7-4: Impacts on the historical significance of individual facilities resulting from demolition or alteration		
Advanced Disinfection	SJ-1	PSM
Lawrence Livermore	SJ-2	N/A
SJPL System	SJ-3	PSM
SJPL Rehabilitation	SJ-4	PSM
Tesla Portal Disinfection	SJ-5	N/A

Two of the San Joaquin Pipelines were built during the assumed period of historical significance of the Hetch Hetchy system (1932 for Pipeline No. 1, and 1953 for Pipeline No. 2). If this pipeline system were considered to be eligible for listing in the National Register or California Register, it would be considered a historical resource for the purposes of CEQA.

The SJPL Rehabilitation project (SJ-4) would rehabilitate existing pipelines. Although the pipeline system would retain its historical function, the pipelines themselves could be altered enough to cause a substantial adverse change in their historical significance. This impact would be *potentially significant*, even though some pipeline segments are underground. It is expected, however, that SFPUC Construction Measure #9 (cultural resource screening) along with mitigation measures, such as historical documentation and compliance with the Secretary of the Interior's *Standards for the Treatment of Historic Properties* (Measures 4.7-4a through 4.7-4f), could reduce this impact to a less-than-significant level.

The SJPL System project (SJ-3) would add a new pipeline at the east and west ends of the San Joaquin Pipeline right-of-way, would modify the existing Oakdale Portal, and replace non-historic facilities. This impact would be *potentially significant*. It is expected, however, that SFPUC Construction Measure #9 (cultural resource screening) along with mitigation measures, such as historical documentation and compliance with the Secretary of the Interior's *Standards for the Treatment of Historic Properties* (Measures 4.7-4a through 4.7-4f), could reduce this impact to a less-than-significant level.

The Advanced Disinfection project (SJ-1) would modify the existing Tesla Portal. This impact would be *potentially significant*. It is expected, however, that SFPUC Construction Measure #9 (cultural resource screening) along with mitigation measures, such as historical documentation and compliance with the Secretary of the Interior's *Standards for the Treatment of Historic Properties* (Measures 4.7-4a through 4.7-4f), could reduce this impact to a less-than-significant level.

The Lawrence Livermore project (SJ-2) would construct new facilities, and the Telsa Portal Disinfection project (SJ-5) would replace and upgrade an existing facility that is not historic. Therefore, this impact would *not apply* to these projects.

Sunol Valley Region

Impact 4.7-4: Impacts on the historical significance of individual facilities resulting from demolition or alteration		
Alameda Creek Fishery	SV-1	N/A
Calaveras Dam	SV-2	PSU
40-mgd Treated Water	SV-3	N/A
New Irvington Tunnel	SV-4	PSU
Treated Water Reservoirs	SV-5	N/A
SABUP	SV-6	PSM

Calaveras Dam was built in 1925 and is currently being evaluated for its eligibility for listing in the National Register and California Register. As described under Impact 4.7-3, the Calaveras Dam project (SV-2) would destroy the existing dam and associated structures and replace them with new dam structures downstream of the location of the original dam. This impact on the historic facility would be *potentially significant and unavoidable* if this complex of resources were considered to be a historical resource for the purposes of CEQA compliance. This impact would be unavoidable even with the application of Measures 4.7-4a through 4.7-4f, which include identification of alternatives and/or relocation of historic resources and documentation of historic sites prior to demolition.

Under the New Irvington Tunnel project (SV-4), the existing Irvington Tunnel would continue its historical role and would not be affected in terms of its function; however, this project would demolish the unique spherical Irvington Portal in Fremont and modify the Alameda West Portal. The impact on the Irvington Portal would be *potentially significant and unavoidable* if the Irvington Portal were determined to be eligible for listing in the National Register or California Register and if relocation of the historic portal were not feasible (Measure 4.7-4a). This impact would be potentially significant and unavoidable even with implementation of Measures 4.7-4a through 4.7-4f, which include historical documentation prior to demolition. Impacts on the Alameda West Portal would be *potentially significant*. It is expected, however, that implementation of Measures 4.7-4a through 4.7-4f, which include historical documentation and compliance with the Secretary of the Interior's *Standards for the Treatment of Historic Properties*, could reduce the impact on the Alameda West Portal to a less-than-significant level.

The SABUP project (SV-6) would construct a new pipeline from the existing overflow outlet near Alameda East Portal to the discharge point on Alameda Creek and would modify the Alameda East Portal, which was built in 1934. If the Alameda East Portal were considered to be a historical resource for the purposes of CEQA compliance, this impact would be *potentially significant*. It is expected, however, that implementation of SFPUC Construction Measure #9 (cultural resource screening) along with Measures 4.7-4a through 4.7-4f, which include historical documentation and compliance with the Secretary of the Interior's *Standards for the Treatment of Historic Properties*, could reduce this impact to a less-than-significant level.

The Alameda Creek Fishery (SV-1), 40-mgd Treated Water (SV-3), and Treated Water Reservoirs (SV-5) projects would not affect historical resources because they involve the construction of new facilities. Therefore, this impact would *not apply* to these projects.

All of the WSIP projects in the Sunol Valley are located in the *Alameda Watershed Management Plan* (Alameda WMP) area. The cultural resource policies and actions of the WMP would guide the implementation of these projects. The Alameda WMP's actions for cultural resources are:

1) Conduct appropriate levels of review in conjunction with the review process for proposed plans and projects, prior to operations and maintenance activities as well as construction activities involving surface disturbance and/or excavation to avoid damage to buried cultural resources in the vicinity of known sites and within mapped cultural sensitivity zones. Sensitivity zones generally include valley floors adjacent to water sources, other flat terrain near creeks and springs, and level areas along ridgetops. Guidelines include:

    A) Prior to any excavation activities, request a database check from the watershed GIS operator and the State of California database for any known cultural resources or sensitive areas within the vicinity of proposed exaction activity.

    B) Authorize archival research and field reconnaissance by a certified specialist or archaeologist of any project site and vicinity of proposed surface disturbance and/or excavation.

    C) Consult with the local Native American tribes as required by federal, state, and local requirements when considering subsurface testing and excavation of prehistoric and archaeological sites. All aspects of proposed actions shall be addressed, including the treatment of cultural materials and in particular the removal, study, and reinternment of Native American burials.

    D) Recommend project modifications or alternative sites that would avoid adverse effects to highly sensitive and significant cultural resource sites and features, including developing and implementing mitigation measures in accordance with all applicable state and federal laws.

2) Authorize data recovery by qualified professionals in circumstances where archaeological deposits cannot be preserved through avoidance or protection measures. (Guidelines are described in the watershed management plan.)

3) When considering demolition or alteration of a historic structure, consult with an architectural historian to determine the feasibility and suitability of relocation; although the integrity of setting would be lost, the structure would be preserved.

4) Evaluate and document the significance of cultural resources threatened by demolition or alteration through application of criteria set forth in the Secretary of the Interior's Standards and Guidelines, CEQA Guidelines, and the California Register of Historical Resources. Where applicable, recommend registration of cultural resources deemed to be eligible for the National Register of Historic Places and the California Register of Historical Resources.

5) Employ nondestructive methods when undertaking research activities, to the maximum extent feasible and where practical, to leave the features of sites and structures in place. Data, objects, and specimens recovered from research sites shall be conserved and curated according to legal requirements.

6) Suspend excavation activities in the event that suspected cultural resources are uncovered; consult with a qualified archaeologist regarding the significance, disposition, and treatment of artifacts; and revise, as necessary, excavation plans to avoid and/or minimize damage to known cultural resources.

7) Suspend excavation activities in the event that human remains are discovered, and immediately inform the county coroner. Consult with a qualified archaeologist to determine if the remains are of Native American origin, and if so, contact the California Native American Heritage Commission to identify most likely descendants for instructions regarding the treatment and disposition of human remains and associated grave artifacts.

8) When previously unknown cultural resources are discovered, report new findings to the California Historical Resources Information System using standard descriptive methods.

9) Implement protective measures, where necessary, to eliminate and minimize potentially negative effects of public access on cultural resources. (Guidelines are described in the watershed management plan.)

10) Prior to initiating new construction, consider reuse of existing historic structures for departmental uses. Prior to modifying historic structures, an architectural historian shall be consulted to determine the feasibility and suitability of any modifications.

11) Periodically inspect historic structures for pest damage and use Integrated Pest Management techniques to control pests in historic structures.

12) Periodically monitor known significant cultural resource sites for evidence of disturbance, damage, or vandalism.

Bay Division Region

Impact 4.7-4: Impacts on the historical significance of individual facilities resulting from demolition or alteration		
BDPL Reliability Upgrade	BD-1	PSM
BDPL 3 and 4 Crossovers	BD-2	PSM
BDPL 3 and 4 Seismic Upgrade at Hayward Fault	BD-3	PSM

The Bay Division Pipelines were built between 1925 and 1936 as a part of the Hetch Hetchy Project. Under the BDPL Reliability Upgrade project (BD-1), a buried section of Bay Division Pipeline No. 1 between the Edgewood and Pulgas Valve Lots would be removed (approximately 1.4 miles) and replaced by a new buried pipeline (Pipeline No. 5). Although most of this pipeline is buried, short stretches are visible where it crosses the creek. The longer visible portions of the pipeline, from the Newark Valve House to the Ravenswood Valve House, would be decommissioned but kept in place. These impacts, on both the underground pipeline and the visible pipelines, would be *potentially significant* if the pipelines were considered to be individual historical resources for the purposes of CEQA compliance. With implementation of SFPUC Construction Measure #9 (cultural resources), as well as implementation of Measures 4.7-4a through 4.7-4f, which include historical documentation and compliance with the Secretary of the Interior's *Standards for the Treatment of Historic Properties*, the impact of this project would be reduced to a less-than-significant level.

The BDPL 3 and 4 Crossovers project (BD-2) would construct three additional crossover facilities along the Bay Division Pipelines. The BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3) would remove and replace portions of Pipeline No. 3, which was built in 1952. Impacts from these projects would be *potentially significant* if the pipelines were considered to be individual historical resources for the purposes of CEQA compliance. However, implementation of SFPUC Construction Measure #9 (cultural resources), as well as implementation of Measures 4.7-4a through 4.7-4f, which include historical documentation and compliance with the Secretary of the Interior's *Standards for the Treatment of Historic Properties*, could reduce these impacts to a less-than-significant level.

Peninsula Region

Impact 4.7-4: Impacts on the historical significance of individual facilities resulting from demolition or alteration		
Baden and San Pedro Valve Lots	PN-1	N/A
CS/SA Transmission	PN-2	PSU
HTWTP Long-Term	PN-3	N/A
Lower Crystal Springs Dam	PN-4	PSU
Pulgas Balancing Reservoir	PN-5	N/A

The Lower Crystal Springs Dam project (PN-4) would alter the historic fabric of the dam, which was built in 1890 as part of a separate plan of development by the Spring Valley Water Company. The Lower Crystal Springs Dam was previously determined eligible for listing in the National Register and would be considered a historical resource for the purposes of CEQA. The impact from this project would thus be potentially significant. Depending on the proposed extent of alteration, it is possible that impacts could be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #9 (cultural resources), as well as implementation of Measures 4.7-4a through 4.7-4f, which include historical documentation and compliance with the Secretary of the Interior's *Standards for the Treatment of Historic*

Properties. However, since the extent of the work on the historic dam is not yet known, this impact is conservatively considered to be *potentially significant and unavoidable*.

The Crystal Springs/San Andreas Pipeline was built between 1898 and 1932. The CS/SA Transmission project (PN-2) would upgrade or replace the existing Crystal Springs Pump Station. Approximately 144 feet of aboveground flume would be modified or replaced. Assuming for the purposes of this analysis that the building would be considered a historical resource for the purposes of CEQA compliance, alteration or replacement of the historic fabric of the pump station is conservatively considered to be *potentially significant and unavoidable*. However, depending on the proposed extent of alteration, it is possible that impacts could be reduced to a less-than-significant level with historical documentation and compliance with the Secretary of the Interior's *Standards for the Treatment of Historic Properties* and project redesign (Measures 4.7-4b and 4.7-4c). This project would also remove and replace the existing Crystal Springs/San Andreas Pipeline. If the pipeline were considered to be a historical resource for the purposes of CEQA, the project's impact on the pipeline could be reduced to a less-than-significant level with implementation of SFPUC Construction Measure #9 (cultural resources), as well as implementation of Measures 4.7-4a through 4.7-4f, which include historical documentation and compliance with the Secretary of the Interior's *Standards for the Treatment of Historic Properties*.

The Lower Crystal Springs Dam (PN-4) and CS/SA Transmission (PN-2) projects are located within the *Peninsula Watershed Management Plan* (Peninsula WMP) area. The Peninsula WMP's cultural resource policies (which are the same as those presented above under the Sunol Valley Region for the Alameda WMP) and cultural resource actions provide guidelines for proposed construction associated with these projects.

The other WSIP projects in this region (Baden and San Pedro Valve Lots, PN-1; HTWTP Long-Term, PN-3; and Pulgas Balancing Reservoir, PN-5) would affect non-historic facilities. Therefore, this impact would *not apply* to these projects.

San Francisco Region

Impact 4.7-4: Impacts on the historical significance of individual facilities resulting from demolition or alteration		
SAPL 3 Installation	SF-1	PSM
Groundwater Projects	SF-2	N/A
Recycled Water Projects	SF-3	LS
