San Antonio Reservoir receives both local runoff (including inflow from Calaveras Reservoir) and Hetch Hetchy water, and its water quality is therefore more variable than that of Calaveras Reservoir. Like Calaveras Reservoir, San Antonio Reservoir exhibits characteristics typical of mesotrophic[5] waters; however, the moderate algal biomass present in San Antonio Reservoir is more typical of eutrophic[6] waters (SFPUC, 2002).

As in Calaveras Reservoir, the biggest water quality concerns in San Antonio Reservoir are turbidity and algae control; the SFPUC has occasionally applied copper sulfate to control algal blooms in San Antonio Reservoir, –but has ceased use of copper sulfate until it receives

5 The ratio of watershed to surface area is 30:1, which places the lake in the “potentially mesotrophic” group.
6 Generally warm and shallow waters, with high nutrient levels and high microbiological activity.

applicable permits from the Regional Water Quality Control Board (RWQCB). **Table 5.4.3-2** summarizes San Antonio Reservoir's water quality parameters, including the nutrient status and associated level of microbiological activity.

TABLE 5.4.3-2
SUMMARY OF WATER QUALITY IN SAN ANTONIO RESERVOIR

Parameter	Value	Status
Nitrate – winter average (mg/L)	0.104	Mesotrophic
Orthophosphate – winter average (mg/L)	0.028	Mesotrophic
Total Phosphorus – winter average (mg/L)	0.060	Eutrophic
Secchi Depth[a] – growth season average (feet)	11.8	
Secchi Depth – growth season minimum (feet)	3.8	Eutrophic
Chlorophyll *a* – annual average (µg/L)	3.187	Eutrophic
Chlorophyll *a* – annual peak (µg/L)	14.68	Eutrophic
Anoxia[b] presence	Regularly	Eutrophic
Anoxia duration	Average approximately 90 days/year	Mesotrophic to Eutrophic
Anoxic extent	Entire hypolimnion	Eutrophic

µg/L = micrograms per liter; mg/L = milligrams per liter

[a] Secchi depth is a parameter used to determine the clarity of surface waters. High secchi depth readings indicate clearer water that allows sunlight to penetrate deeper.
[b] Anoxia generally refers to low-oxygen conditions in the hypolimnion.

SOURCE: SFPUC, 2002.

Occasional transfers of large quantities of South Bay Aqueduct water into San Antonio Reservoir have degraded the reservoir water by adding contaminants, including total dissolved solids, total organic carbon, and bromides. The last such transfer, which occurred during the 1990–1991 drought, significantly degraded water quality in the Alameda system.

Alameda Creek Below the Diversion Dam

Water quality in Alameda Creek is generally good and is protective of beneficial uses. In terms of aquatic life, the key water quality parameter is temperature, which is directly related to hydrologic flow conditions. **Table 5.4.3-3** summarizes weekly water temperature data collected by the ACWD near Sunol, above Arroyo de la Laguna, from 1997 through 2005. Average monthly water temperatures show an expected seasonal trend (i.e., cooler during the winter and warmer during the summer).

Water temperatures in Alameda Creek have been shown to vary widely in Niles Canyon, with average daily temperatures generally peaking in late August in the 20 to 30 °C range (68 to 86 degrees Fahrenheit), and daily temperature fluctuations ranging between 1 and 11 °C, depending on geographic location and the degree of riparian shading (San Francisco Planning Department, 2005).

SOURCES: ACWD (raw data provided by Laura Hidas); Merritt Smith Consulting (data reduction). Note that ACWD temperature data may not have been subject to the rigorous QA/QC procedures required for scientific studies, and therefore should be used only to indicate general conditions (unless otherwise specified by the ACWD).

Water temperatures in Niles Canyon reflect seasonal meteorological conditions, with cool temperatures in winter, warm temperatures in summer, and intermediate temperatures in the spring and fall. Under predevelopment conditions, a naturally high groundwater table in the Sunol Valley may have provided base flow during the low-flow periods. Subsurface accretions such as these can provide thermal benefits during summer periods, because groundwater temperatures tend to be relatively constant at approximately the mean annual air temperature of the local area (Holmes, 2000). The degree of predevelopment groundwater/stream interaction is unknown, and the extent of any potential thermal benefit is likewise uncertain. Nonetheless, under current conditions, the flow of subsurface water into mining pits during gravel mining operations has lowered the groundwater table to the extent that Alameda Creek at the head of Niles Canyon may retain only very low flows during the summer period (Bookman-Edmonston Engineering, Inc., 1995). A review of temperature studies presented by Hanson (2003) indicates that water temperatures in Alameda Creek are at or close to the equilibrium temperature (i.e., in equilibrium with the atmosphere) by the time flows reach Niles Canyon. Thus, in summer periods, water temperatures typically exceed 25 ^{o}C for multiple consecutive days. Although there is topographic and riparian shading in the canyon, local meteorological conditions are not sufficiently moderated by these shading sources to provide consistently low water temperatures through the summer. There are most likely local cool patches where hyporheic flow (water that interchanges between the stream and subsurface media) provides some moderation of water temperatures. However, such areas are not believed to be widespread or to provide extensive, persistent cool water. Summer and fall flows in Alameda Creek and its tributaries are at their seasonal low. Thus, flows in Alameda Creek below its confluence with Arroyo de la Laguna tend to be warm during these periods, because coldwater sources are largely unavailable in these reaches and base flows are low during this time of year, allowing waters to warm towards their natural temperature in equilibrium with meteorological conditions. In addition, flows in Arroyo de la Laguna appears to be higher in total dissolved solids (TDS) than the flows in Alameda Creek originating from the watershed upstream of Arroyo de la Laguna (RWQCB, 2008).

Increased flows may moderate maximum daily temperatures by increasing the thermal mass of the stream (i.e., the quantity of cooler water in the stream that would be subject to warming by the air).

Table 5.4.3-4 provides a summary of TDS data for the same location and period as for temperature, above. Unlike temperature, TDS does not exhibit a seasonal trend. TDS is an indicator of the overall content of inorganic materials in the water. As shown in the table, TDS is well below the secondary maximum contaminant level for drinking water (established to protect aesthetic quality) of 500 mg/L. Nitrate averages were 0.8 mg/L (as N) over the 1997–2005 period; the primary drinking water standard is 10 mg/L.

Regulatory Considerations

As described in Section 5.2, the San Francisco Bay RWQCB regulates water quality in the San Francisco Bay region under the Porter-Cologne Water Quality Control Act. Beneficial uses of surface waters in the Alameda Creek watershed as well as impaired water bodies are shown in **Table 5.4.3-5**. The beneficial uses of the water bodies generally apply to all tributaries.

5.4.3.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to surface water quality, but generally considers that implementation of the proposed program would have a significant surface water quality impact if it were to:

- Substantially impair a water body's ability to support beneficial uses designated by the State Water Resources Control Board or Regional Water Quality Control Board
- Otherwise substantially degrade water quality

TABLE 5.4.3-5
ALAMEDA DRAINAGE WATER QUALITY REGULATIONS

Water Body	
	Designated Beneficial Uses
Alameda Creek	AGR, COLD, GWR, MIGR, REC-1, REC-2, SPWN, WARM, WILD
Arroyo Hondo	COLD, FRSH, MUN, REC-1, REC-2, SPWN, WARM, WILD
Calaveras Reservoir	COLD, MUN, REC-1 (limited), REC-2, SPWN, WARM, WILD
San Antonio Reservoir	COLD, MUN, REC-1 (limited), REC-2, SPWN, WARM, WILD
	Clean Water Act Section 303(d) List of Impaired Water Bodies
Alameda Creek	Pollutant: Diazinon Potential Sources: Urban runoff/storm sewers Total Maximum Daily Load Priority: High

Beneficial Uses Key:

MUN (Municipal and Domestic Supply); AGR (Agriculture); REC-1 (Body Contact Recreation); REC-2 (Noncontact Recreation); WARM (Warm Freshwater Habitat); COLD (Cold Freshwater Habitat); MIGR (Fish Migration); SPWN (Fish Spawning); WILD (Wildlife Habitat); NAV (Navigation); GWR (Groundwater Recharge); FRSH (Freshwater Replenishment); SHELL (Shellfish Harvesting); COMM (Ocean, Commercial, and Sport Fishing); EST (Estuarine Habitat); IND (Industrial Service Supply).

SOURCE: SWRCB, 2003.

Approach to Analysis

Changes in water quality are based on qualitative analyses of potential water quality effects due to changes in flows within creeks and changes in reservoir levels, as predicted by the HH/LSM. An overview of the model is presented in Section 5.1, and the model assumptions are provided in Appendix H.

Impact Summary

Table 5.4.3-6 presents a summary of the impacts on surface water quality in the Alameda Creek watershed that could result from implementation of the proposed water supply and system operations.

TABLE 5.4.3-6
SUMMARY OF IMPACTS – SURFACE WATER QUALITY
IN ALAMEDA CREEK WATERSHED STREAMS AND RESERVOIRS

Impact	Significance Determination
Impact 5.4.3-1: Effects on water quality in Calaveras Reservoir	LS
Impact 5.4.3-2: Effects on water quality in San Antonio Reservoir	LS
Impact 5.4.3-3: Effects on water quality along Calaveras, San Antonio, and Alameda Creeks	LS

LS = Less than Significant impact, no mitigation required

Impact Discussion

Impact 5.4.3-1: Effects on water quality in Calaveras Reservoir.

Under the WSIP, Calaveras Reservoir would be replaced and its original capacity restored (see Chapter 3 for a description of reservoir operations under the WSIP). Compared with existing conditions, the reservoir would be maintained at a higher storage level. In addition, the new dam outlet works would allow greater flexibility to manage both in-pool and downstream conditions by providing a wider range of controlled releases, selective withdrawal, and improved spill management. Maintaining higher overall storage compared with DSOD-imposed levels would create a larger hypolimnion, leading to similar or greater cold/cool water volumes.

Temperature. The temperature impact under proposed operations is expected to be minimal. Maintaining higher overall storage volumes would create a larger hypolimnion, leading to similar or greater cold/cool water volume. Historical summer cool water pool volumes on the order of 25,000 to 35,000 acre-feet could again be expected with the proposed program. Seasonal thermal stratification dynamics would follow a similar pattern, with the onset of stratification occurring in April, and fall destratification largely complete by November. April through October stream releases would average approximately 3,800 acre-feet (13 percent of the cool water pool[7]). In all hydrologic year types except for the wettest years, the April through October release volume would range from approximately 2,850 to 3,050 acre-feet (9 to 10 percent of the cool water pool), while in the wettest year the release volume would be approximately 7,400 acre-feet (25 percent of the cool water pool). These release volumes would not deplete the cool water pool and would not lead to substantial changes in the thermal structure of the reservoir.

Dissolved Oxygen. Historically (i.e., before the 2002 DSOD restriction), Calaveras Reservoir experienced seasonal anoxia (DO concentrations less than 2 mg/L) during summer and early fall thermal stratification. In an effort to maintain aquatic habitat for fish and to minimize water quality impacts under this reduced reservoir storage condition, an oxygenation system was installed to ensure DO concentrations of up to 5 mg/L in the hypolimnion during summer periods. The oxygenation system has the flexibility to be operated in a larger reservoir and would continue to be operated when the dam is replaced. Thus, DO conditions would be equal to or improved over the existing condition, with DO concentrations maintained to eliminate low-oxygen conditions in the hypolimnion.

Water Quality – Nutrients. As described above in Section 5.4.3.1, Setting, Calaveras Reservoir is mesotrophic; implementation by the SFPUC of oxygenation technology has maintained or improved water quality within the reservoir and would continue to do so under the WSIP. Proposed reservoir storage and operations would not affect the maintenance of water quality; with the oxygenation system in place, overall nutrient levels would likely be lower and algal biomass reduced compared with existing conditions. Furthermore, the restored reservoir capacity would result in greater natural sedimentation relative to the current condition, which would attenuate turbidity spikes during heavy runoff.

7 The assumed cool water pool volume is 30,000 acre-feet.

Impact Conclusions

Overall, implementation of the proposed WSIP water supply and system operations would maintain or improve water quality parameters in Calaveras Reservoir. Therefore, impacts on water quality in Calaveras Reservoir would be *less than significant*, and no mitigation measures would be required.

Impact 5.4.3-2: Effects on water quality in San Antonio Reservoir.

Under the WSIP, controlled releases from San Antonio Reservoir would be maintained at zero, while uncontrolled releases (spills) would be reduced under future operations (compared with the modeled existing condition). As noted above, drawdown would be less (i.e., the reservoir would generally be maintained at a higher storage volume); supply to the Sunol Valley WTP would change from historical operations, with larger inflows in the rainy season and lower inflows in the dry season. Maintaining higher overall storage could create a slightly larger hypolimnion, leading to similar or larger cold/cool water volumes during summer periods.

Temperature. The temperature impact under proposed operations is expected to be minimal. Maintaining higher overall storage would create a larger hypolimnion, leading to similar or larger cold/cool water volumes. Historical summer cool water pool volumes were on the order of 12,000 to 20,000 acre-feet and are expected to be similar under future operations. Seasonal thermal stratification dynamics would follow a similar pattern, with the onset of seasonal stratification occurring in April, and fall destratification largely complete by November.

Dissolved Oxygen. Historically, San Antonio reservoir experienced seasonal anoxia (DO concentrations less than 2 mg/L) during summer and early fall thermal stratification. DO conditions are expected to be similar under future operations.

Water Quality – Nutrients. As described above in Section 5.4.3.1, San Antonio Reservoir is mesotrophic; Merritt-Smith Consultants (2003) determined that oxygenation was an appropriate measure to maintain and possibly improve this status. However, this technology has not been implemented. Future operations are expected to minimize inputs of lower quality water from State Water Project sources (i.e., the Delta), which could improve reservoir water quality. Overall nutrient and algae levels under the WSIP are expected to be similar to current conditions.

Impact Conclusions

Overall, implementation of the proposed WSIP water supply and system operations would maintain water quality parameters in San Antonio Reservoir. Therefore, impacts on water quality in San Antonio Reservoir would be *less than significant*, and no mitigation measures would be required.

Impact 5.4.3-3: Effects on water quality along Calaveras, San Antonio, and Alameda Creeks.

Calaveras Creek

The primary source of Calaveras Creek flow is Calaveras Reservoir releases. There are no appreciable tributaries between Calaveras Dam and the Alameda Creek confluence.

Temperature. Water temperatures under future operations are expected to be similar to existing conditions. Winter temperatures are expected to be low due to seasonally wet and cool conditions. During the warmer periods of the year, water temperatures are expected to be similar in normal, above-normal, and wet years because release quantities would be the same. In below-normal and dry years, water temperatures are expected to be similar or lower under future operations because flows would be increased, while release temperatures would stay approximately the same. This increased flow would not lead to an appreciable thermal benefit far downstream, because eventually the waters would warm, attaining equilibrium with local meteorological conditions (see Alameda Creek, below).

Studies conducted for the 1997 MOU between the CDFG and CCSF contemplated that a 7-cfs release from Calaveras Reservoir would result in cooler temperatures for the upper half of the stream reach between the Alameda/Calaveras Creek confluence and the Sunol Valley WTP. Furthermore, the existing oxygenation system, which is also planned to be used in future operations, would maintain desired DO conditions in reservoir waters, which would further enhance DO conditions in the downstream reach. If MOU releases are from Alameda Creek upstream of Calaveras Creek, then Calaveras Creek would not receive the temperature benefits of these releases, and temperatures would remain as in the base case.

Dissolved Oxygen. DO conditions below Calaveras Dam would depend on water quality conditions in the reservoir. Because oxygenation has been implemented in Calaveras Reservoir since 2002 and would continue to be implemented with the WSIP, DO conditions downstream of the dam would be similar to current conditions.

Water Quality – Nutrients. Any improvements in water quality conditions in Calaveras Reservoir would also occur in released waters downstream of the dam. The trapping of nutrients in the reservoir sediments upstream could reduce nutrients in downstream waters. In addition, oxidation of ammonia to nitrate in the reservoir ("nitrification") would minimize the potential for excess ammonia releases from the reservoir. These benefits would maintain low oxygen demands (due to the nitrification of ammonia to nitrate) as well as a low potential for un-ionized ammonia, which can be harmful to aquatic life.

San Antonio Creek

The WSIP would not change release mechanisms at the Turner Dam on San Antonio Reservoir. Controlled releases would be maintained at zero, while modeled uncontrolled releases would increase in January and February, but decrease in March and April. Because reservoir temperature, DO, and levels of nutrients and associated constituents are not expected to change, significant adverse impacts related to these water quality parameters are not expected.

Alameda Creek

Two reaches of Alameda Creek are discussed below:

- Reach 1 – from the diversion tunnel to Alameda Creek's confluence with Calaveras Creek
- Reach 2 – from the confluence with Calaveras Creek downstream

Reach 1

Temperature. Water temperatures in Alameda Creek in the vicinity of the diversion dam reflect seasonal meteorological conditions (cool winter, warm summer, and intermediate spring and fall temperatures). Reach 1 would experience lower flows under future operations. The bulk of the flow changes would occur from December through April, with modest changes in May during the wetter years. In general, Alameda Creek flows below the diversion tunnel to the creek's confluence with Calaveras Creek would be lower under future operations.

Dissolved Oxygen. Although minimal DO data exist for Alameda Creek throughout much of its watershed, DO conditions in the creek are presumed to be consistent with other wildland creeks of the Bay Area (i.e., near saturation and in equilibrium with the atmosphere). Under future operations, these conditions are not expected to change.

Water Quality – Nutrients. Alameda Creek upstream of the diversion dam is largely an undeveloped watershed with no storage reservoirs. This fact, coupled with flow changes that would be largely limited to December through April (when primary production is low), suggests that water quality impacts due to future operations are not likely to change nutrient conditions in this reach.

Settleable Materials, Suspended Materials, and Turbidity. Sections 5.4.1.1 and 5.4.2.1 describes the SFPUC flushing activities intended to remove accumulations of coarse sediment to protect the facility, maintain storage capacity (and thus diversion capacity) above the Alameda Creek Diversion Dam, and support downstream geomorphic processes by passing sediment. The flushing procedure involves opening the sluice gates to flush coarse sediments from upstream of the diversion dam. Sediment flushing discharges approximately 900 cubic yards of sediment from behind the diversion dam each year, and typically occurs in February. This sediment typically consists of sands and gravels. Operations normally occur over a 48-hour period during high-flow events to develop the necessary velocity to mobilize the coarse sediments behind the dam. Flushing operations occur whether or not flows from the creek are being diverted to the diversion tunnel. The sluice gates remain closed year-round, except during the sluicing procedure. If water is not diverted via the diversion gates to the reservoir, the entire volume of the creek flows through the sluice gates in the dam or over the top of the dam. It is assumed that these SFPUC sediment flushing activities and sluice gate operations would continue under the WSIP.

Three water quality parameters—settleable materials, suspended materials, and turbidity—could be affected by changes in the Alameda Creek Diversion Dam operations and sediment flushing procedures. It is likely that more sediment would be transported to Calaveras Reservoir with the WSIP than under current conditions because of increased flows diverted to Calaveras Reservoir. Many of these sediments would settle out in the reservoir, reducing the overall quantity of sediments in the creek. Therefore, less sediment would be available for transport (either in flows over the dam or via sluicing/flushing operations) down Alameda Creek compared to the existing condition. Therefore, the sluicing/flushing procedures under the WSIP would have less-than-significant water quality impacts with respect to settleable materials, suspended materials, and turbidity.

Reach 2

Temperature. Below the Alameda Creek confluence with Calaveras Creek, lower Calaveras Creek temperatures associated with future operations of Calaveras Dam would also affect Alameda Creek temperatures. The effects would be moderated because of mixing with Alameda Creek flows. Cooler waters in Calaveras Creek would commingle with Alameda Creek flows and generally approach equilibrium temperature in response to local meteorological conditions as waters traversed this reach. During winter periods, water temperatures would be the same under future conditions. During summer periods, flows from Calaveras Creek might be less than equilibrium temperature (i.e., cooler than Alameda Creek waters) at the confluence. The result is that proposed Calaveras Creek flows could reduce Alameda Creek water temperatures; however, it is likely that these waters would warm towards equilibrium over the next several miles.

Dissolved Oxygen. Both Alameda and Calaveras Creeks are expected to have DO conditions at or near saturation under existing and future conditions. Deviations from saturation concentration could occur in response to primary production (photosynthesis and respiration of algae), but these conditions are not expected to change under proposed operations. Overall, DO conditions in Alameda Creek are not expected to change substantially under future operations.

Water Quality – Nutrients. Any reduction in nutrients and algae in Calaveras Reservoir would also occur in released waters downstream of the dam, and potentially in Alameda Creek as well. The impact of these reductions in Alameda Creek below the confluence of Calaveras Creek is uncertain. Nutrient and algae conditions in Alameda Creek are expected to be similar under future operations.

As described above, the WSIP would not substantially degrade water quality parameters in Alameda and Calaveras Creeks; therefore, impacts on these conditions would be less than significant.

Impact Conclusions

Overall, impacts on water quality along Calaveras, San Antonio, and Alameda Creeks would be *less than significant*, and no mitigation measures would be required.

[Additional discussion on water quality in Alameda Creek downstream of the diversion dam was prepared in response to comments on the Draft PEIR. Please refer to Section 15.2, response to the letter from the Regional Water Quality Control Board, San Francisco Bay Region, (Vol. 7, Chapter 15)]

5.4.4 Groundwater

The primary groundwater resources in the Alameda Creek watershed are in the Livermore and Sunol Valleys, and farther downstream in the Niles Cone area near the town of Niles. In CCSF-owned watershed areas upstream of the Livermore and Sunol Valleys, small amounts of localized groundwater can be found in the shallow alluvial areas that are interspersed with steeper bedrock sections along watercourses. Groundwater in these areas is often through-flow associated with flows in the streams. Because the proposed program would not affect upstream areas in the Livermore Valley or lower areas in the Niles Cone (which is below the SFPUC's infiltration galleries), this section focuses on describing the groundwater conditions and potential WSIP impacts in the Sunol Valley.

5.4.4.1 Setting

Local Geology

The Alameda Creek watershed generally comprises northwest-trending ridges and intervening valleys, the orientations of which are strongly controlled by the structural grain of the underlying bedrock (refer to Chapter 4, Section 4.3, Geology, Soils, and Seismicity). For the purposes of visualizing the groundwater system in the program area, the geologic units can be divided into two main types. The deepest bedrock is characterized by well-compacted and lithified marine sedimentary rocks (Panoche Formation). Because of their compact nature, low permeability, and strong structural deformation, these rocks are considered non-water-bearing or, at best, very low water-yielding (Ludhorff and Scalmanini, 1993).

In contrast, the younger surficial deposits are unconsolidated to only slightly compacted. These units are nonmarine, alluvial fan, and stream channel deposits of interbedded gravel, sand, silt, and clay beds. The lower portion of this sequence, the Livermore Gravels, is more consolidated than the upper portion and is less water-bearing. The upper coarser-grained sand and gravel beds have high porosity and permeability and are considered water-bearing and high water-yielding. The upper alluvial deposits range from 30 to 60 feet thick and probably constitute the most significant groundwater aquifer in the program area (Luhdorff and Scalmanini, 1993).

Hydrogeology

The upper aquifer described above is "unconfined," meaning that the water table fluctuates in response to recharge (precipitation in the wet season) and discharge (evapotranspiration[1] in the dry season). Significant alluvial deposits have been removed by gravel mining upstream from the location of the former Sunol Dam.

Historical groundwater observations by quarry operators suggest that the majority of groundwater inflow occurs from the upper alluvium within about 50 feet of the ground surface (Luhdorff and Scalmanini, 1993). The water-bearing capability and permeability of the deeper zone, the

1 The return of water from the soil and from plants to the atmosphere by evaporation and transpiration.

Livermore Gravels, is lower than that of the shallow alluvium. The contact between the relatively impermeable Livermore Gravels and the highly permeable shallower zone decreases the potential for recharge of the Livermore Gravels via alluvium. Prior to development, groundwater recharge of Sunol Valley alluvium occurred primarily as seepage from the Alameda Creek stream channel and percolation of direct precipitation. Groundwater levels would have been highest during and just after the rainy season and lowest during summer and until the beginning of the wet season. Discharge from the basin would have consisted primarily of groundwater seepage to the channels of Alameda Creek and Arroyo de la Laguna at the downstream end of the valley (Bookman-Edmonston Engineering, Inc., 1995). Prior to construction of Sunol Dam, which artificially raised the water table, groundwater levels in the downstream end of the valley were lower than those observed today.

Sunol Infiltration Galleries

Sunol Dam was built around 1899 by the Spring Valley Water Company to maintain hydraulic head[2] within the shallow alluvium upstream of the dam, adjacent to and underlying the Alameda Creek bed. These deposits host the Sunol infiltration galleries. The infiltration galleries are comprised of a series of concrete tunnels along with perforated pipe placed in the shallow alluvium under Alameda Creek, perpendicular to the creek banks; the galleries provide a location for temporary aquifer recharge (deposit) and recovery (withdrawal) (see **Figure 5.4.4-1**). Historically, surface water from Alameda Creek, particularly peak storm flows, were detained behind both permanent and temporary dams and seeped into the gravels for recovery by the infiltration galleries. The infiltration galleries were not designed to “draw down” groundwater levels, but rather to intercept surface water from Alameda Creek. In this way, short-duration high flows in Alameda Creek resulting from heavy rainfall events were diverted and temporarily stored before being recovered over a longer time period by the infiltration galleries. Dependable yield from the infiltration galleries was 5 mgd, but under flood conditions the fully operational galleries could produce well over 20 mgd (SFPUC, 1960).

After completion of the Calaveras Pipeline in 1934, flows of stored water from Calaveras Reservoir were reduced, and the yield of the infiltration galleries declined. Recharge to the galleries was further reduced in 1965 when construction of San Antonio Dam eliminated supply from San Antonio Creek. In addition, beginning in the late 1960s, gravel mining began altering groundwater flow patterns in the valley. As a result of the quarry operations, groundwater levels in portions of the valley are lower than during the first half of the last century, and flows formerly captured and diverted into the infiltration galleries have decreased in recent years (Bookman-Edmonston Engineering, Inc., 1995). Sunol Dam was removed in September 2006. Removal of this dam is likely to further decrease flows captured in the infiltration galleries.

---

[2] Hydraulic head is the pressure of the water column and elevation difference. Fluids flow down a hydraulic gradient, from points of higher to lower hydraulic head.

Figure 5.4.4-1
Sunol Groundwater Basin Groundwater Elevations and Flow Directions

Other than the infiltration galleries, only incidental groundwater development, consisting of a small number of wells for water supply, occurred in the Sunol Valley until recent times. The Sunol Valley Golf Course uses up to 1 mgd of local groundwater. The SFPUC recently installed a new irrigation supply system for the golf course.

Groundwater Observations

Available groundwater data for the Sunol Valley are limited. Investigations conducted in 1986 by the ACWD and in 1989 by the Mission Valley Rock Company involved the installation of several small-diameter monitoring wells throughout the valley. Water levels were measured at the time of installation, but since then have not been routinely measured. Luhdorff and Scalmanini measured water levels in existing wells several times in 1992 and 1993. The ground surface elevations of the wells were estimated, either by survey or reference to available topographic maps.

Generally, comparison of seasonally collected water levels showed relatively small variations from spring to fall. Luhdorff and Scalmanini (1993) concluded that overall groundwater levels in the Sunol Valley range from 20 to 30 feet below ground surface, with probable localized depressions around gravel quarries. The inferred groundwater level contours, using 1992 data, approximately parallel the ground surface contours of the valley floor, and generally indicate a direction of groundwater flow parallel to Alameda Creek. As indicated in Figure 5.4.4-1, groundwater levels are lowest at the northwestern end of the valley, near the Sunol Water Temple, and are highest in the southern, upper end of the Sunol Valley. Groundwater was thus determined to flow in a northwesterly direction, with a focus at the entrance to Niles Canyon.

Geomatrix Consultants measured levels in the three groundwater monitoring wells installed in the shallow alluvium deposits (to an approximate depth of 25 feet) and in Alameda Creek above Sunol Dam between April 2004 and April 2005 (San Francisco Planning Department, 2005). The data indicate a steady decline in groundwater levels adjacent to Sunol Dam (approximately 300 feet from the dam) over the summer months (a 5- to 6-foot decline in six months). As noted above, Sunol Dam was recently removed, which eliminates its influence on groundwater levels and is projected to lower those levels by about 5 feet in the vicinity of the dam.

Groundwater between Interstate 680 and the entrance to Niles Canyon flows to the northwest, gradually sweeping to a southwest flow direction in the immediate vicinity of Sunol Dam (see Figure 5.4.4-1). The presence and flow direction of groundwater is complicated by the infiltration galleries, stream confluences, and, formerly, the Sunol Dam. Comparison of ground surface contour values with the inferred water table surface suggests that Alameda Creek is a “losing” waterway for the majority of its course through the Sunol Valley (i.e., water from Alameda Creek recharges the groundwater table via infiltration through the streambed). However, in the vicinity of the confluence between Arroyo de la Laguna and Alameda Creek, this recharge relationship reverses, with groundwater beginning to contribute to Alameda Creek flow. This portion of Alameda Creek is thus classified as a “gaining” stream. By Sunol Dam, groundwater to creek discharge is well established.

Groundwater in the northwesternmost portion of the Sunol Valley is recharged to a large degree by flow from Arroyo de la Laguna. Arroyo de la Laguna, as it crosses the Sunol Valley on its way to the confluence with Alameda Creek, recharges the general groundwater table to the northwest, and the general groundwater table and infiltration galleries to the southeast. In this capacity, Arroyo de la Laguna has the potential to act as an intermediate sub-groundwater divide.

Groundwater in Niles Canyon

The local hydrogeology in Niles Canyon is best envisioned as occurring in two separate and distinct geological units. The broader, and from a resource perspective, lesser aquifer is contained within the Panoche Formation bedrock. The other aquifer is hosted in alluvial deposits immediately beneath and adjacent to Alameda Creek. The alluvial deposits form the floodplain adjacent to the creek; however, the floodplain is limited in extent by the bedrock slopes of Niles Canyon.

The shallow alluvial aquifer system is well connected to surface water in Alameda Creek. It is reasonable to assume that the amount of groundwater in the shallow aquifer is dependent on the water level in Alameda Creek, and that there is a shallow groundwater gradient directing flow toward Alameda Creek. The shallow groundwater gradient could change on a short-term basis as the limited aquifer responds to precipitation and recharge of shallow groundwater, and as the water level in Alameda Creek fluctuates. The range of seasonal groundwater fluctuation at the site of Niles Dam is expected to be about 1 to 3 feet. The floodplain at Niles Dam was slightly elevated from the water table year-round, producing a condition that may help support a riparian community. Niles Dam was removed in September 2006. The removal of this dam is expected to slightly lower groundwater levels.

The bedrock is not considered a significant aquifer host due to the expected low yields. Furthermore, groundwater in the bedrock would not be strongly influenced by changes and fluctuations in Alameda Creek hydrology, as the hydraulic connection between the two is likely limited.

Groundwater Quality

Groundwater within the Sunol Valley area is calcium-magnesium bicarbonate water, with concentrations of individual constituents at generally low levels. Total dissolved solids are low (from about 350 to 500 mg/L), as are nitrate concentrations (from 1 to 6 mg/L), with the exception of some localized and elevated nitrate and total dissolved solids concentrations in shallow groundwater due to historical agricultural practices (Bookman-Edmonston Engineering, Inc., 1995).

5.4.4.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to groundwater, but generally considers that implementation of the proposed program would have a significant groundwater impact if it were to:

- Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of preexisting nearby wells would drop to a level that would not support existing land uses or planned uses for which permits have been granted)
- Substantially impair a water body's ability to support beneficial uses designated by the State Water Resources Control Board or Regional Water Quality Control Board
- Otherwise substantially degrade water quality

Approach to Analysis

Information on potentially affected groundwater bodies was obtained from published sources and through interviews with individuals who are knowledgeable about the hydrogeology of the area or involved with groundwater management in the potentially affected area. Impact assessments were performed by reviewing WSIP-induced changes in stream flow and examining their potential to affect groundwater levels or quality.

Impact Summary

Table 5.4.4-1 presents a summary of the impacts on groundwater bodies in the Alameda Creek watershed that could result from implementation of the proposed water supply and system operations.

TABLE 5.4.4-1
SUMMARY OF IMPACTS –
GROUNDWATER BODIES IN THE ALAMEDA CREEK WATERSHED

Impact	Significance Determination
Impact 5.4.4-1: Changes in groundwater levels, flows, quality, and supplies	LS

LS = Less than Significant impact, no mitigation required

Impact 5.4.4-1: Changes in groundwater levels, flows, quality, and supplies.

Compared to current conditions, increased diversions and storage under the WSIP would reduce peak flows in Alameda Creek between the diversion dam and the confluence with San Antonio Creek. Seasonally, the WSIP would reduce flows in the high-flow months and increase flows in the low-flow months due to fishery releases. It would also increase storage in Calaveras Reservoir. The overall effect of these changes in groundwater supplies downstream in the Sunol aquifer areas is expected to be minor (either slightly positive or slightly negative), depending on the year's rainfall and seasonal conditions. The WSIP would reduce potential infiltration in the Sunol groundwater basin by reducing peak flows in wet years. Impacts on groundwater in the Niles Cone would be less than significant because flows in Alameda Creek downstream of Niles Canyon would be maintained within the range of flows experienced since the Niles Cone began to be managed and utilized as a water supply resource. The program's minor changes in groundwater levels would not affect groundwater quality. This impact would be *less than significant*, and no mitigation measures would be required.

5.4.5 Fisheries

The following setting section describes the fishery resources within the streams and reservoirs of the Alameda Creek watershed that could be affected by the WSIP. The impact section (Section 5.4.5.2) provides a description of the effects of WSIP-induced changes in stream flow and reservoir levels on fishery resources.

5.4.5.1 Setting

Alameda Creek and some of its major tributaries historically contained populations of anadromous steelhead and resident rainbow trout (*Oncorhynchus mykiss*) that supported a local recreational fishery. As described below, water supply projects, gravel mining, urban development, and flood control modifications have reduced this historical fishery; however populations of these and other fish species still inhabit certain reaches of Alameda Creek and its tributaries.

Aquatic Habitats

Alameda Creek flows from its headwaters at Oak Ridge to South San Francisco Bay. The creek has historically been divided into three distinct reaches: upper Alameda Creek and its tributaries, Niles Canyon reach and tributaries such as Arroyo del la Laguna, and lower Alameda Creek. Alameda Creek is characterized by long runs and glides and relatively short, shallow riffles (Hanson Environmental, 2002a). Alameda Creek and its tributaries have highly variable seasonal streamflows (see Section 5.4.1 for further description of stream flow).

The substrate ranges from silt and sand with small cobbles to gravel and larger boulders. The lower reach of the creek is characterized by extensive urban development and has been channelized (rip-rapped) for floodwater conveyance. Portions of Alameda Creek are shaded by mixed riparian forest at the margins of the creek. This vegetation is extensive in the Niles Canyon reach, where it occupies the first terrace from the edge of the creek (i.e., ordinary high water) to approximately 6 to 8 feet above ordinary high water (San Francisco Planning Department, 2005).

Flows in the mainstem Alameda Creek and its tributaries are flashy with high flows during the winter and spring and low flows during the summer and fall. In the past, portions of Alameda Creek, particularly the Niles Canyon, Sunol Valley, and lower reach have had low and intermittent streamflows during the summer of dry years. Similar intermittent stream flow conditions have occurred in the tributaries, with the greatest frequency of intermittent flows occurring in the lower elevation alluvial sections during dry years. The seasonal hydrology of Alameda Creek has changed over the past several decades with the addition of upstream storage reservoirs and flow augmentation from managed releases from the State Water Project's South Bay Aqueduct for groundwater recharge and deliveries to local urban communities.

In addition, major alterations to the creek and its tributaries, including the channelization of the lower 12 miles of the creek for flood control; the construction of San Antonio, Calaveras, and Del Valle Reservoirs for water supply; and the construction of a concrete drop structure to stabilize the channel around the Fremont BART weir have made spawning habitat within the watershed inaccessible for some returning anadromous fishes such as steelhead and Chinook salmon (*Oncorhynchus tshawytscha*) (Gunther et al., 2000).

Upper Alameda Creek

Upper reaches of Alameda Creek include higher elevation steeper gradient stream reaches typically bordered by riparian vegetation. Summer water temperatures are typically cooler than those observed further downstream. Bedrock outcroppings influence channel features in several areas including the Little Yosemite reach. The upper reach supports a reproductive population of resident rainbow trout.

Niles Canyon

Prior to the development of water conveyance facilities, Alameda Creek in Niles Canyon was likely an intermittent to perennial stream characterized by low flows during late summer and fall. Aquatic habitats within Niles Canyon likely functioned as a migratory corridor for anadromous fishes such as steelhead and Pacific lamprey (*Petromyzon marinus)* (Gunther et al., 2000). SFPUC fishery monitoring has documented successful lamprey spawning and rearing within Niles Canyon in recent years (ACA, 2004). However, construction and operation of dams, diversions, and other structures that function as fish migration barriers (e.g., the Sunol and Niles Dams and the grade control structure at the BART weir) have prevented anadromous fishes such as steelhead migrating into Alameda Creek and through Niles Canyon from reaching coldwater habitat further upstream within the watershed (Gunther et al., 2000). The Sunol and Niles Dams were partially removed in September 2006, eliminating them as obstacles to fish passage.

The Alameda County Water District (ACWD) augments summer flows, particularly summer releases from Del Valle Reservoir through Arroyo de la Laguna into Niles Canyon. Although the stream temperatures within the reach are probably higher than predevelopment flows, augmented flows potentially provide atypical fast-water habitat that may provide habitat and food for native and non-native fishes. Thus, some evidence suggests that suitable steelhead/rainbow trout habitat occurs in Niles Canyon (Gunther et al., 2000; Smith, 1999; and McEwan, 1999). Results of water temperature monitoring within the Niles Canyon reach of Alameda Creek during 2001-2002 (Hanson Environmental, 2002) showed summer temperatures in excess of 75 °F which would significantly affect the ability of juvenile and adult steelhead/rainbow trout to oversummer within the canyon reach. Monitoring conducted by Hanson Environmental in 2001 and 2002 also shows that water in Alameda Creek is in thermal equilibrium by the time it flows to the Niles Canyon reach of the river, likely due to the prolonged solar warming occurring from the Sunol Regional Wilderness to the Niles Canyon reach. More suitable summer water temperatures were observed further upstream.

Arroyo de la Laguna, Arroyo Mocho, and Arroyo Valle

Arroyo de la Laguna, Arroyo Mocho, and Arroyo Valle are major tributaries to Alameda Creek that drain watersheds in the Livermore-Amador Valley. These tributary creeks are characterized by highly variable seasonal hydrology. Land use changes over the past 150 years have substantially altered the characteristics and hydrology of these creeks. The creeks have been modified to provide flood control capacity within the urbanized areas of the valley and are also used for water conveyance and groundwater recharge. Arroyo Valle and Arroyo Mocho historically supported resident trout fisheries in the upper watersheds, primarily through routine fingerling plantings from hatcheries including the Mount Whitney Hatchery. Adult steelhead were periodically caught in Arroyo Valle and lower Alameda Creek, although the occurrence of records of adult steelhead in Arroyo Valle suggests that only a small number of fish may have occurred (on an infrequent basis) within this portion of the watershed, periodically under favorable environmental and hydrologic conditions (Hanson et al., 2004). No records of adult steelhead being caught by recreational anglers were found for Arroyo Mocho. It is unlikely that either watershed historically provided consistent suitable habitat conditions for steelhead passage, spawning, and/or juvenile rearing to support self-sustaining populations. Arroyo Mocho channel form would have made adult steelhead migration unlikely prior to channelization based upon historic geomorphic conditions within the lower reaches of the Arroyo Mocho channel. Historically, steelhead passage in Arroyo Valle occurred infrequently, in response to high flow events that provided suitable surface water connectivity between Arroyo Valle and lower Alameda Creek.

Arroyo Hondo

Arroyo Hondo, a tributary to Calaveras Creek upstream from Calaveras Reservoir, is known to contain self-sustaining populations of resident rainbow trout. These resident trout populations may have been derived from coastal steelhead trapped in the upper watershed after Calaveras Dam was constructed (Gunther et al., 2000). The trout spawn and rear in the lower mile of Arroyo Hondo, and then some return to Calaveras Reservoir or remain in Arroyo Hondo where they reside for the rest of the year (Entrix, 2003; SFPUC, 2003). Spawning habitat for the reservoir population may be limited by a historic landslide that prevents upstream migration and spawning at locations more than one mile upstream from Calaveras Reservoir (SFPUC, 2004). Resident rainbow trout also successfully spawn and rear in Arroyo Hondo upstream of the landslide.

Currently, the SFPUC conducts two annual fishery monitoring projects in Arroyo Hondo, an expanded aquatic resource monitoring project, and a predation study. The SFPUC plans to begin a reservoir trout population size study in 2007.

Lower Alameda Creek

The lower reach of Alameda Creek is characterized by in stream pools formed by inflatable rubber dams used to convey water from the creek into lateral gravel quarry pits used for groundwater recharge by ACWD. The rubber dams are typically deflated during periods of high flows and increased turbidity. Substrate is typically fine sand and silt. Summer water temperatures are relatively high. The reach provides habitat for warmwater fish such as largemouth bass. The lower 12 miles of the creek is primarily managed as a flood control facility. The channel is armored by riprap. Sediment removal and channel regrading is periodically required to maintain flood conveyance capacity.

Steelhead/Rainbow Trout

Regulatory Status

Steelhead/rainbow trout[1] is a federally listed threatened species (NMFS, 2006). Critical habitat, which was designated for this species by the National Marine Fisheries Service (NMFS) in February 2000, included the Alameda Creek watershed. However, in April 2002 NMFS withdrew the critical habitat designation pending further economic impact analysis (NMFS, 2002). In September 2003, the NMFS formally withdrew the critical habitat designation for the Central California Coast ESU as well as 18 other ESUs (NMFS, 2002). In June 2004, the NMFS proposed including resident rainbow trout in the Central California Coast ESU due to genetic similarities between resident and migratory trout within the Alameda Creek watershed upstream of ACWD Rubber Dam 1 (NMFS, 2004). The NMFS subsequently determined that resident rainbow trout inhabiting Alameda Creek should not be included in the ESU for anadromous steelhead (NMFS, 2006). Instead, NMFS determined to list as threatened only those rainbow trout/steelhead that exist below the lowest impassible barriers in the Alameda Creek watershed (i.e., the BART Weir). Thus, the resident rainbow trout that occur in the creek above the BART Weir are not designated as a listed species.

The SFPUC would be required to obtain a Clean Water Act Section 404 permit from the US Army Corps of Engineers (USACE) to construct the Calaveras Dam Replacement project (SV-2) downstream of the existing dam. Before issuing a Section 404 permit, the USACE is required under Section 7 of the ESA to consult with NMFS and the USFWS on designated species to obtain a biological opinion of no jeopardy and an incidental take statement. NMFS also advised the SFPUC that while the USACE would need to initiate a Section 7 consultation with NMFS on the Calaveras Dam Replacement project, it was unlikely that operation of Calaveras Dam would adversely affect steelhead in the area below the BART Weir by making conditions unsuitable for successful steelhead spawning, egg incubation, or juvenile rearing. For this reason, NMFS advised that the steelhead issues above the BART Weir would not be addressed in the Calaveras Dam Replacement project Section 7 consultation, and that incidental take coverage for steelhead in the upper watershed would have to be obtained through a habitat conservation plan (HCP) or through a re-initiated USACE consultation on the Calaveras Dam Replacement project after the lower passage problems are remedied.

Life History

O. mykiss have a dynamic life history. All *O. mykiss* hatch in the gravel substrate of coldwater streams. After hatching, the young fry emerge from the gravel and start feeding in the stream. Some begin to disperse downstream in the months following their emergence, but most continue to rear in the stream. Following a rearing period of at least one year, juveniles follow a variety of life-history patterns, including residents (nonmigratory) at one extreme and individuals that migrate to the open ocean (anadromous) at another extreme. Intermediate life-history patterns include fish that migrate within the stream (potamodromous), fish that migrate only as far as estuarine habitat, and fish that migrate to near-shore ocean areas.

---

1 Rainbow trout and steelhead are the same species of trout (*O. mykiss*). The freshwater variety are rainbow trout, and trout that migrate from the ocean to spawn in freshwater (i.e., anadromous) are steelhead.

Juveniles that become migratory typically do so after one or two years of rearing, but sometimes longer. Physiological changes in these fish (called smolts) ultimately allow them to make a transition from freshwater to seawater. Smolts migrate to the ocean, spend a variable amount of time there (typically one to two years), grow rapidly, and return to spawn, generally in the stream where they hatched. Steelhead are unusual among the other Pacific salmonids in that they do not all die after spawning. Some return immediately to the ocean, and others return after holding for a period in freshwater. Within a given stream, some *O. mykiss* do not migrate to the sea, and the proportion may vary considerably depending on local circumstances. These fish reach sexual maturity and spawn without entering the ocean and are often known as resident or stream rainbow trout (Gunther et al., 2000).

Anadromous steelhead exhibit two basic life-history forms. Stream-maturing steelhead enter spawning streams before they are sexually mature, generally during the period between spring and early fall, and spend several months in the stream before they are ready to spawn. Ocean-maturing steelhead enter spawning streams during the fall and winter in a fully mature state and spawn relatively soon after entering freshwater (Gunther et al., 2000). Both forms may occur in the same river system with little or no genetic distinction. Details on the life history of steelhead inhabiting the Alameda Creek watershed are unknown, however the low summer flows and seasonally elevated water temperatures within many of the reaches may have limited opportunities for stream-maturing adult steelhead to have successfully oversummered in many areas. Steelhead habitat requirements are associated with distinct life-history stages, including migration from the ocean to inland reproductive and rearing habitats, spawning and egg incubation, rearing, and seaward migration of smolts and spawned adults. Habitat requirements and life-history timing can vary widely over the steelhead's natural range (Barnhart, 1986; Pearcy, 1992; and Busby et al., 1996; cited in Gunther et al., 2000).

Resident and Migratory Populations

Populations of resident rainbow trout have been reported above the Calaveras Reservoir on several occasions since 1905, in Arroyo Hondo, Isabel Creek, and Smith Creek (Leidy, 1984). Young-of-year *O. mykiss* have been observed in Stonybrook Creek and Sinbad Creek, tributaries to Alameda Creek (Gunther et al., 2000). However, electrofishing in Sinbad Creek in 1997 and 1998 failed to capture any *O. mykiss*. Stonybrook Creek is regarded as potential *O. mykiss* habitat based on the presence of several age classes of resident individuals, including young-of-year (Gunther et al., 2000).

There is some evidence that a native, locally adapted *O. mykiss* stock survives in the Alameda Creek watershed (Gunther et al., 2000). Resident rainbow trout were collected below Niles Dam in 1927 and in Stonybrook Creek, a tributary to Alameda Creek, in 1955. Sampling by the ACWD in 1999 documented the presence of reproducing populations of resident trout in Arroyo Mocho and two tributaries to Alameda Creek, Welch and Pirate Creeks (Buchan et al., 1999). Recent sampling by the East Bay Regional Park District documented the presence of reproducing trout populations in Stonybrook Creek and Alameda Creek in the Sunol Regional Wilderness (Leidy, 2003).

Sightings of migratory steelhead have been reported downstream of the BART weir. In recent years, individual steelhead were captured near the BART weir by citizen groups and released at the mouth of Niles Canyon upstream of the ACWD inflatable diversion dams. One of these fish, a pregnant female, was tracked to Stonybrook Creek, upstream of Niles Dam (Gunther et al., 2000). There are also reports of migratory steelhead spawning in Alameda Creek downstream of the middle inflatable dam, and in 1998 fertilized eggs were collected from the area immediately downstream of the BART weir. The eggs hatched successfully, and the resulting fry were released into Alameda Creek in Sunol Park (Gunther et al., 2000).

Genetic testing by Nielson (2003) was based on a small sample size, but suggests that the present self-sustaining populations of resident rainbow trout may have been derived from migratory steelhead that were isolated in the upper part of the watershed by natural processes or by construction of Calaveras Dam (NMFS, 2004). The presence of migratory barriers, notably the BART weir, prevents upstream movement of migratory steelhead.

Temperature is an important factor affecting habitat quality and availability for migratory and resident trout, particularly during the oversummer rearing period (Gunther et al., 2000; Hanson Environmental 2002b). Temperature in Alameda Creek is discussed in Section 5.4.3. The upper lethal temperature for Pacific salmonids is in the range 23.9 to 25 °C for continuous long-term exposure (Gunther et al., 2000). Some researchers indicate an upper lethal temperature for Pacific salmonids as low as 22.9 °C (Hanson, 2003); however, steelhead can survive for short periods at elevated temperatures, especially if abundant food and dissolved oxygen exists. Recent temperature data suggest that summer and early-fall temperatures in Niles Canyon are within the range considered to be highly stressful or unsuitable for juvenile steelhead (Hanson Environmental, 2002b).

Spawning

The presence of self-sustaining resident rainbow trout populations with multiple age class structure within the watershed provides evidence of consistent successful reproduction (Gunther et al., 2000). The best potential spawning (and rearing) habitat in the watershed exists in the upper reaches of Alameda Creek, upstream tributaries, and the Arroyo Mocho canyon.

Steelhead/rainbow trout, like all Pacific salmon, select spawning sites with specific features. These features include gravel substrate with sufficient flow velocity to maintain circulation through the gravel and provide a clean, well-oxygenated environment for incubating eggs. Preferred gravel substrate is in the range of 0.25 to 2.5 inches in diameter, and flow velocity is in the range of 1 to 3 feet per second. Steelhead will use substrate with larger gravel (up to 4 inches) than will resident trout. Sites with preferred features for spawning occur most frequently in the pool tail/riffle head areas, where flow accelerates out of the pool into the higher gradient section below. In such an area, the female steelhead will create a pit, or redd, by undulating her tail and body against the substrate. This process also disturbs fine sediment in the substrate and lifts it into the current to be carried downstream, cleaning the nest area. Survival of fertilized eggs through hatching and emergence from the gravel is most often limited by radical changes in flow that can dislodge eggs from the substrate, result in sedimentation, or dewater incubation sites (Gunther et al., 2000).

Areas of the watershed that support resident trout all show evidence of successful spawning, as indicated by the presence, abundant in places, of young-of-year trout. Suitable substrate conditions for spawning and egg incubation are found at some level in all stream reaches potentially supporting steelhead. Given the high potential fecundity of steelhead, factors other than availability of spawning habitat are likely to be more limiting; however, reconnaissance surveys conducted to date are not of sufficient detail to quantify the overall extent and quality of suitable substrate (Gunther et al., 2000). It is possible that more detailed observations would reveal opportunities for improving spawning habitat and enhancing production of steelhead juveniles. However, the availability of spawning habitat does not appear to preclude steelhead from completing their life cycle in the Alameda Creek watershed (Gunther et al., 2000).

Juvenile Rearing

Rearing habitat is limited in most of the areas potentially supporting steelhead by low summer stream flow and exposure to seasonally elevated water temperatures (Gunther et al., 2000). This natural condition under which steelhead in these reaches evolved has been exacerbated by urban development. However, areas exist with suitable water temperature for rearing *O. mykiss*, particularly in the upper canyon reaches of the creek and larger tributaries (Gunther et al., 2000; Hanson Environmental 2002b). In some of the stream reaches supporting the greatest numbers of resident trout, low summer stream flow results in relatively small, infrequent, isolated pools (e.g., the reach of Alameda Creek located upstream and downstream of the diversion dam). More pools or larger pools would be expected to allow greater numbers of trout to survive the low-flow period (Gunther et al., 2000), but this is a natural condition in these reaches and one to which steelhead/rainbow trout have adapted. Availability of late-summer habitat may limit the abundance of steelhead/rainbow trout within the watershed, but it does not preclude them from completing their life cycle (Gunther et al., 2000).

Rainbow Trout/Steelhead Migration and Barriers

As described above, Alameda Creek historically hosted a steelhead run, with spawning occurring in the upper reaches of the watershed. That steelhead run was eliminated by the placement of several obstructions to migration within the Alameda Creek channel over the past century. These obstructions include the Alameda County Flood Control and Water Conservation District’s BART Weir located about 9.5 miles upstream from the creek’s confluence with San Francisco Bay; Alameda County Water District (ACWD) rubber dams (ranging in location from about two miles upstream of the Bay to just below Niles Canyon), the USGS gaging station weir in Niles Canyon, and the PG&E drop structure in the Sunol Valley (see **Figure 5.4.5-1**). In addition, the Calaveras, San Antonio, and Alameda Creek Diversion Dams (all owned by the City and County of San Francisco and operated by the SFPUC) and Del Valle Dam (owned and operated by the California Department of Water Resources) are all impassable barriers in the upper part of the watershed. The SFPUC removed above-ground portions of two relict diversion dams located on the creek (Sunol Dam and Niles Dam) in September 2006. Other migration barriers along the creek also have been or are in the process of being removed: two swimming hole dams in the Sunol Regional Wilderness park were removed in the past few years; and the ACWD is

SFPUC Water System Improvement Program . 203287

Figure 5.4.5-1
Potential Barriers to Fish Migration in Alameda Creek Watershed

evaluating plans to remove or provide fish passage at their rubber dams and is currently installing a positive barrier fish screen on an unscreened diversion from the creek.

Despite the recent removal of these structures, currently, steelhead can migrate upstream only as far as the BART Weir. Since 2000, up to seven fish have been found at the base of the BART Weir annually during the migration season. (The area below the weir is monitored by the Alameda Creek Alliance for migrating fish). When found, these steelhead are collected, transported upstream, and released into the creek near Niles Canyon where several have been observed migrating upstream into tributary creeks. The NFMS rule regarding the listing of Alameda Creek steelhead as threatened under the Federal ESA (California Central Coast Distinct Population Segment), finalized in January 2006, applies only to the anadromous form of *O. mykiss* and therefore is limited to populations below the BART Weir.

Steelhead will not have unimpeded access to the upper Alameda Creek Watershed until passage is provided at the remaining downstream barriers to fish migration. The locations of passage barriers within the watershed are shown in Figure 5.4.5-1. These barriers and the status of planning to address passage at these locations is described below:

- Alameda County Flood Control and Water Conservation District's BART Weir – several studies have been conducted regarding potential designs to provide passage at this location. The most recent effort is a report (Wood Rogers, 2006) that outlines options ranging from total removal of the structure ("roughened channel") to three ladder and screen alternatives. The range of low flows estimated to allow suitable passage for adult steelhead among these four options is 10–50 cfs. However, other barriers (e.g., ACWD middle and upper rubber dams, PG&E Drop Structure – see below) within Alameda Creek may be impassable at these low flows. On July 31, 2007, the Alameda County Flood Control and Water Conservation District and the ACWD entered into an agreement to design a fish passage facility over the BART weir and the middle inflatable dam in the Alameda County Flood Control Channel to improve steelhead passage within the Alameda Creek watershed.

- ACWD middle and upper rubber dams – design of fish passage options and/or operational changes are being studied. There is currently no schedule or budget, and environmental review has yet to begin. (CH2MHill, 2001)

- USGS Niles gaging station weir/concrete apron – has been identified as potential barrier (passage impediment) at some flow levels. The Northern California Council Federation of Fly Fishers (NCCFFF) has developed a preliminary study (Federation of Fly Fishers, 2004), which includes a preliminary finding that the apron/weir fails to comply with existing fish passage criteria and would be a severe impediment to upstream migration of steelhead. However, this conclusion has been questioned by other experts, and NCFFF is continuing its studies.

- PG&E Drop Structure – protects a natural gas pipeline under the creek. No studies have been conducted to date regarding fish passage options, and there is no schedule or budget for this project. The SFPUC proposed to coordinate planning for a passage project at this location with PG&E in its Sunol Valley Quarry request for proposals. The SFPUC has yet to make a selection from those responding to the RFP, but the selected entity will be required to provide funds towards this effort.

- The SFPUC's Alameda Creek Diversion Dam could block migration to any migrating steelhead that travel upstream of the Little Yosemite area.

- A number of low-flow passage impediments exist within Alameda Creek including shallow riffles, short falls and bedrock plunge pools, and other small structures.

The SFPUC also is conducting preliminary studies of passage issues in the watershed: (1) natural barriers in the watershed, including the landslide in the Arroyo Hondo above Calaveras Reservoir, and the Little Yosemite reach of Alameda Creek; (2) Calaveras Dam; (3) Alameda Creek Diversion Dam; and (4) critical riffles on Alameda Creek, focusing on the Sunol Valley/Quarry reach.

In addition, the Calaveras, San Antonio, and Alameda Creek Diversion Dams (all owned by the City and County of San Francisco and operated by the SFPUC) and Del Valle Dam (owned and operated by the California Department of Water Resources) are all impassable barriers in the upper part of the watershed. The SFPUC removed above-ground portions of two relict diversion dams located on the creek (Sunol Dam and Niles Dam) in September 2006.

Flows to Support Rainbow Trout/Steelhead

In addition to migration barriers, reduced winter and spring flows in Alameda Creek above the BART Weir also would limit migration and spawning if steelhead were to gain access upstream. The Alameda Creek Fisheries Restoration Workgroup (Workgroup), formed for the purpose of restoring steelhead to Alameda Creek, will be undertaking a series of flow studies to determine the flows necessary to support steelhead in the watershed. The Workgroup includes the SFPUC, Alameda County Flood Control and Water Conservation District, Alameda County Resource Conservation District, ACWD, Alameda Creek Alliance, California State Coastal Conservancy, California Department of Fish and Game, East Bay Regional Park District, National Marine Fisheries Service (NMFS), Natural Resources Defense Council, Pacific Gas and Electric Company (PG&E), and the Zone 7 Water Agency (Zone 7).

These agencies developed a Memorandum of Understanding (MOU) in April 2006 that describes the commitment and process to jointly fund and conduct flow studies to estimate the range, magnitude, timing, duration, frequency and location of flows necessary to restore steelhead within the creek, while also considering other native fishes and riparian communities, in the Alameda Creek watershed while minimizing the potential impacts to agencies responsible for supplying drinking water to Bay Area communities. In December 2006, a consultant was selected to manage the flow studies.

These flow studies are intended to result in a flow strategy that will meet with approval from the state and federal regulatory agencies and satisfy regulatory requirements. This strategy, when combined with other aspects of a fisheries restoration program, is intended to provide long-term assurances and certainties for restoring and maintaining native fishes, as well as providing water agencies and other utilities and special districts with long-term assurances and certainties for continued water supply and other infrastructure operations in the watershed. The flow studies are being conducted in three phases:

Phase 1 will include a review of relevant existing information on hydrologic and geomorphic conditions and fish habitat in the watershed. Based on this foundation, the Workgroup will agree on a detailed work plan for the tasks needed to estimate the range, magnitude, timing, duration, frequency and location of flows necessary to restore a population of steelhead to the creek (while also considering their effects on other native fishes and riparian communities). That work plan, scheduled to be completed by June 2007, will be conducted in the second phase of the studies.

Phase 2 will focus on developing a common understanding of the existing conditions in the watershed and collecting the additional data necessary to estimate the flows needed to restore steelhead in the Alameda Creek watershed. This assessment will be based on the review of existing hydrologic and geomorphic conditions and the estimated flows needed to support steelhead throughout their lifecycle in the watershed. Results from Phase 2 will form the foundation from which flow proposals that will support steelhead can be developed and analyzed. The Workgroup currently anticipates that Phase 2 will be completed by January 2009.

The scope and schedule for Phase 3 will be determined following completion of Phases 1 and 2, and is expected to include the development and analyses of specific flow alternatives, including operational, engineering, and natural resource strategies, with the intent of achieving the restoration goals identified in Phase 2.

The SFPUC plans to incorporate these strategies into its Alameda Watershed Habitat Conservation Plan, which will provide coverage for regional water system operations within the Alameda Creek Watershed under the Federal Endangered Species Act (ESA, Section 10) for covered species, including steelhead.

The design of the fish passage projects, particularly for the BART Weir and the ACWD rubber dams, would be closely coordinated with the Workgroup's flow studies. Passage alternatives range from total removal of barriers to ladder/screen construction projects, and the flows required to provide passage at different times of the year would vary widely until a specific design is selected for each location. It is also critical for these designs to be considered in the context of existing and future water supply operations by ACWD, SFPUC, and Zone 7.

Potential Steelhead Restoration

For the purposes of full disclosure, the PEIR provides this discussion of steelhead in lower Alameda Creek, and the potential for steelhead to be restored to the upper reaches of Alameda Creek (above the BART weir). However, because this steelhead access does not currently exist and there is no current steelhead migration above the BART weir, the potential impact on steelhead migration, spawning, or juvenile rearing upstream of the BART weir as a result of WSIP implementation is not analyzed in this section, which addresses WSIP impacts relative to existing conditions, but instead is analyzed as a future, cumulative impact in Section 5.7.3.

[Additional discussion on steelhead fishery in Alameda Creek was prepared in response to comments on the Draft PEIR. Please refer to Section 14.9, Master Response on Alameda Creek Fishery Issues (Vol. 7, Chapter 14).]

Other Fish Species

Chinook Salmon

Chinook salmon remains within archaeological sites in the lower Alameda Creek floodplain (Gunther et al., 2000). These fish could have been captured in San Francisco Bay or other locations and transported to the site. Historically, Alameda Creek could have supported small runs of Chinook salmon, as have been observed in other South Bay tributaries. In recent years, small numbers of Chinook salmon adults have been recovered from the Alameda Creek flood control channel downstream of the BART weir, as well as from other streams tributary to South San Francisco Bay that were not previously known to support salmon runs. It is generally believed that management of hatchery production has resulted in salmon straying to streams that have not traditionally supported them (Gunther et al., 2000).

Other Species

Approximately seventeen native fish species have been collected in nontidal portions of the Alameda Creek watershed during the past century (**Table 5.4.5-1**). Several other species may also have occurred in the watershed based on collections in tidal portions, evidence from archaeological investigations, and other accounts. Many collections include widely distributed species typical of streams in the region, such as California roach (*Hesperoleucus symmetricus*), hitch (*Lavinia exilicauda*), Sacramento sucker, Sacramento pikeminnow (*Ptychocheilus grandis*), steelhead/rainbow trout, Pacific lamprey (*Lampeta tridentata*), and prickly sculpin (*Cottus asper*) (Gunther et al., 2000). Two species, speckled dace (*Rhinichthys Osculus*) and riffle sculpin (*Leptocottus armatus*), have appeared in only one or two collections. Speckled dace were reported to occur in Arroyo Hondo and Isabel Creek (two Calaveras Creek tributaries above Calaveras Reservoir) by Snyder in 1905, and in Alameda Creek at the confluence with Calaveras Creek by Shapovalov in 1938 (Leidy, 1984).

In surveys conducted between 1972 and 1977, Scoppettone and Smith (1978; Gunther et al., 2000) did not find speckled dace in these areas. Riffle sculpin collected in Alameda Creek at the junction with Calaveras Creek in 1938 by Shapovalov (Gunther et al., 2000) is the only report of the species in the Alameda Creek watershed. Scoppettone and Smith (1978) sampled for riffle sculpin at sites with cool, permanent water in Isabel, Smith, Arroyo Hondo, Arroyo Mocho, and Alameda Creek, but found none. Of the 15 remaining species, all were collected as recently as 2002 (Leidy, 2007). The SFPUC has also conducted an annual fishery survey within the watershed since 1998.

The two species not collected in 1981 were Pacific lamprey and Sacramento blackfish (Gunther et al., 2000). Pacific lamprey have been recently netted in the flood control channel section. Sacramento blackfish have been reported in the ACWD quarry lakes. Sacramento perch, one of the species collected in 1981, are native to California. Aceituno et al. (1976) believed that Sacramento perch were stocked in Calaveras Reservoir some time after 1925 and spread to the stream from there. However, Gobalet (1990) reports Sacramento perch from fish remains at an archaeological site adjacent to Arroyo de la Laguna. In any case, the species has been collected in Niles Canyon since 1953 and currently maintains populations in the off-channel percolation ponds adjacent to the flood control channel (Gunther et al., 2000).

[Additional discussion on other fish species and aquatic habitat in Alameda Creek was prepared in response to comments on the Draft PEIR. Please refer to Section 14.9, Master Response on Alameda Creek Fishery Issues (Vol. 7, Chapter 14).]

5.4.5.2 Impacts

Significance Criteria

The City and County of San Francisco has not formally adopted significance standards for impacts related to fisheries, but generally considers that implementation of the proposed program would have a significant fisheries impact if it were to:

- Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS
- Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites
- Have the potential to degrade the quality of the environment, substantially reduce the habitat of a fish or wildlife species, cause a fish or wildlife population to drop below self-sustaining levels, threaten to eliminate a plant or animal community, substantially reduce the number or restrict the range of an endangered, rare, or threatened species

Approach to Analysis

The effects of the WSIP on river flow and water levels in reservoirs were determined using the Hetch Hetchy/Local Simulation Model, as described in Section 5.4.1. A professional fish biologist assessed the effects of flow, reservoir level, and water temperature changes on fishery resources in the Alameda Creek watershed.

As described in Section 5.1.3, Approach to Analysis for Chapter 5 Water Supply and System Operations, and further discussed in Section 5.4.1, the existing conditions baseline used for impact analysis is based on current flow conditions in Alameda Creek that have occurred since the beginning of 2002 as a result of the DSOD restrictions on the storage capacity of Calaveras Reservoir. The proposed future condition assumes full implementation of the WSIP, including restoration of Calaveras Reservoir storage.

Impact Summary

Table 5.4.5-2 presents a summary of the impacts on aquatic habitats and fishery resources that could result from implementation of the proposed WSIP water supply and system operations.

Impact Discussion

Impact 5.4.5-1: Effects on fishery resources in Calaveras Reservoir.

The storage volume within Calaveras Reservoir under proposed WSIP operations would typically be substantially greater than under current conditions. This increase in storage offers the potential

TABLE 5.4.5-2
SUMMARY OF IMPACTS –
FISHERIES IN ALAMEDA CREEK WATERSHED STREAMS AND RESERVOIRS

Impact	Significance Determination
Impact 5.4.5-1: Effects on fishery resources in Calaveras Reservoir	B
Impact 5.4.5-2: Effects on fishery resources along Calaveras Creek below Calaveras Dam and along Alameda Creek below confluence with Calaveras Creek	B
Impact 5.4.5-3: Effects on fishery resources along Alameda Creek downstream of Alameda Creek Diversion Dam	PSM
Impact 5.4.5-4: Effects on fishery resources in San Antonio Reservoir	B
Impact 5.4.5-5: Effects on fishery resources along San Antonio Creek below San Antonio Reservoir	LS
Impact 5.4.5-6: Effects on fishery resources along Alameda Creek below confluence with San Antonio Creek	LS

LS = Less than Significant impact, no mitigation required
PSM = Potentially Significant impact, can be mitigated to less than significant
B = Beneficial impact

for increased coldwater pool volume, which could benefit coldwater fish species downstream of the reservoir. A greater coldwater pool volume within the reservoir is expected to sustain colder temperatures, particularly during summer months, and improve the quality and availability of habitat downstream of the dam. In addition, increased reservoir storage would increase the volume of habitat available for resident fish species inhabiting the reservoir, including both warmwater and coldwater fish species. The increased reservoir habitat may increase the abundance of non-native predators such as largemouth bass that prey on resident native species.

The increase in reservoir elevation under the proposed program could also provide greater opportunities for connectivity and migration of fish between the reservoir and upstream tributary habitat. As a result of these factors, increased reservoir storage under proposed operations is considered a *beneficial impact* on fishery resources.

Impact 5.4.5-2: Effects on fishery resources along Calaveras Creek below Calaveras Dam and along Alameda Creek below confluence with Calaveras Creek.

Under existing conditions, no instream flow releases have been specifically made to support fishery habitat within either Calaveras or Alameda creeks downstream of Calaveras Dam. As part of the proposed WSIP operations, instream flow releases would be made consistent with the 1997 MOU. Providing instream flow releases represents an environmental benefit to habitat quality and availability for resident rainbow trout and other fish inhabiting Calaveras Alameda creeks. As noted above, the Workgroup is identifying flow studies and analyses that may be used in the future to refine streamflow conditions within the creek. As a result of providing instream flow releases under the WSIP, the proposed program provides an environmental benefit to fishery habitat. Therefore, the proposed operations would have a less-than-significant impact, and in some cases a beneficial impact, on fishery resources in this reach of the creek.

Hydrologic modeling indicates that, in general, releases from Calaveras Dam to Calaveras Creek would be altered under WSIP operations in two ways. Under current conditions (with Calaveras Reservoir operating below design levels), peak winter flows, typically in the range of 300 to 400 cfs, that are made through controlled releases from the cone valve at the dam during January and February, are generally greater than winter flows would be under future operations with the WSIP. Under the proposed operations, instream flow releases from Calaveras Dam to Calaveras Creek would include summer releases that would not occur under current operations. Changes in instream flow releases to Calaveras Creek have the potential to support riparian vegetation along the stream channel. Instream flow releases would occur between the confluence of Calaveras and Alameda Creeks and further downstream to provide habitat for resident trout and other fishery resources. These flows are proposed to be recaptured downstream. A reduction in the magnitude of peak winter flows under the WSIP when compared to current peak flows was considered in the geomorphic analysis (Section 5.4.2) to be less than significant because high flow that could transport substantial quantities of sediment would still occur during heavy rains. The changes in flow conditions under the WSIP throughout the year, including increased average winter releases or bypasses and year-round releases or bypasses, would provide a fishery benefit through increased habitat quality and availability within Alameda Creek downstream of the confluence with Calaveras Creek compared to existing conditions.

Instream flow releases predicted to occur under WSIP operations year-round, including instream flow releases in the summer under the WSIP, would result in *beneficial impacts* on habitat quality and availability for fishery resources within Calaveras and Alameda creeks compared to existing conditions.

Impact 5.4.5-3: Effects on fishery resources along Alameda Creek downstream of Alameda Creek Diversion Dam.

Alameda Creek within the reach between the diversion dam and the confluence with Calaveras Creek provides habitat for spawning and oversummering resident trout. Flows during the summer months are very low and stream habitat is fragmented. The natural low-flow summer conditions also occurred prior to construction of the diversion dam. During the low-flow period, trout and other fishes reside primarily in isolated pools. Alluvial gravels provide substrate for trout spawning, and the occurrence of multiple age classes of trout within the area demonstrates successful reproduction.

Due to restricted storage in Calaveras Reservoir, the SFPUC is generally not diverting most of the winter and spring flows to the reservoir, and those flows continue to flow down Alameda Creek past the diversion dam. As detailed in Section 5.4.1, the diversion dam has been operated infrequently during the past five years while Calaveras Reservoir storage has been reduced but is anticipated to be operated far more frequently in the future after Calaveras Reservoir storage is returned to normal operating levels. Under existing conditions, the flows in the creek support fishery habitat downstream of the diversion dam over the past five years and are expected to continue until Calaveras Reservoir storage is restored in approximately 2012.

As described in Section 5.4.1, under the WSIP, reservoir operations would be restored, and the diversion dam would be operated to divert most flows that currently flow down upper Alameda Creek (up to a maximum diversion of approximately 650 cfs) through the diversion tunnel and into the reservoir. Under the proposed program, the SFPUC would construct a bypass flow structure at the Alameda Creek Diversion Dam and would implement bypass flows consistent with the 1997 CDFG MOU when flows are available to support fishery habitat downstream of the dam. The proposed diversion of most Alameda Creek flows below 650 cfs would result in a significant change in hydrologic conditions in Alameda Creek downstream of the diversion dam when compared to existing conditions. Diversion of most or all flows during the late winter and spring months could adversely affect the ability of resident rainbow trout to spawn and for eggs to successfully incubate in this reach, although the proposed bypass flows at the diversion dam would reduce the severity of this effect. In the future, with Calaveras Reservoir storage operating at higher levels for longer periods under the WSIP, diversions to storage are expected to be reduced and the frequency and magnitude of spills from the reservoir increased.

The diversion dam is equipped with control gates but does not include a positive barrier fish screen or other protective devise that would exclude trout or other fish from being entrained through the diversion structure into Calaveras Reservoir. Trout and other fish species inhabit Alameda Creek upstream of the diversion dam and may be diverted from the creek into the reservoir under the WSIP, preventing fish passage to downstream reaches of Alameda Creek. Calaveras Reservoir provides habitat and therefore fish diverted from Alameda Creek may not be lost from the population but rather would inhabit the reservoir. Passage through the diversion dam, however, has the potential to result in increased stress, physical abrasion, and vulnerability of fish to predation mortality within the reservoir, and other potentially adverse effects. Passage of fish over the diversion dam downstream in Alameda Creek may also result in stress and potential injury to trout and other fish species. No studies have been conducted to document the frequency or significance of entrainment of fish from Alameda Creek into Calaveras Reservoir or the potential significance of future changes in the diversion structure operations under the proposed project conditions for affecting fish entrainment. Based upon results of hydrologic and operational modeling that demonstrate future conditions with the proposed program would substantially increase the frequency and magnitude of water diverted from Alameda Creek through the diversion dam, and results of studies documenting the vulnerability of fish to entrainment at unscreened water diversions, the potential impact of operating the unscreened diversion dam on fishery resources in the future is considered potentially significant.

CDFG Code Section 5980 contains requirements for water diversions greater than 250 cfs that do not affect listed salmonid species that applies to the Alameda Creek Diversion Dam. This code section requires diversion operators to provide an intake screen or other suitable method for avoiding and minimizing fish entrainment, if needed. The code section stipulates that CDFG may have partial responsibility for funding the design and construction of a fish screen. The CDFG code also provides opportunities for a water diversion operator to consult with CDFG, using information on the diversion and adjacent habitat conditions, to determine whether or not a fish screen would be required.

These impacts of diversion dam operations on trout spawning and egg incubation during the winter and spring, and on the increased vulnerability to entrainment from Alameda Creek into Calaveras Reservoir under the WSIP, are potentially significant compared to existing conditions with Alameda Creek flows bypassing the diversion tunnel to a much greater degree. Although trout and other fish passing through or over the diversion dam would be vulnerable to stress and injury, fish entrained into the diversion dam would be removed from Alameda Creek, but would be able to inhabit Calaveras Reservoir.

A reduction in peak flows in the future with Calaveras Reservoir in full operation also has the potential to affect the frequency and magnitude of channel-forming flows that support geomorphic processes within the creek; however, this effect on fishery habitat is considered less-than-significant because flows in excess of about 650 cfs would be bypassed at the diversion dam and continue downstream within Alameda Creek. As discussed in Section 5.4.2 (Geomorphology) this effect is considered to be less than significant because high flows would continue to be produced by heavy rains within the watershed, as would the sediment-clearing sluicing flows. At the same time, the diversion of higher flows up to about 650 cfs at the diversion dam could provide a fishery benefit by reducing the likelihood that eggs incubating in redds downstream of the diversion dam would be vulnerable to scour and erosion and would be expected to contribute to improved reproductive success of those fish spawning within the reach.

In the summer season, the SFPUC operations under the DSOD restrictions imposed in December 2001 and facilities on Alameda Creek allow seepage and through-flow to occur through the diversion dam and down the creek. This practice allows adequate flows to support oversummering of resident trout in Alameda Creek between the diversion dam and confluence with Calaveras Creek. The proposed program would continue this practice, therefore potential impacts on habitat during the summer would be less-than-significant.

Overall, WSIP-related impacts on fishery habitat along Alameda Creek immediately downstream of the diversion dam would be *potentially significant*, despite proposed implementation of bypass flows at the diversion dam. Implementation of Measure 5.4.5-3a: Minimum Flows for Resident Trout on Alameda Creek, which would require the SFPUC to develop operational guidelines and implement minimum instream flow requirements for Alameda Creek downstream of the diversion dam from December through April to support resident trout spawning and egg incubation, would reduce this impact to a less-than-significant level. Measure 5.4.5-3a in conjunction with the proposed bypass flows at the diversion dam may be sufficient to fully mitigate WSIP effects on resident trout in Alameda Creek, including the effects of entrainment through the diversion tunnel. If, after monitoring of this measure and adaptive management of the minimum flow requirements, the monitoring indicates that WSIP effects are not fully mitigated, then the SFPUC also will implement Measure 5.4.5-3b: Alameda Diversion Dam Diversion Restrictions or Fish Screens, to either modify seasonal diversions schedules to minimize impacts on fish or screen its diversion facilities. This measure may be refined as it would be developed in more detail and implemented as part of the Calaveras Dam (SV-2) project.

Impact 5.4.5-4: Effects on fishery resources in San Antonio Reservoir.

Average storage volumes and reservoir elevations in San Antonio Reservoir under proposed operations would typically be slightly greater than under current conditions. Increased reservoir storage volume would increase the volume of habitat available for resident fish species inhabiting the reservoir, including both warmwater and coldwater fish species. The increased reservoir habitat may increase the abundance of non-native predators such as largemouth bass that prey on resident native species. The increase in storage elevations under the proposed program could also provide greater opportunities for connectivity and migration of fish between the reservoir and upstream tributary habitat. As a result of these factors, increased reservoir storage under proposed operations is considered a *beneficial impact* on fishery resources.

Impact 5.4.5-5: Effects on fishery resources along San Antonio Creek below San Antonio Reservoir.

Hydrologic modeling indicates a generally similar seasonal pattern in the magnitude of instream flow releases from San Antonio Reservoir to San Antonio Creek under existing conditions and with the WSIP. Proposed WSIP operations would result, on average, in slightly higher releases during the winter months (December–February) and a reduction in stream flow releases during the spring months (March–April) compared to existing conditions, while neither current nor projected future WSIP operations are anticipated to provide summer and fall base flows. The seasonal change in the timing of releases to San Antonio Creek is not expected to result in a significant impact to fishery resources. Since neither the WSIP nor current conditions provide summer and fall base flows within the creek, impacts to fishery resources are comparable under both existing and proposed operations. Therefore, impacts to fishery resources related to changes in releases from San Antonio Reservoir to San Antonio Creek would be *less than significant*, and no mitigation measures would be required.

Impact 5.4.5-6: Effects on fishery resources along Alameda Creek below confluence with San Antonio Creek.

Releases from San Antonio Reservoir to San Antonio Creek and subsequently into Alameda Creek have historically been rare under baseline conditions and would continue to be rare with the WSIP. Releases past the dam are modeled to occur in about 20 percent of the years under the existing condition and at approximately the same frequency with the WSIP, mostly in above-normal or wet years. The WSIP would have no effect on flow in San Antonio Creek in dry, below-normal, and normal years. WSIP operations would generally reduce flows in the winter and early spring of some wet years, and occasionally in the winter of some above-normal years. Occasionally, the WSIP could result in spills to San Antonio Creek that would not occur under existing conditions. These occasional spills would be the result of the reservoir being drawn less often due to the restoration of Calaveras Reservoir storage capacity and the recapture of the 1997 MOU-flows. Since there would be only minor changes in flows within San Antonio Creek, and the contribution of San Antonio Creek flows to fishery habitat downstream within Alameda Creek between current and future WSIP operations, potential impacts on fishery resources and their habitat along Alameda Creek downstream of the confluence with San Antonio Creek would be *less than significant*, and no mitigation measures would be required.

[Additional discussion on impacts on fisheries in lower Alameda Creek was prepared in response to comments on the Draft PEIR. Please refer to Section 14.9, Master Response on Alameda Creek Fishery Issues (Vol. 7, Chapter 14).]

5.4.6 Terrestrial Biological Resources

Operation of WSIP projects in the Alameda Creek watershed would alter the pattern of water levels in Calaveras and San Antonio Reservoirs as well as alter flows in Alameda and Calaveras Creeks. This section focuses on possible impacts on sensitive natural communities, key special-status species, and species of concern that could result from these changes. Although many terrestrial animal species may use riparian and aquatic systems intermittently for food, water, or cover, this discussion focuses on those species that depend on the riparian ecosystem for essential breeding and/or foraging habitat.

5.4.6.1 Setting

Overview

The Alameda Creek watershed provides habitat for a variety of wildlife. Grassland communities cover more than 50 percent of the watershed, and woodlands cover about 22 percent. Other habitats include freshwater marshes, where streams discharge into reservoirs, and brush, scrub, and chaparral communities in the flatter, drier, or steeper lands (SFPUC, 2007).

Ridgelands and open water make the area an attractive winter foraging and resting habitat for migrating and resident bird species, drawing birds of prey, waterfowl, and perching birds. In total, the watershed contains more than 17 types of wildlife habitat that support a range of animals, including tule elk, black-tailed deer, coyote, mountain lions, and bald eagles.

Alameda Creek Above the Alameda Creek Diversion Dam

The riparian resources along upper Alameda Creek are varied. Alameda Creek is usually a perennial stream above the diversion dam. It flows through relatively narrow alluvial valleys that support California sycamore (*Platanus racemosa*) alluvial woodland, and through narrower, more rocky areas that support bands of Central Coast arroyo willow (*Salix lasiolepis*) riparian forest and white alder (*Alnus rhombifolia*) riparian forest, bordered by coast live oak (*Quercus agrifolia*) woodland, mixed evergreen forest/oak woodland, and Diablan sage scrub.

Alameda Creek from the Diversion Dam to the Confluence with Calaveras Creek

Below the diversion dam, Alameda Creek passes through a steeply sloping, narrow bedrock channel section that supports a band of Central Coast arroyo willow riparian forest and white alder riparian forest. These forests are bordered by coast live oak woodland contained within a confined, rocky canyon. Near the confluence with Calaveras Creek, the canyon opens into a broader floodplain supporting an open California sycamore alluvial woodland and valley oak (*Quercus lobata*) savanna.

Calaveras Reservoir

Upland vegetation surrounding Calaveras Reservoir consists primarily of non-native annual grassland, coast live oak, and mixed evergreen forest and woodland, in addition to a small amount of Diablan sage scrub. An area of serpentine grassland, a sensitive natural community, is found on the east side of Calaveras Reservoir between the dam and Arroyo Hondo. A number of perennial, ephemeral, and intermittent streams enter the reservoir, and many support narrow bands of central coast arroyo willow riparian forest. The largest tributary stream, Arroyo Hondo, is a perennial stream that supports one of the largest stands of white alder riparian forest in the Alameda watershed. Small areas of freshwater marsh and seep habitat often occur at the mouth of intermittent and perennial streams where the groundwater reaches the surface and meets the reservoir level. A small, apparently relict stand of willows persists at the mouth of Calaveras Creek, well above the currently maintained reservoir levels. A large area of seasonal wetland is present in the southern, shallow edge of Calaveras Reservoir. This area may have supported perennial freshwater marsh when the reservoir was maintained at higher levels. Between the currently maintained reservoir elevation and the historically maintained maximum reservoir elevation, wave erosion has left a strip of soil with coarse surface sediments. This area is relatively bare and mainly supports weedy annual plants.

Calaveras Creek

Calaveras Creek from the dam to the confluence with Alameda Creek is situated in a deep, shaded canyon with well-developed riparian vegetation. Although mapped as sycamore alluvial woodland (SFPUC, 2001), riparian vegetation along the creek also includes arroyo willow riparian forest and other species such as Fremont cottonwood (*Populus fremontii*) and valley oak.

Alameda Creek from Calaveras Creek to the Confluence with San Antonio Creek

From the confluence with Calaveras Creek to the confluence with San Antonio Creek, Alameda Creek begins as a broader watercourse with widely arcing bends and a continuous mixed-species riparian canopy composed of arroyo willow riparian forest and white alder riparian forest, with occasional Fremont cottonwoods (*Populus fremontii*), valley oaks, box elder (*Acer negundo* var. *californica*), and sycamores. Some large areas of valley oak savanna are associated with alluvial terraces along this section of the creek (SFPUC, 2001). During the summer months, surface water is present in pools, especially from the confluence with Calaveras Creek to the Sunol Valley WTP. From the Sunol Valley WTP to San Antonio Creek, Alameda Creek is situated in a quarter-mile-wide valley with a broad, cobbly floodplain that support sycamore alluvial woodland on the coarser soils, valley oak savanna on the finer soils, and narrow bands of arroyo willow scrub near the channel. Alameda Creek flows in this reach during the winter and spring rainy season, but dries up completely during the summer and fall due to high infiltration rates, especially in the lower portion of the reach. Portions of the former floodplain in the lower section of this reach have been developed as nurseries and aggregate quarries.

San Antonio Reservoir

Upland vegetation surrounding San Antonio Reservoir is primarily non-native annual grassland. North-facing slopes on the south side of San Antonio Reservoir support mixed evergreen and coast live oak woodland. Where minor tributaries enter San Antonio Reservoir, narrow bands of coast live oak riparian forest follow the watercourse and streambanks. On larger tributaries such as Indian Creek and San Antonio Creek, well-developed stands of sycamore alluvial woodland, valley oak savanna, and possibly white alder riparian forest line the channels. Some areas of emergent vegetation are found at the mouths of the larger creeks. As is typical for reservoirs operated for water storage, a strip of unvegetated, wave-terraced soil is exposed when water levels fall below the usual maximum.

San Antonio Creek

San Antonio Creek below the dam supports native vegetation for a little over a mile (to Calaveras Road) before entering the highly disturbed gravel extraction area. The creek supports a diverse assemblage of central coast arroyo willow scrub in the upper section nearest the dam, and sycamore alluvial woodland in the section farther downstream. The creek flows little if at all, so the riparian vegetation is fed primarily by seepage. As with most sycamore alluvial woodland, the channel-forming processes needed for stand regeneration are no longer present, and all of the trees are large and mature with no evident recruitment.

Alameda Creek Below San Antonio Creek

Below the confluence with San Antonio Creek, Alameda Creek first passes through aggregate quarries. No vegetation and little flow occur in this area. Below the gravel quarries, Alameda Creek passes the Sunol Water Temple. In this area, the creek supports arroyo willow riparian forest, coast live oak riparian forest, and sycamore alluvial woodland before entering Niles Canyon—a broad, rocky canyon with an intermittent riparian canopy of mixed willows, cottonwoods, sycamores, and valley oaks. This section of Alameda Creek, below the confluence with Arroyo de la Laguna, flows year-round. The majority of dry-season flow below Sunol is derived from releases of South Bay Aqueduct water destined for groundwater recharge at the mouth of Niles Canyon.

Natural Communities, including Sensitive Natural Communities

Section 4.6, Biological Resources, presents a general discussion of wildlife habitats and sensitive natural communities. Figure 4.6-2b shows the distribution of habitat types in the Alameda watershed. Section 4.6 also provides additional detail specific to the Alameda watershed, including information on common or widespread natural communities. Roughly half of the Alameda watershed supports grassland, primarily non-native grassland. Diablan sage scrub is found on steep, rocky, exposed uplands with little soil development. Sheltered or drier sites with more soil development support forest and woodlands, while riparian forest and scrub are found along the major watercourses. The *Alameda Watershed Management Plan Environmental Impact Report* (San Francisco Planning Department, 2000) identified 18 natural community types within the watershed, six of which the California Natural Diversity Database (CNDDB) lists as sensitive (CDFG, 2006). Ten natural communities are found within the WSIP program area, of which six are considered sensitive. **Table 5.4.6-1** presents the name, status, and occurrence of natural communities within the program area in the Alameda watershed. These communities are briefly described in the paragraphs that follow.

- **Grasslands.** Serpentine grassland is specifically associated with soils derived from serpentine rock. These grasslands are characterized by a relatively high proportion of native species, many perennial grasses, and relatively low productivity. Typical perennial grasses

include purple needlegrass (*Nassella pulchra*), pine bluegrass (*Poa secunda*), fescue (*Festuca* spp.), and junegrass (*Koeleria cristata*). Within the program area, serpentine grassland is found on the eastern shoreline of Calaveras Reservoir and on the ridge south of the reservoir west of Calaveras Creek. Non-native grassland is dominated by a variety of non-native annual grasses such as brome (*Bromus* spp.), oats (*Avena* spp.), and wild barley (*Hordeum* spp.) as well as herbs such as filaree (*Erodium* spp.), with less abundant native annual and perennial grasses and herbs.

Non-native grassland is the most common natural community on the watershed, bordering most of San Antonio Reservoir and much of the southern half of Calaveras Reservoir. It also adjoins riparian habitats along the creeks. Non-native grassland is dominated by a variety of non-native annual grasses and herbs, with less abundant native annual and perennial grasses and herbs. Small areas of valley needlegrass grassland may also be present in rocky areas, but were too small to map (Jones and Stokes, 2003).

- **Diablan sage scrub (or north coast scrub).** This shrub-dominated community is typically found on steep, rocky, exposed slopes. In the watershed, this community is dominated by coyote brush (*Baccharis pilularis*), poison-oak (*Toxicodendron diversilobum*), bush monkeyflower (*Mimulus aurantiacus*), and California sage (*Artemisia californica*) in various proportions. Diablan sage scrub is found along the Arroyo Hondo arm on the eastern side of Calaveras Reservoir, and in small areas on the western side of the reservoir.

- **Forests and woodlands.** Mixed evergreen forest and coast live oak woodland are the most abundant forest communities on the watershed. These communities are typically found in less-exposed areas that have deeper soils than the scrub and grassland communities. Mixed evergreen forest is dominated by coast live oak, California bay (*Umbellularia californica*), and sometimes madrone (*Arbutus menziesii*), Douglas-fir (*Pseudotsuga menziesii*), and big-leaf maple (*Acer macrophyllum*). It tends to form a closed canopy with a shrubby or grassy understory. Coast live oak woodland is dominated by a single species, coast live oak. Coast live oak can form a nearly closed canopy forest in favorable sites with deep soils and ample soil moisture, or an open woodland with a grassy understory in drier areas. These communities are found in nearly all of the sheltered canyons and north-facing slopes in the watershed, including extensive areas along the shore of Calaveras Reservoir and smaller areas on the south side of San Antonio Reservoir.

  Valley oak woodland is limited primarily to the deep alluvial soils found along the floodplains of the major drainages such as Alameda Creek. It consists of an open canopy of a single tree species, valley oak, with an understory resembling non-native grassland.

- **Riparian forests.** Central coast arroyo willow riparian forest occurs in moist canyons, usually with perennial stream flow or seepage. It is a dense, broadleaved, winter-deciduous forest dominated by arroyo willow, which grows as a large, tree-like shrub. This is the most common riparian type on smaller streams in the Central Coast of California, and it is found in sections of Alameda Creek, Arroyo Hondo, and San Antonio Creek as well as various unnamed tributaries. It requires the least amount of groundwater and surface flow of any of the riparian communities discussed in this section.

  Sycamore alluvial woodland is an open woodland dominated by California sycamore. It is found along streams with very high peak flows and broad floodplains composed mainly of cobbles and other coarse material. Sycamore alluvial woodland in the Alameda watershed is best developed on the broad floodplain of Alameda Creek in the Sunol Valley, although examples also exist along San Antonio Creek.

  White alder riparian forest is a medium-tall, broadleaved, deciduous streamside forest; it is dominated by white alder and has a shrubby, deciduous understory. It is found along flowing perennial streams with coarse sediments such as Alameda Creek and Arroyo Hondo.

  Central coast live oak riparian forest is an evergreen riparian forest dominated by coast live oak. This community is present along the lower sections of Alameda Creek near the Sunol Water Temple and in Niles Canyon.

- **Marshes.** Coastal and valley freshwater marsh is a wetland community dominated by usually dense stands of perennial, emergent grass and grass-like plants up to 15 feet tall. Coastal and valley freshwater marsh is found in areas that are permanently flooded by fresh water. Small examples of this community are found around the perimeter of the reservoirs, where seepage from streams allows for this community to develop.

Seasonal wetland is not recognized by Holland (1986) as a natural community because it typically develops where managed hydrology creates an environment that is flooded or saturated for extended periods and then dries, but the inundation occurs for a shorter time, in a different season, or more irregularly than is required for development of freshwater marsh. The species found in seasonal wetland are variable, but non-native annuals in the grass, sunflower, and buckwheat families often dominate this vegetation type.

Key Special-Status Species and Other Species of Concern

Appendix D presents a list of key special-status plant and animal species and other species of concern considered in the preparation of the PEIR for the *Alameda Watershed Management Plan* (San Francisco Planning Department, 2000). Although very inclusive, the plan concludes that most of the species are unlikely to occur in the watershed because of distributional range or habitat requirements. Section 4.6, Figure 4.6-2b shows the location of federally designated critical habitats in the Alameda watershed. The following key special-status plant and animal species and species of concern (see **Tables 5.4.6-2** and **5.4.6-3**) could be affected by WSIP operations due to their potential to occur in the watershed and their proximity, association, or dependence on reservoirs or streams:

- **Serpentine-associated plants.** Most beautiful jewel-flower (*Streptanthus albidus* ssp. *peramoenus*; California Native Plant Society [CNPS] List 1B) was observed by EDAW (in prep.) during 2006 botanical surveys for the Calaveras Dam project (SV-2). It was located in the serpentine grassland east of Calaveras Reservoir, but was not within the maximum water surface elevation. Suitable serpentine habitat is present in the Alameda watershed for the following species, but none were found during detailed botanical surveys for the Calaveras Dam project (May, 2006): Santa Clara red ribbons (*Clarkia concinna* ssp. *automixa*, CNPS List 1B), Presidio clarkia (*Clarkia franciscana*, federal endangered, California endangered, CNPS List 1B), Fragrant fritillary (*Fritillaria liliacea*, CNPS List 1B), Chaparral harebell (*Campanula exigua*, CNPS List 1B), Mt. Hamilton thistle (*Cirsium fontinale* var. *camplyon*, CNPS List 1B), and Santa Clara Valley dudleya (*Dudleya setchellii*, federal endangered, CNPS List 1B). No suitable habitat was found within the maximum elevation of Calaveras Reservoir or within the riparian habitats potentially affected by WSIP operations.

- **Grassland, scrub, and woodland plants.** Diablo helianthella (*Helianthella castanea*, CNPS List 1B) grows in openings in forest, chaparral, coastal scrub, riparian woodland, and sheltered grasslands. EDAW mapped four occurrences of this species in the Calaveras Reservoir (SV-2) construction area (May, 2006), but not within the area that would be affected by reservoir operations. Suitable habitat is present in the Alameda watershed for the following species, but none were found during detailed botanical surveys for the Calaveras Dam project (May, 2006), and no suitable habitat was present within the maximum elevation of Calaveras Reservoir or within the riparian habitats potentially affected by WSIP operations: bent-flowered fiddleneck (*Amsinckia lunaris*, CNPS List 1B), which occurs in woodland and grassland; big-scale balsamroot (*Balsamorhiza macrolepis* var. *macrolepis*, CNPS List 1B), which grows in chaparral, cismontane woodland, and grasslands, and sometimes in serpentine soils; robust spineflower (*Chorizanthe robusta* var. *robusta*, federal endangered, CNPS List 1B), which is found on sandy or gravelly substrates in woodland openings and coastal scrub; Mt. Hamilton coreopsis (*Coreopsis hamiltonii*, CNPS List 1B), which grows in rocky sites in woodlands (although the Alameda watershed is generally lower in elevation than the species' known range); Hospital Canyon larkspur (*Delphinium californicum* ssp. *interius*, CNPS List 1B), which

FP: California fully protected
– Indicates no federal or state protection

* Indicates key special-status animals, defined here to mean federal- or state-listed as endangered or threatened.

SOURCES: San Francisco Planning Department, 2000; Leeman, 2006; Jennings and Hayes, 1994; CDFG, 2006.

grows in openings in chaparral habitat and cismontane woodland; Hall's bush mallow (*Malacothamnus hallii*, CNPS List 1B), which grows in chaparral and coastal scrub; and maple-leaved checkerbloom (*Sidalcea malvaeflora*, CNPS List 1B), which grows in upland forest and coastal scrub, often in disturbed sites. All of these species have a low to moderate potential to occur at the perimeter of San Antonio Reservoir, but no suitable habitat is present within the maximum water surface elevation of the reservoir.

- **Perennial grassland invertebrates.** Callippe silverspot butterfly (*Speyeria callippe callippe*, federal endangered) requires grasslands supporting the larval foodplant Johnny-jump-up (*Viola pedunculata*) and adult nectar sources such as California buckeye (*Aesculus californica*) nearby. Entomological Consulting Services (2004) found a population of Callippe silverspots on the watershed that is intermediate in appearance between the listed subspecies and a related, non-endangered subspecies. The author concluded that these populations should be protected, but should be considered "near to" the Callippe silverspot. Bay checkerspot butterfly (*Euphydryas editha editha*, federal endangered) occurs on serpentine grasslands supporting native plantain (*Plantago erecta*) and annual owl's-clover (*Castilleja* spp.). Entomological Consulting Services (2005) carried out intensive surveys for Bay checkerspot butterfly in 2004 and 2005. The species was not found, and the author concluded that habitat quality on the watershed for this species was poor.

- **Reptiles and amphibians.** California tiger salamander (*Ambystoma californiense*, federal threatened, California species of special concern) and California red-legged frog (*Rana aurora draytonii*, federal threatened, California species of special concern) are known to occur in several locations in the Alameda watershed. California tiger salamander breeds in vernal pools and permanent ponds or lakes and estivate in burrows in adjacent uplands. The species is known to breed around the perimeter of Calaveras Reservoir and in Calaveras Creek below the dam (Leeman, 2006). Suitable habitat is also present in stock ponds and possibly San Antonio Reservoir and Alameda and San Antonio Creeks. California red-legged frog breeds in still or slow-moving water such as the edges of reservoirs, often with emergent vegetation. This species has been documented in Alameda Creek below Calaveras Creek and in stock ponds in several locations in the Alameda watershed. Suitable habitat is also present at San Antonio Creek and San Antonio Reservoir.

  Foothill yellow-legged frog (*Rana boylii*, California species of special concern) breeds in shallow, flowing streams with cobbles, sunny banks, and some riffles. The species is known to breed in Alameda Creek between the diversion tunnel and the gravel mines at the lower end of the Sunol Valley, as well in Arroyo Hondo (Leeman, 2006). The Alameda watershed may support one of the largest areas of suitable habitat for this species in the Bay Area.

  Western pond turtle (*Actinemys = Clemmys marmorata*, California species of special concern) breeds in Alameda Creek below the confluence with Calaveras Creek where water is present year-round, in Arroyo Hondo, in side channels of Alameda Creek below the Sunol Water Temple, and in at least one other pond within the watershed.

  Alameda whipsnake (*Masticophis lateralis euryxanthus*, federal threatened, California threatened) is known to be present in many localities within the Alameda watershed. It inhabits coastal scrub and nearby grassland and woodland habitats. Suitable habitat is present on the perimeter of Calaveras and San Antonio Reservoirs, but not within the maximum water surface elevation.

- **Riparian-associated birds.** Several bird species of concern are closely associated with the riparian and wetland habitats in the Alameda watershed. Riparian trees have a moderate potential to support nesting and foraging Cooper's hawk (*Accipiter cooperi*, California species of special concern) and sharp-shinned hawk (*A. striatus*, California species of special concern). Long-eared owl (*Asio otus*, California species of special concern) nests in dense riparian and oak woodlands. Suitable habitat is present throughout the program area in the Alameda watershed.

- **Marsh- and lake-dependent birds.** Tricolored blackbird (*Agelaius tricolor*, California species of special concern) nests in freshwater emergent vegetation. Although no colonies are known to occur in the Alameda watershed, suitable habitat may be present on the margins of Calaveras and San Antonio Reservoirs. Northern harrier (*Circus cyaneus*, California species of special concern) nests and forages in wet meadows and pastures; a limited amount of habitat is present within the watershed, primarily in the vicinity of San Antonio and Calaveras Reservoirs. Bald eagle (*Haliaeetus leucocephalus*, federal endangered – delisted and California endangered) and osprey (*Pandion haliaetus*, California species of special concern) forage in lakes and reservoirs and nest in large trees nearby. A pair of nesting bald eagles was recently reported in the Alameda watershed, and the species could breed or winter near San Antonio and Calaveras Reservoirs. Peregrine falcon (*Falco peregrinus anatum*, federal delisted, California endangered) nests in cliffs and outcrops and forages near wetlands and open water. Loggerhead shrike (*Lanius ludovicianus*, California species of special concern) nests in riparian and other woodlands and forages over open country. It may be present throughout the Alameda watershed in suitable habitat.

- **Upland birds.** Burrowing owl (*Speotyto = Athene cunicularia*, California species of special concern) lives in mammal burrows in open, sloping grasslands. The range of this species includes the Alameda watershed. Ferruginous hawk (*Buteo regalis*, California species of special concern) winters in the Bay Area, where it forages in open grasslands and agricultural fields. Suitable habitat may be present in the extensive watershed grasslands, including those near the reservoirs. Golden eagle (*Aquila chrysaetos*, California species of special concern) forages in open grasslands and agricultural areas, and nests in large trees. It has been known to breed in the Alameda watershed and may forage near San Antonio and Calaveras Reservoirs. Foraging habitat may be present throughout the Alameda watershed. Prairie falcon (*Falco mexicanus*, California species of special concern) nests in cliffs or ledges and forages over grasslands. Suitable habitat is present within the Alameda watershed, including near San Antonio and Calaveras Reservoirs and within the Sunol Valley. California horned lark (*Eremophilus alpestris actia*, California species of special concern) nests in sparse grasslands and barren areas. Suitable habitat may be present in the grasslands near the reservoirs and in the Sunol Valley. Bell's sage sparrow (*Amphispiza belli belli*, California species of special concern) nests in chaparral and coastal scrub. Suitable habitat may be present near the reservoirs.

- **Mammal species.** Pallid bat (*Antrozous pallidus*, California species of special concern) roosts in trees and forages over open grassland and could occur throughout the watershed. Pacific western (Townsend's) big-eared bat (*Corynorhinus townsendii*) roosts in caves and buildings and forages in open country. Suitable habitat is present near both Calaveras and San Andreas Reservoirs and the open areas of the Sunol Valley. Western mastiff bat (*Eumops perotis californicus*, California species of special concern) roosts on cliffs and forages in open country. Its primary foraging area in the vicinity of the program area would be near Calaveras and San Antonio Reservoirs.

5.4.6.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to terrestrial biological resources, but generally considers that implementation of the proposed program would have a significant biological impact if it were to:

- Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS
- Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations or by the CDFG or USFWS
- Have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including but not limited to marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means
- Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites
- Have the potential to degrade the quality of the environment, substantially reduce the habitat of a fish or wildlife species, cause a fish or wildlife population to drop below self-sustaining levels, threaten to eliminate a plant or animal community, or substantially reduce the number or restrict the range of an endangered, rare or threatened species
- Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance
- Conflict with the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, or state habitat conservation plan

Approach to Analysis

The assessment of WSIP operational impacts on terrestrial biological resources focuses primarily on the extent to which proposed operations would change the existing habitat near reservoirs and creeks. Operational changes consist of increased diversions from Alameda Creek during late fall, winter, and early spring; increased releases to Calaveras Creek to maintain minimum flows; and changes in the elevation, annual range, and seasonal timing of reservoir levels. An overview of the general types of effects of stream diversions on riparian ecological resources is provided in Section 5.3.7. An assessment of the changes in hydrology in the Alameda Creek watershed under the WSIP is presented in Section 5.4.1.

This section discusses impacts on riparian and wetland habitats, key special-status species, other species of concern, and common habitats and species. The discussion of riparian and wetland habitats addresses the second and third significance criteria listed above. “Key special-status species” include species that are formally listed as endangered or threatened under the state or federal endangered species acts, as well as a few other species (such as burrowing owl and foothill yellow-legged frog) that are afforded some degree of legal protection and have a high risk of local population decline or extirpation. The key special-status species discussion addresses the first significance criterion. “Other species of concern” and “common habitats and species” are more general categories relevant to the fourth and fifth significance criteria.

As discussed in Section 5.1, the existing conditions baseline setting used in the PEIR for impact analysis reflects the current flow conditions in Alameda Creek since DSOD imposed storage restrictions on Calaveras Reservoir in December 2001, which substantially reduced SFPUC’s typical diversions from the creek to the reservoir. Section 5.4.1, above, further describes current flow conditions in Alameda Creek and how they changed in 2002 from the previous 70 years of SFPUC diversion. Riparian stand structure, especially when dominated by long-lived trees, responds slowly to changes in stream flow. Riparian structure today is the result of physical responses that have prevailed over the lifetime of the plants. In general, plants are most vulnerable during germination and establishment; if conditions become less favorable afterward, individuals may continue to persist but without successful recruitment. Therefore, the condition, distribution, and abundance of short-lived or young plants reflect existing stream flow conditions; those of moderately aged trees and shrubs reflect a combination of both older (pre-2002) and existing flow conditions; and those of old trees, such as mature California sycamores and valley oaks, reflect a combination of pre-Calaveras Reservoir, pre-2002 (prior to DSOD restrictions on Calaveras Reservoir storage), and existing operations. The impact analysis uses the existing conditions (2005) baseline but the history of flows in Alameda Creek is discussed in the impact analysis where appropriate because of the role of historic flows in shaping existing resources such as the riparian vegetation.

Impact Summary

Table 5.4.6-4 presents a summary of the impacts on terrestrial biological resources in the Alameda Creek watershed that could result from implementation of the proposed water supply and system operations.

Impact Discussion

Impact 5.4.6-1: Effects on riparian habitat and related biological resources in Calaveras Reservoir.

Sensitive Habitats

Impact of Higher Storage Levels. Calaveras Reservoir is surrounded by wetland and upland habitats that formed since December 2001, when the reservoir storage levels were lowered. These habitats, in turn, are surrounded by well-established riparian, grassland, woodland, and scrub habitats growing above the high-water elevation. Under the WSIP, restoring the original storage capacity of Calaveras Reservoir would result in the inundation and permanent loss of the seasonal wetlands, seeps, perennial freshwater marsh, and riparian habitat that have formed since 2002. Prior to 2002, these areas were regularly inundated, sometimes for several months at a time.

TABLE 5.4.6-4
SUMMARY OF IMPACTS –
TERRESTRIAL BIOLOGICAL RESOURCES IN THE ALAMEDA CREEK WATERSHED

Impacts	Sensitive Habitats	Key Special-Status Species	Other Species of Concern	Common Habitats and Species
Impact 5.4.6-1: Effects on riparian habitat and related biological resources in Calaveras Reservoir	PSM	PSM	LS	LS
Impact 5.4.6-2: Effects on riparian habitat and related biological resources along Alameda Creek, from below the diversion dam to the confluence with Calaveras Creek	LS	PSM	LS	N/A
Impact 5.4.6-3: Effects on riparian habitat and related biological resources along Calaveras Creek, from Calaveras Reservoir to the confluence with Alameda Creek	LS	PSM	LS	LS
Impact 5.4.6-4: Effects on riparian habitat and related biological resources along Alameda Creek, from the confluence with Calaveras Creek to the confluence with San Antonio Creek	LS	PSM	LS	LS
Impact 5.4.6-5: Effects on riparian habitat and related biological resources in San Antonio Reservoir	LS	LS	LS	LS
Impact 5.4.6-6: Effects on riparian habitat and related biological resources along San Antonio Creek between Turner Dam and the confluence with Alameda Creek	LS	LS	LS	N/A
Impact 5.4.6-7: Effects on riparian habitat and related biological resources along Alameda Creek below the confluence with San Antonio Creek	LS	LS	LS	N/A
Impact 5.4.6-8: Conflicts with the provisions of adopted conservation plans or other approved biological resource plans	LS			

LS = Less than Significant impact, no mitigation required
PSM= Potentially Significant impact, can be mitigated to less than significant
N/A = Not Applicable

The Calaveras Dam project (SV-2) would not raise the maximum reservoir levels any higher than historical levels. Therefore, no sensitive upland habitats or riparian habitats higher than the spillway elevation would be inundated. Areas of well-developed riparian forest along Calaveras Creek and Arroyo Hondo above Calaveras Reservoir would therefore not be affected by the proposed WSIP operations. However, because seasonal wetlands, seeps, and other wetland features below the current maximum reservoir elevation would be inundated, the impact on sensitive habitats of restoring reservoir levels at Calaveras Reservoir is *potentially significant*. Although the impact of fluctuating reservoir elevation is discussed for other reservoirs, this impact is not applicable to Calaveras Reservoir because wetlands within the existing operational range would be inundated and lost.

Impacts of Periodic Drawdowns. Under the WSIP, the reservoir would be lowered by up to 20 feet for an extended period during systemwide maintenance (every five years), which could affect riparian and freshwater marsh habitats that depend on sustained moist soil or standing water. However, the existing riparian and wetland habitats above the spillway elevation have tolerated an extended drawdown since December 2001 and can be expected to tolerate periodic drawdowns of shorter duration, such as those proposed under the WSIP. Some studies have suggested that occasional, appropriately timed dewatering can enhance wetland diversity by providing unusual opportunities for germination and establishment (e.g., Schneider, 1994); however, lowering the reservoir level would not necessarily benefit freshwater marsh or riparian vegetation. These potentially beneficial and adverse impacts are relatively minor; the impact of reservoir operations would be less than significant.

Key Special-Status Species

Key special-status species potentially affected by Calaveras Reservoir operations under the WSIP include California red-legged frog, foothill yellow-legged frog, California tiger salamander, and bald eagle. Suitable upland habitat is not present within the operational area of Calaveras Reservoir for other key special-status species discussed in this section, such as Callippe silverspot butterfly, Alameda whipsnake, burrowing owl, and peregrine falcon.

In a study of water level fluctuations for a similar reservoir project in Washington State (but applicable here), Devine Tarbell & Associates (2006) examined the effect of modest daily fluctuations on the two most vulnerable impact receptors: amphibians and waterbirds. First, the study authors note that littoral wetlands (those on or near the shore) are well suited to handling changes in soil moisture and water content that are of short duration. The study evaluated seven species of common amphibians and made several observations. Amphibian eggs are generally laid in shallow water or are attached to vegetation high in the water column. As such, water level fluctuations of even a few inches can expose developing eggs to desiccation, freezing, or increased predation. However, the authors conclude that minor fluctuations are likely less important than other factors governing habitat suitability in habitats connected to the reservoir, such as the presence of predatory fish, wave action, scant vegetative cover, and water temperature. Put another way, lakeside species are adapted to varying water levels, which occur in natural water bodies as well as managed ones.

Restoring the operational capacity of Calaveras Reservoir under the WSIP would result in the inundation and loss of poor-quality upland habitat for California tiger salamander and California red-legged frog. Habitat below the pre-2002 maximum reservoir level was not considered part of the designated critical habitat for California tiger salamander; no critical habitat for California red-legged frog is present in this area. Due to the low quality of upland habitat that would be inundated by restoring Calaveras Reservoir to its former levels, this impact would be less than significant.

Higher reservoir levels under the WSIP would reduce the duration of flowing water in Arroyo Hondo and Calaveras Creek. Arroyo Hondo is a perennial stream and has high-quality habitat for foothill yellow-legged frogs in the well-developed riparian sections above the maximum spillway elevation. Arroyo Hondo has about 10,000 linear feet of stream channel habitat between the DSOD-mandated maximum reservoir elevation and the spillway elevation. Actual reservoir elevations have varied considerably since December 2001, and have sometimes been held 20 to 30 feet higher than the DSOD-mandated level, occasionally reducing this habitat to about a mile. Although Arroyo Hondo is a perennial stream above the former maximum reservoir elevation, the CDFG observed in August 2004 that the section below this elevation was dry (CDFG, 2005), indicating it was not perennial in this section (CDFG, 2005). Yellow-legged frogs have been observed in this section of Arroyo Hondo (between the DSOD maximum and the pre-2002 maximum) since 2002. Although the habitat is of limited quality and apparently intermittent as well, it is occupied by foothill yellow-legged frogs and is of considerable length. Therefore, this impact would be *potentially significant.*

Bald eagle would not be affected by reservoir operations, except that eagle foraging can be enhanced by the shallower water and concentration of fish that occurs during drawdowns.

Other Species of Concern

No plant species of concern would be inundated as a result of Calaveras Reservoir operations under the WSIP. Wildlife species of concern in and near Calaveras Reservoir include western pond turtle, several raptor species that forage in grasslands, songbirds that nest and forage in riparian or marsh habitat, and bat species that roost in riparian habitat or forage over water. Because potential changes to grassland, riparian, and marsh habitats are minor, this impact would be *less than significant*, and no mitigation measures would be required.

Common Habitats and Species

Operation of Calaveras Dam and Reservoir under the WSIP would inundate low-diversity, weedy upland vegetation with little habitat value for wildlife. It would not interfere substantially with the movement of any native wildlife species or wildlife nursery sites, nor would it cause a plant or wildlife population to drop below self-sustaining levels. Impacts related to this loss of low-quality habitat would be *less than significant*, and no mitigation measures would be required.

Impact Conclusions

Overall, implementation of the proposed WSIP water supply and system operations would result in *potentially significant* impacts on sensitive habitats and key special-status species, especially foothill yellow-legged frog. Implementation of Measure 5.4.6-1, Compensation for Impacts on Terrestrial Biological Resources, which involves the creation, preservation, and enhancement of wetland habitat elsewhere within the Alameda watershed, including riparian habitat, would reduce this impact to a less-than-significant level.

Impact 5.4.6-2: Effects on riparian habitat and related biological resources along Alameda Creek, from below the diversion dam to the confluence with Calaveras Creek.

Sensitive Habitats

Sensitive habitats in this reach of Alameda Creek include several riparian forest communities, including Central Coast arroyo willow riparian forest, white alder riparian forest, and sycamore alluvial woodland. Most of this reach is a steeply sloping, confined bedrock channel, and the hydrograph is flashy. Most of the structure and species composition of the riparian habitat is the result of conditions that prevailed prior to 2002.

Flow Impacts. After the new Calaveras Dam is fully operational and the Alameda Creek Diversion Dam can be operated to maximum capacity, flows in Alameda Creek below the diversion dam would be reduced in frequency, duration, and magnitude compared with existing conditions. Peak flows would be diminished when the diversion tunnel is open, which would be most of the winter rainfall season. Under the WSIP, sediment would continue to be cleared annually from the diversion dam and transported downstream, much as under existing conditions. Because flow in Alameda Creek is rainfall-based, the receding flows decline rapidly, and the hydrograph pattern is not as important to riparian vegetation as with snowmelt-based systems. Compared with existing conditions, the pattern and duration of minimum flows in Alameda Creek would be about the same.

For the most part, the composition and structure of the existing riparian communities are a function of the flow conditions that prevailed before the DSOD imposed operational restrictions on the reservoir. The existing sycamore alluvial woodland and valley oak woodland formed under unimpaired flow conditions prior to construction of Calaveras Dam in 1925, and the willow and alder riparian forests formed under pre-2002 Calaveras Dam operations. Therefore, it is more useful to assess the impact of the WSIP by comparing future conditions with the conditions under which these riparian communities formed. Under pre-2002 conditions, as much flow as possible was diverted from Alameda Creek into the diversion tunnel, and, under the WSIP, as much flow as possible would again be diverted. The pattern and quantity of flows in Alameda Creek would be nearly the same as under pre-2002 conditions. The slight increase in late-winter flows under some hydrologic year types would not have a detectable effect on riparian habitat. Neither existing nor future conditions appear to be suitable for stand regeneration of sycamore alluvial woodland or valley oak woodland. A return to the pre-2002 pattern of diversions from Alameda Creek would return flow conditions to those under which the riparian forest and scrub formed; therefore, the impact of the WSIP on the extent, structure, composition, and sustainability of these habitats would be *less than significant*, and no mitigation measures would be required.

Key Special-Status Species

California red-legged frog and foothill yellow-legged frog currently occupy this section of Alameda Creek. Under the WSIP, there would be a substantial reduction in total winter flows compared with existing conditions. Reductions in the highest peak flows could reduce the extent of scouring that removes egg masses and tadpoles, which would be beneficial. However, the general reduction in flow would reduce the total available aquatic breeding habitat for these species and would also reduce the area suitable for producing their food sources, such as benthic macroinvertebrates. Although there could be both beneficial and adverse impacts on habitat for California red-legged frog and foothill yellow-legged frog, the reduction in aquatic breeding habitat would be a *potentially significant* impact.

Other Species of Concern

No plant species of concern would be affected by WSIP operations in this section of Alameda Creek. A number of raptor, songbird, and mammal species of concern could be affected in this section of Alameda Creek. Although the WSIP would reduce flows compared to the existing condition, prevailing habitat conditions are not expected to change because they are more a result of the slightly lower pre-2002 flows. This impact would be *less than significant*, and no mitigation measures would be required.

Common Habitats and Species

The more common upland habitats and species would not be affected by WSIP operational changes in this area. In this reach, the WSIP would not interfere substantially with the movement of any native wildlife species or wildlife nursery sites, nor would it cause a plant or wildlife population to drop below self-sustaining levels. Therefore, this impact would *not apply* to common habitats and species.

Impact Conclusions

Overall, implementation of the proposed WSIP water supply and system operations would result in *potentially significant* impacts on terrestrial biological resources due to a potential reduction in aquatic breeding habitat for key special-status species. Measure 5.4.1-2, Diversion Tunnel Operation, calls for operation of the diversion tunnel in a manner that ensures that flows not required to maintain storage in Calaveras Reservoir are passed down Alameda Creek at the diversion dam. Measure 5.4.5-3a, Minimum Flows for Resident Trout on Alameda Creek, calls for developing and implementing an operational plan to provide minimum bypass flows below the diversion dam to support habitat for rainbow trout and other native stream-dependent species from December through April. Implementation of these measures would ensure that minimum flows in Alameda Creek are allowed to pass by the diversion dam. Taken together, these measures would reduce adverse impacts on key special-status species to a less-than-significant level.

Impact 5.4.6-3: Effects on riparian habitat and related biological resources along Calaveras Creek, from Calaveras Reservoir to the confluence with Alameda Creek.

Sensitive Habitats

Sensitive habitats in Calaveras Creek below Calaveras Dam consist of riparian habitats such as Central Coast arroyo willow riparian forest and sycamore alluvial woodland. For the most part, Calaveras Creek is situated in a confined canyon with a bedrock channel. In addition to groundwater contributions to flow and input from lateral tributaries, releases from Calaveras under existing conditions consist of several weeks of releases averaging 300 to 400 cfs.

Impacts from Winter Flows. Compared with the existing condition, high-flow winter releases into Calaveras Creek under the WSIP would decrease, especially during normal, above-normal, and wet years. Since 2002, no spills have occurred, but cone valve releases of 325 to 375 cfs have occurred during certain high rainfall periods. The confined bedrock channel already limits channel-forming processes and opportunities for riparian regeneration. The reduction of flows in Calaveras Creek would incrementally reduce suitable habitat for riparian vegetation, but the change would be so small as to be impossible to quantify. As a result, the impact would be less than significant.

Similar to Alameda Creek below the diversion dam, most of the existing riparian habitat is the result of flow conditions that prevailed before December 2001, so pre-2002 flow conditions are considered in this impact analysis. Under the WSIP, spills are projected to occur slightly more frequently, but might be smaller in magnitude relative to pre-2002 operations. Under pre-2002 conditions and under the proposed program, the SFPUC would operate Calaveras Reservoir to retain as much water as operationally feasible, minimizing releases and spills to Calaveras Creek. Although there could be some slight changes in the pattern of releases and spills in Calaveras Creek under the WSIP, the overall pattern and quantity of high winter releases and spills would remain very similar to pre-2002 conditions, and the impact on riparian habitats would be less than significant.

Flows in Calaveras Creek below Calaveras Dam would be altered in two ways during the two- to five-year period when the reservoir is being refilled. First, there would be no cone valve releases into Calaveras Creek below the dam. Second, the SFPUC would initiate required minimum instream flow releases (see Table 5.4.1-9) when construction of the new Calaveras Dam is completed. When flows at the confluence of Alameda and Calaveras Creeks fall below the minimum required flow, generally during protracted dry periods, releases would be made from Calaveras Dam or upstream on Alameda Creek. These releases would ensure that existing riparian habitat would be sustained; therefore, impacts on riparian habitats related to filling the reservoir would be *less than significant*, and no mitigation measures would be required.

Impacts from Minimum Flows. Under the WSIP, minimum flows may be maintained year-round, depending if flow releases are from Calaveras Reservoir or from upstream on Alameda Creek. Sustained minimum flows during the dry season could slightly increase groundwater recharge. It could also facilitate the conversion from riparian habitats that require only seasonally flowing water to those that require permanent flowing water, such as alder riparian forest. This potential replacement of one sensitive riparian habitat with another one (with no change in the total extent of riparian habitat) would be *less than significant*.

Impacts from Changes to Pattern of High-Flow Releases. The proposed new Calaveras Dam would be equipped with several means by which to release large volumes of water into Calaveras Creek, allowing for greater control over released flow levels than at present. Peak releases into Calaveras Creek could be greater than under existing conditions because the improved outlet works would be fully operational, which could enhance channel-forming processes. However, the narrow canyon, confined riparian zone, and bedrock channel are limiting factors. There might be slight changes in the pattern of high-flow releases due to the operational goal of maintaining Calaveras Reservoir as full as feasible. However, these changes would be relatively small and would not substantially alter the dynamics of the riparian habitats in Calaveras Creek. Therefore, impacts on sensitive habitats related to changes in the pattern of high-flow releases would be *less than significant*, and no mitigation measures would be required.

Key Special-Status Species

Impact of Changed Minimum and High Flows. Potentially affected key special-status species are California red-legged frog and foothill yellow-legged frog, which could breed in Calaveras Creek. No critical habitat is present in Calaveras Creek below Calaveras Dam. Average winter flows under the WSIP would be lower than under existing conditions, especially during wet and above-normal rainfall years, thus reducing the available breeding and foraging habitat. The WSIP would maintain minimum flows year-round, which would be beneficial in providing more sustained aquatic habitat for breeding and foraging. The peak flows might not be greatly reduced and therefore might not reduce entrainment and scouring.

Impact of Changed Pattern of Releases. A description of operational releases has not been developed at the program level. The rate at which flows are increased during releases and the magnitude of recurring controlled releases are important to breeding amphibians; gradual increases in flows allow adults and juveniles to seek sheltered sites, while rapid increases in flow can wash them downstream. The highest flows can cause significant scouring, resulting in losses of egg masses and tadpoles. At the program level, these impacts are conservatively considered *potentially significant*, because the outlet works at Calaveras Dam would have the capacity for greater releases with more rapid ramping up. Depending on the timing and volume of these releases, they could increase the risk of washing away adults, eggs, or tadpoles.

Other Species of Concern

No plant species of concern would be affected by WSIP operations in the vicinity of Calaveras Creek below the reservoir. Potential changes in riparian habitat could result in a minor change in breeding habitat for riparian-nesting birds such as raptors, egrets, and songbird species of concern. Although there could be some change in the structure and species composition of the riparian habitats, the overall extent would not change. Therefore, this impact would be *less than significant*, and no mitigation measures would be required.

Common Habitats and Species

The WSIP would not interfere substantially with the movement of any native wildlife species or wildlife nursery sites, nor would it cause a plant wildlife population to drop below self-sustaining levels. Impacts on common habitats and species would be *less than significant*, and no mitigation measures would be required.

Impact Conclusions

Overall, implementation of the proposed WSIP water supply and system operations would result in *potentially significant* impacts on terrestrial biological resources in Calaveras Creek, but only with respect to high flows and the resulting loss of frog eggs or egg masses. Measure 5.4.6-3, Operational Procedures for Calaveras Dam Releases, requires the development of procedures to manage releases from Calaveras Dam so as to minimize habitat impacts and maximize benefits by mimicking the natural regime to the extent possible. The measure would include procedures for increasing and decreasing the rate of releases. With implementation this measure, impacts on terrestrial biological resources in this reach of Calaveras Creek would be reduced to a less-than-significant level.

Impact 5.4.6-4: Effects on riparian habitat and related biological resources along Alameda Creek, from the confluence with Calaveras Creek to the confluence with San Antonio Creek.

Sensitive Habitats

Sensitive riparian communities in this section of Alameda Creek include sycamore alluvial woodland, Central Coast arroyo willow riparian forest, valley oak woodland, and white alder riparian forest. The WSIP would substantially reduce winter flows compared to those under existing conditions (they would be similar to, but slightly muted from, flows in the reach directly below the diversion dam). The change in flows would have no effect on the woodland communities; for stand regeneration, sycamore woodland requires flows similar to unimpaired flows. The slight potential reduction in flows (as it relates to stand regeneration for willow and alder riparian forest) would be offset by increased summer flows under the 1997 MOU. Sustained winter and summer minimum flows could facilitate the conversion of existing riparian habitats, such as sycamore alluvial woodland and valley oak woodland, to alder- and willow-dominated habitats, but the extent of this potential impact would be small. Channel incision is not expected to be an important factor because of the large cobble content of the substrate. Overall, these impacts would offset one another; as a result, the impact on sensitive habitats would be *less than significant*, and no mitigation measures would be required.

Key Special-Status Species

This section of Alameda Creek supports California red-legged frog and foothill yellow-legged frog. Flow in this section of Alameda Creek would be lower than under existing conditions but higher than under pre-2002 conditions. Impacts on these species could be both beneficial and adverse, depending on annual rainfall and localized site conditions along the creek. Compared with existing conditions, lower winter flows could improve breeding conditions in the short term but reduce the total available breeding habitat and habitat for macroinvertebrate food resources. Compared with pre-2002 conditions, higher winter flows could cause some breeding losses, but would improve long-term habitat conditions because of greater aquatic habitat complexity. Sustained minimum flows would generally provide more consistent breeding habitat. In general, impacts on key special-status species would be both beneficial and adverse and would likely depend on year-to-year conditions and site-to-site conditions within this reach of the creek. Because of the uncertainty, the potential impact of releases on breeding amphibians is considered *potentially significant*. Alameda whipsnake would not be affected by WSIP operations along Alameda Creek.

Other Species of Concern

No plant species of concern would be affected by WSIP operations in this section of Alameda Creek. A less-than-significant change in the structure and diversity of riparian habitat would not substantially alter the extent or quality of breeding habitat for songbirds, raptors, and mammals. The overall impact on habitat would be less than significant, so the impact on species of concern would be *less than significant.* No mitigation measures would be required.

Common Habitats and Species

Common upland habitats would not be affected by changes in stream flows resulting from WSIP operations. Since the overall extent of riparian habitat is expected to be about the same (even if the structure and composition changes), impacts on common species would be *less than significant*. No mitigation measures would be required.

Impact Conclusions

Overall, implementation of the proposed WSIP water supply and system operations would result in *potentially significant* impacts on key special-status species. Measure 5.4.6-3, Operational Procedures for Calaveras Dam Releases, would require the development of procedures to manage releases from Calaveras Dam so as to minimize amphibian breeding habitat impacts and maximize benefits by mimicking the natural regime to the extent possible. Implementation of this measure would reduce impacts on key special-status species on this reach of Alameda Creek. Measure 5.4.5-3a, Minimum Flows for Resident Trout on Alameda Creek, would ensure adequate flows in Alameda Creek below the diversion dam during December through April. Taken together, these measures would reduce impacts on key special-status species in this portion of Alameda Creek to a less-than-significant level.

Impact 5.4.6-5: Effects on riparian habitat and related biological resources in San Antonio Reservoir.

Sensitive Habitats

Sensitive habitats that could be affected by operations of San Antonio Reservoir include small areas of freshwater marsh and riparian scrub on gently sloping reservoir margins. The maximum reservoir levels would not change. No upland habitats would be affected. As discussed in Section 5.4.1, storage levels at San Antonio Reservoir would drop every fifth year for planned system maintenance. The reservoir would be refilled to typical operating levels within one to two years after the maintenance period. The depth and duration of drawdown would be within the range of historic operating conditions. Thus, WSIP impacts on riparian and freshwater marsh habitat along the margins of San Antonio Reservoir would be *less than significant*, and no mitigation measures would be required.

[Paragraph has been deleted per responses to comments or staff-initiated text changes (Vol. 7, Chapter 16).]

Key Special-Status Species

WSIP operations at San Antonio Reservoir would not result in impacts on upland habitats, and therefore no impacts on Alameda whipsnake would occur. Key special-status species that could be affected by WSIP operations at San Antonio Reservoir include California red-legged frog and California tiger salamander. However, impacts on riparian scrub and freshwater marsh habitat would be less than significant, and therefore impacts on the habitat of California red-legged frog and California tiger salamander would be *less than significant*, and no mitigation measures would be required.

Other Species of Concern

San Antonio Reservoir maximum water surface elevation would not change, and fluctuations in water level that would occur would be within the historic operating range. As noted in the discussion of Calaveras Reservoir, studies of amphibians and breeding birds at a similar reservoir project in Washington State found little change in habitat suitability with relatively minor fluctuations in reservoir elevation. As a result, WSIP-related impacts on other species of concern in San Antonio Reservoir would be *less than significant*, and no mitigation measures would be required.

Finally, waterfowl and other littoral species could be temporarily displaced from preferred habitat during drawdowns; however, the availability of numerous alternative food resources and the minor change in reservoir operations support a determination of a negligible effect.

Common Habitats and Species

No impacts on upland habitats would occur. There could be a slight reduction in the extent of weedy habitat around the periphery of the reservoir below the maximum reservoir elevation. This impact would be *less than significant*, and no mitigation measures would be required.

Impact Conclusions

Overall, impacts on terrestrial biological resources in the San Antonio Reservoir area due to implementation of the proposed WSIP operations would be *less than significant*, and no mitigation measures would be required.

Impact 5.4.6-6: Effects on riparian habitat and related biological resources along San Antonio Creek between Turner Dam and the confluence with Alameda Creek.

Sensitive Habitats

Sensitive habitats along San Antonio Creek include sycamore alluvial woodland and willow scrub and mixed riparian habitats. Releases into San Antonio Creek would be rare, similar to existing conditions. As a result, no change in conditions for riparian and wetland habitats would occur; the impact of the WSIP would be *less than significant*, and no mitigation measures would be required.

Key Special-Status Species

Any impacts on habitat for key special-status species (e.g., California red-legged frog) would be minimal, and the effect on breeding habitat would be *less than significant*. No mitigation measures would be required.

Other Species of Concern

Due to the lack of change from existing conditions, impacts on common species at risk would be *less than significant*, and no mitigation measures would be required.

Common Habitats and Species

No impacts on common habitats would occur as a result of WSIP changes in the operation of Turner Dam. The operational changes in this reach would not interfere substantially with the movement of any native wildlife species or wildlife nursery sites, nor would it cause a plant or wildlife population to drop below self-sustaining levels. Therefore, this impact would *not apply* to common habitats and species.

Impact Conclusions

Overall, impacts on terrestrial biological resources in San Antonio Creek due to implementation of the proposed WSIP water supply and system operations would be *less than significant*, and no mitigation measures would be required.

Impact 5.4.6-7: Effects on riparian habitat and related biological resources along Alameda Creek below the confluence with San Antonio Creek.

Sensitive Habitats

Flow in Alameda Creek between San Antonio Creek and Arroyo de la Laguna would be reduced during the winter months, especially during normal and wetter rainfall years. However, changes in flow would be buffered by other stream inputs from this point downstream. Judged against the baseline of current conditions, impacts on riparian and wetland habitats in this reach of Alameda Creek would be *less than significant*, and no mitigation measures would be required.

Key Special-Status Species

There would be little alteration in habitat for identified key special-status species due to WSIP-related operational changes. As a result, impacts on key special-status species would be *less than significant*, and no mitigation measures would be required.

Other Species of Concern

Potential impacts of WSIP operations on species of concern would be *less than significant*, for the same reasons described above for riparian and wetland habitats. No mitigation measures would be required.

Common Habitats and Species

Because flow changes in this reach of Alameda Creek would be minimal during normal to wet years, there would be limited impacts on terrestrial ecological resources. Thus, common habitats and species would not be affected, and this impact would *not apply*.

Impact Conclusions

Overall, impacts on terrestrial biological resources in Alameda Creek below San Antonio Creek due to implementation of the proposed WSIP water supply and system operations would be *less than significant*, and no mitigation measures would be required.

Impact 5.4.6-8: Conflicts with the provisions of adopted conservation plans or other approved biological resources plans.

The only plan relevant to proposed WSIP operations is the *Alameda Watershed Management Plan*. The WSIP program as a whole would be consistent with the provisions of this plan, which places priority on resource protection while ensuring that the objective of delivering adequate, high-quality water is met. The SFPUC is currently preparing a habitat conservation plan for the Alameda watershed; however, WSIP operations are not considered in this plan, which covers only existing operations. Therefore, impacts related to conflicts with adopted plans would be *less than significant*.

5.4.7 Recreational and Visual Resources

Chapter 4, Section 4.12, Recreational Resources, provided a general overview of the park and recreational facilities and resources in the WSIP study area and near proposed facility projects. This section discusses specific recreational resources and activities within the Alameda Creek watershed that could be affected by the proposed water supply and system operations. Thus, the analysis deals primarily with water-related recreation, including fishing, swimming, boating, rafting, or activities such as scenic viewing, walking, hiking, or camping adjacent to water bodies.

5.4.7.1 Setting

The three main water features within the Alameda Creek watershed are San Antonio Reservoir, Calaveras Reservoir, and Alameda Creek. The natural drainage basin for Calaveras Reservoir includes Arroyo Hondo and Calaveras Creek from the southeast and local drainage areas along the west shore of the reservoir. The natural drainage basin for San Antonio Reservoir, which is the same as the watershed for San Antonio Creek, includes the tributary sub-drainage basins for Indian Creek, La Costa Creek, and Williams Gulch. Alameda Creek also receives limited surface flows from Calaveras Creek, Arroyo Hondo, and San Antonio Creek, as well as flows and runoff from tributary drainages in the Diablo Range and Livermore Valley. Farther downstream, Alameda Creek receives additional flows from Arroyo de la Laguna and Vallecitos Creek. The two reservoirs, as well as much of the rest of the Alameda Creek watershed, are located within the SFPUC Alameda watershed. This watershed is described below under Alameda Creek. The visual quality, recreational uses, and facilities associated with each water feature, including both SFPUC-managed and other uses and facilities, are described below (SFPUC, 2001).

Alameda Creek Recreation and Visual Quality

Alameda Creek runs through several local parks, municipalities (including Alameda County), and the cities of Fremont and Union City. Alameda Creek also runs through the Sunol Regional Wilderness and is adjacent to the Vargas Plateau Regional Preserve, Quarry Lakes Regional Recreation Area, and Coyote Hills Regional Park, all of which are operated by the EBRPD. The recreational uses of the creek are described below.

SFPUC Alameda Watershed

The CCSF owns about 30 percent of Alameda Creek's natural watershed (see Figure 5.4.1-1 in Section 5.4.1). The CCSF-owned portion of the Alameda Creek watershed encompasses approximately 36,000 acres of land, with 23,000 acres in Alameda County and 13,000 acres in Santa Clara County (see Figure 5.4.1-2 in Section 5.4.1). Visually, these areas range from steeply sloped, heavily vegetated semi-wilderness areas to industrialized and gravel mining areas in developed valleys. The CCSF leases some of its upper watershed land to the East Bay Regional Park District (EBRPD) for public recreational use, as described below. Public access to interior parts of the CCSF-owned watershed lands, including stretches of Alameda Creek, is prohibited because of the risk of fire and potential degradation of water quality and natural resources. The creek within these watershed lands is therefore not used for boating, fishing, swimming, or other water-related recreation. However, the SFPUC, which manages the watershed lands, does allow access to some internal fire roads and trails by permit for research or educational purposes to groups accompanied by volunteer leaders (SFPUC, 2001; 2007).

Sunol Water Temple. The Sunol Water Temple, a pavilion and temple situated over a convergence of the infiltration galleries and the downstream end of the defunct Pleasanton-Sunol pipeline, is located within the SFPUC Alameda watershed and adjacent to Alameda Creek. The temple is a destination for picnickers and tourists as a scenic and historic landmark and is open to the public at specified hours. It is also available for public events by SFPUC permit (SFPUC, 2001).

Sunol Regional Wilderness

The 6,858-acre Sunol Regional Wilderness, part of the Sunol-Ohlone Regional Park managed by the EBRPD, lies between San Antonio Reservoir and Calaveras Reservoir, with Alameda Creek running along its eastern edge (see Figure 4.12-1, in Section 4.12). A portion of the Sunol Regional Wilderness is located on SFPUC Alameda watershed lands leased by the EBRPD. Aesthetically, this parkland is comprised of undeveloped canyon, streamside, and ridgeline areas; some of the ridges offer expansive views of the surrounding areas.

The Sunol Regional Wilderness includes more than 26 miles of hiking, equestrian, and biking trails, including the Ohlone Wilderness Regional Trail (see below). Facilities and programs include picnic areas, barbeque pits, group and backpack camps, a visitor's center, naturalist-led activities, and equestrian facilities. At least one camping area is situated next to Alameda Creek. Little Yosemite, a scenic gorge on Alameda Creek, is located within the Sunol Regional Wilderness. Swimming is permitted within the wilderness area, except in Little Yosemite. Other water sports, including boating, rafting, and canoeing, are generally not feasible in this portion of Alameda Creek due to the creek's water level, and fishing is not allowed in creek (EBRPD, 2007a).

Ohlone Wilderness Regional Trail

The Ohlone Wilderness Regional Trail, managed by the EBRPD, is a 28-mile trail for hikers and equestrians (no bicycles or motor vehicles are permitted) that stretches across and connects four regional parks and wilderness areas, including Ohlone Regional Wilderness, Mission Peak Regional Preserve, Sunol Regional Wilderness, and Del Valle Regional Park. It also passes through two watershed areas leased from the CCSF. The trail crosses Alameda Creek within the Sunol Regional Wilderness. This trail affords both secluded canyon views and expansive ridge-top vistas.

Alameda Creek Regional Trail

The Alameda Creek Regional Trail follows the banks of Alameda Creek in southern Alameda County from the mouth of Niles Canyon (in the Niles District of Fremont) westward to San Francisco Bay for a distance of 12 miles. The trail runs on both sides of the creek; on the north side of the creek, it is an unpaved trail for pedestrians, equestrians, and cyclists, and on the south side is a paved trail for pedestrians and cyclists only. Motor vehicles are not allowed on the trail. This trail includes views of both semi-natural and urban landscapes.

The trail is accessible from several thoroughfares in the Fremont, Union City, and Newark areas. It provides access to Coyote Hills Regional Park (from the south side of the creek only) and

Quarry Lakes Regional Recreation Area (from both sides of the creek). The Alameda Creek Stables Staging Area, Beard Staging Area, Isherwood Staging Area, and Niles Staging Area are stationed along the trail, providing facilities such as restrooms, picnic areas, and drinking fountains (EBRPD, 2007b).

Vargas Plateau Regional Preserve

The Vargas Plateau Regional Preserve, managed by the EBRPD, is located adjacent to the SFPUC Alameda watershed along a common boundary line on the east side of the preserve. Its northern boundary touches Alameda Creek for a distance of about 2,500 feet. A portion of the decommissioned Sunol Aqueduct crosses the park within a utility easement. Currently, the preserve is not suitable for active public use due to the lack of public road access, the need to protect natural or man-made resources, and other factors related to public safety and access. The EBRPD is currently in the process of adopting the *Vargas Plateau Regional Park Land Use Plan*, which would create a regional park that provides trails, outdoor recreation, campgrounds, and nature appreciation areas (EBRPD, 2007e).

Quarry Lakes Regional Recreation Area

Quarry Lakes Regional Recreation Area, managed by the EBRPD, borders the north side of Alameda Creek for approximately 1.8 miles in the city of Fremont. The Alameda Creek Trail is accessible from several points in the recreation area. The recreation area has several lakes; public access is provided to these lakes for fishing, swimming, and boating (EBRPD, 2007c). The lakes afford open-space and water-feature views for park users.

Coyote Hills Regional Park

Coyote Hills Regional Park, managed by the EBRPD, borders the south side of Alameda Creek for approximately 1.1 miles in the city of Fremont (see Figure 4.12-1 in Section 4.12). The Alameda Creek Trail is accessible from several points in the park. The park provides naturalist programs, a visitor center, group campgrounds, several miles of trails, cultural artifact displays, and a boardwalk through marshlands. Nature viewing and hiking are encouraged within the park (EBRPD, 2007d).

Don Edwards San Francisco Bay National Wildlife Refuge

The Don Edwards San Francisco Bay National Wildlife Refuge borders Alameda Creek as it approaches San Francisco Bay (see Figure 4.12-1 in Section 4.12). The wildlife refuge, managed by the USFWS, includes trails and nature viewing. One of the refuge's stated goals is to provide opportunities for wildlife-oriented recreation and nature study (USFWS, 2007). The wildlife refuge provides views of the bay and associated wetland areas as well as of the nearby salt ponds.

Other Access to Alameda Creek

Other recreational facilities in Fremont and Union City that either abut or provide access to Alameda Creek and the Alameda Creek Trail include Shinn Pond, Niles Community Park, Kaiser Pond, the Model Mariners boat club, Rancho Arroyo Park, William Cann Park, and David Jones Park (EBRPD, 2007b).

San Antonio and Calaveras Reservoirs

San Antonio and Calaveras Reservoirs are located entirely within the SFPUC Alameda watershed. As mentioned above, public access to interior parts of the Alameda watershed lands is prohibited, and the reservoirs are not available for water-related recreation; however, the SFPUC does allow access to some internal fire roads and trails by permit for research or educational purposes to groups accompanied by volunteer leaders (SFPUC, 2001). Both reservoirs appear as visually prominent water features in views from surrounding ridges.

Regulatory Considerations

As discussed in Chapter 4, Section 4.2, Plans and Policies, the *Alameda Watershed Management Plan* includes the following policy related to visual quality:

- *Policy WA 9*: If new facilities require additional new locations, require that view shed studies be conducted to minimize, eliminate or conceal the violation of scenic values.

However, the WSIP water supply and system operations analyzed in this section would not require any new facilities, other than those already discussed and analyzed in Section 4.3, Land Use and Visual Quality. Therefore, this policy is not addressed further in this section.

5.4.7.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to recreational or visual resources, but generally considers that implementation of the proposed program would have a significant impact on these resources if it were to:

Recreation

- Increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated (Secondary impacts of growth are evaluated in Chapter 7, Growth-Inducement Potential and Indirect Effects of Growth)
- Include recreational facilities or require the construction or expansion of recreational facilities that might have an adverse physical effect on the environment (Secondary impacts of growth are evaluated in Chapter 7)
- Physically degrade existing recreational resources

The physical degradation of existing resources could occur if the WSIP were to: (1) remove or damage existing recreational resources; (2) cause environmental impacts (such as air quality or noise effects) that would indirectly cause a deterioration in the quality of the recreational experience; or (3) disrupt access to existing recreational facilities (which would divide a community from some of the established amenities used by its members).

Visual Quality

- Have a substantial adverse effect on a scenic vista
- Substantially damage scenic resources, including but not limited to trees, rock outcroppings, and other features of the built or natural environment that contribute to a scenic public setting
- Substantially degrade the existing visual character or quality of the site and its surroundings

Approach to Analysis

The WSIP would change water levels in reservoirs and alter flow in streams in the Alameda watershed. WSIP-induced changes in reservoir water levels and stream flow in the Alameda Creek watershed were estimated using the HH/LSM (see Appendix H). WSIP-induced changes in reservoir water levels and stream flow were estimate semi-quantitatively. A specialist in recreational and visual resources assessed the impacts of the WSIP on these environmental elements based on the estimated WSIP-induced changes in reservoir water levels and stream flow (see Section 5.4.1).

Impact Summary

Table 5.4.7-1 presents a summary of the impacts on recreational and visual resources in the Alameda Creek watershed that could result from implementation of the proposed water supply and system operations.

TABLE 5.4.7-1
SUMMARY OF IMPACTS –
RECREATIONAL AND VISUAL RESOURCES IN THE ALAMEDA CREEK WATERSHED

Impact	Significance Determination
Impact 5.4.7-1: Effects on recreational facilities and/or activities	LS
Impact 5.4.7-2: Visual effects on scenic resources or the visual character of water bodies	LS

LS = Less than Significant impact, no mitigation required

Impact Discussion

Impact 5.4.7-1: Effects on recreational facilities and/or activities.

The WSIP would not affect water-related recreational facilities or activities in the Alameda Creek watershed. As described above in Section 5.4.7.1, Setting, water recreation is not allowed on the SFPUC reservoirs; because there would be no change to this policy under the WSIP, impacts on recreation would not occur as a result of water level changes in the reservoir. With respect to recreation in and along the creeks in the watershed there is either: (1) no or only very limited water recreation occurring at present, and/or (2) the WSIP-related flow changes described in Section 5.4.1 would not change creek flows to an extent that existing recreational use would be affected. The proposed program would reduce peak flows along Alameda Creek in the Sunol Regional Wilderness in the winter and early spring months. The reduced flows would somewhat degrade the recreational experience for hikers on the trails near (or with views of) Alameda Creek, however, with the proposed minimum flows for resident trout on Alameda Creek to be released from the Alameda Creek Diversion Dam when such flows are present, this would be a *less-than-significant* impact.

Impact 5.4.7-2: Visual effects on scenic resources or the visual character of water bodies.

As described in Section 5.4.1, changes in stream flow and reservoir water levels under the WSIP are not beyond the range of flow and water level variation that occurs now. The reductions in peak flows in average, above-average, and wet years under the proposed program would not be visually apparent to most recreational users and others viewing the creeks and reservoirs. The main exception would be the reductions in peak flows in Alameda Creek in the Sunol Regional Wilderness, including the scenic Little Yosemite area, during winter and spring months. Reduced peak flows in Alameda Creek in the Little Yosemite area would somewhat degrade the visual character Alameda Creek, however, with the proposed minimum flows for resident trout on Alameda Creek to be released from the Alameda Creek Diversion Dam when such flows are present, this would be a *less-than-significant* impact.

Proposed summer releases to support fisheries would increase flows in Calaveras Creek and downstream in Alameda Creek and would have a beneficial visual effect, because the releases would enhance the creek's appearance in the summer months when recreational use is highest. Therefore, no significant adverse visual impacts would occur, and no mitigation is required.

5.5 San Francisco Peninsula Streams and Reservoirs

5.5 San Francisco Peninsula Streams and Reservoirs

Section 5.5 Subsections

5.5.1 Stream Flow and Reservoir Water Levels

The following setting section describes the streams and reservoirs on the San Francisco Peninsula that could be affected by the WSIP. The impact section (Section 5.5.1.2) provides a description of the changes in stream flow and reservoir water levels that would result from implementation of the WSIP.

5.5.1.1 Setting

The SFPUC operates four water supply reservoirs on the San Francisco Peninsula: Pilarcitos, Upper and Lower Crystal Springs, and San Andreas Reservoirs. The Spring Valley Water Company built the reservoirs between 1864 and 1890. The four reservoirs and two streams (San Mateo Creek and Pilarcitos Creek) on the Peninsula could be affected by the WSIP. San Mateo Creek, and its tributary San Andreas Creek, flow southward in the rift valley formed by the San Andreas fault and then turn east, flowing to San Francisco Bay. Pilarcitos Creek also flows southward, but it turns to the west and flows to the Pacific Ocean. **Figure 5.5.1-1** shows the boundaries of the drainage areas of the four Peninsula reservoirs, and **Figure 5.5.1-2** shows the SFPUC regional facilities associated with these reservoirs. The SFPUC's water supply facilities on the San Francisco Peninsula lie within two watersheds, the San Mateo Creek and Pilarcitos Creek watersheds, which are referred to collectively as the Peninsula watershed.

San Mateo Creek

General Description

San Mateo Creek, and its major tributary San Andreas Creek, rises in the Coast Range mountains west of the city of Millbrae. San Mateo and San Andreas Creeks are fed by rainfall, which varies with altitude and is in the range of 25 to 40 inches annually. Almost all of the rainfall occurs between October and April.

Figure 5.5.1-2
Peninsula Watershed Facilites and Flow Locations Analyzed

THIS PAGE INTENTIONALLY LEFT BLANK

The upper reaches of San Mateo Creek and all reaches of San Andreas Creek are in undeveloped land, most of which is owned by the City and County of San Francisco (CCSF). The lower reaches of San Mateo Creek below Lower Crystal Springs Dam flow through a densely developed urban area to San Francisco Bay, about 1.6 miles north of the Hayward–San Mateo Bridge. The main tributary of San Mateo Creek downstream of Lower Crystal Springs Dam is Polhemus Creek.

Stream Flow and Water System Operations

Flow in San Mateo and San Andreas Creeks was first affected by water system operations in 1870 when San Andreas Dam was built in the upper reaches of San Andreas Creek. The dam impounds San Andreas Reservoir. Upper Crystal Springs Dam was built just upstream of the confluence of San Andreas Creek and San Mateo Creek in 1877 and formed Upper Crystal Springs Reservoir. In 1890, Lower Crystal Springs Dam was built on San Mateo Creek downstream of Upper Crystal Springs Reservoir, forming Lower Crystal Springs Reservoir. In 1924, culverts were built through Upper Crystal Springs Dam to hydraulically link Upper and Lower Crystal Springs Reservoirs. The current maximum capacities of San Andreas and Crystal Springs Reservoirs are 19,000 and 56,800 acre-feet, respectively. (The California Department of Water Resources, Division of Safety of Dams, currently restricts Crystal Springs Reservoir storage). **Figures 5.5.1-3** and **5.5.1-4** show historical water surface elevations in San Andreas and Crystal Springs Reservoirs between 1998 and 2006.

San Andreas and Crystal Springs Reservoirs serve as terminal reservoirs for the SFPUC water system. They not only capture local runoff but also store water conveyed from the Tuolumne River, the Alameda Creek watershed, and Pilarcitos Creek; consequently, the reservoirs are larger than would be necessary if their sole purpose were to capture runoff from local watersheds. The reservoirs on San Andreas and San Mateo Creeks eliminate flow in the creeks immediately below the dams, except for occasional spills or releases from the reservoirs and seepage through the dams. The creeks gain flow in a downstream direction as a result of tributary flow from surface and groundwater sources. No measurements of flow in either creek are available.

Although flood reduction was not one of the original purposes of the CCSF's reservoirs in the San Mateo Creek watershed, Crystal Springs Reservoir reduces peak flow in the creek most of the time. Space for floodwaters is provided in the reservoir when major storms are expected. Once the space allocated for flood storage is filled, uncontrolled flow over the spillway at Lower Crystal Springs Dam can occur, or controlled releases can be made from outlets equipped with valves. Before the valves are opened, the SFPUC considers potential downstream effects. The dam is operated so that peak flows do not increase above the peak flows that would have existed had the reservoirs not been constructed.

Pilarcitos Creek/Pilarcitos Reservoir

General Description

Pilarcitos Creek rises on the eastern flanks of Montara Mountain in the Coast Ranges. The creek flows southward through the mountains before turning westward and discharging to the Pacific Ocean at Half Moon Bay, as shown in **Figure 5.5.1-5**. Rainfall in the Pilarcitos Creek watershed

SFPUC Water System Improvement Program . 203287

Figure 5.5.1-5
Pilarcitos Creek Watershed

is variable, ranging from 26 inches annually at the coast to 42 inches near Pilarcitos Reservoir. The approximately 27-square-mile Pilarcitos Creek watershed consists primarily of relatively rugged uplands, characterized by shrubs and grasslands. The CCSF owns substantial portions of the upper watershed, and the Peninsula Open Space Trust protects large areas of the lower watershed above Arroyo Leon. Developed lands within the watershed are primarily agricultural and are located along the lower reaches of the stream corridors. Residential land uses are also present in the watershed, generally along roadways. Other land uses include a cemetery on Highway 92 at Skyline Boulevard, a sanitary landfill in upper Corrida Los Trancos Canyon, and a quarry in Nuff Creek Canyon.

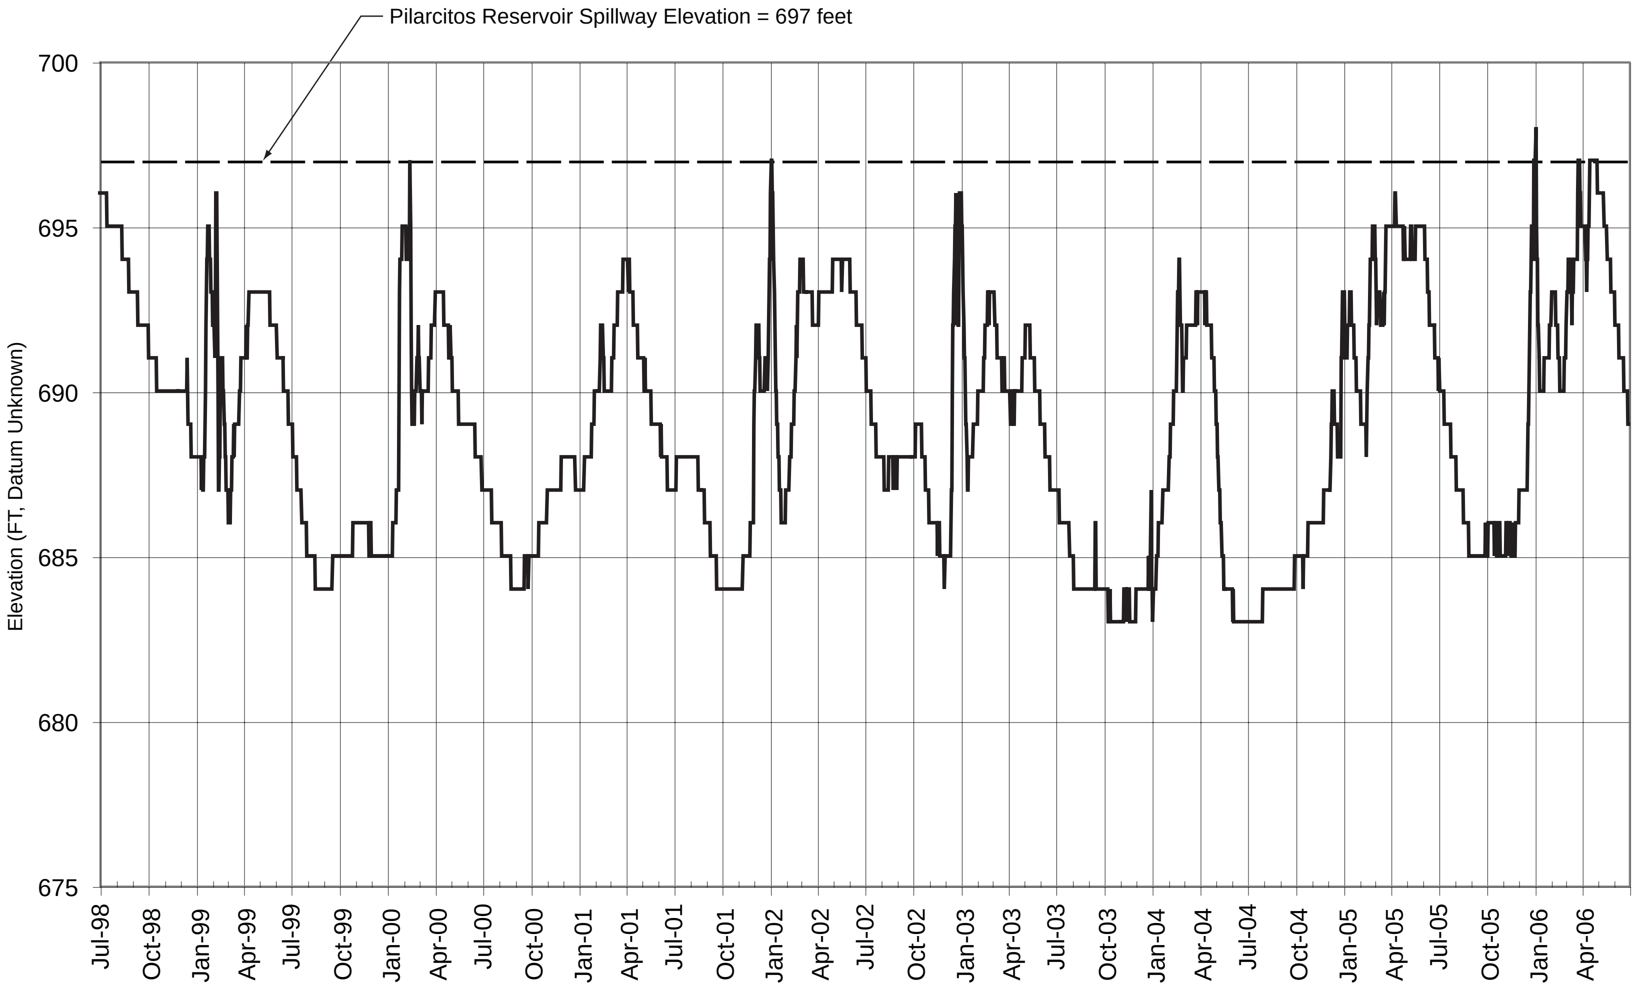
Stream Flow and Water System Operations

Flow in Pilarcitos Creek was first affected by water system operations in 1864 when Pilarcitos Dam was built, and again in 1871 when Stone Dam was built. Pilarcitos Dam impounds Pilarcitos Reservoir, which has a maximum capacity of 3,100 acre-feet of water. Stone Dam, which is about two miles downstream of Pilarcitos Reservoir, is essentially a diversion dam; it impounds about 15 acre-feet of water.

Local runoff from an approximately six-square-mile watershed is Pilarcitos Reservoir's only source of water. Inflow to the reservoir occurs predominantly from rainfall during December through April. Annual runoff to Pilarcitos Reservoir is quite variable and has ranged from almost nothing to more than 15,000 acre-feet. Average annual runoff is estimated to be approximately 4,000 acre-feet per year. Tributaries that join Pilarcitos Creek between Pilarcitos Reservoir and Stone Dam contribute an average annual of about 1,850 acre-feet per year.

The SFPUC uses Pilarcitos Reservoir to store water for use by the Coastside County Water District (Coastside CWD) and to store and divert water for its own use. During the winter months, the SFPUC typically diverts most of the runoff into Pilarcitos Reservoir from the Pilarcitos Creek watershed to its reservoirs in the San Mateo Creek watershed, primarily to San Andreas Reservoir, but also to Crystal Springs Reservoirs. At the end of the rainy season, diversions from Pilarcitos Creek to San Andreas Reservoir are curtailed, with the goal of filling Pilarcitos Reservoir by the late spring. As indicated in **Figure 5.5.1-6**, which shows historical water surface elevations in Pilarcitos Reservoir from 1998 to 2006, the reservoir refills or almost refills in the winter or spring of most years. After the reservoir has filled, the SFPUC attempts to limit releases from Pilarcitos Reservoir to that amount requested by Coastside CWD to meet its water needs. However, at times, additional water may be released from Pilarcitos Reservoir and diverted to Crystal Springs Reservoir at Stone Dam or released from Stone Dam (see discussion below regarding experimental releases from Stone Dam to Pilarcitos Creek).

The SFPUC releases water from Pilarcitos Reservoir to Pilarcitos Creek during the summer for use by Coastside CWD and during the winter diverts water from Pilarcitos Reservoir to San Andreas Reservoir through Pilarcitos Tunnels No. 1 and 2. It can also divert water from Pilarcitos Reservoir to Crystal Springs Reservoir through Pilarcitos Tunnel No. 1 and from Stone Dam to Crystal Springs Reservoir through Stone Dam Tunnel No. 1; this is less desirable than transfers to San Andreas Reservoir, however, because San Andreas Reservoir is at a higher elevation than Crystal Springs Reservoir. Any water diverted from Pilarcitos Creek to Crystal Springs Reservoir must ultimately be pumped to San Andreas Reservoir before it is treated and delivered to retail customers. Consequently, the SFPUC only diverts water from the Pilarcitos Creek watershed to



SOURCE: SFPUC, 2007

Figure 5.5.1-6
Pilarcitos Reservoir, Historical Water Levels, 1998 to 2006

Crystal Springs Reservoir when the available water at Pilarcitos Reservoir exceeds the conveyance capacity of Pilarcitos Tunnels No. 1 and 2, or when water is available as result of tributary flow between Pilarcitos Reservoir and Stone Dam.

Water released from Pilarcitos Reservoir flows down Pilarcitos Creek to Stone Dam. Water is diverted at Stone Dam into a tunnel and pipeline that leads to Stone Dam Tunnel No. 1. Coastside CWD has a turnout from the pipeline just upstream of Stone Dam Tunnel No. 1. Coastside CWD's own pipeline, which has a maximum capacity of about 2 million gallons per day (mgd), conveys water from this turnout to the Nunes Water Treatment Plant and on to its service area.

Coastside CWD supplies water to the city of Half Moon Bay and several unincorporated communities, including El Granada, Miramar, and Princeton-by-the Sea. Its water sources are surface water from Denniston Creek, two groundwater wellfields, and the SFPUC. Coastside CWD's total water demand currently averages 2.5 mgd, but varies seasonally. Demand in December, January, and February is about 1.6 mgd, and in July and August is about 3.2 mgd. Coastside CWD meets its customers' water demand from its own water sources to the degree it can, and then supplements its own supplies with water from the SFPUC.

Because Coastside CWD's own water sources produce only a modest amount of water, Coastside CWD supplements its own water supplies with water from the SFPUC year-round. In the winter months, when demand in the Coastside CWD service area is at its seasonal minimum, Coastside CWD obtains 0.5 to 1 mgd from the SFPUC. In the summer when demand is at its seasonal maximum, Coastside CWD obtains 1.5 to 3 mgd from the SFPUC.

When Coastside CWD needs water from the SFPUC, it requests that the SFPUC release water from Pilarcitos Dam for diversion by Coastside CWD at Stone Dam. During the summer months, Coastside CWD is unable to receive enough water from the Pilarcitos Creek watershed to meet its need for supplemental water supplies. This may be because (1) Pilarcitos Reservoir is drawn down and the SFPUC is unable to release enough water down Pilarcitos Creek to meet Coastside CWD's needs or (2) the capacity of the upper portion of the pipeline from Stone Dam to the Nunes Water Treatment Plant is insufficient to convey the needed volume of water to the Coastside CWD, even when sufficient water is available from the Pilarcitos Creek watershed. Under these circumstances, Coastside CWD activates a pump to lift water out of Crystal Springs Reservoir to a ridge-top storage tank; from there, the water is conveyed to the Nunes Water Treatment Plant.

Currently, and in a normal year, about half the water from the upper Pilarcitos Creek watershed is diverted to San Andreas and Crystal Springs Reservoirs; the other half is released down Pilarcitos Creek and diverted for use by Coastside CWD at Stone Dam. Currently, approximately three-quarters of Coastside CWD's water supply is provided by the SFPUC, either from Pilarcitos Creek or Crystal Springs Reservoir.

Flow in Pilarcitos Creek between Pilarcitos Reservoir and Stone Dam consists of tributary flow from surface and groundwater sources, releases from the reservoir to supply Coastside CWD, and occasional spills from Pilarcitos Reservoir in wet periods. During the dry season, and until recently, no intentional releases were made from Stone Dam to Pilarcitos Creek, and flow in the creek immediately below the dam consisted only of leakage through the spillway boards and seepage through the dam. Currently, experimental releases of a few cubic feet per second (cfs) are being made as part of a study of aquatic resources. In the wet months of wet years, spills over Stone Dam to Pilarcitos Creek are frequent. A tributary adds water to Pilarcitos Creek about one-tenth of a mile below Stone Dam in all but a few months of the driest years.

Flow in Pilarcitos Creek is measured at two gages—one just below Stone Dam, and the other near the creek mouth at Half Moon Bay. Flow measured at the gage in Half Moon Bay varies seasonally, with average monthly flow reaching a seasonal maximum of 53 cfs in February and a seasonal minimum of less than 1 cfs in August and September. Flow varies greatly from year to year. In 1976 and 1977, two very dry years, average monthly flow in the creek did not exceed 2.5 cfs. In 1998, a very wet year, a monthly average flow of 329 cfs was recorded.

Minimum Instream Flow Requirements

No releases are required from Crystal Springs, San Andreas, and Pilarcitos Reservoirs to maintain minimum stream flows in San Mateo, San Andreas, and Pilarcitos Creeks.

5.5.1.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to stream flow and reservoir levels, but generally considers that implementation of the proposed program would have a significant impact if it were to:

- Substantially alter stream flows such that they are outside of the range of pre-WSIP conditions and result in adverse hydrologic effects

The stream flow significance threshold is based on the fact that natural stream flows have varied substantially in the past 50 years, and that such variations are a part of the existing baseline. Therefore, variations substantially outside of these past levels due to implementation of the proposed program that would result in adverse hydrologic effects (such as flooding, dewatering, erosion, or drainage alteration, among others) would be considered a significant direct impact.

In addition to direct impacts resulting from changes in stream flows and reservoir levels, this PEIR also considers indirect impacts. However, for organizational purposes, the indirect impacts are not described in this section of the document, but rather in the sections describing the resources that would be indirectly affected by changes in steam flows and reservoir levels. These include geomorphology, surface water quality, groundwater, fisheries, terrestrial biological resources, recreation, and visual resources. It should be noted that there might be cases in which significant indirect impacts could result from less-than-significant direct impacts.

Approach to Analysis

Changes in reservoir storage and water levels attributable to the WSIP in the San Mateo Creek watershed and changes in reservoir storage, water levels and stream flows in the Pilarcitos Creek watershed attributable to the WSIP were estimated using the Hetch Hetchy/Local Simulation Model (HH/LSM). An overview of the model is provided in Section 5.1. Detailed information on the model and the assumptions that underlie it are provided in Appendix H. Stream flows in San Mateo Creek and stream flows and changes in reservoir storage and water levels for the Pilarcitos Creek watershed were estimated semi-quantitatively based on results from the model in addition to interviews with individuals knowledgeable about historical, current and expected future (with-WSIP) water system operations. Information on the limitations of the HH/LSM and reasons for using supplemental information are provided in Section 5.1. Information on current and expected future operations in the Pilarcitos Creek watershed is provided in Appendix H2-3 and H2-7.

Total water demand in the Coastside CWD service area is expected to increase from an annual average of 2.7 mgd in 2005 to an annual average of about 3.2 mgd in 2030. Coastside CWD intends to meet future demand by increasing its purchase request from the SFPUC. The SFPUC and Coastside CWD are currently discussing how the SFPUC might meet the increased purchase request, but no decision on a course of action has yet been made. However, in order to perform a conservative assessment of potential environmental impacts, a course of action was assumed that would have greater environmental consequences for Pilarcitos Reservoir and Pilarcitos Creek than other possible courses of action. Under the assumed scenario, the SFPUC would supply water to Coastside CWD from both Pilarcitos Creek and Crystal Springs Reservoir, as it does currently, but it would take more water from both sources. Most of the additional water would come from Crystal Springs Reservoir.[1] The SFPUC already takes all of the water from the Pilarcitos Creek watershed upstream of Stone Dam in normal, below-normal, and dry years, so any further use of Pilarcitos Creek water would come at the expense of spills from Stone Dam in the wet months of wet years.

Meeting Coastside CWD's future purchase requests might require the construction of new facilities. The environmental impacts of the new facilities are not analyzed in this PEIR, but would be addressed during subsequent, project-level CEQA review. The project-level review would occur after the SFPUC determines how it will meet Coastside CWD's 2030 purchase request, but before the facilities are constructed. However, it is expected that any construction impacts could be reduced to a less-than-significant level by conventional and project-specific construction mitigation measures.

Impact Summary

Table 5.5.1-1 presents a summary of the impacts on stream flow in Peninsula watershed water bodies that could result from implementation of the proposed water supply and system operations.

---

1 Increased diversions of water from Crystal Springs Reservoir could in turn increase diversions of water from the Tuolumne River. Chapter 8 provides an analysis of the environmental effects of several variants of the proposed program. The environmental analysis of Variant 1, which would involve meeting all of the additional purchase requests from the Tuolumne River, provides an indication of the likely effects of increased diversions from the Tuolumne River, as would occur (but on a much smaller scale) under this scenario.

Impact Discussion

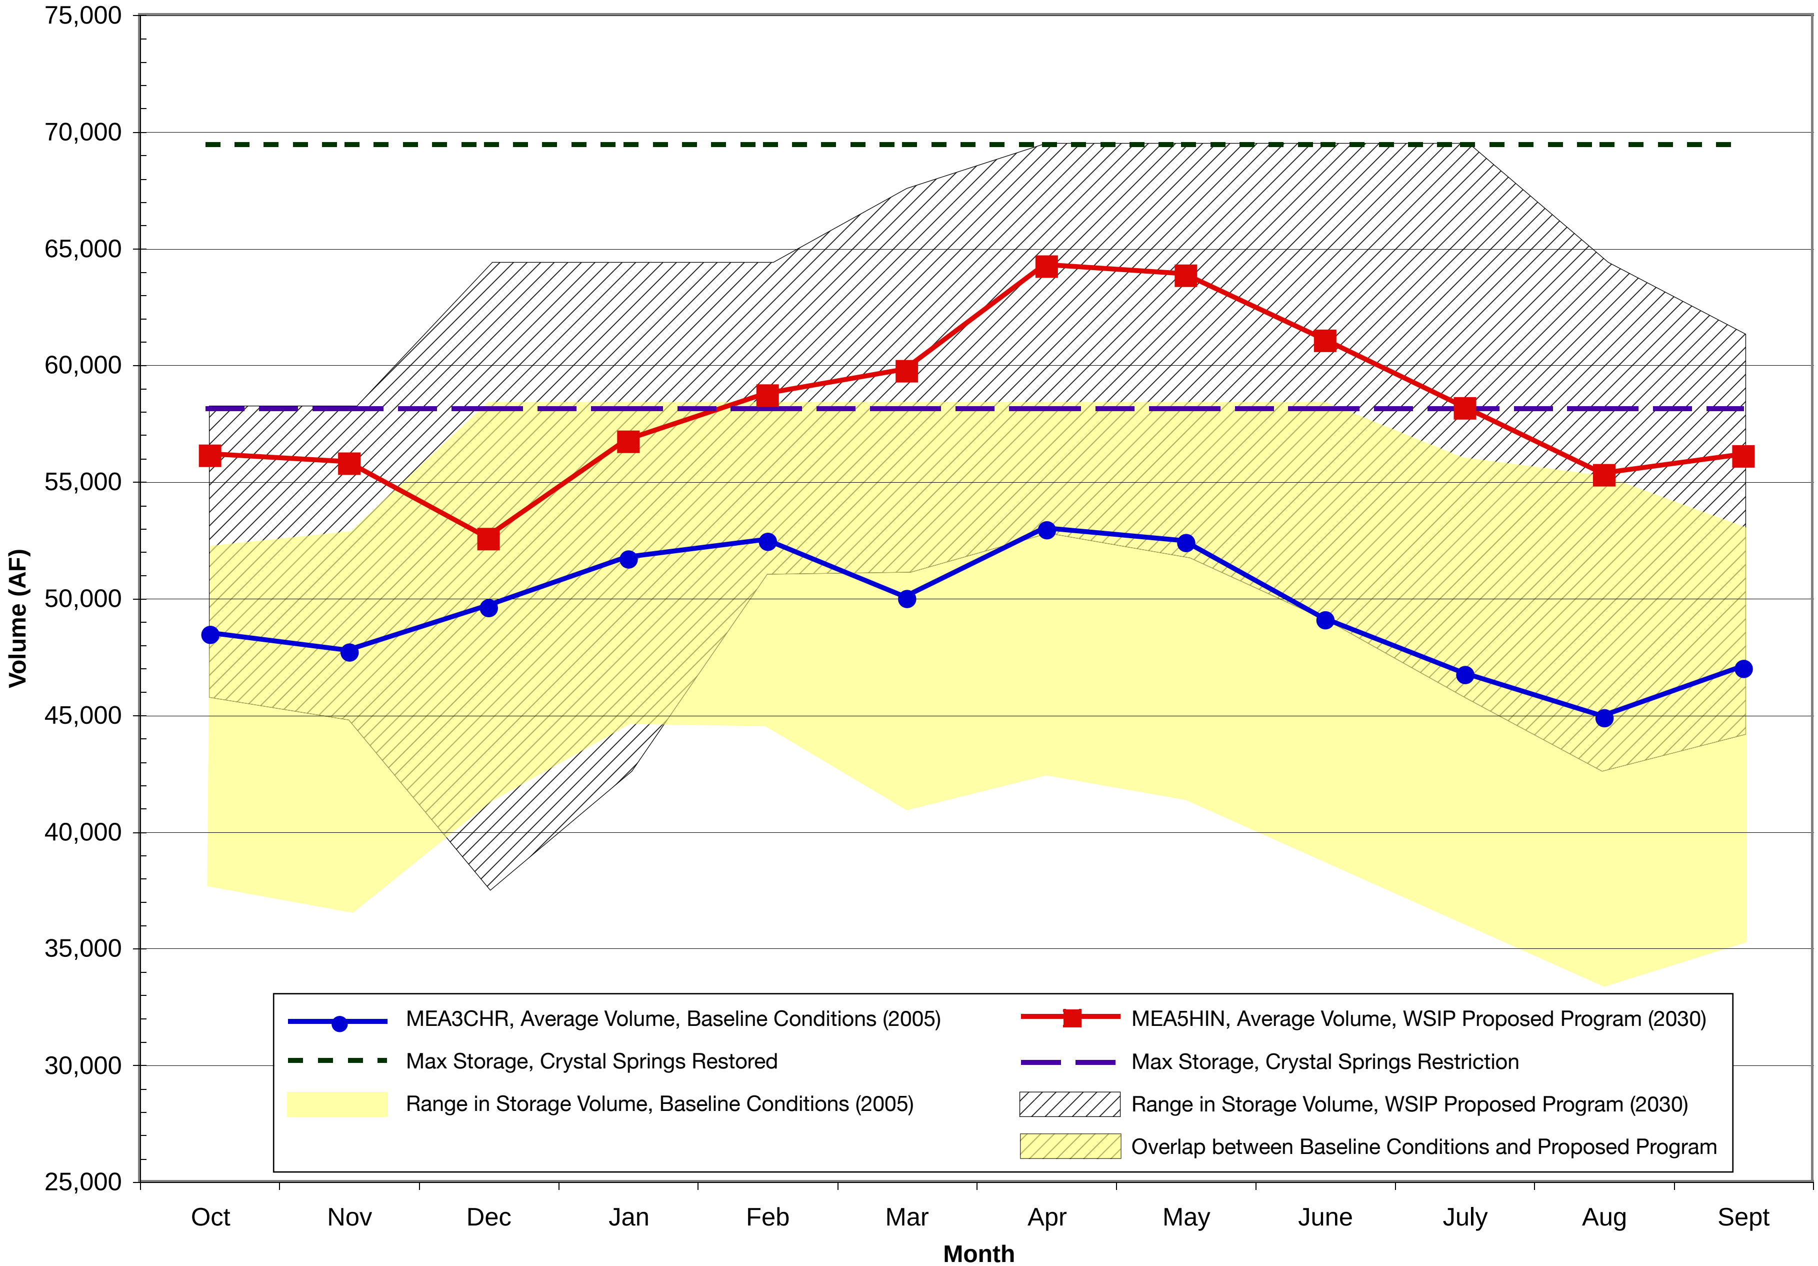
Impact 5.5.1-1: Effects on flow along San Mateo Creek.

Reservoir Operations

Crystal Springs and San Andreas Reservoirs store water from their local watersheds and water imported from the Tuolumne River and Pilarcitos Creek. The reservoirs are filled during the rainy season in the Bay Area and the snowmelt season in the Sierra Nevada. During the summer, when local demand exceeds the supply of water that can be delivered from the Tuolumne River, water is drawn from Crystal Springs and San Andreas Reservoirs to meet part of the demand. Storage in the reservoirs is replenished in the following winter, spring, and early summer. The reservoirs are operated to minimize spills from Crystal Springs Reservoir to San Mateo Creek. The WSIP would not change the SFPUC’s operational goals for Crystal Springs and San Andreas Reservoirs, but it would affect water levels in the reservoirs and could affect the volume of spills from Crystal Springs Reservoir to San Mateo Creek.

Water Storage and Water Levels in Crystal Springs and San Andreas Reservoirs

The proposed program would increase average monthly storage in Crystal Springs Reservoir year-round compared to the existing condition. **Figure 5.5.1-7** shows average monthly storage in the reservoir. The increase in average monthly storage would mostly be attributable to the Lower Crystal Springs Dam project (PN-4), but also to improvements to the SFPUC regional water system as a whole. The improvements to Crystal Springs Dam are part of the WSIP and would allow the reservoir to be operated at its full capacity of 68,000 acre-feet, or 22.2 billion gallons. The Division of Safety of Dams currently limits the maximum storage capacity in Crystal Springs Reservoir to 56,800 acre-feet (18.5 billion gallons) due to concerns regarding the ability of the dam spillway to safely pass the largest floods that could occur in the watershed. The other system improvements, also a part of the WSIP, would increase the SFPUC’s ability to convey Tuolumne River water across the San Joaquin Valley and thus improve its ability to maintain storage in Crystal Springs Reservoir. With the WSIP, storage in the reservoir would typically fluctuate during the year between full and 58,000 acre-feet (19 billion gallons), except during maintenance of the conveyance components of the Hetch Hetchy system (primarily



SOURCE: SFPUC, HH/LSM (see Appendix H)

SFPUC Water System Improvement Program . 203287

Figure 5.5.1-7
Average Monthly Storage Volume, Crystal Springs Reservoir

Mountain Tunnel and the San Joaquin Valley Pipeline) and during years of little local inflow or curtailed imports from the Tuolumne River.

Because the WSIP would restore Crystal Springs Reservoir storage, average monthly water levels would rise by 2 to 8 feet compared to the existing condition, with an average increase of 5 feet. The average monthly water levels with the WSIP would fluctuate more than under the existing condition. Currently, the difference between the annual average monthly maximum and minimum water levels is 7 feet; with the WSIP it would be 9 feet. The increased fluctuation would be due in part to periodic drawdown of storage in Crystal Springs Reservoir during maintenance of the conveyance components of the Hetch Hetchy system, as described below.

Figure 5.5.1-8 shows chronological modeled storage in Crystal Springs Reservoir using hydrology data from the period 1920 to 2002. The figure compares the WSIP to the existing condition and shows that Crystal Springs Reservoir storage with the WSIP would be greater in most years. The exception occurs every fifth year, as maintenance of the conveyance components of the Hetch Hetchy system would reduce the importation of water and require that water be withdrawn from local storage to meet water deliveries. Although maintenance is predicted to occur every five years, flexibility in the schedule could shift the years in which maintenance occurs. Maintenance would occur during the months of October, November, and December, when the demand for water is at its seasonal minimum. During these months, water levels in Crystal Springs Reservoir would fall by as much as 16 feet, and then recover when maintenance is completed.

Average monthly storage in San Andreas Reservoir is shown in **Figure 5.5.1-9** with the WSIP and under the existing condition. Under both scenarios, storage in the reservoir would typically fluctuate during the year between the full capacity of 19,000 acre-feet (6.2 billion gallons) and 17,200 acre-feet (5.6 billion gallons). Average monthly water levels with the WSIP and under existing conditions would be within a foot or two of each other, except during maintenance activities, as described below.

With implementation of the WSIP, storage in San Andreas Reservoir would be drawn down in every fifth year for planned maintenance of the conveyance components of the Hetch Hetchy system. When maintenance occurs, it would be in the months of October, November, and December. During these months, water levels in San Andreas Reservoir would fall by as much as 14 feet, and then recover when maintenance is completed.

Flow in San Mateo Creek

The SFPUC attempts to capture as much runoff as possible from the upper San Mateo Creek watershed in San Andreas and Crystal Springs Reservoirs. Most of the time, the SFPUC captures all of the runoff from the upper watershed, and no water is released to San Mateo Creek below Crystal Springs Dam. During the rainy season, the operators of the reservoir obtain frequent weather forecasts and manage the reservoir to capture as much runoff as possible from the sequence of winter storms that cross the watershed. The operators' decisions with respect to reservoir management are made on a day-to-day, sometimes hour-to-hour basis. In some

San Andreas Reservoir

circumstances, the operators are unable to capture all of the runoff due to the unpredictability of the weather. Releases to the creek only occur when runoff cannot be contained in the reservoirs or conveyed to customers after treatment at the Harry Tracy Water Treatment Plant.

As a consequence of the reservoir operations described above, no releases are usually made from Crystal Springs Reservoir in dry, below-normal, and normal hydrologic years, and flow in San Mateo Creek immediately below Lower Crystal Springs Dam typically occurs only as a result of groundwater infiltration and seepage around the dam. Occasionally in wet months of wet and above-normal years, the SFPUC releases water from the reservoir, thus increasing flow in San Mateo Creek. As the creek flows toward San Francisco Bay, it gains flow from tributaries, groundwater infiltration, and discharges of urban stormwater. There is no stream gage on San Mateo Creek, so actual flows are not known. When the infrequent releases from Crystal Springs Reservoir occur, they probably represent a substantial proportion of flow in the creek. In the dry season, flow in the nontidal reach of the creek is minimal, consisting primarily of groundwater infiltration and urban stormwater associated with car washing and over-irrigation of landscaping.

With the WSIP in place, the SFPUC would operate the reservoirs in the San Mateo Creek watershed as they are currently operated. Releases to San Mateo Creek would occur infrequently, as they do under the existing condition, and would be of a similar magnitude.

Impact Conclusions

The WSIP would not alter the character of San Mateo Creek immediately below Lower Crystal Springs Dam—it is an intermittent stream under the existing condition and would remain so with the WSIP. Releases to the creek are infrequent under the existing condition and would remain so with the WSIP. The total volume of releases might be somewhat higher or lower than under the existing condition depending on circumstances, but the range of flows with the WSIP would be similar to those under the existing condition. Adverse impacts on flow along San Mateo Creek would be *less than significant*, and no mitigation measures would be required.

Impact 5.5.1-2: Effects on flow along Pilarcitos Creek.

Reservoir Operations

Pilarcitos Reservoir fills with runoff from the upper Pilarcitos Creek watershed. It receives only local runoff and cannot be filled with imported water. Water from the upper Pilarcitos Creek watershed is diverted to Crystal Springs and San Andreas Reservoirs for use by the SFPUC and is used to supply water to the Coastside CWD. Coastside CWD diverts water from Pilarcitos Creek at Stone Dam, about two miles below Pilarcitos Reservoir. During the rainy season, flow in Pilarcitos Creek at Stone Dam is sufficient to meet the Coastside CWD's needs. During the drier months, when creek flow below Pilarcitos Reservoir subsides, the SFPUC releases water from the reservoir for diversion by Coastside CWD. Pilarcitos Reservoir is drawn down in the drier months and then refilled in the rainy season. Pilarcitos Reservoir and Stone Dam are typically operated to minimize spills from Stone Dam to Pilarcitos Creek, although small experimental releases are currently being made as part of a study of aquatic resources. The WSIP would not change the SFPUC's operational goals for Pilarcitos Reservoir and Stone Dam, but, assuming implementation of the scenario described earlier, the program would affect water levels in the reservoir and flow in Pilarcitos Creek, both between Pilarcitos Reservoir and Stone Dam and below Stone Dam.

Water Storage and Water Levels in Pilarcitos Reservoir

Seasonal changes in storage and water surface elevation in Pilarcitos Reservoir under the existing condition are shown in Figure 5.5.1-6. **Figure 5.5.1-10** shows chronological modeled storage in Pilarcitos Reservoir using hydrology data from the period 1920 to 2002. The figure compares the WSIP to the existing condition. With the WSIP, storage in the reservoir would follow a similar seasonal pattern as under the existing condition, but would average somewhat less than under the existing condition and would be drawn down more rapidly in some years in the late spring and summer. The increased rate of drawdown is primarily attributable to increased water demand in the Coastside CWD service area, which is served by releases from the reservoir, and increased transfers of water to the San Mateo Creek watershed. As water demand increases in the Coastside CWD service area, additional water would be drawn from Pilarcitos Reservoir to meet demand, although diversion of water from Pilarcitos Creek to Coastside CWD is currently limited to a maximum of 2 mgd because of pipeline capacity. The HH/LSM assumes that when Coastside CWD's monthly demand from Pilarcitos Creek exceeds 2 mgd the SFPUC serves Coastside CWD from Crystal Springs Reservoir. Additional water would also be transferred from the Pilarcitos Creek watershed to the SFPUC's reservoirs in the San Mateo Creek watershed with the WSIP than under the existing condition. This is because with the WSIP more reservoir capacity in the San Mateo Creek watershed would be available at times when water is available from Pilarcitos Creek.

Under existing conditions and in most years, storage in Pilarcitos Reservoir becomes depleted by the late summer, and the only releases made to Pilarcitos Creek are the consequence of inflow from groundwater and tributary streams. Depletion of the reservoir in dry periods would occur earlier in the year with the WSIP.

Flow in Pilarcitos Creek between Pilarcitos Reservoir and Stone Dam

Releases to Pilarcitos Creek from Pilarcitos Reservoir under the existing condition and with the WSIP are shown in Figure 5.5.1-10. In normal, below normal, and dry years, the WSIP would have little or no effect on releases to Pilarcitos Creek from the reservoir. In average wet years and with the WSIP, releases would be reduced by about 6 percent. In average above normal years and with the WSIP, releases would be reduced by about 34 percent. The differences between releases under the existing condition and with the WSIP are shown in **Table 5.5.1-2** in every month for the period 1921 through 2002. Negative values indicate the months in which releases to the creek with the WSIP would be less than under the existing condition.

Under the existing condition, releases are typically made from Pilarcitos Reservoir to the creek to provide water to Coastside CWD, with the releases rising to the capacity of Coastside CWD's delivery pipeline in the summer when water demand is at its seasonal maximum. No releases are

made if the runoff from tributary streams between Pilarcitos Reservoir and Stone Dam is sufficient to meet demand in the Coastside CWD service area, although spills from the reservoir may occur if it is full. With the WSIP, releases would follow the same seasonal pattern of water demand as under the existing condition, but the releases would be at the capacity of Coastside CWD's delivery pipeline more of the time in order to meet increased water demand in the Coastside CWD service area.

Under the existing condition during normal, below-normal, and dry years, storage in Pilarcitos Reservoir is routinely drawn down so far by late summer that the releases do not meet Coastside CWD's needs. During these times, Coastside CWD activates a pump and draws water from Crystal Springs Reservoir. This would occur more frequently in the future with the WSIP, given the expected increase in Coastside CWD's water demand.

Most runoff into Pilarcitos Reservoir occurs between November and April. In normal, above-normal, and wet years, when the reservoir is full and runoff exceeds the capacity of the diversion tunnels to San Andreas and Crystal Springs Reservoirs, or those reservoirs are full, the reservoir spills to Pilarcitos Creek.

As shown in Figure 5.5.1-10, the WSIP would not affect wintertime spills in most years, but it would reduce spills in some wet and above normal years. Occasionally (for example, under 1940, 1943, 1965 and 1976 hydrologic conditions), wintertime spills that occur under the existing condition would be completely or almost completely eliminated with the WSIP.

The WSIP would increase flow in Pilarcitos Creek immediately below Pilarcitos Reservoir in some late spring and summer months of most hydrologic year types as a result of increased releases from the reservoir to meet Coastside CWD's needs. The increases are shown as positive values in April, May, June and July in Table 5.5.1-2. In the summer months of some years, Pilarcitos Reservoir would become depleted earlier in the year with the WSIP than it does under the existing condition. Coastside CWD would activate its pumps and draw water from Crystal Springs Reservoir earlier in the year than it does under the existing condition. At such times, there would be no releases from Pilarcitos Reservoir to the creek except for dry season inflow to the reservoir. Flow in the creek below the reservoir would be the same as under the existing condition, consisting of inflow releases, seepage from the dam, infiltration from groundwater, and tributary flow. The period of minimal flow below Pilarcitos Reservoir would be extended with the WSIP, because the reservoir would be drawn down to its minimum elevation earlier in the year. Table 5.5.1-2 shows negative values in some years between May and September. These are months in which releases from Pilarcitos Reservoir occur under the existing condition but which would be reduced or eliminated under the WSIP.

Flow in Pilarcitos Creek Below Stone Dam

Under the existing condition, water occasionally spills over Stone Dam to Pilarcitos Creek. There is little flow in Pilarcitos Creek immediately below Stone Dam most of the time, and no flow in dry periods. Spills over Stone Dam occur when releases from Pilarcitos Reservoir and runoff into Pilarcitos Creek between the reservoir and Stone Dam exceed the capacity of the diversion at Stone Dam. Occasional spills over Stone Dam would continue under the WSIP. The volume of spills would be reduced by the additional amount of Pilarcitos Creek water the SFPUC supplies to Coastside CWD or diverts to its reservoirs in the San Mateo Creek watershed.

Spills at Stone Dam typically occur when Pilarcitos Reservoir is full, Coastside CWD's demand is met, and the SFPUC cannot transfer water to the San Mateo Creek watershed, either because available water in the Pilarcitos Creek watershed exceeds the capacity of the SFPUC's tunnels to San Andreas and Crystal Springs Reservoirs, or those reservoirs are already full. Spills very rarely occur in dry and below normal years under the existing condition and would very rarely occur with the WSIP. With the WSIP, average annual spills in wet, above normal and normal years would be reduced by about 11, 60, and 25 percent, respectively, compared to the existing condition.

Because most flow from the upper watershed of Pilarcitos Creek is diverted for municipal water supply, most of the flow in the creek below Stone Dam is supplied by runoff from the lower watershed. For example, in the four-month period between January and April of 1998 (a wet year), total measured flow in Pilarcitos Creek at Half Moon Bay, near the mouth of the creek, was about 32,300 acre-feet (equivalent to a continuous flow of 136 cfs). At a gage that records both spills at Stone Dam and flow in a Pilarcitos Creek tributary downstream of the dam, flow was measured at 10,500 acre-feet (equivalent to a continuous flow of 44.2 cfs) for the same period. Thus, spills in 1998 over Stone Dam represented less than one-third of total flow in Pilarcitos Creek.

Impact Conclusions

The WSIP would not alter the character of Pilarcitos Creek immediately below Stone Dam. Flow in the creek immediately below the dam is intermittent under the existing condition and would continue to be intermittent with the WSIP, so no adverse hydrologic effects would occur. With the WSIP, total spills to the creek immediately below Stone Dam would be reduced, but the magnitude of the flows in the lower reaches of the creek would be similar to those under existing conditions. Therefore, adverse impacts on water levels in Pilarcitos Reservoir and on flow along Pilarcitos Creek below Stone Dam would be *less than significant*, and no mitigation measures would be required.

Flow in Pilarcitos Creek immediately below Pilarcitos Reservoir would be the same or greater with the WSIP than under the existing condition most of the time. In dry periods and in the summer, releases to the creek from Pilarcitos Reservoir would be reduced to dry-season reservoir inflow at an earlier date than under the existing condition. The creek's character in the reach immediately below Pilarcitos Reservoir would not be altered from its existing condition. The creek experiences minimal flow in most summers under the existing condition and would continue to do so with the WSIP. Therefore, this impact would be *less than significant*, and no mitigation measures would be required.

5.5.2 Geomorphology

The following setting section describes the geomorphology of the streams on the San Francisco Peninsula that could be affected by the WSIP. The impact section (Section 5.5.2.2) provides a description of the changes in stream channel form and erosion and siltation rates that would result from WSIP-induced changes in stream flow, as described in Section 5.5.1.

5.5.2.1 Setting

Geomorphology

The geomorphology of the SFPUC Peninsula watershed is defined by the San Andreas fault and its associated steep terrain, northwest-trending ridges and valleys, and ongoing uplifting and erosional processes. Fifield and Cahill Ridges divide the two principal watersheds, San Mateo Creek to the east and Pilarcitos Creek to the west. The San Mateo Creek watershed above Crystal Springs Dam is 22.5 square miles in size, in addition to the 4.4-square-mile watershed above San Andreas Reservoir. The Pilarcitos Creek watershed above Pilarcitos Reservoir is 3.8 square miles.

San Mateo Creek below Crystal Springs Dam initially flows eastward through a steep canyon for about 1.5 miles, then enters the broad, gently sloping lands surrounding San Francisco Bay. The canyon itself is rather narrow, but contains several alluvial terraces for most of its length. In the canyon, San Mateo Creek has a 1 percent slope. It passes through Franciscan Complex sandstone and some serpentine, then through the Colma Formation, a Pleistocene formation of marine and nonmarine sands and clays, and the recent Temescal Formation, which is composed primarily of fine-textured sand. The channel in San Mateo Creek canyon is primarily riffle and pool. The creek channel is comparatively deep and broad for the current flow due to the high historical unimpaired flows. The channel bed is composed primarily of sand and silt, with some gravel deposits. Below the canyon, San Mateo Creek is a meandering channel with a slope of about 0.25 percent. This reach of the creek has been highly modified and constrained by urbanization. The creek flows through several culverts before discharging to San Francisco Bay.

Above Crystal Springs Dam, San Andreas Creek empties into San Andreas Reservoir. Its natural course below the dam follows a straight, narrow valley along the San Andreas fault southeasterly into Lower Crystal Springs Reservoir. San Mateo Creek itself originates to the southwest, in the steep country between Fifield and Sawyer Ridges. It follows a relatively straight course for nearly eight miles before emptying into Lower Crystal Springs Reservoir. The creek’s slope varies from about 1 percent in the upper reaches and about 2 percent in the narrow canyon before it enters the reservoir. From the southeast, Laguna Creek is the principal tributary to Upper Crystal Springs Reservoir, which is connected via culverts with Lower Crystal Springs Reservoir. Rainfall within the watershed ranges from about 30 to 40 inches per year (USDA, 1961).

The northern portion of the upper San Mateo Creek watershed is steep and rugged. Like the Pilarcitos Creek watershed, average hillslope gradients range from 3:1 to 1:1 (horizontal to vertical ratio), while the southern portion of the watershed has average gradients ranging from

5:1 to 3:1 (San Francisco Planning Department, 2001). The San Andreas Creek and San Mateo Creek watersheds are composed of Franciscan Complex sedimentary and metamorphic rocks. Sandstone, shale, chert, and conglomerate marine deposits are predominant to the southwest of the San Andreas fault, while metamorphosed Franciscan rock, such as serpentine, is widespread on the northeastern side of the fault. The watershed surrounding Upper Crystal Springs Reservoir is composed of Butano Formation, Eocene marine sedimentary rocks such as fine-textured sandstones and shale (Jennings and Burnett, 1961).

Sediment transport thresholds and rates have not been monitored or evaluated in these reaches. No sediment transport data have been quantified for these watersheds. However, the steep slopes are inherently highly erodible, and natural landslides are an important landscape-forming influence. This watershed has been unaffected by livestock grazing and wildfire for many decades. The SFPUC has constructed and maintains a system of sediment catchment basins around the reservoirs to capture the incoming sediment.

Pilarcitos Creek originates in between Fifield Ridge and the western Coast Ranges. It follows the Pilarcitos fault, parallel to and west of the San Andreas fault. Three unnamed tributaries flow into Pilarcitos Reservoir through relatively low-gradient valleys consisting of Farallone coarse sandy loam. Below the reservoir, Pilarcitos Creek flows in a southeasterly direction past Stone Dam, eventually emptying into the Pacific Ocean near Half Moon Bay. The upper reaches above Pilarcitos Reservoir are composed of Franciscan Complex volcanic, metavolcanic (metamorphosed volcanic rock), and sedimentary Cretaceous rock. Below the dam, Mesozoic granite underlies the western side of the creek, and Franciscan Complex bedrock underlies the eastern side (Jennings and Burnett, 1961). The corresponding soils are Hugo and Josephine loam and Sheridan coarse sandy loam.

Slopes in the Pilarcitos Creek watershed have average gradients ranging from 3:1 to 1:1 (San Francisco Planning Department, 2001). The slopes in the canyon below Pilarcitos Dam are extremely steep. For about a mile downstream from Pilarcitos Dam, Pilarcitos Creek has a slope of about 1 percent. Soils are mapped as a gravelly substrate with no further classification (USDA, 1961). There is very little terracing in the narrow valley, and bedrock is frequently exposed. Average annual rainfall is 45 inches at Pilarcitos Reservoir, and the typical five-year storm brings 3.6 inches of rainfall in 24 hours (USDA, 1961).

5.5.2.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to geomorphology, but generally considers that implementation of the proposed program would have a significant impact if it were to:

- Substantially change the topography such that ecological, hydrologic, or aesthetic functions are adversely affected, or substantially change any unique geologic or physical features of the site or area

- Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of the stream or river, in a manner that would result in substantial erosion or siltation or adversely affect the ecological, hydrologic, or aesthetic functions of the site or area

Although the “substantial change in topography” criterion is typically applied to upland areas, it is considered applicable to stream channel/bank topography in this instance because of the sensitivity of the resources that depend on the topography of these features (i.e., riparian vegetation and fisheries). For a stream channel, the relevant aspect of topography to be evaluated are those associated with channel form and the related movement and distribution of sediment.

Approach to Analysis

This impact section presents a discussion of projected changes in sediment transport and geomorphology based on changes in stream flow, reservoir storage, and related reservoir water levels that would result from WSIP implementation, as described in Section 5.5.1. A qualitative assessment of potential effects was conducted based on generalized channel bed/bank characteristics and consideration of proposed changes in stream flow that would result from implementation of the WSIP.

Impact Summary

Table 5.5.2-1 presents a summary of the impacts on sediment transport and geomorphology in the Peninsula watershed that could result from implementation of the proposed water supply and system operations.

TABLE 5.5.2-1
SUMMARY OF IMPACTS – GEOMORPHOLOGY
OF SAN FRANCISCO PENINSULA STREAMS AND RESERVOIRS

Impact	Significance Determination
Impact 5.5.2-1: Changes in sediment transport and channel morphology in the Peninsula watershed	LS

LS = Less than Significant impact, no mitigation required

Impact Discussion

Impact 5.5.2-1: Changes in sediment transport and channel morphology in the Peninsula watershed.

Changes in storage and water levels in reservoirs in the San Mateo Creek watershed attributable to the WSIP were estimated using the HH/LSM. An overview of the model is presented in Section 5.1. Detailed information on the model and the assumptions that underlie it is provided in Appendix H. Changes in stream flow and reservoir storage and water levels in the Pilarcitos

Creek watershed attributable to the WSIP were estimated semi-quantitatively by reviewing historical data and consulting with individuals knowledgeable about past and expected future reservoir operations.

Releases to San Mateo Creek downstream of Lower Crystal Springs Dam are expected to be approximately the same with the WSIP as they are under the existing condition. Thus, the WSIP would have no effect on channel-forming events and sediment transport in this already highly impaired creek.

Implementation of the WSIP would also result in higher average reservoir levels in Upper and Lower Crystal Springs Reservoirs, which in turn would cause tributary streams to deposit their sediment at correspondingly higher elevations. The amount of incoming sediment would not be affected. The reservoir level at San Andreas Reservoir is projected to change very little, so no impact on sediment transport and channel morphology would occur, even at the mouths of tributary streams.

Increased releases from Pilarcitos Reservoir into Pilarcitos Creek in most spring and early summer months would increase sediment transport and channel-forming processes in the creek compared to the existing condition. The projected lower flows in the summer months of dry years would reduce sediment transport and channel-forming processes compared to the existing condition. Both the increases and decreases in sediment transport would be small and relatively inconsequential, because channel form is largely a function of the magnitude and frequency of occasional large winter flows, which would not be affected by the WSIP.

Under the WSIP, spills over Stone Dam in the wet months of above-normal and wet years would be reduced in frequency and magnitude. This could in turn reduce sediment movement and channel-forming processes in the reach of Pilarcitos Creek immediately below the dam, but with decreasing effect in a downstream direction as tributaries add flow to the creek.

WSIP-induced changes in flow in San Mateo and Pilarcitos Creeks and the changes in reservoir level in Pilarcitos, San Andreas, and Upper and Lower Crystal Springs Reservoirs would result in small incremental reductions or no change in sediment transport and channel-forming processes.

The projected changes in flow would result in insignificant changes in topography, drainage patterns, erosion, and siltation in and away from the creeks and reservoirs in the Peninsula watershed. Therefore, impacts on fluvial geomorphologic characteristics in the Peninsula watershed would be *less than significant*, and no mitigation is required.

5.5.3 Surface Water Quality

The following setting section describes surface water quality in streams and reservoirs on the San Francisco Peninsula that could be affected by the WSIP. The impact section (Section 5.5.3.2) provides a description of the changes in water quality in streams and reservoirs that would result from WSIP-induced changes in stream flow and reservoir water levels.

5.5.3.1 Setting

The SFPUC operates four reservoirs on the Peninsula: the Pilarcitos, Upper and Lower Crystal Springs, and San Andreas Reservoirs. The Upper and Lower Crystal Springs Reservoirs function as a single water body. The WSIP could affect water quality in the reservoirs. Water quality in two streams on the San Francisco Peninsula could also be affected by the WSIP. They are San Mateo Creek and Pilarcitos Creek, both of which rise in the Coast Range mountains. San Mateo Creek, and its tributary San Andreas Creek, flow southward in the rift valley formed by the San Andreas fault and then turn east, flowing to San Francisco Bay. Pilarcitos Creek also flows southward, but it turns to the west and flows to the Pacific Ocean.

Crystal Springs Reservoir, San Andreas Reservoir, and San Mateo Creek

Water quality in San Andreas and Crystals Springs Reservoirs reflects that of its sources—local runoff, Alameda Creek, Pilarcitos Creek, and the Tuolumne River. Because the Tuolumne River is the source of most of the water, it is the predominant influence on water quality in the reservoirs. Water quality is generally very good, exhibiting low concentrations of total dissolved solids and plant nutrients (nitrates and phosphates).

Crystal Springs Reservoir stratifies in the summer months; that is, the upper part of the reservoir (the "epilimnion") warms, while water in the lower part of the reservoir (the "hypolimnion") remains cool. The dividing line between the two zones is called the thermocline and is typically 25 to 50 feet below the surface of the reservoir. The two zones do not mix, and water in the hypolimnion becomes depleted of oxygen. As air temperatures drop in the fall and water in the epilimnion cools, the reservoir "turns over." The reservoir then destratifies and water in the two zones mixes.

Although nutrient concentrations in the reservoirs are low, they are sufficient to support the growth of algae in the summer months. Algae in a water source can make water treatment more difficult and cause taste and odor problems with finished water. In 2005, the SFPUC changed the method it uses to disinfect water in order to comply with drinking water standards. Formerly, the SFPUC disinfected water with chlorine; now it uses chloramine, a chemical compound that contains both chlorine and ammonia. Ammonia is a form of nitrogen that rapidly decomposes in natural waters to another form of nitrogen called nitrate. Past studies have shown that the growth of algae in Crystal Springs Reservoir is limited by a lack of nitrogen and phosphorus, both of which are plant nutrients; therefore, an increase in the concentration of either could increase the growth of algae. To avoid the discharge of nitrogen and the possible consequent increase in algae concentration in Crystal Springs Reservoir, the SFPUC constructed dechloramination facilities at the same time it constructed chloramination facilities. The dechloramination facilities completely remove the chlorine and remove most of the ammonia from water before it is discharged to Crystal Springs Reservoir. The use of chloramine as a disinfectant has resulted in a small increase in the concentration of nitrate in Crystal Springs Reservoir (SFPUC, 2006).

When Lower Crystal Springs Reservoir spills, water quality in San Mateo Creek is very similar to reservoir water quality. However, most of the time, when creek flow immediately below Lower Crystal Springs Dam consists of seepage from the dam and inflow from the ground, the quality of water in the creek is lower than that in the reservoir. **Table 5.5.3-1** shows water quality at three locations along San Mateo Creek below Lower Crystal Springs Dam as measured between May 2003 and February 2004. Water quality at the Polhemus sampling station 0.7 mile below Lower Crystal Springs Dam was generally good, with a total dissolved solids concentration in the range 124 to 211 milligrams per liter (mg/L) and dissolved oxygen concentrations at or near saturation. Water quality deteriorated as San Mateo Creek flowed through the urban areas to San Francisco Bay. Total dissolved solids concentrations at the Gateway Park station, 5.1 miles downstream of Crystal Springs Dam, were in the range of 332 to 427 mg/L, except on one occasion when sampling results were affected by the tide. Late-summer and fall dissolved oxygen concentrations were at about 50 percent saturation.

Pilarcitos Reservoir and Pilarcitos Creek

Water quality in Pilarcitos Reservoir is good because the Pilarcitos Creek watershed above the reservoir is largely undeveloped. Plant nutrient concentrations in Pilarcitos Reservoir water are low, but 50 to 100 percent greater than in the water stored in the San Andreas and Crystal Springs Reservoirs. Summertime algae concentrations in Pilarcitos Reservoir are also greater than those in Crystal Springs and San Andreas Reservoirs.

Like Crystal Springs Reservoir, Pilarcitos Reservoir stratifies in the summer months. Water in the bottom part of the reservoir becomes depleted of oxygen.

Beneficial Uses and Water Quality Objectives

Pursuant to the federal Clean Water Act and the Porter-Cologne Water Quality Control Act, the San Francisco Bay Regional Water Quality Control Board has designated beneficial uses that Crystal Springs, San Andreas, and Pilarcitos Reservoirs and San Mateo and Pilarcitos Creeks must support. Designated existing beneficial uses for Crystal Springs, San Andreas, and Pilarcitos Reservoirs are municipal and domestic water supply (MUN), non-water-contact recreation (REC-2), cold freshwater habitat (COLD), warm freshwater habitat (WARM), fish spawning (SPWN), wildlife habitat (WILD), and rare and endangered species (RARE). Pilarcitos Reservoir is listed as having water-contact recreation as a limited beneficial use.

Existing designated beneficial uses for San Mateo Creek are freshwater replenishment (FRSH), SPWN, and RARE. Potential beneficial uses of San Mateo Creek are water contact recreation (REC-1), REC-2, and COLD. Current designated beneficial uses of Pilarcitos Creek are agricultural water supply (AGR), MUN, COLD, WARM, SPWN, RARE, WILD, and migration of aquatic organisms (MGR). Potential designated uses of Pilarcitos Creek are REC-1 and REC-2.

SOURCE: SFPUC, 2004.

Prior to being discharged into Upper Crystal Springs Reservoir, Hetch Hetchy system water that has been disinfected with chloramine is treated to remove chlorine and ammonia and to adjust its pH. Chloramine contains chlorine and ammonia, both of which are toxic to aquatic organisms. The Regional Water Quality Control Board has established a discharge limit of 0.0 mg/L for chlorine residual, which includes both free chlorine[1] and chloramine. In order to meet this limit, the SFPUC neutralizes the chloramine residual in Hetch Hetchy water before it is discharged to the two reservoirs, thus eliminating toxicity to aquatic life. However, some residual ammonia remains after neutralization (SFPUC, 2006).

1 Free chlorine consists of a compound, hypochlorous acid, and the hypochlorite ion, both of which form when chlorine gas is added to water.

Unlike chlorine, ammonia is regulated as a water quality objective for receiving waters. Ammonia exists in two forms in water: un-ionized and ionized forms. Un-ionized ammonia is toxic, whereas its ionized form is relatively harmless. The water quality objective for ammonia is specified as un-ionized ammonia (the toxic form), and the water quality objective of 0.40 mg/L of un-ionized ammonia as nitrogen applies. The relative concentration of the two forms of ammonia depends on the pH and temperature of the water. The un-ionized (toxic) form increases as the temperature and pH increase. In the temperature and pH range of natural waters, the nontoxic form of ammonia predominates; in most instances, ammonia in discharges is diluted or degraded to a nontoxic form fairly rapidly. In the SFPUC water supply, the maximum total ammonia concentration before dechloramination is about 0.5 mg/L. When added to Crystal Springs Reservoir under typical receiving-water conditions (pH = 8.5, and water temperature = 24 °C), the maximum resulting concentration of un-ionized ammonia would be about 0.07 mg/L, which is well below the objective of 0.40 mg/L. However, because water is dechloraminated prior to discharge into the reservoir, the actual concentrations of un-ionized ammonia would be close to zero.

5.5.3.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to surface water quality, but generally considers that implementation of the proposed program would have a significant surface water quality impact if it were to:

- Substantially impair a water body's ability to support beneficial uses designated by the State Water Resources Control Board or Regional Water Quality Control Board
- Otherwise substantially degrade water quality

Approach to Analysis

Changes in reservoir storage and water levels in the San Mateo Creek watershed and changes in reservoir storage, water levels and stream flows in the Pilarcitos Creek watershed attributable to the WSIP were estimated using the HH/LSM. An overview of the model is presented in Section 5.1. Detailed information on the model and the assumptions that underlie it are provided in Appendix H. Changes in stream flows in the San Mateo Creek watershed attributable to the WSIP were estimated semi-quantitatively in consultation with individuals knowledgeable about historical, current, and expected future (with-WSIP) water system operations.

Impact Summary

Table 5.5.3-2 presents a summary of the impacts on the water quality of Peninsula watershed streams and reservoirs that could result from implementation of the proposed water supply and system operations.

TABLE 5.5.3-2
SUMMARY OF IMPACTS – WATER QUALITY
OF SAN FRANCISCO PENINSULA STREAMS AND RESERVOIRS

Impact	Significance Determination
Impact 5.5.3-1: Effects on water quality in Crystal Springs Reservoir, San Andreas Reservoir, and San Mateo Creek	LS
Impact 5.5.3-2: Effects on water quality in Pilarcitos Reservoir and along Pilarcitos Creek	PSM

LS = Less than Significant impact, no mitigation required
PSM = Potentially Significant impact, can be mitigated to less than significant

Impact Discussion

Impact 5.5.3-1: Effects on water quality in Crystal Springs Reservoir, San Andreas Reservoir, and San Mateo Creek.

Crystal Springs and San Andreas Reservoirs

The proposed program would affect water quality in Crystal Springs and San Andreas Reservoirs. Average monthly storage would increase in Crystal Springs Reservoir by 5 to 10 percent. The reservoir would capture more local runoff and hold more water from the Hetch Hetchy system. However, the proportions of local runoff and Hetch Hetchy water in the reservoir with the WSIP would remain about the same most of the time compared to existing conditions.

It is possible, however, that with the WSIP the proportion of Hetch Hetchy water in Crystal Springs Reservoir could increase at times relative to existing conditions, particularly in the winter. An increase in the proportion of Hetch Hetchy water, which is disinfected with chloramine, would increase the concentration of nitrogen to the reservoir. Although the SFPUC removes chlorine and ammonia, the constituents of chloramine, from Hetch Hetchy water before it is discharged into Crystal Springs Reservoir, the removal of ammonia is not complete, and so some nitrogen is added to the reservoir. As noted earlier, the nitrate concentration has risen in Crystal Springs Reservoir waters since chloramine disinfection was initiated. If the proportion of Hetch Hetchy water placed in Crystal Springs Reservoir increased as a result of the WSIP, then the rate of discharge of nitrogen into the reservoir would also increase. The increase in nitrogen concentration in the reservoir would have the potential to increase the growth of algae.

The increase in storage and water level in Upper Crystal Springs Reservoir could increase the stability of thermal stratification. The increase in storage would be a result of restored capacity in Crystal Springs Reservoir and improvements to the conveyance components of the Hetch Hetchy system that would enable the SFPUC to refill local reservoirs with Tuolumne River water more reliably than under the existing condition. More stable thermal stratification combined with the input of oxygen-demanding substances associated with chloramination and dechloramination could deplete oxygen levels below the thermocline to a greater degree than under existing conditions. Under oxygen-depleted conditions, nutrients are released from the sediments at the bottom of the reservoir. If the proposed program increased the volume of oxygen-depleted water at the bottom of the reservoir, it could increase the release of phosphorus. Increased release of phosphorus and increased phosphorus concentrations in reservoir water would have the potential to increase the growth of algae.

Studies completed over the last several years indicate that the growth of algae in Crystal Springs Reservoir has historically been limited by both nitrogen and phosphorus concentrations. After the SFPUC began disinfecting Hetch Hetchy water with chloramine, the nitrogen concentration in the reservoir increased, and the concentration of phosphorus in reservoir water became the factor limiting the growth of algae. Thus, the addition of more nitrogen as a result of a WSIP-induced increase in the proportion of Hetch Hetchy water in Crystal Springs Reservoir would not alone increase the growth of algae. Increased phosphorus concentrations in the reservoir as a result of the more stable thermal stratification induced by the WSIP would increase the growth of algae.

The WSIP would have very little effect on average monthly storage in San Andreas Reservoir. The proportion of local runoff and Hetch Hetchy water is expected to remain the same as under existing conditions.

The WSIP could have a minor effect on water quality in Crystal Springs Reservoir and a negligible effect on water quality in San Andreas Reservoir. Any water quality changes would be too small to affect beneficial uses. If water quality changes in Upper Crystal Springs Reservoir resulted in increased growth of algae, water treatment could become more difficult and expensive. Adverse impacts of the WSIP on water quality in Crystal Springs and San Andreas Reservoirs would be less than significant, and no mitigation is required.

San Mateo Creek

Most of the time, flow in San Mateo Creek immediately below Lower Crystal Springs Dam is very low and consists of seepage through and around the dam. Occasionally, in wet months of wet and above-normal years, the SFPUC releases water to the creek from the dam. The creek then gains water from tributaries, groundwater, and urban runoff as it flows to San Francisco Bay. Water quality is good immediately below the dam and deteriorates in a downstream direction.

Under current conditions, the releases from Crystal Springs Reservoir in the winter and spring months of wet and above-normal years probably affect water quality in San Mateo Creek in two ways. The releases have a direct and beneficial effect on water quality during the releases themselves because a higher proportion of stream flow consists of high-quality Crystal Springs Reservoir water. The second effect of the releases is to contribute to periodic large “flushing flows” that serve to wash debris and accumulated organic matter out of the stream and into San Francisco Bay. In California’s Mediterranean climate, leaves, lawn clippings, and the detritus of urban life tend to accumulate in the beds of urban streams during the dry summer months. The accumulated organic matter has an adverse effect on water quality, depleting the dissolved oxygen content of stream water and producing plant nutrients. Wintertime flushing flows remove some of the organic matter, reducing its ability to adversely affect water quality.

Under current conditions, releases of high-quality Crystal Springs Reservoir water occur about 10 percent of the time, with beneficial effects on creek water quality. With the WSIP, releases would also occur about 10 percent of the time and at about the same magnitude. Water quality in the creek would be improved by the releases, as it is under the current condition.

Impact Summary

Overall, impacts of the WSIP on water quality in Crystal Springs and San Andreas Reservoirs and in San Mateo Creek would be *less than significant*, and no mitigation is required.

Impact 5.5.3-2: Effects on water quality in Pilarcitos Reservoir and along Pilarcitos Creek.

Pilarcitos Reservoir

Figure 5.5.1-6 shows recent past storage levels in Pilarcitos Reservoir from 1998 to 2006. Under the existing condition, the reservoir is drawn down through the summer, reaching minimum storage in October and November, just before the rainy season begins. With the WSIP, drawdown would occur more rapidly in some years. The more rapid drawdown attributable to the proposed program could cause the reservoir to destratify earlier than under existing conditions. This would not adversely affect water quality; in fact, mechanical destratification in the fall has been recommended to the SFPUC as a means of improving water quality (SFPUC, 2002).

One of the beneficial uses of Pilarcitos Reservoir is cold freshwater habitat (COLD). Because water is released from Pilarcitos Reservoir near the surface, a pool of cool water is retained through the summer near the bottom of the reservoir and below the lowest release point. Under the WSIP, the volume of the pool of cool water below the thermocline would be reduced compared to the existing condition, but would never be exhausted (for the reason noted above). However, the ability of Pilarcitos Reservoir to support the COLD beneficial use under the WSIP could be reduced. This impact would be potentially significant.

Pilarcitos Creek Between Pilarcitos Reservoir and Stone Dam

The WSIP could affect water quality in Pilarcitos Creek between Pilarcitos Reservoir and Stone Dam in two ways – by altering the quality of water released from Pilarcitos Reservoir to the creek and by altering flow in the creek. As discussed above, with the WSIP in place, the volume of the pool of cool water in Pilarcitos Reservoir below the thermocline would be reduced earlier in the year in some years compared to the existing condition, but the quality of water released to Pilarcitos Creek from the reservoir would change little.

The WSIP would increase flow in this reach of the creek in most spring and summer months compared to the existing condition because larger volumes of water would be released from Pilarcitos Reservoir to meet the Coastside CWD's water demand. This increased flow would generally have a beneficial effect on water quality, because water temperature in the spring and summer months would not rise as rapidly in the stream as it flows from the foot of Pilarcitos Dam to Stone Dam as it does under the existing condition. On the other hand, during dry years the

WSIP would extend the period in which no releases are made from Pilarcitos Reservoir to Pilarcitos Creek compared to the existing condition. This is because increased releases to meet Coastside's demand would deplete storage in Pilarcitos Reservoir earlier than under the existing condition. Water quality in the reach of Pilacitos Creek between Pilarcitos Reservoir and Stone Dam could deteriorate as a result. Creek flow would consist only of seepage from Pilarcitos Reservoir, groundwater infiltration, and tributary flow, none of which would be expected to contribute much water to the stream during the summer of a dry year for a longer period with the WSIP than under the existing condition. Water in the creek immediately below Pilarcitos Reservoir at such times could be reduced to isolated pools. Water temperature in the pools could rise, although the extensive vegetative cover in this reach of the creek would likely limit the potential for any such increase.

The proposed program would also reduce flow in Pilarcitos Creek between Pilarcitos Reservoir and Stone Dam in wet months of some wet years. It is not expected that the wet-year flow reductions would have an adverse effect on water quality in the stream because, during the winter, water in the creek would be cool and well oxygenated.

Two of the beneficial uses of Pilarcitos Creek are cold freshwater habitat (COLD) and migration of aquatic organisms (MGR). The MGR beneficial use cannot currently be supported in Pilarcitos Creek above Stone Dam because the dam prevents fish passage. The WSIP would extend the period in which releases from Pilarcitos Reservoir would be eliminated in the summer of dry years, which would degrade water quality in the creek between the reservoir and Stone Dam and reduce the creek's ability to support the COLD beneficial use. This impact would be potentially significant.

Pilarcitos Creek Below Stone Dam

The proposed program would have no effect on flow in Pilarcitos Creek below Stone Dam in dry and below-normal years, and consequently would have no effect on water quality in those hydrologic year types. There is no flow in the creek immediately below Stone Dam in dry and below-normal years under existing conditions, and there would be no flow with the proposed program.

With the WSIP, less water would pass over Stone Dam in winters of wet, above normal, and normal years than it does under the existing condition. It is unlikely that the reductions in spill over Stone Dam would have much effect on water quality in Pilarcitos Creek below Stone Dam. The reductions in spills would occur in months of wet, above normal, and normal years when runoff from the Pilarcitos Creek watershed below Stone Dam would be high. For this reason, the effect of the flow reductions on water quality in the creek below Stone Dam would be minor.

Two of the beneficial uses of Pilarcitos Creek are cold freshwater habitat (COLD) and migration of aquatic organisms (MGR). Because the proposed program would have little effect on water quality in Pilarcitos Creek below Stone Dam, impacts on water quality in Pilarcitos Creek below Stone Dam would be less than significant.

Impact Summary

The adverse impacts of the WSIP on water quality along Pilarcitos Creek between Pilarcitos Reservoir and Stone Dam would be *potentially significant*; however implementation of Measure 5.5.3-2a Low-head Pumping Station at Pilarcitos Reservoir, would restore flow to this reach of Pilarcitos Creek in the late summer and reduce the impact to a less than significant level.

The adverse impacts of the WSIP on water quality in Pilarcitos Reservoir would also be potentially significant. Furthermore, Measure 5.5.3-2a, Low-head Pumping Station at Pilarcitos Reservoir, would exacerbate adverse impacts on water quality at the reservoir by lowering the water level in some summers. Implementation of Measure 5.5.3-2b, Aeration System at Pilarcitos Reservoir, would improve water quality and reduce impacts in the reservoir to a less than significant level.

5.5.4 Groundwater

The following setting section identifies groundwater bodies in the Peninsula watershed that could be affected by the WSIP. The impact section (Section 5.5.4.2) provides a description of the changes in groundwater levels and quality that would result from WSIP-induced changes in stream flow.

5.5.4.1 Setting

The upper reaches of the San Mateo and Pilarcitos Creek watersheds are composed primarily of non-water-bearing igneous, metamorphic, and sedimentary rocks, together with recent alluvium and colluvium.[1] The main groundwater-bearing units associated with San Mateo and Pilarcitos Creeks are in their lower watersheds. Groundwaters in the lower San Mateo Creek watershed are not used for municipal water supply. Groundwaters in the lower Pilarcitos Creek provide a portion of Coastside CWD's municipal supply (Coastside CWD, 2005).

Within the lower Pilarcitos Creek watershed, the main water-bearing units are the marine terrace deposits, which are sand and gravel deposits ranging from 30 to 60 feet thick. The aquifer is bounded on the east by bedrock and on the west by the Pacific Ocean, and is underlain by the relatively impermeable Purisima Formation. Within this groundwater basin, flow is from east to west, discharging to the ocean. Total aquifer storage is estimated at 10,600 acre-feet (Todd Engineers, 2003). Percolation of Pilarcitos Creek flow is an important part of overall local aquifer recharge.

Groundwater quality is of concern in the lower Pilarcitos Creek groundwater basin, especially with respect to iron and manganese; in addition, the water is hard. Seawater intrusion is not considered a problem in the basin, but slightly elevated salt contents were probably incorporated into the aquifer during its formation. A summary of local groundwater quality is presented in **Table 5.5.4-1**; the table provides an average from a sampling program of five wells in the lower Pilarcitos Creek groundwater basin.

5.5.4.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to groundwater, but generally considers that implementation of the proposed program would have a significant groundwater impact if it were to:

- Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of preexisting nearby wells would drop to a level that would not support existing land uses or planned uses for which permits have been granted)

---

1 Alluvium consists of unconsolidated mixtures of gravel, sand, clay, and silt and is typically deposited by streams. Colluvium is a loose deposit of rock debris accumulated through the action of gravity at the base of a cliff or slope.

TABLE 5.5.4-1
SUMMARY OF GROUNDWATER QUALITY PARAMETERS, LOWER PILARCITOS CREEK BASIN

Parameter	Average Value (mg/L, unless otherwise noted)
Total Hardness	228
Alkalinity	184
pH Units	6.9
Total Dissolved Solids	426
Calcium	43
Sodium	60
Bicarbonate	188
Sulfate	50
Chloride	93
Iron	7.5
Manganese	0.61
Nitrate	8.7
Boron	0.166
Arsenic	0.0030

SOURCE: Todd Engineers, 2003.

- Substantially impair a water body's ability to support beneficial uses designated by the State Water Resources Control Board or Regional Water Quality Control Board
- Otherwise substantially degrade water quality

Approach to Analysis

Information on potentially affected groundwater bodies was obtained from published sources related to hydrogeology and groundwater management in the potentially affected area. Impact assessments were performed by reviewing WSIP-induced changes in stream flow and examining their potential to affect groundwater levels or quality.

Impact Summary

Table 5.5.4-2 presents a summary of the impacts on groundwater bodies in the Peninsula watershed that could result from implementation of the proposed water supply and system operations.

TABLE 5.5.4-2
SUMMARY OF IMPACTS – GROUNDWATER BODIES IN PENINSULA WATERSHED

Impact	Significance Determination
Impact 5.5.4-1: Alteration of stream flows along Pilarcitos Creek, which could affect groundwater levels and water quality	LS

LS = Less than Significant impact, no mitigation required

Impact Discussion

Impact 5.5.4-1: Alteration of stream flow along Pilarcitos Creek, which could affect groundwater levels and water quality.

As discussed in Impact 5.5.1-2, the proposed program would have very little effect on flow in Pilarcitos Creek below Stone Dam. There would be some reduction in wintertime spills over the dam in wet and above-normal years as a result of the WSIP, but the reduction would be too small to have an appreciable effect on groundwater recharge in the lower Pilarcitos Creek watershed. Under the existing condition and with the proposed program, the upper Pilarcitos Creek watershed contributes very little flow to the lower watershed. Most wintertime flow in the stream originates below Stone Dam, and this stream flow is the primary source of groundwater recharge. Overall, the effects of the WSIP on groundwater levels and groundwater quality would be *less than significant*, and no mitigation measures would be required.

5.5.5 Fisheries

The following setting section describes the fishery resources within the streams and reservoirs of the San Francisco Peninsula that could be affected by the WSIP. The impact section (Section 5.5.5.2) provides a description of the effects of WSIP-induced changes in stream flow and reservoir levels on fishery resources.

5.5.5.1 Setting

Water Development

The Crystal Springs, San Andreas, and Pilarcitos Reservoirs are located in the Peninsula watershed at the base of San Mateo, Pilarcitos, and San Andreas Creeks, which are fed by coastal mountain drainage headwaters. Crystal Springs and Pilarcitos Reservoirs are stratified and become slightly anoxic during the late summer and fall, while San Andreas Reservoir remains well mixed. Water flow in San Mateo Creek below Crystal Springs Reservoir is dependent on stormwater runoff from the watershed below Lower Crystal Springs Dam, seepage from the dam, and groundwater infiltration. Water flow in Pilarcitos Creek below Stone Dam is similarly dependent on stormwater runoff from the watershed below Stone Dam and groundwater infiltration. Releases from Crystal Springs Reservoir and Stone Dam historically have occurred only in wet months of wet years. The SFPUC permits only limited recreational activity on its lands and reservoirs within the Peninsula watershed; water-contact activities, fishing, and boating on the reservoirs are not allowed.

Aquatic Habitat

San Mateo Creek

San Mateo Creek and its tributary watersheds, including San Andreas Creek, are tributary to the southern portion of San Francisco Bay. San Mateo Creek enters South San Francisco Bay approximately 1.6 miles south of the Hayward–San Mateo Bridge. Stream flows and associated fishery habitat within the San Mateo Creek watershed are affected by seasonal patterns in local rainfall and runoff as well as by San Andreas Dam (constructed in 1870), Upper Crystal Springs Reservoir (constructed in 1877), and Lower Crystal Springs Dam (constructed in 1890). Crystal Springs Reservoir is a barrier to upstream migration by Central California Coast anadromous steelhead. Central California Coast steelhead, which inhabit tributaries to South San Francisco Bay as well as coastal watersheds, have been listed by the National Marine Fisheries Service (NMFS) as a threatened species under the Federal Endangered Species Act. The common species inhabiting the watershed include steelhead/rainbow trout and threespine stickleback (Leidy *et al.* 2005); other species present include suckers, tule perch, and sculpin (RWQCB, 2002). Other fish species recently documented in San Mateo Creek include sculpin, which are found to inhabit the upper part of the watershed, and suckers, carp, and stickleback, which are found within the lower reaches of the creek (Taylor, 2002; Leidy, 2002).

The San Mateo Creek watershed originates in undeveloped lands flowing downstream through urbanized areas adjacent to South San Francisco Bay. The creek corridor within this downstream urban region has been highly modified. The upstream impoundments, in combination with channel modifications within the downstream reaches, are intended in part to provide flood control protection for urban areas. Changes in channel structure and function as a result of both reservoir impoundments and channel modifications have affected instream habitat for steelhead and other fish species.

In 1860, prior to construction San Andreas and Upper and Lower Crystal Springs Reservoirs, steelhead/rainbow trout were collected from San Mateo Creek (Leidy *et al.*, 2005). Leidy (1984) and Smith (1991) collected rainbow trout within San Mateo Creek both upstream and downstream of Lower Crystal Springs Reservoir. Leidy *et al.* (2005) concluded that San Mateo Creek historically supported resident rainbow trout populations, and that small numbers of anadromous steelhead may have utilized the creek downstream of Crystal Springs Reservoir as spawning and juvenile rearing habitat. For purposes of management under the Federal Endangered Species Act, the NMFS defines “steelhead” to include resident rainbow trout inhabiting streams and rivers downstream of impassable reservoirs (including Crystal Springs Dam) and other barriers to migration. Therefore, trout inhabiting the stream upstream of the dam are considered to be resident rainbow trout, while trout downstream of the dam (which could potentially migrate successfully to the ocean) are considered to be steelhead. Fishery studies conducted within other watersheds tributary to South San Francisco Bay have also reported small populations of both spawning and rearing adult steelhead (and in some tributaries, fall-run Chinook salmon). Modification of many of these tributaries, including the lower reaches of San Mateo Creek, present impediments or barriers to upstream access by migrating salmonids and have therefore affected the ability of many of the tributary streams to successfully support populations of anadromous steelhead. Streambank erosion into the creek within the lower reaches may also be contributing to compromised steelhead habitat quality. Potentially compromised water quality in this reach of the creek may have decreased substrate quality, increased temperatures, and reduced dissolved oxygen levels, which can reduce habitat for both salmonids, resident fish populations, and other benthic macroinvertebrate species (RWQCB, 2002). Local watershed groups and state and federal resource agencies are currently developing habitat enhancement measures for San Mateo Creek and other South San Francisco Bay tributaries to enhance access to suitable spawning and juvenile rearing habitat and to improve overall fishery habitat conditions within these small streams.

Pilarcitos Creek

Pilarcitos Creek, a small coastal stream approximately 12 miles long, flows into the Pacific Ocean near Half Moon Bay. Two impoundments regulate flow within Pilarcitos Creek: Pilarcitos Dam and Reservoir, located 10.8 miles upstream (constructed in 1866), and Stone Dam, located 8.5 miles upstream (constructed in 1874). Pilarcitos Creek and Spring Valley Creek provide water supplies to Pilarcitos Reservoir, which can convey water through a tunnel into San Andreas Reservoir and Lower Crystal Springs Reservoir. A total of six small tributaries—four of which enter Pilarcitos Creek in the reach between Pilarcitos Dam and Stone Dam, and two located downstream of Stone Dam—provide additional inflow to Pilarcitos Creek. Water can be diverted from Stone Dam to Lower Crystal Springs Reservoir, and also to the Coastside County Water District. Flow within Pilarcitos Creek downstream of Stone Dam, which has no outlet structure other than a flashboard weir and spillway, primarily originates as tributary inflow.

Stone Dam has been identified as a barrier that prohibits access by anadromous steelhead to upstream habitat. Therefore, Pilarcitos Creek has been characterized as having two separate fishery habitat reaches: the anadromous salmonid reach located downstream of Stone Dam and a resident trout reach located upstream of Stone Dam. The NMSF has expressed interest in developing fish passage opportunities at Stone Dam that would allow anadromous steelhead access to upstream habitat for spawning and juvenile rearing. Alternatives identified for providing upstream access at Stone Dam include complete dam removal, partial dam removal, or construction and operation of a fish ladder.

Information on seasonal stream flows within Pilarcitos Creek downstream of Stone Dam is available from the U.S. Geological Survey Gaging Station No. 11162620. Flow at the gaging station reflects the effects of the upstream impoundments and water diversions on Pilarcitos Creek. Flow within the creek downstream of Stone Dam shows a typical seasonal pattern within coastal watersheds, with consistently low flows during the spring, summer, and early fall (April–November) and higher stream flows during the winter months (December–March) in response to rainfall and runoff. The highest average monthly flows and peak daily flows have occurred during January and February. Peak daily flows during January and February have exceeded 90–100 cfs, with corresponding average monthly flows of approximately 7 cfs in January and 15 cfs in February. Average monthly flows during the spring, summer, and fall within Pilarcitos Creek downstream of Stone Dam typically range from approximately 0.1 to 0.5 cfs. The increased flows during January and February within the tributaries and watershed generally correspond with the seasonal life history of Central California Coast anadromous steelhead, with adult upstream migration and juvenile downstream migration during the winter.

Pilarcitos Creek is characterized by a moderately steep stream gradient downstream of Stone Dam. The substrate within the creek is predominantly fine sediment, sand, and small gravel. Although present, boulders and bedrock outcroppings are rare. Upstream and downstream of Stone Dam, reaches of the creek are characterized predominantly by run habitat and, to a lesser extent, pools and riffles. During the summer months, pool habitat is typically shallow (generally less than 1.5 feet deep). Pilarcitos Creek to the Highway 92 crossing has an adequate riparian corridor, with instream cover provided by overhead vegetation, undercut banks, and other structures. From that point downstream, the creek traverses agricultural and residential areas, and riparian habitat in these areas is limited.

Several barriers or impediments to fish movement have been identified within Pilarcitos Creek, including culverts that would prevent or impede migration under low-flow conditions but would potentially be passable at higher flows. As noted above, Stone Dam is a complete barrier to anadromous steelhead migration at all flow levels within Pilarcitos Creek. Pilarcitos Dam is also a barrier to fish movement within the creek. Several additional passage impediments, such as low-flow riffles, limit fish movement within the creek under low-flow conditions, but are expected to be passable at higher stream flows such as those occurring during the winter.

Another possible factor in reducing available fishery habitat within Pilarcitos Creek, particularly for steelhead, is increased sedimentation and siltation, which may limit spawning grounds and reduce the ability of fishes to capture their prey (RWQCB, 2001). Although these effects have not been quantified, there is a linkage between degradation of steelhead habitat and sedimentation within this watershed. Future studies by stakeholders and others may provide more conclusive data on the extent and effects of sedimentation within the creek (RWQCB, 2001).

Results of limited fishery sampling within Pilarcitos Creek during the mid-1990s (Balance Hydrologics, 1997) confirm that steelhead/rainbow trout successfully spawn and rear within reaches of Pilarcitos Creek both upstream and downstream of Stone Dam. Evidence of multiple year-classes (based on length frequency analysis) confirms successful rearing and oversummering of salmonids within the creek. The relative contribution of resident rainbow trout and anadromous steelhead to the population of fish inhabiting Pilarcitos Creek has not been determined. In addition to steelhead/rainbow trout, other resident fish species such as sculpin are expected to inhabit the creek. Specific instream flows needed to support resident fish populations downstream of Pilarcitos Reservoir or anadromous steelhead downstream of Stone Dam have not been identified.

Pilarcitos Reservoir

Pilarcitos Reservoir, at the base of Pilarcitos Creek, is one of three reservoirs in the Peninsula watershed; it contains populations of rainbow trout, Sacramento sucker, tule perch, and various species of sculpin (RWQCB, 2002). In 1931, Pilarcitos Reservoir was documented as having a good trout population (Skinner, 1962). During the Depression, bass were introduced to the reservoir to serve as a food source and are thought to have contributed to the decline of native fish due to predation. Conditions within Pilarcitos Reservoir are stratified and anoxic during the late summer and fall.

Crystal Springs Reservoir

Water from San Mateo Creek and Pilarcitos Creek can be diverted into Crystal Springs Reservoir, a lake that has been a designated fish and game refuge for many years (Skinner, 1962). A number of important and sensitive fish species are present within the reservoir, including such native fishes as rainbow trout. Crystal Springs Reservoir also contains populations of Sacramento sucker, tule perch, and various species of sculpin (RWQCB, 2002). During the Depression, bass were introduced to Crystal Springs Reservoir to serve as a food source; this planting of largemouth bass, the first in California, is thought to have contributed to the decline of native fish due to predation. Although rainbow trout have been collected throughout the reservoir, native fish species such as Sacramento sucker, tule perch, and various sculpin species appear to be either absent or few in number. Sacramento sucker and tule perch are not listed as threatened or endangered species; however, their decline as a result of the presence and operation of the reservoirs indicates their sensitivity to environmental disturbances. A variety of factors are thought to affect the abundance of resident fish within the reservoir, including predation by species such as largemouth bass and seasonal water quality conditions. Crystal Springs Reservoir exhibits stratification and anoxic conditions in late summer and fall.

San Andreas Reservoir

San Andreas Reservoir contains populations of rainbow trout, Sacramento sucker, tule perch, and various species of sculpin (RWQCB, 2002). Bass were also introduced to this reservoir during the Depression to serve as a food source and are thought to have contributed to the decline of native fish due to predation. San Andreas Reservoir, much like Crystal Springs Reservoir, contains a population of warmwater fishes (Skinner, 1962). San Andreas Reservoir remains well mixed, with relatively good water quality for fishery populations throughout the year.

5.5.5.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to fisheries, but generally considers that implementation of the proposed program would have a significant fisheries impact if it were to:

- Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Game or U.S. Fish and Wildlife Service

- Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites

- Have the potential to degrade the quality of the environment, substantially reduce the habitat of a fish or wildlife species, cause a fish or wildlife population to drop below self-sustaining levels, threaten to eliminate a plant or animal community, substantially reduce the number or restrict the range of an endangered, rare, or threatened species

Approach to Analysis

Changes in reservoir storage and water levels in the San Mateo Creek watershed and changes in reservoir storage, water levels and stream flows in the Pilarcitos Creek watershed attributable to the WSIP were estimated using the HH/LSM. An overview of the model is presented in Section 5.1. Detailed information on the model and the assumptions that underlie it are provided in Appendix H. Changes in flow in streams in the San Mateo Creek watershed attributable to the WSIP were estimated semi-quantitatively based on interviews with individuals knowledgeable about the historical, current, and expected future (with-WSIP) water system operations.

Impact Summary

Table 5.5.5-1 presents a summary of the impacts on water bodies in the Peninsula watershed that could result from implementation of the proposed water supply and system operations.

TABLE 5.5.5-1
SUMMARY OF IMPACTS – FISHERIES
IN SAN FRANCISCO PENINSULA STREAMS AND RESERVOIRS

Impact	Significance Determination
Impact 5.5.5-1: Effects on fishery resources in Crystal Springs Reservoir (Upper and Lower)	PSU
Impact 5.5.5-2: Effects on fishery resources in San Andreas Reservoir	LS
Impact 5.5.5-3: Effects on fishery resources along San Mateo Creek	LS
Impact 5.5.5-4: Effects on fishery resources in Pilarcitos Reservoir	PSM*
Impact 5.5.5-5: Effects on fishery resources along Pilarcitos Creek below Pilarcitos Reservoir	PSM

LS = Less than Significant impact, no mitigation required
PSM = Potentially Significant impact, can be mitigated to less than significant
PSU = Potentially Significant impact, unavoidable

* Based on the refined Pilarcitos watershed impact analysis (see Section 13.3), this impact is PSM due to adverse effects that would result from implementing replacement Measure 5.5.3-2a.

Impact Discussion

Impact 5.5.5-1: Effects on fishery resources in Crystal Springs Reservoir (Upper and Lower).

Results of hydrologic modeling indicate that average monthly storage within Crystal Springs Reservoir would be greater under proposed WSIP operations than under existing conditions. An increase in storage within the reservoir offers the potential for increased coldwater pool volume within the reservoir hypolimnion, which could benefit coldwater fish species inhabiting the stream downstream of the reservoir. In addition, increased reservoir storage would provide an increase in the volume of habitat available for resident fish species inhabiting the reservoir, including both warmwater and coldwater fish species. The increase in storage elevation under the WSIP could also provide greater opportunities for connectivity and migration of fish between the reservoir and upstream tributary habitat. As a result of these factors, increased reservoir storage under proposed operations is considered a beneficial impact on fishery resources.

Only minor changes in water quality conditions would occur within Crystal Springs Reservoir under proposed WSIP operations compared to existing conditions (see Section 5.5.1). Based on the general similarity in water quality conditions with and without the proposed program, potential changes in water quality in Crystal Springs Reservoir and related impacts on fishery resources would be less than significant.

Restoring the levels of the reservoir under the Lower Crystal Springs Dam Improvements project (PN-4) would eliminate approximately 750 linear feet of trout spawning habitat from Laguna and San Mateo Creeks, the two named tributaries to the reservoir, resulting in a total loss of approximately 1,500 linear feet of spawning habitat. However, upstream areas may provide suitable replacement habitat to support the population and this prospect is currently under evaluation in the project-level CEQA review for the Lower Crystal Springs Dam Improvements project. Thus, implementation of Measure 5.5.5-1, Create New Spawning Habitat Above Crystal Springs Reservoir, if feasible, may reduce this impact to less than significant. The project-level CEQA review for the Lower Crystal Springs Dam Improvements project will further evaluate the severity of this impact and the efficacy of Measure 5.5.5-1. To be conservative, at the program-level of analysis, this impact is considered *potentially significant and unavoidable*.

Impact 5.5.5-2: Effects on fishery resources in San Andreas Reservoir.

Results of hydrologic modeling indicate that average monthly storage in San Andreas Reservoir would be similar under proposed operations and existing conditions. Reservoir storage would continue to fluctuate seasonally, as under existing conditions. Based on the similarity of water storage operations, potential impacts on resident fishery resources within San Andreas Reservoir under proposed operations are considered less than significant.

Only minor changes in water quality conditions would occur within San Andreas Reservoir under proposed WSIP operations compared to existing conditions (see Section 5.5.1). Based on the general similarity in water quality conditions with and without the proposed program, potential changes in water quality in San Andreas Reservoir and related impacts on fishery resources would be *less than significant*, and no mitigation measures would be required.

Impact 5.5.5-3: Effects on fishery resources along San Mateo Creek.

San Mateo Creek is an intermittent stream and would remain so under the proposed program. Similar to existing conditions, no releases would be made under the proposed program from Crystal Springs Reservoir to San Mateo Creek in normal, below-normal, or dry years. In wet and above-normal years, releases to the creek would be similar to those under existing conditions. The upper third of San Mateo Creek downstream of the reservoir provides suitable fishery habitat, while the lower creek reaches serve only as a potential migratory corridor. Since actual operations and fishery habitat conditions on San Mateo Creek would be comparable under existing and proposed operations, impacts on fisheries in San Mateo Creek would be *less than significant*, and no mitigation measures would be required.

Impact 5.5.5-4: Effects on fishery resources in Pilarcitos Reservoir.

Storage in Pilarcitos Reservoir varies seasonally. The reservoir typically fills in the winter and is drawn down in the late spring and summer. By late summer, releases from the reservoir are typically limited to reservoir inflow. The volume of habitat available for resident aquatic species varies seasonally from about 3,000 acre-feet in the winter and spring to 1,600 acre-feet in the late summer or fall.

With the WSIP, the reservoir would be drawn down more rapidly and earlier in the season than under the existing condition. The period in which the reservoir would be at its minimum elevation would be extended by days or weeks. The volume of habitat available for resident aquatic species would be at its minimum. Because the WSIP would cause the volume of water stored within Pilarcitos Reservoir to reach its seasonal minimum several days or weeks earlier in the year than under the existing condition, it would also be expected to reduce the coldwater pool volume within the reservoir hypolimnion to its seasonal minimum earlier in the year. This could in turn have an adverse effect on resident coldwater species in the reservoir. However, because water is released from close to the surface of the reservoir, a cool water pool is usually retained below the level of the outlet. Overall, the impacts of the proposed program on resident aquatic species in Pilarcitos Reservoir would be *less than-significant.*

Implementation of Measure 5.5.3-2a, Low-head Pumping Station at Pilarcitos Reservoir, would reduce the storage volume in Pilarcitos Reservoir by about 350 acre-feet in the late summer and fall of about one in four years. In these years, the seasonal minimum storage volume in Pilarcitos Reservoir would be 1,600 to 1,700 acre-feet. However, implementation of Measure 5.5.3-2b, Aeration System at Pilarcitos Reservoir, would improve water quality at such times as the reservoir was drawn down. The periodic reduction in volume of water available to aquatic species, attributable to Measure 5.5.3-2a, coupled with the improvement in water quality attributable to Measure 5.5.3-2b would have a *less-than-significant* impact on resident aquatic species.

Impact 5.5.5-5: Effects on fishery resources along Pilarcitos Creek below Pilarcitos Reservoir.

Pilarcitos Creek Below Pilarcitos Reservoir

Flow in Pilarcitos Creek would increase during many spring and early summer months as a result of the WSIP; however, flow reductions would occur during the summer of dry years. Under the WSIP, instream flow releases (other than dam seepage and reservoir inflow) would cease in Pilarcitos Creek downstream of Pilarcitos Reservoir during summer months of dry years at an earlier date than under the existing condition. Flow reductions in Pilarcitos Creek downstream of Pilarcitos Reservoir under the WSIP would result in potentially significant impacts on resident trout, other resident fish species and aquatic resources.

In addition, as described above, releases from Pilarcitos Reservoir to Pilarcitos Creek are made from close to the surface of the reservoir, so summer and fall releases under existing conditions are warm. With the proposed program in place, summer and fall releases would also be warm (possibly warmer at times), because Pilarcitos Reservoir would be drawn down several days or weeks earlier than under the existing condition. Exposure to higher water temperatures in the late summer and fall could significantly affect habitat quality and availability for coldwater fish species inhabiting Pilarcitos Creek below Pilarcitos Reservoir, including resident trout. This would be a potentially significant impact.

Pilarcitos Creek Below Stone Dam

Pilarcitos Creek supports a population of anadromous steelhead. The creek channel is used as a migration corridor for upstream migration of adults and downstream migration of both adults and juvenile steelhead between approximately December 1 and May 31. Under the proposed WSIP, winter flows within the creek below Stone Dam, during normal or wetter hydrologic years, would be reduced. Although no specific barriers to passage have been identified downstream of Stone Dam, this reduction in peak winter flows could potentially adversely impact steelhead migratory passage and spawning at critical riffles and gravel bars due to the shallow nature of these habitat types.

Currently, there are occasional spills over Stone Dam when releases from Pilarcitos Reservoir and runoff into Pilarcitos Creek above Stone Dam exceed the capacity of the diversion at the dam. The spills occur in the winter months of wet, above normal and normal years. With implementation of the proposed program, occasional spills over Stone Dam would continue but with reduced frequency and magnitude. The volume of spills in average wet, above normal, and normal years would be reduced by 11, 60, and 25 percent, respectively.

Approximately, one-third of the Pilarcitos Creek watershed lies upstream of Stone Dam, and most of the runoff from the watershed is used for municipal water supply by the SFPUC and Coastside CWD. Spills over Stone Dam currently provide up to 15 percent of the flow in the lower reach of Pilarcitos Creek in Half Moon Bay, based on data from gages just downstream of Stone Dam and in Half Moon Bay.

With the WSIP, spills would be reduced and flow in Pilarcitos Creek would be reduced in the winter months, when occasional large flows are important to migratory fish. The effects of the reduced spills would be primarily felt in the reach of Pilarcitos Creek from Stone Dam to the first major downstream tributary at Albert Canyon. The reduction in flows due to the WSIP and related impacts on fish habitat would be potentially significant. In addition, the National Marine Fisheries Service has raised concerns regarding stream flows in Pilarcitos Creek below Stone Dam, and the SFPUC is currently making experimental summer releases and undertaking studies in an effort to address these concerns.

Impact Conclusions

Overall, impacts on fishery resources along Pilarcitos Creek between Pilarcitos Reservoir and Stone Dam related to reduced flows, degraded water quality and elevated temperatures in the late summer and fall would be *potentially significant*. Implementation of Measures 5.5.3-2a, Low-head Pumping Station at Pilarcitos Reservoir, and Measure 5.5.3-2b, Aeration System at Pilarcitos Reservoir, would reduce this potential impact to a less-than-significant level.

Impacts on fishery resources in Pilarcitos Creek below Stone Dam related to reduced wintertime flows would be *potentially significant*. Implementation of Measure 5.5.5-5, Establish Flow Criteria, Monitor and Augment Flow, would reduce this potential impact to a *less-than-significant* level.

5.5.6 Terrestrial Biological Resources

The following setting section describes the terrestrial biological resources within the streams and reservoirs of the San Francisco Peninsula that could be affected by the WSIP. The impact section (Section 5.5.6.2) provides a description of the effects of WSIP-induced changes in stream flow and reservoir levels on terrestrial biological resources.

5.5.6.1 Setting

The Peninsula watershed is a unique ecological resource that hosts extensive and varied habitats in a predominantly urbanized region. It supports the highest concentration of rare, threatened, and endangered species in the entire Bay Area (SFPUC, 1994; 2006). The watershed supports over 550 species of plants (Oberlander, 1953). A high diversity of animals can also be found in the Peninsula watershed, including many that require large areas of contiguous, relatively undisturbed habitat such as mountain lions, deer, bobcats, coyotes, bald eagles, and golden eagles. Due to the extent and variety of habitats, total vertebrate species diversity is likely to include virtually all species found in upland and freshwater habitats in San Mateo County.

This assessment of impacts focuses on sensitive natural communities such as riparian communities and wetlands, and on special-status species (excluding fish) specifically associated with streams and reservoirs that could be affected by WSIP operations. This section distinguishes between WSIP projects for which separate, project-level CEQA analysis would address operational impacts in greater detail (such as the Lower Crystal Springs Dam project [PN-4], which would affect Upper and Lower Crystal Springs Reservoirs and San Mateo Creek below the dam), and projects for which no further CEQA analysis would take place (such as the operation of San Andreas and Pilarcitos Reservoirs and Pilarcitos Creek).

Figure 4.6-1 in Section 4.6, Biological Resources, shows the habitat types found in the Peninsula watershed within the WSIP program area. Habitat types are broader groupings than natural communities, but are useful when describing both wildlife and vegetation resources together.

San Mateo Creek

Immediately below Crystal Springs Dam, seepage supports a small area of freshwater marsh. Below this, San Mateo Creek flows through a steep, largely undeveloped canyon where it supports a well-developed central coast arroyo willow (*Salix lasiolepis*) riparian forest, with coast live oak (*Quercus agrifolia*) riparian forest farther downstream. Coast live oak woodland, mixed evergreen forest, and coastal scrub grow on the adjacent uplands. San Mateo Creek then flows through the town of Hillsborough and the city of San Mateo, emptying into San Francisco Bay south of Coyote Point. In this section the creek is not culverted, but is closely surrounded by urbanization.

Riparian processes along San Mateo Creek have already been considerably affected by the presence of the Crystal Springs Dam. Sediment supply and base flows have been cut off to lower San Mateo Creek, and the magnitude of peak flows at all recurrence intervals has been greatly diminished. Stream releases are infrequent under existing conditions and occur only when runoff into Crystal Springs Reservoir cannot be contained by available storage or conveyed elsewhere. There are no releases during the summer months, and none during normal, below-normal, and dry years.

Upper and Lower Crystal Springs Reservoirs

Lower Crystal Springs Reservoir is surrounded primarily by oak woodland and Douglas-fir (*Pseudotsuga menziesii*) forest on the western side, with oak woodland, serpentine grassland, valley needlegrass grassland, and non-native grassland on the eastern side. Lower Crystal Springs Reservoir supports a large area of valley and foothill freshwater marsh on its northwestern tip where San Andreas Creek enters the reservoir (referred to as Tracy Lake). This area currently supports more extensive freshwater marsh than it did in the 1950s, when Crystal Springs Dam was operated at full capacity (Oberlander, 1953). White alder riparian forest extends to Lower Crystal Springs Reservoir along San Mateo Creek. Central coast arroyo willow riparian forest is present along the smaller creeks, sometimes expanding where creeks enter the reservoir.

Upper Crystal Springs Reservoir is surrounded primarily by coast live oak woodland, with extensive areas of serpentine and valley needlegrass grassland and small areas of northern coastal scrub on the eastern side. Large areas of arroyo willow riparian forest and freshwater marsh are found at Adobe Marsh and at the mouth of Laguna Creek at the southeastern end. The overall extent of current freshwater marsh wetland vegetation surrounding Upper Crystal Springs Reservoir is less than existed historically, and many areas have converted to arroyo willow riparian forest (Oberlander, 1953; San Francisco Planning Department, 2001).

San Andreas Reservoir

San Andreas Reservoir is surrounded primarily by northern coastal scrub. In the absence of fire, a coast live oak tree layer is developing within the scrub on deeper soils. The eastern edge of the reservoir supports non-native grassland and exotic forests dominated by Monterey pine (*Pinus radiata*) and eucalyptus (*Eucalyptus* sp.). Some small areas of native grassland may also be present. The two northern arms of the reservoir support some of the largest freshwater marshes in the watershed. Depending on elevation, these marshy areas variously support cattails, bulrushes, spikerush, rush, and other emergent species. Historically, the freshwater marsh wetland was less extensive on the eastern arm of the upper portion of the reservoir; in 1993, this area was mapped as open water. The western upper arm of the reservoir supported more extensive freshwater marsh wetland. The truncated shoreline mapped by Oberlander (1953) suggests that there may have been an impoundment in this area that functioned to increase the extent of freshwater marsh.

Pilarcitos Creek and Reservoir

The vegetation above Pilarcitos Dam consists mostly of coastal scrub, with areas of Douglas-fir and redwood (*Sequoia sempervirens*) forest and mixed evergreen/coast live oak forest in the deeper and more sheltered slopes. A small area of freshwater marsh was mapped by Oberlander (1953) on the southern arm of the reservoir. Central coast arroyo willow riparian forest lines the major tributaries to Pilarcitos Reservoir for a considerable distance upstream. Below Pilarcitos Dam, Pilarcitos Creek follows a deep canyon heavily wooded with Douglas-fir forest. A well-developed white alder (*Alnus rhombifolia*) riparian forest grows along the creek between Pilarcitos Dam and Stone Dam. Below Stone Dam, Pilarcitos Creek is lined with central coast arroyo willow riparian forest.

Natural Communities, including Sensitive Natural Communities

The *Peninsula Watershed Management Plan Environmental Impact Report* (San Francisco Planning Department, 2001) identified 14 natural communities occurring within the watershed, eight of which are listed as sensitive in the California Natural Diversity Database (CNDDB) (CDFG, 2006). Eleven natural communities, including all eight of the sensitive natural communities, occur adjacent to San Andreas, Pilarcitos, and Upper and Lower Crystal Springs Reservoirs and associated creeks. The natural community name, CNDDB code, sensitivity, and occurrence within the WSIP program area are presented in **Table 5.5.6-1** and briefly described below. More detail will be provided in the project-specific EIR for the Lower Crystal Springs Dam project (PN-4).

Grasslands

Serpentine grassland and valley needlegrass grassland are found on the open ridges of the Peninsula watershed, often on less fertile soils. Serpentine grassland is specifically associated with soils derived from serpentine rock. Both grasslands are characterized by a high proportion of native species, many perennial grasses, and low productivity. Typical perennial grasses include needlegrass (*Nassella* spp.), pine bluegrass (*Poa secunda*), fescue (*Festuca* spp.), and junegrass (*Koeleria cristata*). Within the WSIP study area, extensive areas of serpentine grassland are found along the eastern shores of Upper and Lower Crystal Springs Reservoirs. Valley needlegrass grassland is found on the eastern shores of San Andreas Reservoir and Upper and Lower Crystal Springs Reservoirs. Disturbed Valley needlegrass grassland may also be present in San Mateo Canyon below Crystal Springs Dam.

Non-native grassland is found in many areas with a history of disturbance. It is dominated by a variety of non-native annual grasses such as brome (*Bromus* spp.), oats (*Avena* spp.), and wild barley (*Hordeum* spp.) as well as herbs such as filaree (*Erodium* spp.), with less abundant native annual and perennial grasses and herbs. This community is found along the shores of San Andreas Reservoir and Upper and Lower Crystal Springs Reservoirs.

Chaparral and Scrub

Northern mixed chaparral and northern coastal scrub are shrub-dominated communities typically found on steep, rocky, exposed slopes. Both tend to form dense, rather impenetrable stands that are regenerated by periodic wildfires. On the Peninsula watershed, northern mixed chaparral is dominated by scrub oak (*Quercus dumosa*), chamise (*Adenostoma fascicularis*), and several species of ceanothus (*Ceanothus* spp.). Northern coastal scrub is dominated by coyote brush (*Baccharis pilularis*), poison-oak (*Toxicodendron diversilobum*), and bush monkeyflower (*Mimulus aurantiacus*). Northern coastal scrub is found on much of the western shore of San Andreas Reservoir, the shores of most of the upper, northern branches of Pilarcitos Reservoir, and in small areas around Upper and Lower Crystal Springs Reservoirs.

Forests and Woodlands

Mixed evergreen forest and coast live oak woodland are the most abundant forest communities on the watershed. These communities are typically found in more sheltered sites that have deeper soils than scrubs and grasslands. Mixed evergreen forest is dominated by coast live oak, California bay (*Umbellularia californica*), madrone (*Arbutus menziesii*), Douglas-fir, and big-leaf maple (*Acer macrophyllum*). It tends to form a closed canopy with shrubby or grassy understory and is found in more sheltered sites such as canyons. Coast live oak woodland is dominated by a single species, coast live oak, which forms a nearly closed canopy forest in favorable sites with deep soils and ample soil moisture, or open woodland with a grassy understory in drier areas. Mixed evergreen forest and coast live oak are found in nearly all of the deep canyons on the east side of San Andreas and Crystal Springs Reservoirs, and most of the sheltered western sides of these reservoirs. A small stand is also found on the west side of Pilarcitos Reservoir. Douglas-fir forest and redwood forest are tall, dense, forests dominated by Douglas-fir and coast redwood. Some of the largest old-growth stands in the Bay Area are found on the eastern slopes of the larger ridges in the Peninsula watershed. These communities extend to the shores of Pilarcitos

Reservoir. Small areas of Douglas-fir forest also occur on the western shore of Lower Crystal Springs Reservoir.

Riparian Forests

Central coast arroyo willow riparian forest occurs in moist canyons, usually with perennial stream flow or seepage. It is a dense, broadleaved, winter-deciduous forest dominated by arroyo willow (*Salix lasiolepis*), which grows as a large, tree-like shrub. This common riparian natural community is found in sections of Pilarcitos Creek both above Pilarcitos Reservoir and below Stone Dam, on the major tributaries draining into San Andreas and Upper and Lower Crystal Springs Reservoirs, and in portions of San Mateo Creek below Crystal Springs Dam. White alder riparian forest is a medium-tall, broadleaved, deciduous streamside forest dominated by white alder (*Alnus rhombifolia*) with a shrubby, deciduous understory. It is found along rapidly flowing perennial streams with coarse sediments and is more typical of the North Coast. It is found along Pilarcitos Creek between Pilarcitos Dam and Stone Dam and in San Mateo Creek between Mud Dam and Lower Crystal Springs Reservoir. Central coast live oak riparian forest is an evergreen riparian forest dominated by coast live oak. This community may be present in portions of San Mateo Creek below Crystal Springs Dam.

Coastal and Valley Freshwater Marsh

Coastal and valley freshwater marsh is a wetland community dominated by usually dense stands of perennial, emergent grass and grass-like plants up to 15 feet tall. Typical species include cattails (*Typha* spp.), tule (*Scirpus* spp.), rushes (*Juncus* spp.), and sedges (*Carex* spp.). Coastal and valley freshwater marsh is found in areas that are permanently flooded or saturated. Examples of this community are found around the perimeter of all of the reservoirs in the Peninsula watershed, usually in areas of gentle topography and fine-textured alluvial soils where streams deposit sediment. Upper and Lower Crystal Springs Reservoirs and San Andreas Reservoir support extensive areas of freshwater marsh, while Pilarcitos Reservoir has little of this habitat.

Key Special-Status Species and Other Species of Concern

The name and status of key plant and animal special-status species and species of concern with the potential to occur within the WSIP program area on the Peninsula watershed, based on the EIR for the *Peninsula Watershed Management Plan* (San Francisco Planning Department, 2001), are shown in Appendix D. **Tables 5.5.6-2** and **5.5.6-3** present the name, status, habitat, and potential for occurrence of key plant and animal species that could be affected by WSIP projects in the Peninsula watershed; these species are further discussed in the text below.

Because of proposed changes in the operation of Upper and Lower Crystal Springs Reservoirs and the presence of extensive serpentine grassland habitats along their shores, many species could be affected by the Lower Crystal Springs Dam project (PN-4). These species are discussed briefly below and will be described in more detail in the project-specific EIR. The consultant team (Lebednik, 2006) provided preliminary survey results of 2006 wildlife and botanical surveys for the Lower Crystal Springs Dam project area.

TABLE 5.5.6-2
KEY SPECIAL-STATUS PLANTS AND PLANT SPECIES OF CONCERN IN THE WSIP PENINSULA WATERSHED OPERATIONAL AREA

			Potential to Occur, by WSIP Operational Area[a]		
Common Name *Scientific Name*	**USFWS/CDFG/ CNPS Status**[b]		**Upper/Lower Crystal Springs Reservoirs, San Mateo Creek**	**San Andreas Reservoir**	**Pilarcitos Reservoir and Creek**
San Mateo thorn-mint *Acanthomintha duttonii*	FE/CE/1B*	Open areas in serpentine clay soils	Low potential		
Franciscan onion *Allium peninsulare* var. *franciscanum*	–/–/1B	Woodland, grassland, clay soils, often on serpentine	Present		
Bent-flowered fiddleneck *Amsinckia lunaris*	–/–/1B	Woodland and valley grassland	Potential	Potential	Potential
Fountain thistle *Cirsium fontinale var. fontinale*	FE/CE/1B*	Serpentine seeps	Present		
San Francisco collinsia *Collinsia multicolor*	–/–/1B	Closed-cone coniferous forest, coastal scrub, sometimes serpentinite	Present		
Western leatherwood *Dirca occidentalis*	–/–/1B	Mesic sites in forest, woodland, and scrub	Present	Potential	Potential
San Mateo woolly sunflower *Eriophyllum latilobum*	FE/CE/1B*	Openings in oak woodland on serpentine	Present		
Fragrant fritillary *Fritillaria liliacea*	–/–/1B	Clay soils, often on serpentine	Present nearby		
Marin western flax *Hesperolinon congestum*	FT/CT/1B*	Grassland and chaparral, often on serpentine	Present		
Hillsborough chocolate lily *Fritillaria biflora* var. *ineziana* (=*F. grayiana*)	–/–/1B	Woodland and grassland, often on serpentine	Low potential		
Crystal Springs lessingia *Lessingia arachnoidea*	–/–/1B	Woodland, scrub, grassland, usually on serpentine	Present		
Arcuate bush mallow *Malacothamnus arcuatus* (=*M. fasciculatus*)	–/–/1B	Chaparral on gravelly alluvium	Present	Potential	Potential
Dudley's lousewort *Pedicularis dudleyi*	–/CR/1B*	Maritime chaparral, north coast coniferous forest, and cismontane woodland; deep shady woods of redwood forests	Low potential		Potential
White-rayed pentachaeta *Pentachaeta bellidiflora*	FE/CE/1B*	Open dry rocky slopes and grassy areas, usually on serpentine soils	Low potential		

[a] The WSIP operational area is the extent that could be affected by program operations, such as below reservoir maximum elevations, or within riparian areas where changes in flows could affect habitat.
[b] Federal (USFWS), state (CDFG), and California Native Plant Society protection status codes are as follows:

FC: Federal candidate for listing
FE: Federal endangered
FT: Federal threatened
FD: Federal delisted
CE: California endangered
CT: California threatened
CR: California rare
1B: California Native Plant Society rare and endangered
– Indicates no federal or state protection

* Indicates key special-status species, defined as having a state or federal listing as rare, threatened, or endangered.

FE: Federal endangered
FT: Federal threatened
FD: Federal delisted
CE: California endangered
CT: California threatened
CP: California fully protected
CSC: California species of special concern
– Indicates no federal or state protection
* Indicates key special-status species, defined as having a state or federal listing as endangered or threatened.

SOURCES: CDFG, 2007; Lebednik, 2006.

Serpentine-Associated Plants

Several upland special-status plants occur in serpentine-influenced habitats near the margins of Upper and Lower Crystal Springs Reservoirs, especially on the eastern side of Upper Crystal Springs Reservoir, where a large serpentine outcrop adjoins the reservoir. Franciscan onion (*Allium peninsulare* var. *franciscanum*, federal species of concern, CNPS List 1B), fountain thistle (*Cirsium fontinale* var. *fontinale*, federal endangered, California endangered), Marin western flax (*Hesperolinon congestum*, federal threatened, California threatened), and Crystal Springs lessingia (*Lessingia arachnoidea*, federal species of concern, CNPS List 1B) have been observed in serpentine grassland below the elevation of 291 feet along the eastern shoreline of Upper Crystal Springs Reservoir (Lebednik, 2006). San Mateo thorn-mint (*Acanthomintha duttonii*, federal endangered, California endangered), Hillsborough chocolate lily (*Fritillaria grayiana*, CNPS List 1B), fragrant fritillary (*Fritillaria liliacea*, CNPS List 1B), and white-rayed pentachaeta (*Pentachaeta bellidiflora*, federal endangered, California endangered, CNPS List 1B) are known to occur in serpentine grasslands near Upper Crystal Springs Reservoir, but have not been identified in the WSIP program area during recent protocol-level surveys. San Mateo woolly sunflower (*Eriophyllum latilobum*, federal endangered, California endangered, CNPS List 1B) is known to occur serpentine soils in woodland openings in San Mateo Canyon.

Other Upland Plants

Western leatherwood (*Dirca occidentalis*, CNPS List 1B) occurs in woodland, forest, and scrub habitats in many localities in the Peninsula watershed, and suitable habitat is present in the vicinity of all three reservoirs. Arcuate bush mallow (*Malacothamnus fasciculatus=M. arcuatus*, CNPS List 1B) grows in chaparral on gravelly alluvium. It was observed on the shore of Upper and Lower Crystal Springs Reservoirs in 2006, and suitable habitat may also be present in coastal scrub near the other reservoirs. Although not observed during 2006 field surveys (Lebednik, 2006), suitable habitat is present in the vicinity of Upper and Lower Crystal Springs Reservoirs for bent-flowered fiddleneck (*Amsinckia lunaris*, CNPS List 1B) and for Dudley's lousewort (*Pedicularis dudleyi*, federal species of concern, California rare, CNPS List 1B) near Upper and Lower Crystal Springs Reservoirs and Pilarcitos Reservoir and Creek.

Perennial Grassland Invertebrates

Bay checkerspot butterfly (*Euphyhydras editha bayensis*, federal threatened), is discussed in Chapter 4, Section 4.6. It is believed to be extirpated from the Peninsula watershed lands. Mission blue butterfly (*Icaricia icarioides missionensis*, federal endangered) is found in native grasslands and coastal scrub, where it depends on three perennial species of lupine (*Lupinus* spp.) for its larval foodplant. This species was originally believed to be restricted to San Francisco as far south as San Bruno Mountain; however, a population was discovered in the vicinity of San Andreas Dam in 1985 (San Francisco Planning Department, 2001). It is not known to occur in the vicinity of Upper and Lower Crystal Springs Reservoirs, but foodplants were observed in this area during surveys in 2006 (Lebednik, 2006).

Aquatic-Dependent Reptiles and Amphibians

California red-legged frog (*Rana aurora draytonii*, federal threatened, California species of special concern) is discussed in Section 4.6. According to recent surveys (LSA, in prep.), the distribution of California red-legged frog in the Peninsula watershed is patchy despite the presence of widespread, apparently suitable habitat. Within the WSIP program area, the species is known to occur in Upper and Lower Crystal Springs Reservoirs and Tracy Lake, San Andreas Reservoir, Stone Dam, Pilarcitos Creek, San Mateo Creek below Crystal Springs Dam, and on the parapet of the dam itself, as well as in many other localities within the Peninsula watershed (CDFG, 2006; Swaim, 2006; CDFG, 2007).

Foothill yellow-legged frog (*Rana boylii*, federal species of concern, California species of special concern) is a stream-dwelling species, preferring shallow, flowing water, preferentially in small to moderate sized streams. Although this species is historically known to occur in low-elevation streams in the Sierra Nevada, Transverse Ranges, and Coast Ranges northward to Oregon, its current distribution is not well known. There are historical records for many streams on the San Francisco Peninsula, including some in or near the Peninsula watershed (Swaim, 2006), but the current extent of the species in the Peninsula watershed is not known. Potential habitat may be present in Pilarcitos Creek and the tributaries to San Andreas and Upper and Lower Crystal Springs Reservoirs. Western pond turtle (*Actinemys = Clemmys marmorata*, federal species of concern, California species of special concern) lives in permanent water such as lakes, ponds, and deep areas in streams. It requires logs, rocks, or emergent vegetation for basking. Western pond turtle is known to occur in Upper and Lower Crystal Springs Reservoirs, and suitable habitat is present at San Andreas Reservoir and Pilarcitos Reservoir.

San Francisco garter snake (*Thamnophis sirtalis tetrataenia*, federal endangered, California endangered) is discussed in Section 4.6. Within the WSIP program area on the Peninsula watershed, this species is known to occur in San Andreas Reservoir, Upper and Lower Crystal Springs Reservoirs, the Pulgas Water Temple, the upper headwaters of Pilarcitos Creek, the vicinity of Pilarcitos Reservoir, and at Stone Dam.

Marbled Murrelet

The marbled murrelet (*Brachyramphus marmoratus*, federal threatened) is a small, diving seabird that nests in large trees in coniferous forests as much as 50 miles inland, and forages on small fish and invertebrates in near-shore marine waters. A nesting murrelet was detected in 1998 and 2003 on the west side of Pilarcitos Creek within designated critical habitat for the species.

Riparian-Dependent Birds

Several bird species of special concern are closely associated with the riparian habitats in the WSIP program area. Riparian trees throughout the watershed have a moderate potential to support nesting and foraging Cooper's hawk (*Accipiter cooperi*, California species of special concern) and sharp-shinned hawk (*A. striatus*, California species of special concern). The riparian vegetation at the southern end of Upper Crystal Springs Reservoir supports a breeding population of saltmarsh common yellowthroat (*Geothlypis trichas sinuosa*, California species of special concern). Suitable habitat may also be present at San Andreas Reservoir. Loggerhead shrike

(*Lanius ludovicianus*, California species of special concern) nests in riparian and other woodlands and forages over open country. It may be present throughout the Peninsula watershed in suitable habitat.

Marsh- and Lake-Dependent Birds

Tricolored blackbird (*Agelaius tricolor*, California species of special concern) has been observed during the breeding period in the vicinity of Upper and Lower Crystal Springs Reservoirs and thus may breed there. Suitable habitat may also be present at San Andreas Reservoir. Northern harrier (*Circus cyaneus*, California species of special concern) nests and forages in wet meadows and pastures such as those found at San Andreas Reservoir and Upper and Lower Crystal Springs Reservoirs. California black rail (*Laterallus jamaicensis coturniculus*, California threatened) generally breeds in saltmarsh habitat, but sometimes breeds in freshwater marsh at low elevations. Suitable habitat may be present at Upper and Lower Crystal Springs Reservoirs and San Andreas Reservoir. Double-crested cormorant (*Phalacrocorax auritus*, California species of special concern) nests in rookeries on cliffs and along lake margins, and forages for fish. It has been observed at Crystal Springs Reservoir and may also forage at San Andreas Reservoir. The bank swallow (*Riparia riparia,* California threatened) nests in banks along large rivers and forages over open water. Although there are no current records for this species in the Peninsula watershed, it may forage at Crystal Springs and San Andreas Reservoirs. Peregrine falcon (*Falco peregrinus anatum*, federal delisted, California endangered) nests in cliffs and outcrops and forages near wetlands and open water. Foraging habitat may be present throughout the Peninsula watershed, especially near Crystal Springs and San Andreas Reservoirs.

Upland Birds

Bell’s sage sparrow (*Amphispiza belli belli*, California species of special concern) nests in chaparral and coastal scrub. Suitable habitat may be present on the shores of all of the reservoirs. Vaux’s swift (*Chaetura vauxi*, California species of special concern) nests in hollow trees and forages over woodlands and open water. The species was observed at Upper and Lower Crystal Springs Reservoirs, and suitable habitat may be present near San Andreas and Pilarcitos Reservoirs. Merlin (*Falco columbarius*, California species of special concern) is a winter visitor and may forage in all project areas.

Mammals

Pallid bat (*Antrozous pallidus*, California species of special concern) roosts in trees and forages over open grassland. The species could occur throughout the watershed, but foraging areas within the WSIP program area would be found primarily along the shores of Upper and Lower Crystal Springs Reservoirs. Pacific western big-eared bat (*Corynorhinus townsendii*) roosts in caves and buildings and forages in open country. Suitable habitat is present at Upper and Lower Crystal Springs Reservoirs and San Andreas Reservoir. Small-footed myotis (*Myotis ciliobabrum*, California species of special concern) roosts in trees as well as old buildings and caves and forages in open country. Like the pallid bat, the primary foraging areas near the WSIP program area would be along the shores of Upper and Lower Crystal Springs Reservoirs, but roosting habitat would be present throughout the program area within the Peninsula watershed. Long-eared myotis (*Myotis evotis*, California species of special concern) roosts in hollow trees and forages along rivers, streams, and ponds. It would be expected to occur throughout the WSIP program area in the Peninsula watershed. Fringed myotis (*Myotis thysanodes*, California species of special concern) roosts in trees and forages at the forest edge. It would be expected to occur throughout the WSIP program area. Long-legged myotis *(Myotis volans*) roosts in hollow trees and feeds primarily in open areas. Suitable roosting habitat could be present throughout the WSIP program area in the Peninsula watershed, but foraging areas would be present primarily at the margins of San Andreas and Upper and Lower Crystal Springs Reservoirs. Yuma myotis (*Myotis yumanensis*, California species of special concern) roosts in trees and crevices and forages over emergent vegetation and still water. It would be most likely to occur near the reservoirs—Pilarcitos, San Andreas, and Upper and Lower Crystal Springs.

The San Francisco dusky-footed woodrat (*Neotoma fuscipes annectens,* California species of special concern) inhabits oak woodlands where it forages primarily on oak leaves. Suitable habitat is present in oak woodlands throughout the Peninsula watershed.

5.5.6.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to terrestrial biological resources, but generally considers that implementation of the proposed program would have a significant biological impact if it were to:

- Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS
- Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations or by the CDFG or USFWS
- Have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including but not limited to marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means
- Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites
- Have the potential to degrade the quality of the environment, substantially reduce the habitat of a fish or wildlife species, cause a fish or wildlife population to drop below self-sustaining levels, threaten to eliminate a plant or animal community, or reduce the number or restrict the range of a rare or endangered plant or animal
- Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance

- Conflict with the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, or state habitat conservation plan

Approach to Analysis

The assessment of WSIP operational impacts on terrestrial biological resources is based primarily on the extent to which altered operations would change the existing habitat near reservoirs and creeks. Operational changes consist of increased diversions during winter high flows, increased releases to streams to maintain minimum flows, and changes in the elevation, annual range, and seasonal timing of reservoir water levels. Section 5.5.1 presents an assessment of the changes in hydrology in the Peninsula watershed that would occur under the WSIP.

This section discusses impacts related to sensitive habitats, key special-status species, other species of concern, and common habitats and species. The discussion of riparian and wetland habitats addresses the second and third significance criteria listed above. "Key special-status species" include species that are formally listed as endangered or threatened under the state or federal endangered species acts, as well as a few other species (such as foothill yellow-legged frog) that are afforded some degree of legal protection and have a high risk of local population decline or extirpation. The key special-status species discussion addresses the first significance criterion. "Other species of concern" and "common habitats and species" are more general categories relevant to the fourth and fifth significance criteria.

There would be no impacts related to conflicts with local policies or ordinances protecting biological resources or the provisions of a habitat conservation plan (the last two significance criteria). The SFPUC has prepared a management plan for the Peninsula watershed and is preparing a habitat conservation plan, but the WSIP would be consistent with their provisions.

The responses of terrestrial biological resources to changes in stream and reservoir operations are complex in both space and time. This section describes the general impacts associated with certain categories of operational changes to reservoirs and streams. The project EIR for the Lower Crystal Springs Dam project (PN-4) would address operational impacts in detail. The other Peninsula Region projects would have limited, if any, operational impacts on creeks and reservoirs. Potential impacts on San Andreas Reservoir, Pilarcitos Reservoir, and Pilarcitos Creek are analyzed in this PEIR at a project level because the operational effects on these facilities would not be analyzed in a project-specific EIR.

Unlike the Alameda Creek watershed and Calaveras Reservoir, which have experienced DSOD-mandated operational changes for a relatively short period of time, Crystal Springs Reservoir has been maintained at lower, DSOD-mandated water levels since 1983—nearly 25 years. The freshwater marsh and riparian habitats have adapted to the prevailing conditions, and no reference to earlier operational conditions is required in this assessment of impacts.

Impact Summary

Table 5.5.6-4 presents a summary of the impacts on terrestrial biological resources in the Peninsula watershed that could result from implementation of the proposed water supply and system operations.

TABLE 5.5.6-4
SUMMARY OF IMPACTS –
TERRESTRIAL BIOLOGICAL RESOURCES IN THE PENINSULA WATERSHED

Impacts	Sensitive Habitats	Key Special-Status Species	Other Species of Concern	Common Habitats and Species
Impact 5.5.6-1: Impacts on biological resources in Upper and Lower Crystal Springs Reservoirs	PSM	PSM	PSM	PSM
Impact 5.5.6-2: Impacts on biological resources in San Andreas Reservoir	LS	LS	LS	LS
Impact 5.5.6-3: Impacts on biological resources along San Mateo Creek below Lower Crystal Springs Dam	LS	LS	LS	LS
Impact 5.5.6-4: Impacts on biological resources in Pilarcitos Reservoir	LS	PSM*	LS	LS
Impact 5.5.6-5: Impacts on biological resources along Pilarcitos Creek below Pilarcitos Reservoir	LS	LS	LS	LS
Impact 5.5.6-6: Impacts on biological resources along Pilarcitos Creek below Stone Dam	LS	LS	LS	LS
Impact 5.5.6-7: Conflicts with the provisions of adopted conservation plans or other approved biological resource plans	LS			

LS = Less than Significant impact, no mitigation required
PSM= Potentially Significant impact, can be mitigated to less than significant

* Based on the refined Pilarcitos watershed impact analysis (see Section 13.3), this impact is PSM due to adverse effects that would result from implementing replacement Measure 5.5.3-2a.

Impact Discussion

Impact 5.5.6-1: Impacts on biological resources in Upper and Lower Crystal Springs Reservoirs.

Sensitive Habitats

Elevating the average storage and reservoir levels under the WSIP would inundate all existing freshwater marsh and riparian habitats below an elevation of 283 feet, resulting in the loss of these sensitive habitats. Freshwater marsh would become established at higher elevations in response to higher reservoir levels. As the reservoir fills, there could be a short-term reduction in the overall extent of freshwater marsh, although the greater perimeter of the reservoir at the higher levels could eventually support an increase in the extent of these habitats. This impact would be potentially significant.

Under the WSIP, the average monthly water levels in Crystal Springs Reservoir would fluctuate more than under the existing condition. This increased fluctuation would be due in part to periodic drawdown (up to 16 feet) for Hetch Hetchy system maintenance, which would occur approximately every five years. This drawdown would expose deep-water emergent vegetation such as cattails and tules and could dry the soils supporting shallow emergent vegetation and wet meadow vegetation. However, the maintenance would be scheduled during the onset of cool fall or early winter weather (October–December), when wetland vegetation is entering its winter dormancy period. Provided the reservoir was refilled during the winter, impacts on sensitive habitats related to this change in operations would be less than significant, and no mitigation measures would be required.

Other than the periodic drawdown, the annual range of fluctuation in reservoir water levels would be similar to levels under existing conditions; therefore, the impact on riparian and wetland resources would be less than significant, and no mitigation measures would be required.

The WSIP proposes to maintain maximum reservoir water levels for longer periods during the summer than under existing conditions. This operational strategy could favor perennial freshwater marsh habitats over willow scrub, but any such effect cannot be quantified at the program level of analysis. Therefore, this PEIR conservatively considers this impact to be potentially significant.

Sensitive upland habitats would be affected by the higher reservoir water levels. Maximum water levels would be sustained higher and longer with the WSIP than under existing conditions (or before the DSOD-imposed operational restrictions). Habitats and species that could not tolerate these longer periods of inundation would be lost, including oak woodland, mixed evergreen forest, serpentine grassland, and valley needlegrass grassland. This impact would be potentially significant.

The EIR for the Lower Crystal Springs Dam project (PN-4) will provide a more detailed analysis of project impacts, including a determination of the acreage of sensitive upland, wetland, and riparian habitat that would be affected by the change in reservoir water levels. However, this PEIR conservatively considers the effects of the WSIP on sensitive upland, wetland, and riparian habitats to be *potentially significant*.

Key Special-Status Species

Proposed operation of Upper and Lower Crystal Springs Reservoirs under the WSIP would affect several key special-status species. Populations of serpentine-associated fountain thistle and Marin western flax would be inundated and their habitat potentially permanently lost. At the program level of analysis, this impact is considered potentially significant. More detailed impact analysis will be conducted as part of the project-level CEQA review for the Lower Crystal Springs Dam project (PN-4).

WSIP-related operations could also affect San Francisco garter snake and California red-legged frog in several ways. Direct mortality by drowning could occur if the reservoir level is raised while San Francisco garter snakes are in hibernation. Both species would experience a loss of habitat throughout Upper and Lower Crystal Springs Reservoirs when existing freshwater marsh vegetation is inundated. Once freshwater marsh wetland is established at higher levels, the WSIP could increase the extent of available habitat for California red-legged frog and San Francisco garter snake. However, raising the water level in reservoirs could permit largemouth bass (*Micropterus salmoides*) and other predators to gain access to habitat for San Francisco garter snake and California red-legged frog in areas that are currently isolated due to elevational barriers. Examples include Tracy Lake in the northern arm of Lower Crystal Springs Reservoir, and the proposed Laguna Creek sedimentation basin at the southern end of Upper Crystal Springs Reservoir. Thus, at the program level of analysis, potentially significant adverse and beneficial impacts on habitat for special-status species would be expected to occur due to higher and more variable water levels in Upper and Lower Crystal Springs Reservoirs. Impacts will be analyzed in more detail in the project-specific EIR for the Lower Crystal Springs Dam project (PN-4).

Annual summer drawdown has been cited as a potential problem for San Francisco garter snakes because the exposed, unvegetated shoreline separates emergent vegetation foraging habitat from water and protective cover (Barry, no date). Hydrologic models of the proposed program indicate that summer drawdown would be about the same as the current pattern, except for the drawdown that would occur for periodic maintenance. San Francisco garter snakes usually enter their winter hibernation period by mid-November (Barry, no date). Because the drawdown period overlaps somewhat with the active period of this species, this impact would be potentially significant with respect to foraging habitat for both adult and young garter snakes.

Other key special-status species that could be affected by reservoir operations under the WSIP include peregrine falcon and black rail. Both species utilize freshwater marsh habitats, but to a limited degree. Therefore, impacts on these species due to alteration of habitats would be less than significant.

Overall, the effects of the WSIP on key special-status species would be *potentially significant.*

Other Species of Concern

The loss of existing habitat and ultimate establishment of habitat at higher elevations would also affect a number of reptile, bird, and bat species of concern that depend on freshwater marsh and riparian habitat. Those that depend on freshwater marsh habitat would experience a loss of habitat when the reservoir level is raised, but would ultimately benefit when freshwater marsh becomes established at higher elevations. Such species include western pond turtle, tricolored blackbird, saltmarsh yellowthroat, northern harrier, Vaux’s swift, and double-crested cormorant, all known to occur at the reservoirs. Individuals of these species could be directly affected by a rise in water level during the breeding season, and a temporary loss of suitable habitat could result if wetland vegetation changes occur. Both of these changes would result in potentially significant impacts.

Bird and mammal species of concern that depend on large trees and woodland for nesting, roosting, or foraging would be adversely affected by the loss of upland trees along the shoreline. Such species include Cooper’s hawk, sharp-shinned hawk, loggerhead shrike, several bat species, and San Francisco dusky-footed woodrat. Species of concern that depend on grassland and coastal scrub, including Bell’s sage sparrow and pallid bat, could be affected by the loss of these habitats when reservoir water levels are raised. Due to the extent of habitat and the number of species that would be affected, impacts on species of concern due to the loss of upland habitat would be potentially significant.

Serpentine- and grassland-associated plant species of concern and their habitats could be lost due to increased water levels at Upper and Lower Crystal Springs Reservoirs, depending on species tolerance for extended inundation, saturation of the seed bank, and the length of inundation. Species that could be affected include Franciscan onion, Crystal Springs lessingia, western leatherwood, and arcuate bush mallow. San Francisco collinsia would potentially be affected by loss of forested or coastal scrub habitat. Impacts due to the loss of habitat and populations of these species of concern would be potentially significant.

Overall, the effects of the WSIP on other species of concern would be *potentially significant*.

Common Habitats and Species

The WSIP proposes to maintain Upper and Lower Crystal Springs Reservoirs at maximum levels for longer periods during the summer than under existing conditions, and for longer periods than under the DSOD imposed operational restrictions. Many upland plant species can tolerate inundation for brief periods, especially during their winter dormant period, but lack adaptations for surviving extended flooding during their period of active growth. Longer periods of maximum reservoir levels may result in mortality of valley oaks, coast live oaks, and other upland species at elevations below 283 feet. The loss of common upland habitats and species at the periphery of Upper and Lower Crystal Springs Reservoirs is considered a *potentially significant* impact because of the extent of area involved.

Impact Conclusions

Impacts on sensitive habitats, key special-status species, species of concern, and common habitats and species at Upper and Lower Crystal Springs Reservoirs would be *potentially significant*. For all resources except plant species adapted to serpentine seeps, such as the fountain thistle, implementation of Measure 5.5.6-1a, Adaptive Management of Freshwater Marsh and Wetlands at Upper and Lower Crystal Springs Reservoirs, and Measure 5.5.6-1b, Compensation for Impacts on Terrestrial Biological Resources, would be sufficient to fully mitigate impacts of the WSIP. For the fountain thistle (key special-status species) and other plant species adapted to serpentine seeps, the additional implementation of Measure 5.5.6-1c, Compensation for Serpentine Seep-Related Special-Status Plants, would reduce the impact to a less-than-significant level.

Impact 5.5.6-2: Impacts on biological resources in San Andreas Reservoir.

Sensitive Habitats

With the WSIP, San Andreas Reservoir would be maintained in much the same pattern as it is under existing conditions, and operation of the reservoir would not substantially affect sensitive freshwater marsh habitats. Every fifth year, the reservoir would be drawn down for maintenance during the winter months, when freshwater marsh vegetation is not typically in active growth. As a result, impacts on sensitive habitat at San Andreas Reservoir would be *less than significant*.

Key Special-Status Species

Since the composition and extent of emergent vegetation is not expected to change significantly at San Andreas Reservoir as a result of WSIP operations, impacts on San Francisco garter snake and California red-legged frog would be *less than significant*. Since the maximum reservoir water level would not change, no impact would occur on key terrestrial upland special-status species such as Mission blue butterfly.

Other Species of Concern

Since changes in the extent and composition of freshwater emergent and upland habitat are expected to be minimal, no impact would occur on upland plant species such as western leatherwood, and arcuate bush mallow. Likewise, any impact on western pond turtle, foraging and roosting bats, tricolored blackbird, northern harrier, merlin, peregrine falcon, Vaux’s swift, saltmarsh yellowthroat, and double-crested cormorant would be *less than significant*.

Common Habitats and Species

Impacts on common habitats and species would be *less than significant*, since the extent and composition of upland and wetland habitats are expected to remain stable.

Impact Conclusions

Impact on sensitive habitats, key special-status species, species of concern, and common habitats and species at San Andreas Reservoir would be *less than significant*.

Impact 5.5.6-3: Impacts on biological resources along San Mateo Creek below Lower Crystal Springs Dam.

Sensitive Habitats

Under the WSIP, Crystal Springs Dam and Reservoir would be operated in much the same way as under existing conditions with respect to maximizing storage and minimizing releases to San Mateo Creek. Because the volume, magnitude, and frequency of releases are projected to be much the same as at present, the impact of the WSIP on riparian vegetation in San Mateo Creek would be *less than significant*.

Key Special-Status Species

Section 4.6, Biological Resources, discusses impacts on freshwater-marsh-dwelling species (such as California red-legged frog) due to the alteration of freshwater marsh habitat immediately below the dam. Since releases from Crystal Springs Dam to San Mateo Creek are projected to be much the same as under existing conditions, any impacts on aquatic-dependent key special-status species would be *less than significant*. WSIP operations would not affect key special-status plants such as San Mateo woolly sunflower.

Other Species of Concern

Any impacts on riparian- and creek-associated species of concern (such as western pond turtle) would be so small as to not be quantifiable and would therefore be *less than significant*.

Common Habitats and Species

Operations under the WSIP would not affect common upland habitats. The impacts on common species would be *less than significant*.

Impact Conclusions

Impacts of WSIP operations on sensitive habitats and key special-status species at San Mateo Creek would be *less than significant*.

Impact 5.5.6-4: Impacts on biological resources in Pilarcitos Reservoir.

Sensitive Habitats

The earlier drawdown of the reservoir under the WSIP would not increase the extent of unvegetated, weedy, or seasonal wetland areas below the maximum water levels, although these areas would be exposed several days or weeks earlier than under the existing condition in some years. This impact would be less-than-significant.

Key Special-Status Species

Proposed operations with the WSIP at Pilarcitos Reservoir would have no effect on the extent of suitable habitat at the reservoir for California red-legged frog and San Francisco garter snake. Similarly, the extent and condition of adjacent upland vegetation would not be affected by the proposed reservoir operations. As a result, the WSIP would have no effect on species such as the marbled murrelet that nest or forage in upland habitats adjacent to the reservoir.

Other Species of Concern

Proposed operations at Pilarcitos Reservoir could slightly reduce the extent of suitable habitat for western pond turtle, Vaux’s swift, Yuma myotis, long-eared myotis, and bird species that forage over open water and emergent vegetation, but this impact would be *less than significant*. However, the extent and condition of adjacent upland vegetation would not be affected by the proposed reservoir operations. As a result, this impact would not apply to nesting or foraging upland habitats for species such as Cooper’s hawk, sharp-shinned hawk, Bell’s sage sparrow, Vaux’s swift, merlin, peregrine falcon, loggerhead shrike, special-status bat species, San Francisco dusky-footed woodrat, and western leatherwood.

Common Habitats and Species

No impact on common habitats would occur as a result of WSIP operations. The potential impact on common species that depend on water levels in Pilarcitos Reservoir and flow in Pilarcitos Creek would be *less than significant*.

Impact Conclusions

Impacts of the WSIP on sensitive habitats, key special-status species, other species of concern, and common habitats and species at Pilarcitos Reservoir would be *less than significant.* However, implementation of Measure 5.5.3-2a, Low-head Pumping Station at Pilarcitos Reservoir, would lower the water level in the reservoir by 3 or 4 feet in some summers. This could have a potentially significant impact on the extent of suitable habitat at the reservoir for California red-legged frog and the San Francisco garter snake. Implementation of Measure 5.5.3-2c, Habitat Monitoring and Compensation, would reduce this impact to a less-than-significant level.

Impact 5.5.6-5: Impacts on biological resources along Pilarcitos Creek below Pilarcitos Reservoir.

Sensitive Habitats

Under the WSIP, flow in Pilarcitos Creek between Pilarcitos Reservoir and Stone Dam would increase in some spring months, a beneficial impact. In the summer months of some drier years, the period during which releases from Pilarcitos Reservoir would be limited to reservoir inflow would be extended, potentially for up to three months. Because willows exist in the riparian forest in this section, it is apparent that the riparian forest is adapted to periods without flowing water. The channel-forming processes in Pilarcitos Creek would be reduced insignificantly under the WSIP. Thus, some changes in flow would be beneficial and some adverse. The overall impact on sensitive riparian habitat is considered *less than significant.*

Key Special-Status Species

Flows in Pilarcitos Creek below Pilarcitos Dam would have a minor impact on riparian habitat; therefore, the impact on habitat for foothill yellow-legged frog would be *less than significant*.

Other Species of Concern

Proposed operations at Pilarcitos Reservoir could slightly reduce the extent of suitable habitat for western pond turtle, Vaux's swift, Yuma myotis, long-eared myotis, and bird species that forage over open water and emergent vegetation, but this impact would be less than significant. However, the extent and condition of adjacent upland vegetation would not be affected by the proposed reservoir operations. As a result, this impact would not apply to nesting or foraging upland habitats for species such as Cooper's hawk, sharp-shinned hawk, Bell's sage sparrow, Vaux's swift, merlin, peregrine falcon, loggerhead shrike, special-status bats, San Francisco dusky-footed woodrat, western leatherwood, and Dudley's lousewort.

Flows in Pilarcitos Creek below Pilarcitos Dam and below Stone Dam would have a less-than-significant impact on riparian habitat; therefore, the impact on habitat for foothill yellow-legged frog and any special-status birds and bats that forage over streams would be less than significant.

Overall, WSIP impacts on other species of concern would be *less than significant*.

Common Habitats and Species

No impacts on common habitats would occur as a result of WSIP operations. The potential impact on common species that depend on water levels in Pilarcitos Reservoir and flow in Pilarcitos Creek would be *less than significant*.

Impact Conclusions

Impacts on sensitive riparian habitat at Pilarcitos Creek between Pilarcitos Reservoir and Stone Dam would be *less than significant*.

Impact 5.5.6-6: Impacts on biological resources along Pilarcitos Creek below Stone Dam.

Sensitive Habitats

The central coast arroyo willow riparian forest below Stone Dam, which relies on seepage and on the contribution of tributary creeks, would not be significantly affected by the WSIP. The overall reduction in high winter flows would result in a slight incremental reduction in channel-forming processes, but the overall impact on sensitive riparian resources along Pilarcitos Creek below Stone Dam would be *less than significant*.

Key Special-Status Species

Flows in Pilarcitos Creek below Stone Dam would have a minor impact on riparian habitat; therefore, the impact on habitat for foothill yellow-legged frog would be *less than significant*.

Other Species of Concern

Flows in Pilarcitos Creek below Stone Dam would have a minor impact on riparian habitat; therefore, the impact on habitat for foothill yellow-legged frog and any special-status birds and bats that forage over streams would be *less than significant*.

Common Habitats and Species

No impacts on common habitats would occur as a result of WSIP operations. The potential impact on common species that depend on water levels in Pilarcitos Reservoir and flow in Pilarcitos Creek would be *less than significant*.

Impact Conclusions

Impacts on biological resources along Pilarcitos Creek below Stone Dam would be *less than significant*, and no mitigation measures would be required.

Impact 5.5.6-7: Conflicts with the provisions of adopted conservation plans or other approved biological resources plans.

The only plan relevant to proposed WSIP operations is the *Peninsula Watershed Management Plan*. The WSIP program as a whole would be consistent with the provisions of this plan, which places priority on resource protection while ensuring that the objective of delivering adequate, high-quality water is met. The SFPUC is currently preparing a habitat conservation plan for the Peninsula watershed; however, WSIP operations are not considered in this plan, which covers only existing operations. Therefore, impacts related to conflicts with adopted plans would be *less than significant.*

5.5.7 Recreational and Visual Resources

Chapter 4, Section 4.12, Recreational Resources, provided a general overview of the park and recreational facilities and resources near proposed WSIP facility projects. This section discusses specific recreational resources and activities within the Peninsula watershed that could be affected by the proposed water supply and system operations. The discussion focuses primarily on water-related recreation, including fishing, swimming, boating, rafting, or activities such as scenic viewing, walking, hiking, or camping adjacent to water bodies, that could be affected by the WSIP.

5.5.7.1 Setting

The water features of interest for this analysis are the four SFPUC Peninsula reservoirs (Upper Crystal Springs Reservoir, Lower Crystal Springs Reservoir, San Andreas Reservoir, and Pilarcitos Reservoir) and San Mateo and Pilarcitos Creeks. All four reservoirs and portions of the two creeks are located within the SFPUC Peninsula watershed, as shown on Figure 5.5.1-2. The recreational uses and visual resources in the Peninsula watershed that could be affected by the WSIP water supply or system operations are described below.

As described in Section 4.2, Plans and Policies, and 4.3, Land Use and Visual Quality, the Peninsula watershed area is protected by two easements that were established through a four-party agreement among the CCSF, the U.S. Department of the Interior, the California Department of Transportation, and San Mateo County. The scenic and recreation easement covers 4,000 acres located in the eastern periphery of the watershed, generally along the I-280 corridor and adjacent to the communities to the east. The easement abuts Upper and Lower Crystal Springs Reservoirs and the southern end of San Andreas Reservoir. Recreational activities are permitted in this easement area, but are limited to those considered compatible with water quality protection. Portions of these reservoirs are visible from trails within the easement, but public access to the four reservoirs is prohibited, along with all forms of water sports. The scenic easement, which covers 19,000 acres, does not permit recreational activities. This area encompasses the four reservoirs and a stretch of Pilarcitos Creek (SFPUC, 2002). Only a very short stretch of San Mateo Creek is located within the scenic easement; the rest of the creek is outside of both easements and outside of Peninsula watershed lands.

The *Peninsula Watershed Management Plan* also prohibits recreational activities that are detrimental to watershed resources, including swimming, boating, fishing, and hiking at or near the shoreline (SFPUC, 2002).

Recreational Uses

Public trails in the watershed provide both recreational opportunities and scenic views of the Upper Crystal Springs, Lower Crystal Springs, Pilarcitos, and San Andreas Reservoirs. The trails are generally located between the reservoirs and I-280, along the eastern edge of the watershed, where they are easily accessible from the adjacent communities. They are available to the public for hiking, running, bicycling, rollerblading, and horseback riding (though horseback riding and bicycles are allowed only on certain designated trails).

Sawyer Camp Trail

When the SFPUC fenced off the watershed lands in the vicinity of Crystal Springs Reservoir, it left the six-mile Sawyer Camp Trail open to the public for nonmotorized recreational use. This trail, once the main highway between San Francisco and Half Moon Bay, is visited by approximately 300,000 people each year. The trail parallels Crystal Springs and San Andreas Reservoirs and is currently managed by San Mateo County under the name Crystal Springs Park. San Mateo County envisions the Sawyer Camp Trail as an uninterrupted multi-use route from San Bruno to Woodside (San Mateo County, 2007).

San Andreas Trail

The San Andreas Trail extends from San Bruno Avenue on the north to Hillcrest Boulevard on the south, where it connects to the Sawyer Camp Trail. In its northerly section, this popular trail provides scenic views of San Andreas Reservoir. A portion of the trail is paved and is heavily used by bicyclists, joggers, and hikers (San Mateo County, 2006).

Sweeney Ridge Trail

The Sweeney Ridge Trail, which extends from the end of Sneath Lane in San Bruno to the San Francisco Bay Discovery Site (a National Historic Landmark), provides views of the northern watershed and San Francisco Bay (San Mateo County, 2006).

Fifield-Cahill Ridge Trail

Since 2003, the Fifield-Cahill Ridge Trail has been open to the public on a reservation-only basis, with groups of up to 20 people led by docents three days a week. This trail segment is the SFPUC-managed component of the 400-mile-long Bay Area Ridge Trail (SFPUC 2007b).

Connector Trails

Numerous connector trails cross I-280 and provide linkages to communities to the east such as San Mateo, Belmont, and Redwood City. In addition, portions of the San Andreas Reservoir are visible from Junipero Serra County Park (located to the northeast of SFPUC Peninsula watershed).

Pulgas Water Temple

The Pulgas Water Temple is located south of the Upper Crystal Springs Reservoir, east of Cañada Road. It consists of a Roman Renaissance–style structure and pool, surrounded by manicured lawns, landscaping, and a parking lot. The site is open to the public on weekdays and for special events such as weddings, as well as on weekends (SPFUC, 2007c).

Crystal Springs Golf Course

There is one golf course within the watershed, the Crystal Springs Golf Course, but it does not offer any forms of water recreation to the public.

Pilarcitos Creek

Pilarcitos Creek starts at Pilarcitos Reservoir within the SFPUC Peninsula watershed. No water recreation or access to this reservoir is allowed. The creek runs south until it reaches Highway 92, then runs west to its mouth on the Pacific Ocean within Half Moon Bay State Beach. No organized recreational activities are established within or adjacent to the creek in the upper watershed. However, trails within Half Moon Bay State Beach run adjacent to and across Pilarcitos Creek, and the public is allowed access to portions of this stretch of the creek (Bay Area Hiker, 2007).

San Mateo Creek

San Mateo Creek starts at Lower Crystal Springs Reservoir within the SFPUC Peninsula watershed (see above for a description of activities allowed within the watershed). The creek runs east through the town of Hillsborough and city of San Mateo to San Francisco Bay. The San Mateo Creek Trail, maintained by San Mateo County, runs adjacent to the creek for several miles. The creek is not part of any City-managed recreation facility until it reaches San Mateo's Shoreline Parks on San Francisco Bay. Shoreline Parks, which includes Ryder Park and Seal Point Park, includes amenities such as trails, picnic areas, play areas, and an outdoor classroom. These parks incorporate the natural features of the creek and shoreline to some extent and provide some wilderness-based recreation, but are primarily paved and developed. The creek does not appear to be used for any purpose other than as a scenic resource (City of San Mateo, 2007).

Crystal Springs, Pilarcitos, and San Andreas Reservoirs

These reservoirs are located entirely within the SFPUC Peninsula watershed lands. As mentioned above, public access to the interior portion of these watershed lands is prohibited, and the reservoirs are not available for water-related recreation.

Visual Quality Considerations

Due to its use for water collection and storage, the Peninsula watershed area has been protected from urbanization. A wide variety of habitats exist on the watershed due to its diversity of climate, topography, geology and soils. These include old growth Douglas fir forests, grasslands dominated by native bunchgrasses, areas of coastal scrub and chaparral, stream corridors, and wetlands (SFPUC, 2007a). While many of the SFPUC facilities located within the Peninsula watershed are aboveground structures, they are typically screened with existing vegetation and blend with the watershed's landscape. The reservoirs appear as visually prominent water features in views from nearby trails and surrounding ridges as well as from I-280 and Highway 92.

The provisions of the scenic and scenic and recreation easements include the following:

- Except as required to accomplish the improvements hereinafter permitted or as otherwise permitted to the Grantor hereunder, the general topography of the landscape shall be maintained in its present condition and so substantial excavation or topographic changes shall be made without the concurrence of a regional representative of the Department of the Interior…

- Except as required to accomplish the purposes and uses herein permitted to Grantor, there shall be no cutting or permitting of cutting, destroying or removing any timber or brush without the concurrence in writing by a regional representative of the Department of the Interior…

As discussed in Chapter 4, Section 4.2, Plans and Policies, the *Peninsula Watershed Management Plan* includes the following policy related to visual quality:

- *Policy WA 9*: If new facilities require additional new locations, require that view shed studies be conducted to minimize, eliminate or conceal the violation of scenic values.

However, the proposed WSIP water supply and system operations analyzed in this section would not require any new facilities, other than those already discussed and analyzed in Section 4.3, Land Use and Visual Quality. Therefore, this policy is not addressed further in this section.

5.5.7.2 Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to recreation or visual resources, but generally considers that implementation of the proposed program would have a significant impact on these resources if it were to:

<u>*Recreation*</u>

- Increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated (Secondary impacts of growth are evaluated in Chapter 7, Growth-Inducement Potential and Indirect Effects of Growth)

- Include recreational facilities or require the construction or expansion of recreational facilities that might have an adverse physical effect on the environment (Secondary impacts of growth are evaluated in Chapter 7)

- Physically degrade existing recreational resources

The physical degradation of existing resources could occur if the WSIP were to: (1) remove or damage existing recreational resources directly; (2) cause environmental impacts (such as air quality or noise effects) that would indirectly result in deterioration in the quality of the recreational experience; or (3) disrupt access to existing recreation facilities (which would divide a community from some of the established amenities used by its members).

<u>*Visual Quality*</u>

- Have a substantial adverse effect on a scenic vista
- Substantially damage scenic resources, including but not limited to trees, rock outcroppings, and other features of the built or natural environment that contribute to a scenic public setting
- Substantially degrade the existing visual character or quality of the site and its surroundings

Approach to Analysis

The WSIP would change water levels in reservoirs and alter flow in streams in the Peninsula watershed. WSIP-induced changes in reservoir water levels in the San Mateo Creek watershed were estimated using the HH/LSM (see Appendix H). WSIP-induced changes in reservoir water levels in the Pilarcitos Creek watershed and stream flow in the Pilarcitos Creek and San Mateo Creek watersheds were estimate semi-quantitatively. A specialist in recreation and visual resources assessed the impacts of the WSIP on these environmental elements using the estimated WSIP-induced changes in reservoir water levels and stream flow (see Section 5.5.1).

Impact Summary

Table 5.5.7-1 presents a summary of the impacts on recreational and visual resources in the Peninsula watershed that could result from implementation of the proposed water supply and system operations.

TABLE 5.5.7-1
SUMMARY OF IMPACTS – RECREATIONAL AND VISUAL RESOURCES IN THE PENINSULA WATERSHED

Impact	Significance Determination
Impact 5.5.7-1: Effects on recreational facilities and/or activities	LS
Impact 5.5.7-2: Visual effects on scenic resources or the visual character of water bodies	LS

LS = Less than Significant impact, no mitigation required

Impact Discussion

Impact 5.5.7-1: Effects on recreational facilities and/or activities.

The WSIP would have no impact on water-related recreational facilities or other recreational activities in the Peninsula watershed. As described in the Setting, no water recreation is allowed on the SFPUC reservoirs; because there would be no change to this policy under the WSIP, no impacts on recreation would occur as a result of water level changes in the Peninsula reservoirs. In addition, new trails are prohibited at or near the shoreline, so no land-based recreation would be affected. With respect to recreation in and along the creeks in the watershed, there is either (1) no or only very limited water recreation occurring at present, and/or (2) the WSIP-related flow changes described in Section 5.5.1 would not appreciably change creek flows to an extent that existing recreational use would be affected. The changes in stream flow or reservoir levels would not physically degrade existing recreational resources. Therefore, impacts on recreation associated with the proposed WSIP system operations would be *less than significant*, and no mitigation is required.

Impact 5.5.7-2: Visual effects on scenic resources or the visual character of water bodies.

As described in Section 5.5.1 flow changes and reservoir water level changes that would occur under the WSIP in the future are not beyond the range of flow and water level variation that occurs now. The Lower Crystal Springs Dam Improvements project (PN-4) would restore the historic reservoir capacity and would raise the water level to historic conditions. The reservoir is visible from a number of trails, parks, and scenic roads. However, while the higher reservoir water level could change the visual appearance at close range, it would not change the scenic quality of the reservoir, either at close range or from distant viewpoints. Therefore, visual impacts associated with the proposed WSIP system operations would be *less than significant*, and no mitigation is required.

5.6 Westside Groundwater Basin Resources

5.6 Westside Groundwater Basin Resources

This section describes the potential effects of the WSIP water supply and system operations and associated WSIP projects on the Westside Groundwater Basin and related water resources, including Lake Merced. The proposed water supply sources under the WSIP include 10 million gallons per day (mgd) of supply every year in all years (including nondrought periods) from implementation of conservation, water recycling, and groundwater supply programs in San Francisco; in addition, the proposed water supply option includes a long-term conjunctive-use program in the San Mateo County portion of the Westside Groundwater Basin, referred to as the South Westside Groundwater Basin, as part of the drought-year water supply for the regional system. The recycled water and groundwater components of this supply would be achieved through two WSIP projects, the Local and Regional Groundwater Projects (SF-2) and the Recycled Water Projects (SF-3), which are described in Chapter 3. The potential effects of the WSIP on the Westside Groundwater Basin and related resources are discussed in the context of ongoing activities in this area occurring among the SFPUC, City of Daly City, California Water Service Company (Cal Water, the municipal water purveyor to South San Francisco), and the City of San Bruno.

5.6.1 Setting

5.6.1.1 Westside Groundwater Basin

The Westside Groundwater Basin extends from San Francisco south to San Mateo County (**Figure 5.6-1**). With an area of about 45 square miles, this groundwater basin is the largest in San Francisco. The Westside Groundwater Basin is separated from the Lobos Basin to the north by a northwest-trending bedrock ridge through the northeastern part of Golden Gate Park (DWR, 2006). San Bruno Mountain and San Francisco Bay form the eastern boundary, and the San Andreas fault and Pacific Ocean form the western boundary. The southern limit of the Westside Groundwater Basin is defined by an area of high bedrock that separates it from the San Mateo Plain Groundwater Basin. The basin opens to the Pacific Ocean on the northwest and San Francisco Bay on the southeast. The portion of the Westside Groundwater Basin north of the San Francisco/San Mateo County line is referred to as the North Westside Groundwater Basin. The portion of the Westside Groundwater Basin south of the San Francisco/San Mateo County line is referred to as the South Westside Groundwater Basin.

Geology

The four major geologic units in the Westside Groundwater Basin are the Mesozoic-age Franciscan Complex, Pleistocene-age Merced and Colma Formations, and the Pleistocene to recent Dune Sands, as illustrated in **Figure 5.6-2** (Luhdorff and Scalmanini, 2006). There are also minor but widespread units of recent alluvium along historical stream channels.

Figure 5.6-2
Regional Cross Section
Through Westside Groundwater Basin

Exposed in the low hills east and northeast of Lake Merced, the Franciscan Complex forms the basement rock for the aquifer system.[1] The surface of the bedrock slopes southwestward to Daly City, occurring at depths of almost 600 feet near the center of Lake Merced and nearly 1,000 feet beneath the southern portion of Daly City (SFPUC, 2005).

The Merced Formation comprises three units (lower, middle, and upper) and is the deepest water-bearing formation overlying the basement rock. The upper unit consists of a sequence of thin-bedded beach, dune, estuarine, and fluvial deposits of weakly consolidated fine sandstone with some gravel and mudstone beds. This unit is up to approximately 500 feet thick and is the primary water-producing aquifer in the basin (the primary production aquifer). The middle and lower units of the Merced Formation form the deep aquifer in the basin within the San Francisco and Daly City areas and are composed of fine sandstone, siltstone, and mudstone.

The majority of the surficial geologic units in the North Westside Groundwater Basin are composed of the Colma Formation and Dune Sands, which form the basin's shallow aquifer system. The Colma Formation is a surficial unit consisting of fine-grained sand with some clay, sand, and gravel beds of fluvial, floodplain, alluvial fan, and dune sand origin. Dune Sands are also a surficial unit of fine-grained sands with some clay soil horizons. The separation between these units and the Merced Formation is not clearly defined, thus preventing an accurate measurement of their thickness.

Aquifer System

The portion of the Westside Groundwater Basin beneath San Francisco (the North Westside Groundwater Basin), has an area of approximately 14 square miles; it extends from Golden Gate Park to the San Francisco/San Mateo County line in the vicinity of Lake Merced and from the Pacific Ocean to inland bedrock exposures generally associated with Mount Sutro and Mount Davidson (SFPUC, 2005). This portion of the basin is characterized by relatively shallow depths to groundwater (5 to 60 feet) and, in the vicinity of Lake Merced and the San Francisco Zoo, is comprised of three aquifers[2] (see Figure 5.6-2). The shallow, unconfined aquifer in the Lake Merced area extends from the water table to the top of the "-100 ft clay" -- a clay layer at approximately 100 feet below sea level that separates the shallow aquifer from the underlying primary production aquifer in the Lake Merced area (Luhdroff and Scalmanini, 2006). The elevation of the water table in this area varies between 10 and 20 feet above mean sea level (msl).[3] The primary production aquifer (the main target for municipal and irrigation pumping in the basin) overlies the W-Clay, and the deep aquifer underlies the W-Clay. The -100-foot clay and W-Clay are aquitards[4] and appear to thin and pinch out beneath the Sunset District.

---

1 Basement rock is impermeable bedrock that restricts groundwater flow, forming the vertical boundaries of a groundwater basin, and sometimes the lateral boundary.

2 An aquifer is a geologic unit, typically composed of sand and gravel, that transmits and stores water and yields a substantial quantity of water to a well. In the Westside Groundwater Basin, aquifer materials are typically medium sand to fine sand.

3 Under a program of managed lake levels, future conditions are expected to be closer to the higher value in the range (i.e., 20 feet above msl).

4 An aquitard is a fine-grained unit (such as clay or silt) that restricts the vertical movement of groundwater. Where groundwater occurs beneath an aquitard, the aquifer is considered confined.

Two surface water features, Lake Merced and Pine Lake, are incised in the shallow aquifer. The lakes are in hydraulic continuity with the shallow groundwater, and water levels in the lakes generally reflect the shallow groundwater level. In the vicinity of Lake Merced, the primary production aquifer is confined. It is separated from the shallow aquifer by the -100-foot clay, and lower water levels in the primary production aquifer indicate the potential for flow from the shallow aquifer to the primary production aquifer.

The South Westside Groundwater Basin has an area of approximately 31 square miles (SFPUC, 2005) and is effectively the portion of the Westside Groundwater Basin that underlies Daly City, Colma, South San Francisco, San Bruno, Millbrae, and parts of Burlingame and Hillsborough. The northern portion of the South Westside Groundwater Basin which is beneath Daly City, Colma, South San Francisco, and San Bruno, is characterized by greater depths to groundwater (which can be over 300 feet). The -100-foot clay is absent in the Daly City area, and the aquifer system is composed of the primary production aquifer and deep aquifer (Luhdorff and Scalmanini, 2006). In the South San Francisco area, the W-Clay is absent, and the primary production aquifer is split into shallow and deep units separated by a fine-grained unit at an elevation of approximately 300 feet below mean sea level (msl). The primary production aquifer in the San Bruno area is at an elevation of less than 200 feet below msl and underlies a thick surficial fine-grained unit.

5.6.1.2 Monitoring Network and Program

There has been no regular historical analysis or reporting on groundwater conditions in the Westside Groundwater Basin (Luhdorff and Scalmanini, 2006). Over the last several years, however, the SFPUC, the City of Daly City, Cal Water, and the City of San Bruno have substantially increased data collection efforts and cooperative management of groundwater and interrelated surface water resources in the basin. Initial cooperative efforts among these four entities have included increased monitoring of groundwater and lake level elevations in the North Westside Groundwater Basin and the initiation of a semiannual basinwide monitoring program in the spring of 2000.

The San Mateo County Environmental Health Division managed the semiannual monitoring program until 2004, at which time the program was merged into the ongoing cooperative basinwide monitoring program. The basinwide monitoring program initially focused on the Lake Merced area, but has been expanded to include more of the basin as well as monitoring of coastal monitoring wells. The basinwide monitoring program currently includes semiannual to annual monitoring of the monitoring well network shown in Figure 5.6-1, which consists of 28 dedicated monitoring wells. Data from the monitoring program are used to evaluate coastal conditions and the potential for seawater intrusion, to define lake-aquifer interaction, and to assess general conditions in the basin resulting from ongoing pumping, the In-Lieu Recharge Demonstration Study (described in Section 5.6.1.9), and the recycled water program. Water-level measurements are collected manually on a quarterly or semiannual basis in some wells, or daily (or more frequently) through the use of electronic pressure transducers in other wells. The first comprehensive hydrogeologic report for the basin describes conditions in 2005 (Luhdorff and

Scalmanini, 2006), and further reports are intended to be prepared on an annual or biennial basis and serve as regular and complete reporting on all aspects of ongoing groundwater management activities in the Westside Groundwater Basin.

5.6.1.3 Groundwater Uses

While there has been some groundwater development in the North Westside Groundwater Basin (primarily for nonpotable irrigation), the South Westside Groundwater Basin has historically been the primary groundwater production area and continues to be used for a number of purposes. Major groundwater production areas in the Westside Groundwater Basin are shown in Figure 5.6-1 and discussed below.

North Westside Groundwater Basin

By the early 1900s, wells were drilled north, east, and south of Lake Merced for farming and drinking water supply (Luhdorff and Scalmanini, 2006). During that time, the Spring Valley Water Company had two wells located near the Lake Merced outlet that pumped about 0.1 mgd, or 100 acre-feet per year (afy).[5] At that time, the total of Lake Merced, Sunset District, and Golden Gate Park pumpage averaged 0.4 mgd (400 to 500 afy). In the early 1930s, the San Francisco Board of Public Works installed production wells in the Sunset District as an emergency water supply. Between 1930 and 1935, these wells pumped an average of 5 mgd (5,600 afy) from the Sunset District as an emergency water supply, but were discontinued after Hetch Hetchy water became available in the mid-1930s.

In 2005, groundwater in the North Westside Groundwater Basin was used for irrigation and other nonpotable uses, primarily 1.0 mgd (1,100 afy) at Golden Gate Park[6] and 0.4 mgd (400 afy) at the San Francisco Zoo. In addition, less than 0.02 mgd (13 afy) is used for other purposes, including 8 afy at the Edgewood School, and 5 afy in Stern Grove (Luhdorff and Scalmanini, 2006). As of 2005, there are no other substantial users of the North Westside Groundwater Basin.

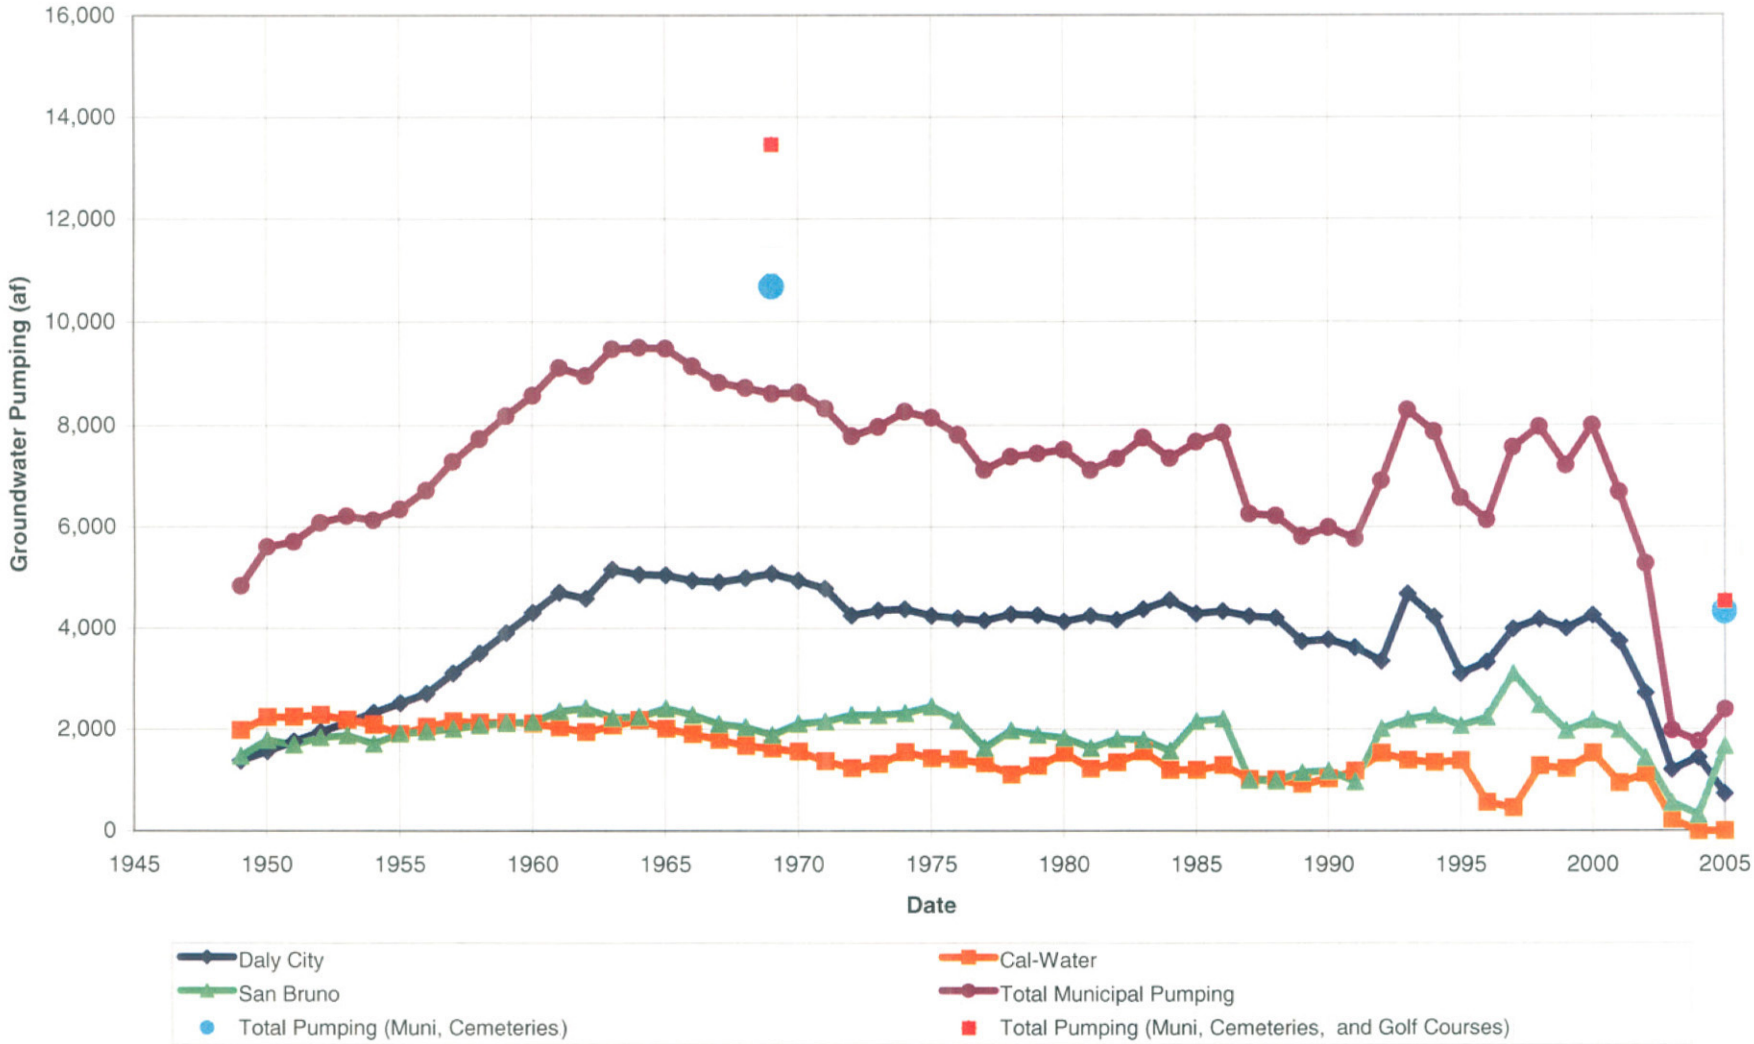
South Westside Groundwater Basin

Groundwater in the South Westside Groundwater Basin has been principally used for municipal and irrigation supply. Groundwater has been a source of water supply to Daly City, South San Francisco (through Cal Water), and San Bruno for about 50 years. Production well locations for each of these municipalities and other groundwater production areas are shown in Figure 5.6-1. Total pumping for metered municipal and estimated irrigation uses reached a combined maximum of approximately 12.8 mgd (14,300 afy) in the 1960s (Luhdorff and Scalmanini, 2006). As indicated in **Figure 5.6-3** and discussed below, total pumping from the South Westside Groundwater Basin (including municipal and irrigation uses) was about 4.1 mgd (4,600 afy) in

---

[5] One acre-foot is the volume of water required to cover one acre of land to a depth of 1 foot, or 325,851 gallons. The unit "acre-feet per year" is the number of acre-feet of water used in one year.

[6] Historical pumping rates for the Golden Gate Park wells are estimated. Recent installation of flow meters on two of the wells will allow more accurate measurement of the pumping rates of these wells in the future.



SOURCE: Luhdorff & Scalmanini, 2006

SFPUC Water System Improvement Program . 203287

Figure 5.6-3
Historical Pumping in the South Westside Groundwater Basin

2005. The major reasons for lower pumping in 2005 were that nearly all irrigation pumping around Lake Merced was replaced with recycled water and there was a temporary reduction in municipal pumping as part of the In-Lieu Recharge Demonstration Study (described in Section 5.6.1.9). In addition, there are some private wells within the basin, but the estimated amount of pumping by private well owners is small compared to municipal and irrigation pumping.

Municipal Pumping

Historical municipal groundwater pumping by Daly City, Cal Water, and San Bruno, shown in Figure 5.6-3, reached a high of approximately 8 mgd (9,000 afy) in the mid-1960s and ranged between approximately 5.4 mgd (6,000 afy) and 7.1 mgd (8,000 afy) from the mid-1970s until 2001 (Luhdorff and Scalmanini, 2006). During implementation of the In-Lieu Recharge Demonstration Study from 2002 to 2005 (described in Section 5.6.1.9), total municipal pumping was decreased to an average of approximately 1.8 mgd (2,000 afy), as shown in **Figure 5.6-4**. Although the In-Lieu Recharge Demonstration Study has ended, Daly City continued to receive system water from the SFPUC in lieu of groundwater pumping under the conditions of a term sheet implemented in 2004 (SFPUC, 2004). In 2005, Daly City pumped approximately 0.6 mgd (700 afy) of groundwater. As of 2006, Cal Water had not resumed pumping and San Bruno had resumed pumping at rates of approximately 1.5 mgd (1,700 afy).

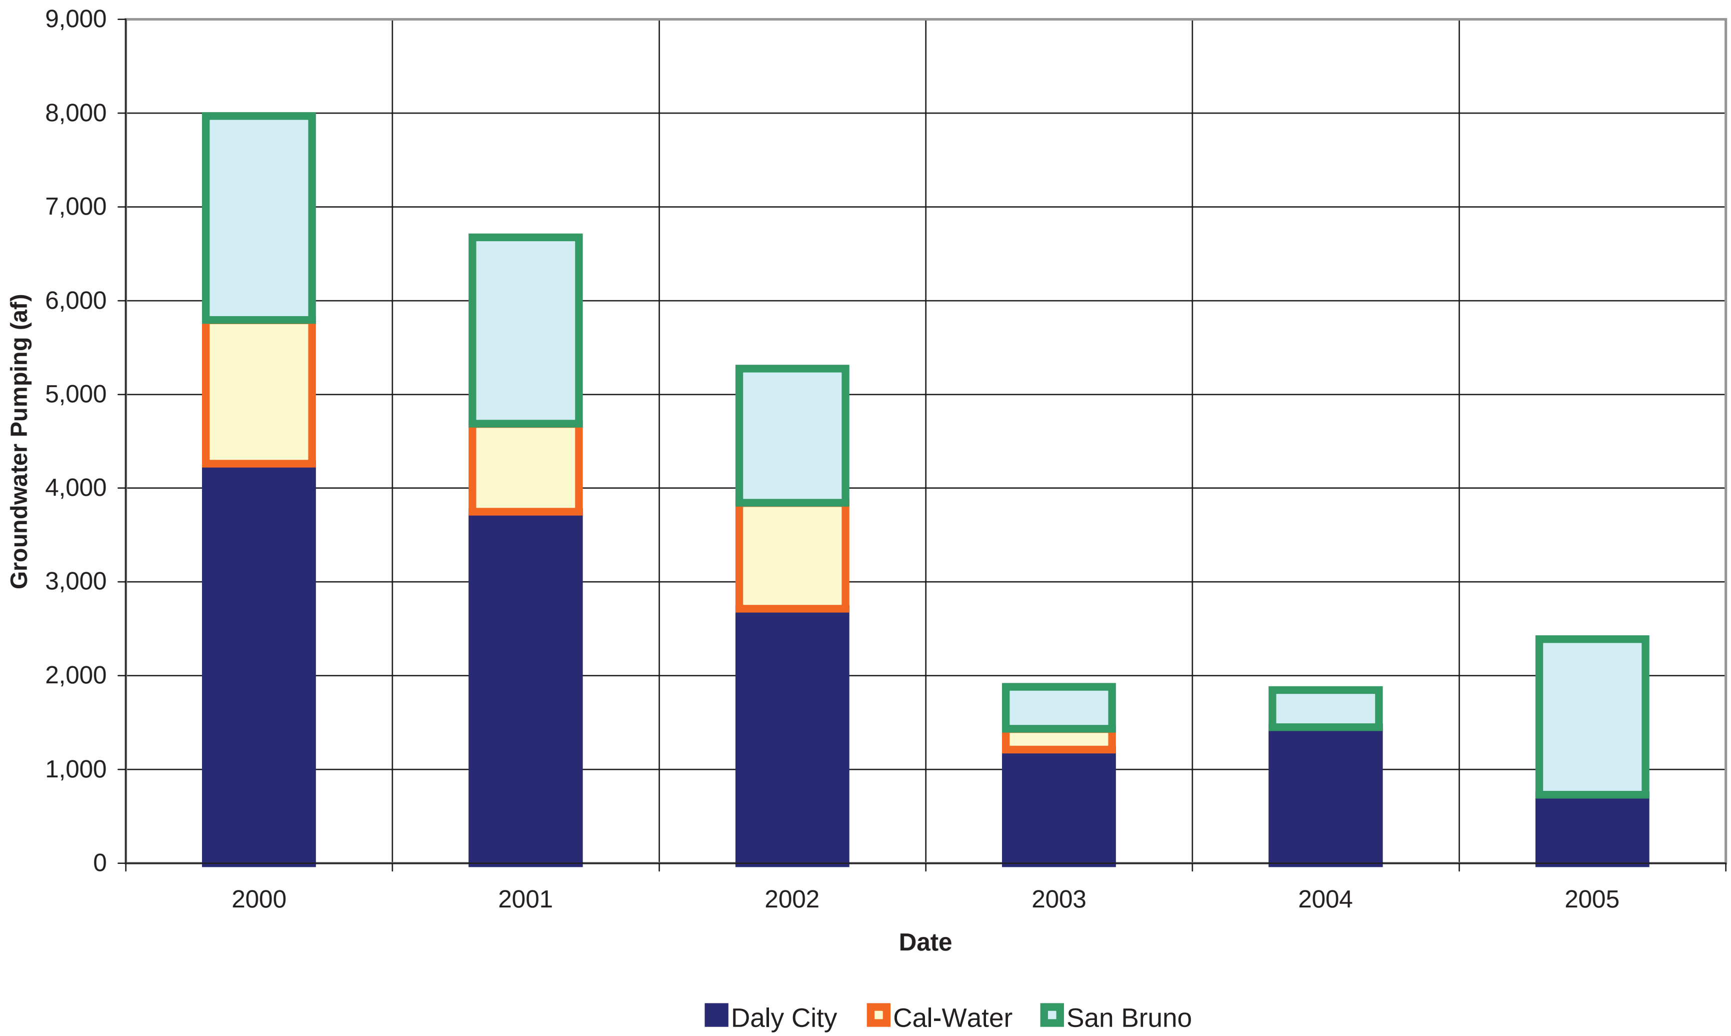
Irrigation Pumping

Historical golf course and cemetery irrigation in the 1960s was previously estimated at about 4.7 mgd (5,300 afy) of groundwater,[7] and irrigation for three golf courses in the vicinity of Lake Merced (the Olympic Club, San Francisco Golf Club, and Lake Merced Golf Club) accounted for approximately 2.1 mgd (2,235 afy) of this amount (Luhdorff and Scalmanini, 2006). In 2005, irrigation pumping at these three golf courses was reduced to approximately 0.04 mgd (45 afy) when recycled water was made available from north San Mateo County (Daly City) as a substitute irrigation supply.

Other continued uses of irrigation pumping in the South Westside Groundwater Basin in 2005 were consistent with historical pumping rates and are estimated at up to 2.1 mgd (2,400 afy) of irrigation pumping for cemeteries in Colma, and 0.1 mgd (120 to 150 afy) of irrigation pumping for the California Golf Club[8] in South San Francisco (Luhdorff and Scalmanini, 2006). The Golden Gate National Cemetery in San Bruno has historically used groundwater for irrigation, but the cemetery has not been irrigated using groundwater for over 20 years (Schem, 2007).

7 Historical irrigation pumping amounts were estimated. Recent metered use of recycled water at the Lake Merced area golf courses indicates that actual usage may have been less than previously estimated. Therefore, estimates of historical unmetered irrigation pumping may be high.

8 2005 estimated pumping rates for the California Golf Club were reduced from the historical estimate of 665 afy to 120–150 afy based on information on actual water use rates at the Lake Merced area golf courses obtained when metered recycled water was provided to these golf courses.



SOURCE: Luhdorff & Scalmanini

SFPUC Water System Improvement Program . 203287

Figure 5.6-4
Recent Municipal Pumping in
Westside Groundwater Basin

In all, irrigation pumping in the South Westside Groundwater Basin has recently been estimated at approximately 2.3 mgd (2,600 afy) in 2005 —a reduction of 2.4 mgd (2,700 afy) from a high of approximately 4.7 mgd (5,300 afy) in the 1960s. The principal reduction in irrigation pumping has been as a result of replacement of recycled water for irrigation purposes at the Lake Merced area golf courses.

Pumping from Private Wells

There are over 90 backyard wells in Hillsborough residential areas; most were installed during the 1987–1992 drought and serve multiple adjoining lots. In 2003, total pumping from these wells was estimated at 0.27 mgd (300 afy) (Yates, 2003). There are not likely a large number of private wells in the San Bruno to Daly City portion of the South Westside Groundwater Basin, which typically has small lot sizes with limited irrigation areas. Also, San Mateo County requires well setbacks from sewer lines, which make small lots more difficult to permit for water wells.

5.6.1.4 Groundwater Levels and Flow Directions

North Westside Groundwater Basin

Prior to the early 1940s, water levels in the North Westside Groundwater Basin and in the northern portions of San Mateo County were above sea level, with a northwesterly gradient in the shallow and primary production aquifers (SFPUC, 2005). Based on regular monitoring of water levels in the North Westside Groundwater Basin since 2004 (see Section 5.6.1.2), groundwater levels remain above sea level in both aquifers, with the exception of primary production aquifer groundwater levels in the vicinity of the San Francisco Zoo. At the zoo, groundwater levels range from slightly above to slightly below sea level, probably due to pumping at the zoo (Luhdorff and Scalmanini, 2006).

Groundwater levels generally increased through 2005, most notably in the primary production aquifer in the vicinity of the zoo. The increase is possibly due to decreased pumping from this aquifer including reduced golf course irrigation pumping in the vicinity of Lake Merced and reduced municipal pumping in the South Westside Groundwater Basin under the In-Lieu Recharge Demonstration Study (discussed in Section 5.6.1.9). In 2005, the groundwater flow direction in both the shallow and primary production aquifers of the North Westside Groundwater Basin was westerly (see **Figures 5.6-5** and **5.6-6**); groundwater elevations ranged from 9 to 35 feet above msl in the shallow aquifer and from 5 to an estimated 100 feet above msl in the primary production aquifer.

Coastal monitoring wells at Fort Funston and Thornton Beach indicate groundwater elevations above sea level in both the primary production and deep aquifer (the shallow aquifer is not present in this area). The aquifers at these locations appear to be hydraulically separated from the main portion of the Westside Groundwater Basin by faults and resultant steeply dipping geologic units, which act as hydraulic barriers to flow.

SFPUC Water System Improvement Program . 203287

Figure 5.6-6
Contours of Equal Groundwater Elevations
Primary Production Aquifer, Spring 2005

South Westside Groundwater Basin

Beginning in the 1950s and 1960s, groundwater levels in the South Westside Groundwater Basin declined to below sea level. This decline continued through the 1970s, after which groundwater levels stabilized at elevations of more than 100 feet below msl, resulting in vacated aquifer storage of up to 75,000 acre-feet in the Daly City, South San Francisco, and northern San Bruno areas (Kirker, Chapman & Associates, 1972; Luhdorff and Scalmanini, 2005).

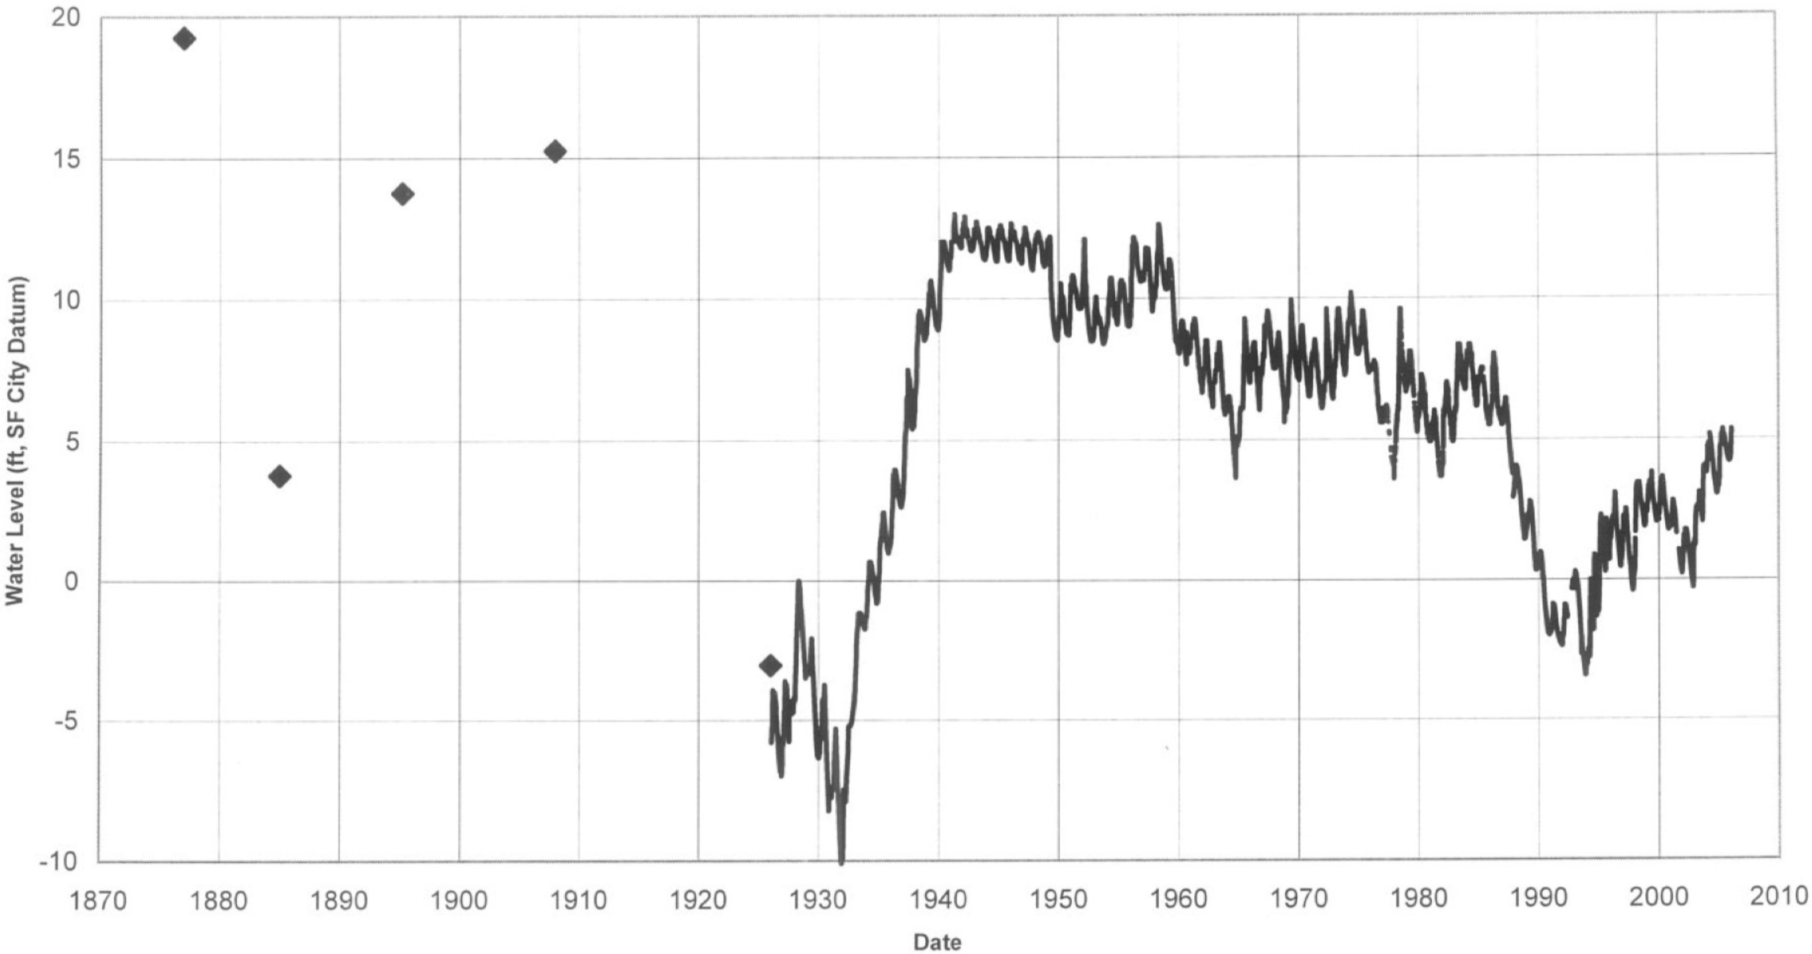
In 2005, groundwater elevations in the primary production aquifer in the South Westside Groundwater Basin ranged from approximately 8 feet below msl immediately south of Lake Merced to 102 feet below msl in Daly City and 75 feet below msl in South San Francisco (see Figure 5.6-6); groundwater flow in the vicinity of Lake Merced continued to be southerly and the steepest groundwater gradient was between Lake Merced and Daly City (Luhdorff and Scalmanini, 2006). On the bay side, groundwater levels in the primary production aquifer beneath San Bruno were approximately 180 feet below msl in 2005.

5.6.1.5 Lake Merced

The San Francisco Recreation and Park Department manages the recreational areas of the lake under a 1950 agreement with the SFPUC (SFPUC, 2007). The SFPUC manages the water aspects of the lake and has the ability to pump untreated water from South Lake into the SFPUC distribution system in an emergency. At one time, Lake Merced served as a municipal water supply source, with a water treatment plant on the north end of the Lake. The Lake has also served as an emergency water supply. However, Lake Merced has not been used as a potable water supply since the 1930s. Refer to Table 4.5-1 for a description of the existing beneficial uses of Lake Merced.

Lake Merced is now comprised of four lake bodies (North Lake, East Lake, South Lake, and Impound Lake), but until the early 1900s was one continuous body of water fed by local runoff and springs (Luhdorff and Scalmanini, 2006). The lake had an outlet to the Pacific Ocean through a stream at the northwestern end of North Lake. The primary sources of recharge to the lake bodies have historically been from spring discharge from the shallow aquifer, local runoff, and precipitation.

Lake Merced water levels have fluctuated greatly over the years and were substantially lowered by diversions in the 1920s and early 1930s during drought conditions (see **Figure 5.6-7**). Lake levels increased between the 1930s and 1960, but began declining again in 1960 and were experiencing an accelerated decline by the late 1980s. San Francisco and other stakeholders in the Westside Groundwater Basin have conducted investigations into the declining lake levels and concluded that the reduction in water levels since the 1960s is likely due to a number of factors, including groundwater pumping in the primary production aquifer and increased urbanization, which has reduced historical recharge to the lake from natural springs and diverted stormwater runoff from the lake to the combined sewer system (SFPUC, 2005).



SOURCE: Luhdorff & Scalmanini, 2006

SFPUC Water System Improvement Program . 203287

Figure 5.6-7
Long-Term Lake Level Hydrograph
Lake Merced (South Lake)

This reduction in subsurface recharge and runoff to the lake has resulted in a long-term decline in water levels and, in the short term, lake levels that are more sensitive to fluctuations in precipitation. In addition, lowered water levels in the shallow aquifer have caused a shift in the shallow groundwater flow direction (from northwesterly to southwesterly) and a corresponding reversal of current flow direction through the lake, away from the historical northwesterly lake outlet.

Public agencies and community members have generally agreed that higher water levels are desirable for Lake Merced. Between 2002 and the spring of 2004, water levels were restored to about 4 feet City Datum,[9] primarily through three additions of dechlorinated SFPUC system water (Luhdorff and Scalmanini, 2004). By December 2005, the lake elevation had further increased to about 5.5 feet City Datum, or nearly 17 feet above msl, due to above-average rainfall and the addition of a total of 34 acre-feet of treated stormwater delivered via the Vista Grande Canal as part of a Daly City pilot program to explore other potential sources for restoring lake levels. (Luhdorff and Scalmanini, 2006). Implementation of the In-Lieu Recharge Demonstration Study (described in Section 5.6.1.9) and local replacement of groundwater pumping with recycled water for irrigation at three Lake Merced area golf courses in the South Westside Groundwater Basin (described in Section 5.6.1.3) also indirectly contributed to the increase in Lake Merced water levels. The 2005 water level was the highest water level in almost 20 years. During the water additions, it was confirmed that Lake Merced is well connected to the shallow aquifer, but that large amounts of shallow groundwater did not percolate to the primary production aquifer (Luhdorff and Scalmanini, 2004).

The In-Lieu Recharge Demonstration Study and local replacement of groundwater pumping with recycled water for irrigation at three Lake Merced area golf courses in the South Westside Groundwater Basin have also resulted in an increase in groundwater levels in the primary production aquifer in the vicinity of Lake Merced. In 2005, groundwater levels in the shallow aquifer were in the range of 12 to 18 feet above msl; in the underlying primary production aquifer, groundwater elevations were deeper - in the range of 18 feet below to 8 feet above msl (Luhdorff and Scalmanini, 2006). Deeper groundwater levels in the primary production aquifer indicate a potential for flow from the shallow aquifer/lake system toward the underlying aquifer, from which nearby production wells withdraw water.

In July 2004, the SFPUC prepared the *Lake Level Management Plan*, which proposed to maintain the lake elevation between 3 and 5 feet City Datum through 2007 while a long-term plan is being developed to maintain the lake at an elevation (or range) to be determined. Since 2003, the SFPUC has maintained the lake levels between 3 and 5 feet City Datum through the activities described above. The SFPUC has not finalized all the details of the long-term plan, but has proposed 8.5 feet City Datum as the recommended lake elevation to be maintained by seasonal additions of supplemental water as required, allowing for seasonal lake level variations. Additional studies are underway under the Local Groundwater Projects (SF-2) to complete the evaluation of supplemental water sources to maintain the lake at the desired level.

9 San Francisco City Datum is a reference datum that has been used by San Francisco for surveying purposes since the early 1900s. To convert to the North American Vertical Datum of 1988 (approximately mean sea level), add 11.37 feet to City Datum.

5.6.1.6 Pine Lake

Pine Lake, one of San Francisco's few natural lakes, is located north/northeast of Lake Merced in the westernmost portion of Stern Grove and Pine Lake Park (Luhdorff and Scalmanini, 2006). It is a small, shallow lake approximately three acres in size. The lake has historically been overgrown with aquatic plants, which have been periodically removed. The San Francisco Recreation and Park Department is implementing a park improvement program for the Stern Grove and Pine Lake area. In November and December 2004, the San Francisco Department of Public Works augmented lake levels using groundwater pumped from a nearby well as part of a study to evaluate the rate of lake level decline following the addition of water. The study concluded that the lake level could be maintained at 31.5 feet by augmenting the lake with approximately 0.08 mgd of water from the existing well to make up for the loss of lake water, and that regular water additions might not be required in the rainy season (Bennett Consulting Group, 2005). During the test, the shallow groundwater elevation rose nearly 7 feet and stabilized at 31.6 feet msl, at which point it did not fluctuate in response to changes in lake levels. The Department of Public Works plans to begin full-scale replenishment of Pine Lake with groundwater from the primary production aquifer in May 2007 (Mosqueda, 2007).

5.6.1.7 Seawater Intrusion

Seawater or saltwater intrusion refers to the migration of higher density saltwater into a freshwater aquifer, which can occur when groundwater levels are lowered by pumping or other means. Seawater intrusion becomes an environmental problem when saltwater reaches a pumped well, making it unsuitable for its intended purpose, or when inland surface water features are affected by the saltwater, compromising habitats or beneficial uses of the surface water.

Coastal monitoring to the west of Lake Merced and north to Golden Gate Park indicates groundwater elevations above sea level and chloride concentrations of less than 40 milligrams per liter (mg/L), except near the zoo, where chloride concentrations are as high as 71 mg/L; based on these results, seawater intrusion is not occurring along the western boundary of the Westside Groundwater Basin (Luhdorff and Scalmanini, 2006). Even though the shallow aquifer in the North Westside Groundwater Basin is in direct connection with the ocean near the coastline, limited development of this portion of the groundwater basin and a groundwater gradient towards the ocean have prevented seawater intrusion in this area, with the exception of temporary effects on the shallow aquifer that occurred during dewatering for construction of the Oceanside Water Pollution Control Plant in the mid-1990s.[10]

Along the coastline to the south of Lake Merced, including Fort Funston and Thornton Beach, it appears that faulting and steeply dipping beds of the Merced Formation provide a physical barrier between the South Westside Groundwater Basin aquifer system and the Pacific Ocean; this barrier has prevented seawater intrusion, despite the fact that groundwater levels in Daly City

---

10 Dewatering for construction of the Oceanside Water Pollution Control Plant resulted in a temporary reversal of groundwater gradients, allowing seawater to intrude into the shallow aquifer. However, once dewatering stopped, the induced landward gradient that allowed seawater to migrate into the shallow aquifer reversed, and the natural outflow of freshwater to the ocean resumed.

were lowered to over 120 feet below msl prior to implementation of the In-Lieu Recharge Demonstration Study (described in Section 5.6.1.9).

Seawater intrusion has not been documented along the bay side of the South Westside Groundwater Basin, although groundwater levels were over 200 feet below msl in the primary production aquifer prior to implementation of the In-Lieu Recharge Demonstration Study. It is understood that seawater intrusion in this area is impeded by a thick sequence of bay mud deposits that extend from San Francisco Bay into San Bruno and by a subsurface bedrock ridge below San Francisco International Airport that provides a further barrier to seawater intrusion. The City of San Bruno constructed two monitoring well clusters in 2006 along the bay side that have provided additional geologic information and allow for monitoring of groundwater levels and groundwater quality at different depths along the bay margin.

5.6.1.8 Groundwater Quality

With the exception of manganese and nitrate, groundwater quality in the Westside Groundwater Basin generally meets primary and secondary drinking water standards (Luhdorff and Scalmanini, 2006). In the North Westside Groundwater Basin, nitrate concentrations in the primary production aquifer have exceeded the primary maximum contaminant level of 45 mg/L in the Edgewood School production well and Elk Glen 2 well. In the South Westside Groundwater Basin, nitrate has exceeded this drinking water standard in the South San Francisco and Daly City areas.

In the North Westside Groundwater Basin, manganese concentrations have exceeded the secondary maximum contaminant level of 0.05 mg/L in the Edgewood School production well, the test well at the South Sunset Playground, in monitoring wells near the Central and Lake Merced Pump Stations, and in Golden Gate Park. In the South Westside Groundwater Basin, manganese has exceeded the secondary drinking water standard in San Bruno and Daly City in the untreated groundwater, but the water is treated to meet secondary standards prior to use in the water supply.

5.6.1.9 In-Lieu Recharge Demonstration Study

In the fall of 2002, Cal Water and the Cities of San Bruno and Daly City implemented the In-Lieu Recharge Demonstration Study in conjunction with the SFPUC to evaluate the potential increase in groundwater storage that could be achieved if groundwater pumping were replaced with system water from the SFPUC. As part of this project, each municipality reduced or stopped groundwater pumping. By the spring of 2005, groundwater levels in the primary production aquifer had risen but were still below sea level (Luhdorff and Scalmanini, 2005). The increased groundwater levels resulted in a flatter hydraulic gradient between Lake Merced and Daly City, and the total increase in groundwater storage was approximately 13,000 acre-feet through March 2005 (6,300 acre-feet in the Daly City area, 3,600 acre-feet in the South San Francisco area, and 3,000 acre-feet in the San Bruno area). These results indicate that in-lieu recharge can be employed to add water to storage in the northern part of the South Westside Basin, thus making use of the available aquifer storage for development of a large-scale conjunctive-use program.

5.6.1.10 Groundwater Management

Final Draft North Westside Groundwater Basin Management Plan

In April 2005, the SFPUC prepared the *Final Draft North Westside Groundwater Basin Management Plan* (Groundwater Management Plan) (SFPUC, 2005) which addresses monitoring and stewardship of the groundwater basin and describes potential groundwater supply projects in the North Westside Groundwater Basin. At this time, the SFPUC does not propose to formally adopt the plan but is instead using the plan to help develop specific projects for implementation. The SFPUC is further developing the potential groundwater projects under the WSIP (local portion of Groundwater Projects, SF-2) through the preparation of a conceptual engineering report. The Groundwater Management Plan sets forth the following four management objectives, or goals, to address stewardship of the North Westside Groundwater Basin:

Goal 1: Development of Local Groundwater for San Francisco Water Supply
Goal 2: Avoidance of Overdraft and Saltwater Intrusion
Goal 3: Protection of Interrelated Surface Water Resources
Goal 4: Preservation of Groundwater Quality

The following 13 interrelated elements specified in the plan address these goals:

Element 1: Monitoring of Groundwater Levels, Quality, Production, and Subsidence. Expansion of the existing monitoring of groundwater levels, quality, and production to provide basic data on which to assess the condition of the groundwater basin and to assess the impacts of groundwater production on groundwater levels, groundwater quality, subsidence, and on surface waters.

Element 2: Monitoring and Management of Surface Water Resources. Continued and possibly expanded monitoring of surface water levels and quality, most notably at Lake Merced, to further the understanding of their interaction with groundwater.

Element 3: Determination of Basin Yield and Avoidance of Overdraft. Determination of the yield of the basin on both a regular (average annual) and an intermittent (dry year or emergency) basis in order to accomplish one of the primary objectives for the basin: that it be operated within its safe yield and thus not be overdrafted, and that it be effectively sustained as an ongoing reliable water supply without depletion of groundwater storage or degradation of quality.

Element 4: Development of Groundwater to Augment SFPUC Municipal Water Supplies. Exploration and development of groundwater for regular and dry period/emergency water supply, including possible development of water supply well sites in Golden Gate Park, in the Sunset District, near Stern Grove (Pine Lake), and in the vicinity of Lake Merced.

Element 5: Initiation of Conjunctive-Use Operations. Future pursuit of conjunctive-use program in the basin as a component or extension of the conjunctive use activities that have been initiated on a demonstration basis since late 2002 in the southern part of the basin, in Daly City, South San Francisco, and San Bruno, subject to agreement with these entities. A conjunctive use program would ideally take advantage of any vacated storage space by purposely recharging it with surplus surface water when it is available in wet years, and thus allowing the stored water to be recaptured by pumping during dry periods when surface supplies are decreased.

Element 6: Integration of Recycled Water. Incorporation of recycled water as a component of the nonpotable water supply in the basin, initially for recently initiated golf course irrigation and subsequently for other nonpotable uses, in order to reduce groundwater pumping for nonpotable uses and thus provide increased groundwater availability for regular as well as dry-period/emergency water supply.

Element 7: Development and Continuation of Local, State, and Federal Agency Relationships. Development and continuation of relationships with local, state, and federal agencies, primarily to continue cooperative efforts in the overall basin toward integrated data collection, initiation of conjunctive use, and development of supplemental water for augmentation of Lake Merced.

Element 8: Continuation of Public Education and Water Conservation Program. Continuation of public education and water conservation programs, primarily to inform interested groups on technical and related details about surface and groundwater details, to solicit public input to lake management and conjunctive-use planning, and to obtain community support for basin management actions.

Element 9: Identification and Management of Recharge Areas and Wellhead Protection Areas. Identification and management of recharge and wellhead protection areas.

Element 10: Identification of Well Construction, Abandonment, and Destruction Policies. Continued implementation of well construction, abandonment, and destruction policies, pursuant to the San Francisco Well Ordinance.

Element 11: Identification and Mitigation of Soil and Groundwater Contamination. Identification and mitigation of soil and groundwater contamination.

Element 12: Groundwater Management Reports. Preparation of regular and ad-hoc reports to complement a number of technical reports that have been prepared over the last decade on groundwater in the Westside Basin and its interrelationship with Lake Merced.

Element 13: Provisions to Update the Management Plan. Provisions to update the groundwater management plan, a recognition that the currently drafted plan reflects the most updated understanding of the occurrence of groundwater in the basin, but that the plan's elements could result in knowledge that suggests a change in currently planned management actions. This plan is intended to be a flexible document which can be updated to modify its existing elements and/or incorporate new elements as appropriate in order to recognize and respond to future groundwater and surface water conditions.

Maintenance of Lake Merced water levels and development of the North Westside Groundwater Basin as a municipal water supply under the Local Groundwater Projects (SF-2) would fulfill Elements 2 and 4 of the Groundwater Management Plan. Implementation of a long-term conjunctive-use program in the South Westside Groundwater Basin under the Regional Groundwater Projects (SF-2) would fulfill Element 5. Furthermore, implementation of the Recycled Water Projects (SF-3) would fulfill Element 6, increase groundwater availability in the North Westside Groundwater Basin, and alleviate demands on surface water supplies for irrigation purposes. The Groundwater Management Plan also contains elements specifying that the Groundwater and Recycled Water Projects would be implemented in a manner that preserves the quantity and quality of groundwater in the Westside Groundwater Basin, as well as requiring regular communication of results to the public, environmental groups, and local, state, and federal agencies, and obtaining input from these entities.

5.6.1.11 Regulatory Framework

Groundwater Quality

The Porter-Cologne Water Quality Control Act (Division 7 of the California Water Code) provides the basis for water quality regulation in California. The act allows the state to adopt water quality control plans, which serve as the legal, technical, and programmatic basis of water quality regulation for a region. The *Water Quality Control Plan for the San Francisco Bay Basin*, known as the Basin Plan, was adopted in 1995 (with subsequent amendments) and is administered by the Regional Water Quality Control Board (RWQCB), San Francisco Bay Region (RWQCB, 1995).

The Basin Plan identifies the Westside Groundwater Basin as a “significant groundwater basin.”[11] Agricultural water supply is identified as an existing beneficial use of the aquifer; municipal and domestic water supply, industrial process water supply, and industrial service water supply are identified as potential beneficial uses. However, groundwater has served municipal and industrial purposes in the Westside Groundwater Basin for decades. The beneficial uses serve as a basis for establishing water quality objectives and discharge prohibitions. The RWQCB is charged with protecting these uses from pollution and nuisance.

The Basin Plan also addresses groundwater protection and management. The groundwater program goals include: (1) identify and update beneficial uses and water quality objectives for each groundwater basin; (2) regulate activities that affect or have the potential to affect the beneficial uses of groundwater in the region; and (3) prevent future impacts on the groundwater resource through local and regional planning, management, and education.

California has adopted the “Statement of Policy with Respect to Maintaining High Quality of Waters in California,” known as the Antidegradation Policy, which prohibits actions that tend to degrade the quality of groundwater. The San Francisco Bay RWQCB performs oversight of this policy. The policy requires the continued maintenance of existing high-quality water and outlines the conditions under which a change in water quality is allowable. The conditions for an allowable change in water quality include the following:

- A change must be consistent with maximum benefit to the people of the state.
- A change must not unreasonably affect present and anticipated beneficial uses of water.
- A change must not result in water quality less than that prescribed in water quality control plans or policies.

[11] The San Francisco Bay RWQCB adopted groundwater basin plan amendments at its April 19, 2000 board meeting. These amendments are still subject to approval by the State Water Resources Control Board and the State Office of Administrative Law. Designation as a significant groundwater basin is based on the adopted groundwater basin plan amendments.

Wellhead Protection

In 1999, the California Department of Health Services established the Drinking Water Source Assessment and Protection (DWSAP) program to protect sources of drinking water, in accordance with Section 11672.60 of the California Health and Safety Code. The DWSAP program includes both a source water assessment program and a wellhead protection program as required by the federal Safe Drinking Water Act.

The DWSAP program includes two components: a mandated drinking water source assessment and a voluntary source water protection program. The drinking water source assessment is the first step and includes a delineation of the area around a drinking water source through which contaminants might move and reach that drinking water supply; an inventory of possible contaminating activities that might lead to a release of microbial or chemical contaminants within the delineated area; and a determination of possible contaminating activities to which the drinking water source is most vulnerable. Source water protection is not a mandated element of the DWSAP program, but is required for a complete wellhead protection program. To address this, the second step in the DWSAP program is the voluntary development and implementation of a source water protection program, which affords a public water system or community the opportunity to build on work performed for the drinking water source assessment.

Well Permitting Requirements

The agencies responsible for permitting well construction within the Westside Groundwater Basin are the San Francisco Department of Public Health (North Westside Groundwater Basin) and the City of Daly City and San Mateo County Environmental Health Division (South Westside Groundwater Basin). San Francisco and San Mateo County well permitting regulations contain conditions to ensure that basin overdraft would not occur as a result of construction of a new well. Chapter 13.20 of the Daly City Municipal Code specifies well permitting requirements for Daly City. Although this code does not include provisions related to overdraft of the Westside Groundwater Basin, Section 13.20.070 allows for denial of a permit when the request is judged not to be in the public interest.

In accordance with Article 12B of the San Francisco Health Code, the Department of Public Health refers permit applications for water wells to the San Francisco Planning Department for an environmental determination under CEQA. Following CEQA review, the applicant must obtain approval from the SFPUC authorizing the withdrawal of groundwater. For the purposes of managing groundwater resources in San Francisco, the operator of the well must comply with any conditions or restrictions on use of the water well imposed by the SFPUC or as mitigation measures by the Planning Department. Failure to reach an agreement with the SFPUC for the operation of a proposed water well would result in denial of the water well permit application by the Department of Public Health, and failure to comply with the conditions or restrictions on use of the water well would result in revocation of the permit.

In accordance with Section 4.68.225 of the San Mateo County Code, the San Mateo County Environmental Health Division would not grant a well permit for a large well[12]

[12] A large well means any individual well that pumps an amount equal to or greater than 50 gallons per minute or 1,000 gallons per day, or multiple small wells on the same land use parcel which cumulatively pump an amount equal to or greater than 50 gallons per minute or 1,000 gallons per day.

that could potentially cause overdraft of the South Westside Groundwater Basin or be located in an area subject to a specific and localized groundwater problem. The Environmental Health Division could also deny, revoke, or suspend a permit for a large well to avoid pollution or contamination of water resources.

5.6.2 Impacts

5.6.2.1 Significance Criteria

The City and County of San Francisco has not formally adopted significance standards for impacts related to groundwater, but generally considers that implementation of the proposed program would have a significant impact on groundwater if it were to:

- Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of preexisting nearby wells would drop to a level that would not support existing land uses or planned uses for which permits have been granted)
- Potentially result in onsite or offsite land subsidence that would cause substantial structural damage, increased flooding, or altered drainage patterns
- Violate any water quality standards or waste discharge requirements
- Otherwise substantially degrade water quality

Criteria for evaluating the depletion of groundwater resources are based on whether groundwater pumping would reduce groundwater levels to a degree such that adverse effects would occur, including saltwater intrusion, effects on surface water resources, or land subsidence. Criteria for evaluating groundwater quality are based on beneficial uses and water quality objectives established by the RWQCB in the Basin Plan, as authorized under the Porter-Cologne Water Quality Control Act and Clean Water Act. In addition, for groundwater to be used as a public water supply, groundwater quality evaluation criteria are based on the California Drinking Water Standards, as established by the state and federal Safe Drinking Water Acts.

5.6.2.2 Approach to Analysis

This section assesses program-level impacts of the proposed water supply option with respect to the recycled water and groundwater projects in San Francisco and the Westside Basin conjunctive use program on the groundwater resources of the Westside Groundwater Basin and associated surface water resources. The analysis is based on the WSIP proposed actions as implemented through Local and Regional Groundwater Projects (SF-2) and Recycled Water Projects (SF-3) based on project description information presented in Chapter 3 and Appendix C. It also identifies groundwater management activities planned as part of the projects or proposed as mitigation measures to ensure that impacts on groundwater and associated surface water resources are less than significant. Potential impacts and their significance determinations are summarized in

Table 5.6-1. More detailed analysis of the Groundwater and Recycled Water Projects will be conducted during subsequent, project-level environmental review. Chapter 4, Section 4.5 evaluates the program-level impacts related to construction and operation (not including long term operational effects on groundwater resources) of the Groundwater and Recycled Water Projects.

Impact Summary

Table 5.6-1 presents a summary of the impacts on Westside Groundwater Basin groundwater and surface water resources that could result from implementation of the proposed water supply and system operations.

TABLE 5.6-1
SUMMARY OF IMPACTS – WESTSIDE GROUNDWATER BASIN

	Significance Determination	
Impact	**North Westside Groundwater Basin**	**South Westside Groundwater Basin**
Impact 5.6-1: Basin overdraft due to pumping from the Westside Groundwater Basin	PSM	LS
Impact 5.6-2: Changes in water levels in Lake Merced and other surface water features, including Pine Lake, due to decreased groundwater levels in the Westside Groundwater Basin	PSM	N/A
Impact 5.6-3: Seawater intrusion due to decreased groundwater levels in the Westside Groundwater Basin	PSM	LS
Impact 5.6-4: Land subsidence due to decreased groundwater levels in the Westside Groundwater Basin if the historical low water levels are exceeded	LS	LS
Impact 5.6-5: Contamination of drinking water due to groundwater pumping in the Westside Groundwater Basin	PSM	PSM
Impact 5.6-6: Drinking water contaminants above maximum contaminant levels and adverse effects of adding treated groundwater to the distribution system	LS	LS

LS = Less than Significant impact, no mitigation required
PSM = Potentially Significant impact, can be mitigated to less than significant
N/A = Not Applicable

Impact Discussion

Impact 5.6-1: Basin overdraft due to pumping from the Westside Groundwater Basin.

Excessive groundwater pumping that results in a prolonged and continual lowering of groundwater levels is referred to as basin overdraft. Overdraft in the Westside Groundwater Basin could cause a number of deleterious effects, including decreased water levels in surface waters (such as Lake Merced), seawater intrusion, and/or land subsidence. Management of groundwater resources entails implementing an operating strategy that limits and/or spatially distributes groundwater pumping so that overdraft conditions and related adverse effects do not occur in the groundwater basin.

North Westside Groundwater Basin

The proposed water supply option would include installation of up to four primary production and deep aquifer production wells in San Francisco to provide a total of 2 mgd of annualized production rate, as implemented through Local Groundwater Projects (part of SF-2). Candidate well sites include the Lake Merced Pump Station, South Sunset Playground, West Sunset Playground, and Golden Gate Park. Alternate locations under consideration are the Central Pump Station and the Francis Scott Key Annex. In addition, other sites may be identified during project design and would be evaluated during project-level environmental review. Existing irrigation wells at the San Francisco Zoo, Golden Gate Park, and/or other locations would provide an additional production rate of 2 mgd of water supply for the regional system once recycled water is available to provide replacement irrigation water at these sites (to be developed under the Recycled Water Projects, SF-3). The San Francisco Zoo well was modified and commissioned for emergency use in 2006, and an existing well at Golden Gate Park could also be modified to provide emergency supply to local residents in the event of a major earthquake or other disaster. Once these projects are implemented, up to 0.5 mgd (560 afy) of pumping for nonpotable uses would continue in the North Westside Groundwater Basin for uses such as irrigation of sensitive plants in Golden Gate Park and water for some animal exhibits at the San Francisco Zoo.[13]

With full implementation of the WSIP, production of up to 4 mgd (4,500 afy) under the Local Groundwater Projects (SF-2) and continued nonpotable pumping of 0.5 mgd (560 afy) would be the major groundwater use in the North Westside Groundwater Basin once irrigation pumping is replaced with recycled water at the San Francisco Zoo and Golden Gate Park; thus, the maximum total annual pumping by 2030 is estimated to be 5,060 afy. Based on water years 1987 and 1988, the annual recharge to this basin was estimated at 4,850 afy (Phillips et al., 1993). However, this analysis was done during the first two-years of an on-going drought and therefore is considered to be a low estimate of groundwater recharge to the North Westside Groundwater Basin relative to average conditions. Estimates of recharge to the basin are being refined as part of ongoing groundwater modeling efforts on behalf of the SFPUC, and this analysis indicates that recharge to the basin could range from about 4,850 afy to 6,950 afy (Luhdroff and Scalmanini, 2007).

The total proposed pumping rate of 4.5 mgd (5,060 afy) would be within the range of recharge to the groundwater basin. However, because it exceeds the lower end of the range, and the studies indicating the range have not been completed at this program-level of analysis, potential impacts related to depletion of groundwater resources in the North Westside Groundwater Basin would be considered *potentially significant*. Under this program-level determination, implementation of Measure 5.6-1, Groundwater Monitoring to Determine Basin Safe Yield, would reduce this impact to a less-than-significant level. This measure requires determination of the basin's yield on both a regular (average annual) and an intermittent (dry-year or emergency) basis, in accordance with Element 3 of the Groundwater Management Plan, as well as implementation of water level

[13] Pumping rates for nonpotable purposes may actually be less than estimated if recycled water is found to be of suitable quality for these uses.

and quality monitoring, as specified in Element 1 of the Groundwater Management Plan. The measure is designed to have the SFPUC monitor the effects of pumping from the North Westside Groundwater Basin, and to use the monitoring data to inform decisions regarding appropriate pumping patterns to avoid overdraft and the undesirable effects associated with overdraft. The SFPUC would undertake a more detailed analysis of the basin yield and may refine the mitigation as part of the project-level CEQA review on the Local Groundwater Projects (SF-2).

Emergency groundwater pumping rates could temporarily exceed the average sustainable yield of the aquifer. During emergencies, the potential for adverse pumping effects would depend on the magnitude and duration of the emergency event, but any effects on groundwater that did occur would be localized and short term. They would not be of a long-term nature that would result in overdraft. In addition, wells installed under the Local Groundwater Projects (SF-2) would be located and operated to avoid interference[14] with the operation of existing wells at Golden Gate Park, the San Francisco Zoo, Edgewood School, and Stern Grove (Pine Lake), the current users of groundwater in the North Westside Groundwater Basin. Ultimately, however, most of water supplied by the Golden Gate Park and San Francisco Zoo wells would be replaced with recycled water produced under the Recycled Water Projects (SF-3).

South Westside Groundwater Basin

As discussed in the Setting, municipal and irrigation pumping has historically reduced groundwater levels in the South Westside Groundwater Basin to elevations of 100 to 200 feet below msl, resulting in an estimated 75,000 acre-feet of vacated aquifer storage in the Daly City, South San Francisco, and northern San Bruno areas. Under the WSIP's proposed water supply option (i.e., Regional Groundwater Projects, SF-2), the SFPUC would implement a long-term conjunctive-use program in coordination with Daly City, Cal Water, and San Bruno (referred to as the participating pumpers) to take advantage of this vacated aquifer storage and to increase groundwater levels in the South Westside Groundwater Basin.

Under this program, the SFPUC would provide potable water from the regional system to the participating pumpers during nondrought conditions when there are sufficient surface water supplies to substitute for groundwater currently used for municipal purposes. As a result, the participating pumpers would reduce their groundwater pumping by a comparable amount and allow the groundwater basin to recharge naturally. Therefore, during nondrought years, there would be a larger quantity of groundwater in the South Westside Groundwater Basin due to the in-lieu recharge resulting from deliveries of SFPUC system water and correspondingly reduced groundwater pumping. This increased quantity of groundwater basin during nondrought years is referred to as "banked" water. During drought conditions, the SFPUC would be able to reduce the quantity of SFPUC system water delivered to the participating pumpers, and the stored groundwater, or banked water, would be available for local use to supplement supplies from the regional water system.

As part of the proposed program, the SFPUC and the participating pumpers would enter into an operating agreement(s) specifying the terms and conditions of groundwater storage and

[14] Well interference is the lowering of groundwater levels in one well due to pumping-induced drawdown in another well, thus reducing the capacity of the well or lowering water levels below the intake interval.

withdrawals (see Chapter 3, Section 3.14, Required Actions and Approvals) to ensure that adverse conditions do not occur under the Regional Groundwater projects (SF-2). Under the proposed agreement(s) the SFPUC would have a right to store up to 61,000 acre-feet of groundwater in the South Westside Groundwater Basin. The SFPUC would construct about 10 new groundwater production wells in San Mateo County with the capacity to develop about 7 mgd (or nearly 8,100 afy) of potable groundwater as a supplemental drought-year supply for the participating pumpers. [15] During drought conditions, the participating pumpers would be able to pump the amount of surface water delivered by the SFPUC during nondrought years, the banked quantity of groundwater. Because groundwater withdrawals would be restricted to the amount of water banked under the Regional Groundwater projects, groundwater levels as a result of implementation of the proposed conjunctive-use program would be expected to be consistently in a range higher than those that have resulted from long-term historical groundwater pumping.

The proposed operating agreement(s) would also specify that an operating committee be established to develop annual operating maintenance plans and an annual operating schedule projecting groundwater storage and/or extraction from the SFPUC's storage account. The operating committee would be composed of representatives from the SFPUC and the participating pumpers and would also provide an accounting of water stored in and extracted from the SFPUC storage account and confirm compliance with water delivery accounting.

The conjunctive-use program would consider the potential effects of all other pumpers in the South Westside Groundwater Basin, particularly the participating pumpers as well as irrigation pumping by cemeteries and golf courses. Monitoring and modeling would also be conducted to assess the conjunctive-use program's performance and to identify and avoid potential problems. Based on monitoring data and modeling results, conjunctive-use management strategies would be adjusted and implemented as necessary to avoid adverse conditions.

Overall, the conjunctive-use program under the Regional Groundwater Projects (SF-2) would be designed to take advantage of vacated aquifer storage that has become available as a result of historical groundwater pumping in the South Westside Groundwater Basin. An operating agreement(s) would be executed with the participating pumpers outlining allowable operating parameters for pumping during drought periods to avoid long-term adverse conditions; an operating committee would be formed to develop annual operating maintenance plans as well as an annual operating schedule; and groundwater monitoring and modeling would be conducted to identify the potential for adverse conditions and inform decisions to modify the recharge or pumping strategy in response to changing conditions over time. Therefore, programmatic impacts related to basin overdraft and associated adverse conditions are considered *less than significant* for the South Westside Groundwater Basin. The SFPUC would conduct a more detailed analysis

[15] As described in Chapter 3, Section 3.6, the proposed water supply option under the WSIP assumes the use of the extraction component of the conjunctive-use program during drought years. The program is being designed to provide an extraction capacity of approximately 8,100 acre-feet of water during a drought year (an equivalent of about 7 mgd). The initiation of the extraction component of the conjunctive use program occurs as the first response to an anticipated drought. However, the realization of a drought does not typically occur until the second year of a dry sequence, thus in the 8.5-year Design Drought groundwater pumping would only occur for 7.5 years. Although pumping over this 7.5 year period would be about 7 mgd, the equivalent amount of pumping over 8.5 years is 6 mgd.

of the conjunctive-use program as part of the project-level CEQA review on the Regional Groundwater Projects (SF-2).

Impact 5.6-2: Changes in water levels in Lake Merced and other surface water features, including Pine Lake, due to decreased groundwater levels in the Westside Groundwater Basin.

North Westside Groundwater Basin

As discussed in the Setting, water levels in Lake Merced have declined over the past 50 years, and Pine Lake has also experienced water level declines. Investigation by the SFPUC into the interrelationship between these lakes and groundwater has been a major focus over the past 5 to 10 years, and has included installation of dedicated monitoring facilities in the individual Lake Merced lakes as well as numerous monitoring wells around and near Lake Merced and Pine Lake. Analysis of the lake-aquifer system at Lake Merced to date indicates that the lake system can be separately managed by adding water to achieve a desired lake level, or range of levels, while also pumping from the underlying primary production aquifer (SFPUC, 2005).

The Local Groundwater Projects under SF-2 would include the addition of some combination of treated stormwater, recycled water, groundwater, and/or dechlorinated SFPUC system water to restore and maintain Lake Merced at the desired level(s). Maintenance of water levels would be expected to beneficially affect the North Westside Groundwater Basin by contributing additional recharge to the shallow aquifer. Furthermore, implementation of the long-term conjunctive-use project (the Regional Groundwater Projects under SF-2) and cessation of irrigation pumping in the vicinity of Lake Merced (already accomplished, as described in the Setting) would allow groundwater levels in the primary production aquifer to the south of Lake Merced to rise, which would reduce the long-term effects of historical groundwater pumping on groundwater levels in the shallow aquifer.

Because the primary production aquifer is not in direct hydraulic connection with the shallow aquifer in the Lake Merced vicinity or with Lake Merced, proposed pumping from the primary production aquifer under Local Groundwater Projects (SF-2) is not expected to have a direct effect on lake levels, but could potentially cause an indirect effect. Shallow groundwater levels could decline due to flow from the shallow aquifer under Lake Merced toward the primary production aquifer in which future production wells would be completed under the proposed program. Therefore, the potential to adversely affect water levels in Lake Merced and other surface water features would be *potentially significant*, but would be reduced to a less-than-significant level with implementation of Measure 5.6-1, Groundwater Monitoring to Determine Basin Safe Yield, and Measure 5.6-2, Implementation of a Lake Level Management Plan. Measure 5.6-1 includes groundwater and surface water monitoring as specified in Elements 1 and 2 of the Groundwater Management Plan to monitor the effects of groundwater pumping on surface water features. The monitoring data would be used to inform decisions regarding the alteration of pumping patterns to avoid undesirable effects on surface water features. Measure

5.6-2 includes development and implementation of a lake level management plan identifying strategies for altering pumping patterns or lake augmentation to maintain Lake Merced water levels within the desired long-term range, should monitoring conducted under Measure 5.6-1 indicate the potential for adverse effects on lake levels due to groundwater pumping. The SFPUC would coordinate the implementation of both measures. The SFPUC would undertake a more detailed analysis of the lake-aquifer relationship and may refine the mitigation as part of the project-level CEQA review on the Local Groundwater Projects.

South Westside Groundwater Basin

There are no major surface features in the South Westside Groundwater Basin that would be affected by decreased groundwater levels. Therefore, impacts on the water levels of water surface features in the South Westside Groundwater Basin would *not apply*.

Impact 5.6-3: Seawater intrusion due to decreased groundwater levels in the Westside Groundwater Basin.

Seawater intrusion (the movement of saline water into a freshwater aquifer) can occur in coastal aquifers such as the Westside Groundwater Basin, where shallow aquifers are hydraulically connected with the ocean or bay. Intrusion of saltwater into a freshwater aquifer degrades water quality for most beneficial uses and, depending on the degree of salinity, can render the aquifer unusable. Once freshwater aquifers are affected by saltwater intrusion, it is difficult and costly to reclaim the aquifer.

North Westside Groundwater Basin

In the North Westside Groundwater Basin, the shallow aquifer is in direct connection with the ocean from approximately Lake Merced to the north, as discussed in the Setting. Dewatering of this aquifer during construction of the Oceanside Water Pollution Control Plant caused temporary seawater intrusion in the shallow aquifer; however, once the dewatering stopped, the induced landward gradient that resulted in seawater migration into the shallow aquifer reversed, and the natural outflow of freshwater to the ocean resumed.

Because the shallow aquifer is in direct connection with the ocean and groundwater pumping would lower groundwater levels, impacts related to the potential to cause seawater intrusion in the North Westside Groundwater Basin would be *potentially significant*, but would be reduced to a less-than-significant level through implementation of Measure 5.6-1, Groundwater Monitoring to Determine Basin Safe Yield. This measure requires groundwater level and quality monitoring in accordance with Element 1 of the Groundwater Management Plan, including monitoring of the coastal monitoring well network in the western part of the basin along the Old Great Highway (at Kirkham, Ortega, and Taraval Streets; the Oceanside Water Pollution Control Plant; and the San Francisco Zoo). This monitoring would provide an early indication of whether seawater intrusion is occurring and would be used to inform decisions regarding the alteration of groundwater pumping strategies to avoid seawater intrusion.

Although emergency groundwater pumping could temporarily lower groundwater levels in the primary production aquifer, the potential for seawater intrusion to occur would depend on the magnitude and duration of the emergency event, and any effects on groundwater would be short term. In the event that groundwater gradients were temporarily induced landward, they would be restored toward the ocean once pumping returned to normal levels, and the temporary reversal of gradient would not be likely to cause long-term seawater intrusion. The SFPUC will undertake a more detailed analysis of the potential for seawater intrusion and may refine the mitigation as part of the project-level CEQA review on the Local Groundwater Projects (SF-2).

South Westside Groundwater Basin

Although groundwater levels in the South Westside Groundwater Basin have been lowered to depths of up to 200 feet below msl in some areas over the past 50 years, seawater intrusion into the aquifer system has not been detected. As discussed in the Setting, this is attributed to faulting and folding of the Merced Formation along the western border with the Pacific Ocean and the presence of bedrock and bay mud along the eastern border with the bay. In-lieu recharge of groundwater resulting from deliveries of SFPUC system water under the long-term conjunctive-use program (the Regional Groundwater Projects under SF-2), and correspondingly reduced groundwater pumping when SFPUC system water is available, would result in higher groundwater levels in the South Westside Groundwater Basin during nondrought periods, which would further reduce the potential for seawater intrusion.

As discussed in Impact 5.6-1, an operating agreement(s) would be executed with each participating pumper involved in the long-term conjunctive-use program (the Regional Groundwater Projects under SF-2); under the proposed agreement(s), participating pumpers would be able to extract groundwater up to the amount of water stored via in-lieu recharge as a result of surface water previously delivered by the SFPUC during nondrought years. Because the participating pumpers would not pump more than the banked quantity of groundwater, groundwater levels would be expected to be consistently in a range higher than those that have resulted from long-term historical groundwater pumping. For this reason, and because historical pumping has not caused seawater intrusion into the primary production aquifer, seawater intrusion under the long-term conjunctive-use program is not expected. Therefore, programmatic impacts related to seawater intrusion in the South Westside Groundwater Basin are considered *less than significant*. The SFPUC would conduct a more detailed analysis of the conjunctive-use program as part of the project-level CEQA review on the Regional Groundwater Projects.

Impact 5.6-4: Land subsidence due to decreased groundwater levels in the Westside Groundwater Basin if the historical low water levels are exceeded.

The groundwater within aquifers and aquitards helps support the weight of the overlying sediments, because the water contained in the pore spaces of sediments creates an internal water pressure. Land subsidence (i.e., the lowering of ground surface elevations caused by the compaction of sediments) can occur if groundwater pumping reduces the water pressure within the pore spaces of the saturated sediments, causing them to compress. The type and degree of subsidence depends on the presence of fine-grained sediments and the extent that water pressure is reduced by groundwater pumping.

Under some conditions, this process would reverse when the groundwater is replenished and the pore pressure increases; this type of subsidence is known as elastic or temporary subsidence. Under conditions of elastic subsidence, the compaction is relatively small and is reversed when pore pressures increase with rising water levels. In general, subsidence in coarse-grained materials of aquifers is elastic.

Under certain conditions, however, groundwater pumping can result in a permanent change in the structure of the sediments, known as inelastic subsidence, and cause an unrecoverable compaction of the aquifer system. Inelastic subsidence occurs when the water pressure in fine-grained sediments (such as clay beds) separating groundwater aquifers is reduced beyond historical lows, resulting in a permanent change in the intergranular structure of the sediments that cannot be reversed when water levels recover. The compressibility of sediments under inelastic conditions is much greater than under elastic conditions, and the subsidence associated with inelastic conditions may require decades to millennia to complete.

In the event of permanent, inelastic subsidence, the ground surface elevation would gradually decrease over a widespread area overlying the affected groundwater basin. Depending on where inelastic subsidence occurred, potential effects could include increased flooding, greater backflushing of surface waters from the bay or ocean, saltwater intrusion in shallow aquifers, submergence of existing marshlands, or changes in gradients within canals and other gravity-flow features. Damage to infrastructure and public and private structures would not be expected, because subsidence effects would occur on a gradual, widespread basis. Subsidence has not been noted in the Westside Groundwater Basin despite heavy pumping in the South Westside Groundwater Basin in the past.

North Westside Groundwater Basin

It is unlikely that inelastic subsidence would occur in the North Westside Groundwater Basin because the formations comprising the aquifers of the North Westside Groundwater Basin are primarily composed of sands and dewatering of the fine-grained aquitards separating the aquifers would not be expected. Therefore, impacts related to the potential for land subsidence are considered *less than significant.* The SFPUC will undertake a more detailed analysis of the potential for subsidence as part of the project-level CEQA review on the Local Groundwater Projects (SF-2).

South Westside Groundwater Basin

Land subsidence is not expected to occur with implementation of the Regional Groundwater Projects (SF-2) in the South Westside Groundwater Basin. During nondrought years, municipal groundwater pumping would be reduced by increased delivery of SFPUC system water, thereby increasing groundwater storage in the primary production aquifer as described in Impact 5.6-1. During drought years, groundwater withdrawals under the Regional Groundwater Projects would be limited to the banked quantity of water stored through in-lieu recharge. Therefore, because groundwater levels associated with the Regional Groundwater Projects would likely be higher than historical lows, the potential for land subsidence would be low, and impacts related to land subsidence in the South Westside Groundwater Basin would be *less than significant.* The SFPUC would conduct a more detailed analysis of the conjunctive-use program as part of the project-level CEQA review on the Regional Groundwater Projects (SF-2).

Impact 5.6-5: Contamination of drinking water due to groundwater pumping in the Westside Groundwater Basin.

During operation, groundwater production wells constructed under the Local and Regional Groundwater Projects (SF-2) could induce migration of chemical or microbiological contamination from sources surrounding the wells, potentially resulting in an exceedance of drinking water standards in the groundwater. However, under the California Department of Health Services DWSAP program, described in the Setting, the SFPUC would develop a drinking water source assessment. At a minimum, the assessment would include a delineation of the area around the well(s) through which contaminants might move and reach the well(s), referred to as the groundwater protection zone; an inventory of possible contaminating activities that could lead to a release of microbiological or chemical contaminants within the delineated area; and a determination of the potentially contaminating activities to which the well(s) are most vulnerable. Groundwater protection zones would be established on the basis of average well discharge volumes and groundwater flow directions. In accordance with the DWSAP program, the drinking water source assessment would be updated every five years.

The second step in the DWSAP program is the voluntary development and implementation of a source water protection program. Development of this program is not mandated under the DWSAP program, but protection of water quality is an important component of a complete wellhead protection program for the protection of drinking water quality. Until production well locations are selected and a drinking water source assessment performed, the potential for contamination of a drinking water well cannot be fully evaluated. Therefore, impacts related to potential contamination of a drinking water source are considered *potentially significant* for the Local and Regional Groundwater Projects (SF-2); however, impacts would be reduced to a less-than-significant level with implementation of Measure 5.6-5, Drinking Water Source Assessments for Groundwater Wells, which would require development and implementation of a source water protection program for wells that are considered vulnerable to contamination. Implementation of the source water protection program would serve to prevent contamination of the drinking water supply. The SFPUC would undertake a more detailed analysis of the potential for contamination of a drinking water source and may refine the mitigation as part of the project-level CEQA review on the Local and Regional Groundwater Projects (SF-2).

Impact 5.6-6: Drinking water contaminants above maximum contaminant levels and adverse effects of adding treated groundwater to the distribution system.

As discussed in the Setting, nitrate and manganese levels exceed primary and secondary drinking water standards in some areas of the Westside Groundwater Basin. However, as described in Chapter 3, the groundwater developed for potable uses under the WSIP would be treated or blended with system water to meet all primary and secondary drinking water standards. Therefore, programmatic impacts related to exceedances in drinking water standards would be *less than significant*. The SFPUC would undertake a more detailed analysis of the need for treatment and proposed treatment methods as part of the project-level CEQA review on the Local and Regional Groundwater Projects (SF-2).

Although treated groundwater from the Local and Regional Groundwater Project (SF-2) wells would meet all primary and secondary drinking water standards, including those for nitrate and manganese, the water quality would differ from that currently in the SFPUC regional water system. The blending of groundwater in the system could result in changes in water quality, such as changes in taste and odor; however, the potential for these effects would depend on the quality of the groundwater produced, treatment methods, and proposed blending operations. In any event, the SFPUC would continue to meet all drinking water standards in the use of groundwater to supplement its current supply during both nondrought and drought periods. Therefore, impacts related to the blending of treated groundwater with SFPUC system water are expected to be *less than significant.* The SFPUC would undertake a more detailed analysis of the potential water quality effects related to the blending of treated groundwater with SFPUC system water as part of the project-level CEQA review on the Local and Regional Groundwater Projects.

5.7 Cumulative Projects and Impacts Related to WSIP Water Supply and System Operations

5.7 Cumulative Projects and Impacts Related to WSIP Water Supply and System Operations

5.7.1 Introduction and Approach

5.7.1.1 CEQA Statutory Guidance

Cumulative impacts, as defined in Section 15355 of the CEQA Guidelines, refer to two or more individual effects which, when considered together, are "considerable" or which compound or increase other environmental impacts. The cumulative impact from multiple projects is the total change in the environment that could result from the incremental impact of the proposed project in combination with impacts of other closely related past, present, or reasonably foreseeable (i.e., probable) future projects. Pertinent guidance for cumulative impact analysis is given in Sections 15065(a) and 15130 of the CEQA Guidelines:

- An EIR [environmental impact report] shall discuss cumulative impacts of a project when the project's incremental effect is "cumulatively considerable" (i.e., the incremental effects of an individual project are significant when viewed in connection with the effects of past, current, and probable future projects, including those outside the control of the agency, if necessary).
- An EIR should not discuss impacts that do not result in part from the project evaluated in the EIR.
- A project's contribution is less than cumulatively considerable, and thus not significant, if the project is required to implement or fund its fair share of a mitigation measure or measures designed to alleviate the cumulative impact.
- The discussion of impact severity and likelihood of occurrence need not be as detailed as for effects attributable to the project alone.
- The focus of analysis should be on the cumulative impact to which the identified other projects contribute, rather than attributes of other projects that do not contribute to the cumulative impact.

In accordance with CEQA Guidelines Section 15130(a), if a project has an incremental effect that is not cumulatively considerable, then that effect need not be considered significant; however, the EIR must describe the basis for determining that the incremental effect is not cumulatively considerable. The discussion of cumulative impacts must reflect the severity of the impacts and the likelihood of their occurrence, but need not provide as much detail as is provided for the effects of the project alone. The CEQA Guidelines require that the discussion of cumulative impacts include:

- Either: (1) a list of past, present, and probable future projects producing related or cumulative impacts; or (2) a summary of projections contained in an adopted general plan or similar document, or in an adopted or certified environmental document, that described or evaluated conditions contributing to a cumulative impact.
- A discussion of the geographic scope of the area affected by the cumulative impact.
- A summary of expected environmental effects to be produced by these projects.

- Reasonable, feasible options for mitigating or avoiding the project's contribution to any significant cumulative effects.

5.7.1.2 Approach

This analysis of cumulative effects addresses water resources and related environmental resources discussed in Chapter 5. This analysis employs the list-based approach, and the list includes other SFPUC projects or activities as well as other non-SFPUC projects or activities under the jurisdiction of various local agencies. The following factors were used to determine an appropriate list of projects to be considered in this cumulative analysis:

- *Geographic Scope and Location* – a relevant project is located within a defined geographic scope for the cumulative effect.

- *Similar Environmental Impacts* – a relevant project contributes to effects on resources that would also be affected by the proposed program. This analysis considers potential effects on water resources and the related environmental resources discussed in Chapter 5: hydrology, geomorphology, surface water quality, groundwater, fisheries, terrestrial biological resources associated with water resources (e.g., wetlands and riparian areas and the habitats and species they support), and recreational and visual resources.

Geographic Scope

The potential effects of the WSIP on water resources and related environmental resources are discussed in Sections 5.3, 5.4, 5.5, and 5.6 for four distinct geographic areas within the overall regional system: the Tuolumne River system (and related downstream water bodies), the Alameda Creek watershed system, the Peninsula watershed system, and the Westside Groundwater Basin. This analysis of cumulative effects is organized by the same four geographic areas. Other past, present, and probable future projects within these geographic areas are considered in this analysis if those projects have had or could have similar impacts on water resources and related environmental resources in those areas.

Similar Environmental Impacts

Past, present, and future projects or activities are considered in this analysis if they have contributed or would contribute to effects on resources also affected by the WSIP. The following environmental resources and geographic areas affected by the proposed program were used to screen potential projects for inclusion in the cumulative analysis. If a project would not contribute to effects on the resources analyzed in Chapter 5 (i.e., hydrology, geomorphology, surface water quality, groundwater, fisheries, terrestrial biological resources, recreational and visual resources or energy), it was not included in the cumulative analysis. In particular, the cumulative analysis focused on the following types of projects or activities:

- Projects or activities that would affect flow in a stream, creek, or river, including additional diversions or changes in diversions, removal or installation of obstructions/barriers or flow impediments, or flood or erosion control projects

- Projects or activities that would alter the volume, timing, or duration of releases from the reservoirs or otherwise affect water levels
- Projects or activities that would degrade, improve, restore, or protect water quality or degrade, improve, restore, or protect biological resources (including fisheries) along or in an affected stream, creek, river, or associated watershed
- Projects or activities that would alter groundwater withdrawal or recharge

Assessment of Cumulative Effects

Cumulative impacts are analyzed based on the CEQA guidance described above in Section 5.7.1.1 and are organized by geographic area (i.e., watershed or subarea within a watershed or Westside Groundwater Basin). The cumulative analysis first describes relevant projects for each geographic area and includes the major past/present projects and activities on the water bodies within the watersheds or groundwater basin affected by the WSIP, followed by probable future projects in that same area. For each watershed, these projects include past and present activities related to water supply and hydropower development as well as probable future projects related to watershed restoration and enhancement; similarly, for the Westside Groundwater Basin, past, present, and future projects include activities related to groundwater withdrawal or replenishment. The analysis then describes the effects of past and present projects on each resource area within each geographic area. Since many of these past water system/water supply projects are still in operation today, the existing environmental conditions reflect the cumulative effects of these past projects and their present operations; these conditions also form the basis for the analysis of the WSIP impacts described in Sections 5.3 through 5.6 as well as the basis for assessing the effects of probable future projects and cumulative impacts.

The analysis then discusses the potential effects of probable future projects and describes the cumulative impacts of past, present, and probable future projects together with impacts of the WSIP. Finally, the analysis determines whether the additional contribution of WSIP impacts to the cumulative effects of past, present, and probable future projects on an environmental resource is cumulatively considerable. As described above, "cumulatively considerable" means that the incremental effects of the proposed program would be significant when viewed in combination with the effects of past, present, and probable future projects.

The WSIP's contribution to cumulative impacts is considered prior to mitigation, but the effects of recommended mitigation measures identified in Sections 5.3 through 5.6 and described in Chapter 6 are assessed in determining the significance of overall cumulative impacts. The incremental contribution of the program's residual effects after mitigation to the overall cumulative impact is then analyzed to determine if it would be cumulatively considerable. If the WSIP's contribution to cumulative effects is determined to be cumulatively considerable (i.e., significant) even with implementation of measures identified in Section 5.3 through 5.6, then additional mitigation measures are identified to reduce the WSIP's contribution to cumulative effects. In other words, the analysis assumes that the proposed measures identified in Sections 5.3 through 5.6 would be needed to address not only water supply and system operations impacts, but also the WSIP's incremental contribution to any significant cumulative effects.

For each geographic area, the cumulative impact analysis includes a summary table showing the components considered in the analysis as well as the results of the analysis for each resource area. For each resource topic the table first summarizes the effects of past and present projects without the WSIP and represents the existing condition against which all other impacts are compared. The effects of the past plus present projects and/or activities and operations are described as having either moderately or substantially altered natural environmental conditions as a relative measure of the change that has occurred over time. (There were no cases where there had been little or no change from natural conditions over time, thus these terms are not used.). Next, the table summarizes the findings of the WSIP impact analyses presented in Sections 5.3 through 5.6, both prior to and after mitigation. Then, the table presents a summary of the potential effects of probable future projects, followed by the cumulative impacts of past, present, and probable future projects combined with the WSIP impacts after mitigation. Finally, the table indicates whether the WSIP's contribution to cumulative impacts would be cumulatively considerable. In the case where no other future projects would contribute to cumulative impacts (other than the WSIP), there is no additional cumulative impact and the WSIP's contribution to cumulative impacts would not be applicable (since the cumulative impact would be the same as the direct impact of the program as analyzed in the previous sections of Chapter 5).

5.7.2 Cumulative Effects on the Tuolumne River System and Downstream Water Bodies

The effects of past, present, and future projects are described separately for the Tuolumne River corridor above and including Don Pedro Reservoir, the Tuolumne River corridor between Don Pedro Reservoir and the confluence with the San Joaquin River, and the San Joaquin River downstream to the Sacramento–San Joaquin Delta. The cumulative impacts of all projects including the WSIP, and the WSIP's contribution to cumulative impacts, are summarized at the end of each of these subsections.

5.7.2.1 Relevant Projects

Tuolumne River – Hetch Hetchy Reservoir to Don Pedro Reservoir

Past and Present Projects

Development of various components of the SFPUC regional water and power system has substantially affected environmental resources in the Tuolumne River corridor upstream of Don Pedro Reservoir. These facilities, built over a period ranging from 90 to 20 years ago, have been in continuous operation. Existing environmental conditions in this corridor reflect the past and ongoing operation of these facilities. These water system components, shown in Section 5.3, Figure 5.3.1, include:

- O'Shaughnessy Dam and Hetch Hetchy Reservoir
- Cherry Dam and Lake Lloyd
- Eleanor Dam and Lake Eleanor
- Holm and Kirkwood Powerhouses
- Cherry and Canyon Power Tunnels
- Mountain Tunnel

Lake Eleanor, Hetch Hetchy Reservoir, and Lake Lloyd were completed and put into service in 1918, 1923, and 1956, respectively. Various improvements to the reservoirs, tunnels, and powerhouses were made between the 1920s and the present. Use of the facilities has increased over the same time period to keep pace with the demand for water in the Bay Area.

Land use in the Tuolumne River watershed upstream of Don Pedro Dam has not changed considerably from conditions that existed prior to Euro-American settlement. Water projects developed by agencies other than the SFPUC on the South Fork of the Tuolumne River are small and do not have much effect on the river system beyond their immediate vicinity.

Future Projects

Four future SFPUC projects/actions and two future non-SFPUC projects/actions could affect this reach of the Tuolumne River corridor:

- Hetch Hetchy Communications System Upgrade Project
- Hetch Hetchy Repair and Rehabilitation Program
- Discretionary fishery flow releases from Hetch Hetchy Reservoir
- SFPUC Watershed and Environmental Improvement Program
- Don Pedro Pumped Storage Project
- Tuolumne Wild and Scenic River Comprehensive Management Plan

In addition to the listed projects, the SFPUC would conduct routine maintenance on its facilities in the Tuolumne River corridor.

Hetch Hetchy Communications System Upgrade Project. The Hetch Hetchy Communications System Upgrade Project would replace and improve an aging communications system in Tuolumne and Stanislaus Counties and expand coverage to the O'Shaughnessy Dam, Lake Lloyd, and Lake Eleanor areas (SFPUC, 2007). Additionally, a Federal Communications Commission rule (Section 101.69 et seq.) requires SFPUC Power Enterprise (formerly part of Hetch Hetchy Water and Power Enterprise) to vacate use of its current operating frequencies in the 2-gigahertz band when an emerging technology licensee needs these frequencies. The SFPUC would undertake the project in partnership with the National Park Service and the U.S. Forest Service. The project would improve communication facilities at 26 developed sites and add communication facilities at three undeveloped sites. New communication towers and equipment shelters would be built at the three undeveloped sites: the Cherry Tower, Burnout Ridge, and Poopenaut Pass sites.[1] In addition, the proposed project would remove communications equipment at three locations.

Hetch Hetchy Repair and Rehabilitation Program. The SFPUC has developed the Repair and Rehabilitation Program for its facilities in the Tuolumne River corridor. Several projects have been scheduled for implementation between 2008 and 2012. They include repairing Early Intake Dam, lining Moccasin Reservoir, improving and enlarging the Lower Cherry Aqueduct, and

[1] Cherry Tower, Burnout Ridge, and Poopenaut Pass are not formal names adopted by the U.S. Forest Service, National Park Service, or any other local, state, or federal entity. These names were given solely to identify precise locations for project purposes.

expanding the Moccasin Creek bypass (SFPUC, 2006). Likely future projects that have not yet been scheduled include repair of existing roads and bridges and implementation of a vegetation management program for water and power rights-of-way and areas surrounding Priest and Moccasin Reservoirs.

Discretionary Fishery Releases from Hetch Hetchy Reservoir. As described in Chapter 2, Section 2.5.3, an agreement between the City and County of San Francisco (CCSF) and the U.S. Department of the Interior (DOI) provided for several supplemental releases of water from Hetch Hetchy Reservoir, in addition to the current required minimum releases (shown in Table 5.3.1-2), to support resident trout populations. As agreed, the SFPUC releases an extra 64 cubic feet per second (cfs) at Hetch Hetchy Reservoir on any day that flow in Canyon Tunnel exceeds 920 cfs. Also, the U.S. Fish and Wildlife Service (USFWS), an agency within the DOI, has the discretion to require this additional water to be released from Hetch Hetchy Reservoir in an amount varying from 4,400 to 15,000 acre-feet, depending on hydrologic conditions, for the benefit of resident trout. If shown to be necessary for fish habitat, the USFWS may also seek to have additional water released in wetter hydrologic year types under certain conditions (CCSF, 1987).

In March 1987, the CCSF and DOI agreed on the amounts and a procedure for determining whether supplemental flow releases were necessary. The agreement provided for a study of the relationship between the resident trout population and stream flow below O'Shaughnessy Dam. The study was intended to establish whether additional releases were actually needed and, if so, the appropriate timing of such releases. The SFPUC made supplemental releases as part of the experimental program to study the relationship between the flow rate in the river, the depth of water in the channel, and the extent of trout habitat. The USFWS produced a draft study in 1992 that called for the release of greater amounts of water, but did not provide guidance on the timing of releases. The CCSF provided comments on this draft study questioning the basis of some of the recommendations, and matters were left unresolved. Beginning in 2005, the SFPUC began working again with the USFWS to resolve issues regarding these additional releases (4,400 – 15,000 acre-feet). The SFPUC has produced two documents to supplement the 1992 draft study: the *Upper Tuolumne River: Available Data Sources, Field Work Plan and Initial Hydrology Analysis* (October 2005) and the *Upper Tuolumne River: Description of River Ecosystem and Recommended Monitoring Actions* (April 2007).

The SFPUC plans to build on this foundation and work collaboratively with the USFWS to pursue the recommendations in these reports; develop and test hypotheses by conducting field work; and reach agreement on these supplemental releases by 2009. For the purpose of this cumulative analysis, the supplemental or discretionary flow releases were modeled using the amounts from the 1987 release schedule (4,400 to 15,000 acre-feet, see Table 5.3.1-2) and conservation assumptions for the timing of releases in combination with full implementation of the WSIP under the 2030 conditions. These assumptions represent a potential worst-case scenario for use in the impact assessment, but may not reflect the ultimate release requirements if any are determined to be necessary.

Watershed and Environmental Improvement Program. The SFPUC is developing this program to protect and restore lands and natural resources critical to the operation of the SFPUC regional water system. As described in Chapter 3, the program could include ecosystem and habitat protection, improvements, and restoration and would address such issues as fish passage, riparian habitat degradation, and sensitive species recovery in the Tuolumne, Alameda, and Peninsula watersheds. Program planning is in progress, and initial activities include field surveys and information gathering on current ecological and geomorphic conditions in the Tuolumne River from O'Shaughnessy Dam to Don Pedro Reservoir, Cherry Creek downstream of Cherry Dam, and Eleanor Creek downstream of Eleanor Dam (McBain & Trush, 2006). However, no specific projects or actions affecting Hetch Hetchy Reservoir or the Tuolumne River below the reservoir have been identified.

Don Pedro Pumped Storage Project. The Turlock Irrigation District (TID) and Modesto Irrigation District (MID) are considering the possibility of constructing a pumped storage project. As envisaged, water would be pumped from Don Pedro Reservoir to a new adjacent reservoir at a higher elevation at times when electrical power is inexpensive. Water would be released from the new reservoir and conveyed back to Don Pedro Reservoir via a new hydroelectric power plant at times when the demand for electrical power is high and the value of the power is at its greatest. Two potential sites for the upper reservoir have been identified. Reservoir capacity would be 30,000 acre-feet or 14,000 acre-feet. If TID and MID choose to proceed with the project it would take ten years to complete (Morris, 2006).

Tuolumne Wild and Scenic River Comprehensive Management Plan. The National Park Service is currently preparing a plan for the 54 miles of the Tuolumne River designated as wild and scenic within Yosemite National Park. Even though Hetch Hetchy Reservoir and the lands immediately surrounding it would not be subject to the future management plan, the plan will include reaches of the Tuolumne River immediately upstream and downstream of the reservoir. This plan is currently under development, and no specific projects or actions affecting the reservoir or the Tuolumne River downstream of the reservoir have been identified. Therefore, this plan was not included in the modeling for the cumulative analysis, but it is assumed that implementation of the plan would result in beneficial effects on environmental resources.

Tuolumne River – Don Pedro Reservoir to the San Joaquin River

Past and Present Projects

Projects and activities that have substantially affected environmental quality in the Tuolumne River corridor below Don Pedro Reservoir between La Grange Dam and the river's confluence with the San Joaquin River include:

- Don Pedro Reservoir
- La Grange Diversion Dam
- Modesto and Turlock Canals
- Historical dredging for gold
- Gravel mining
- River channelization and development of floodplains for agricultural and urban use

- 1995 Federal Energy Regulatory Commission Settlement Agreement (New Don Pedro Project, P-2299-024)

Beginning in 1871, diversion dams with minimal storage capacity were built on the Tuolumne River in the vicinity of the present La Grange Dam. La Grange Dam itself was completed in 1893. The original Don Pedro Reservoir, which was built upstream of La Grange Dam, was put into service in 1923 and expanded to its current capacity in 1971. Since the 1870s, TID and MID have diverted water from the Tuolumne River into canals at or near the site of La Grange Dam. The canals deliver water to farmers for agricultural irrigation. In the last decade, MID began treating some canal water and providing it for municipal water supply. The canal system has been progressively expanded and improved since the 1870s. The volume of diverted water increased over many decades, but is now stable and unlikely to increase in the future.

Flow in the reach of the Tuolumne River between La Grange Dam and the San Joaquin River confluence is not only affected by Don Pedro Reservoir and the diversions into the Modesto and Turlock Canals, but also by upstream components of the SFPUC regional water system described above. They include O'Shaughnessy Dam and Hetch Hetchy Reservoir, Cherry Dam and Lake Lloyd, Eleanor Dam and Lake Eleanor, Holm and Kirkwood Powerhouses, Cherry and Canyon Power Tunnels, and Mountain Tunnel.

The Federal Energy Regulatory Commission (FERC) regulates most hydropower projects. The New Don Pedro Project includes both a reservoir and a hydropower component and operates in accordance with a FERC license. In 1996, FERC ordered new minimum releases, which are shown in Table 5.3.1-3.

Gold mining in the mid-19th century and gravel mining in the 20th century occurred throughout the Tuolumne River corridor. Gravel mining in the riverbed itself was discontinued in the 1970s but continues in the floodplain. Levee construction and conversion of floodplain lands to agricultural and urban use occurred primarily in the last 50 years.

Future Projects

Future plans, projects, and regulatory changes that could affect the Tuolumne River between Don Pedro Reservoir and the confluence with the San Joaquin River include:

- TID Infiltration Gallery Project
- TID Regional Surface Water Supply Project
- 1995 FERC Settlement Agreement
- New Don Pedro Project FERC relicensing
- Expansion of MID municipal water treatment plant

TID Infiltration Gallery Project. TID began development of the Infiltration Gallery Project in the 1990s. The project consists of an infiltration gallery, a raw water pump station, and a pipeline to TID's Ceres Main Canal. The infiltration gallery is an array of perforated pipes installed in the Tuolumne River bed just west of the Geer Road Bridge. The infiltration gallery was built in 2003 with a capacity of 100 cfs, but the pump station and pipeline have not yet been built. Once completed, the project would move the point of diversion for some of TID's Tuolumne River water downstream from La Grange Dam to the infiltration gallery near the Geer Road Bridge. Water that would otherwise be diverted at La Grange Dam would flow downstream to the infiltration gallery and be pumped into the Ceres Main Canal. The purpose of the project is to increase flow in the 26-mile reach of the Tuolumne River between La Grange Dam and Geer Road Bridge in order to improve conditions for aquatic life (EIP Associates, 2006).

TID Regional Surface Water Supply Project. TID is currently proposing a Regional Surface Water Supply Project, which would consist of a water treatment plant and about 20 miles of treated water pipeline to deliver water to the cities of Ceres, Hughson, Keyes, South Modesto, and Turlock. The treatment plant would be located adjacent to the existing infiltration gallery (see above) and would obtain water from it. Up to 66 cfs, or 42.5 million gallons per day (mgd), of water would be released from La Grange Dam and diverted from the Tuolumne River at the infiltration gallery for treatment and municipal use. The releases would be above and beyond already required flow releases to the lower river. The treatment plant would provide the base load water supply to cities in the TID service area. Peak daily and seasonal water demand would be met by supplementing water from the treatment plant with water from wells. By 2030, it is expected that the treatment plant would run continuously at 42.5 mgd (Brown and Caldwell, 2003; Selsky, 2006).

In 2030, 66 cfs would be released from La Grange Dam year-round to supply water to the downstream infiltration gallery and the treatment plant. An additional 34 cfs could be released from La Grange Dam during the irrigation season, diverted at the infiltration gallery, and conveyed to the Ceres Main Canal for agricultural use. The release for agricultural purposes would likely extend from mid-March to mid-October.

1995 FERC Settlement Agreement. The 1995 FERC Settlement Agreement included provisions intended to improve conditions in the Tuolumne River below La Grange Dam. Although some improvement projects have been completed, others would be completed in the future.

TID and MID, the owners and operators of Don Pedro Reservoir, have a legal and historical role as managers of flow in the lower Tuolumne River. Sharing in the responsibility for stewardship of the river's natural resources are several state and federal resource agencies, public utilities, and private organizations that are signatories to the 1995 FERC Settlement Agreement. The signatories are TID, MID, the California Department of Fish and Game (CDFG), the USFWS, FERC, the National Marine Fisheries Service, the CCSF, the San Francisco Bay Area Water Users Association (now the Bay Area Water Supply and Conservation Agency), Friends of the Tuolumne, the Tuolumne River Preservation Trust, Tuolumne River Expeditions, and the California Sports Fishing Protection Alliance.

The FERC Settlement Agreement created the Tuolumne River Technical Advisory Committee (TRTAC) to coordinate and administer restoration and management activities on the lower Tuolumne River. The TRTAC includes the FERC Settlement Agreement signatories and other interested groups. The TRTAC developed the *Habitat Restoration Plan for the Lower Tuolumne River Corridor* (TRTAC, 2000) to identify and implement high-priority restoration projects focused on improving conditions for the Chinook salmon population. The restoration plan is a technical resource designed to help the TRTAC fulfill its obligations under the FERC Settlement Agreement.

The restoration plan accepts that the Tuolumne River is a managed system, and that it is not possible to return the river to its pre-Euro-American settlement condition. Instead, the plan seeks to reverse more than a century of environmental degradation by identifying and implementing various improvement projects to restore the ecological health and integrity of the lower Tuolumne River. Plan recommendations include establishing a minimum 500-foot-wide riparian corridor along the river, removing levees and non-native vegetation, and reconstructing the river channel and terraces to match the current flow regime. Other recommendations involve reducing sand input to the river, providing additional spawning gravel, and restoring riparian vegetation. The plan identified 14 high-priority restoration projects, of which two have been implemented (see Section 5.2 for further description of the plan) (TID and MID, 2005).

New Don Pedro FERC Relicensing. The FERC will need to relicense the New Don Pedro Project in 2016 (see Chapter 2, Section 2.5 for a description of the New Don Pedro Project). Data gathered as required under the 1995 FERC settlement agreement, and the effectiveness of restoration measures, will be considered during the relicensing process. The current minimum flow requirements will also be reevaluated. Although the conditions of the new license are not known, it is likely that the minimum flow requirements will remain the same or will increase.

Expansion of MID Municipal Treatment Plant. MID owns and operates a 40-mgd municipal water treatment plant that obtains water from Modesto Reservoir. Modesto Reservoir is located north of the Tuolumne River and is supplied with water from the Tuolumne River via the Modesto Canal. Tuolumne River water is diverted into the Modesto Canal at La Grange Dam, and treated water is delivered to the city of Modesto. MID intends to increase the capacity of the treatment plant to 60 mgd in the near future (Jones and Stokes, 2004).

Downstream Water Bodies: the San Joaquin River, Stanislaus River, and Delta

This section discusses the projects that affect flow contributions to the San Joaquin River and the Delta downstream of the Tuolumne River or otherwise have or might affect water quality and/or aquatic ecosystem resources (i.e., species or habitats) in these water bodies.

Past and Present Projects

Past and present actions that have substantially affected the San Joaquin and Stanislaus Rivers include local water diversions, major water supply and flood control projects, gravel mining operations, and agricultural activities.

San Joaquin River. Friant Dam, which created Millerton Lake, was completed in 1942 as part of the federal Central Valley Project. The Central Valley Project's Friant-Kern and Madera Canals convey most of the runoff from the San Joaquin River drainage above Millerton Reservoir to agriculture and urban water users. The U.S. Bureau of Reclamation (USBR) releases enough water from the dam to maintain a flow of 5 cfs past Gravelly Ford, which is 35 miles below the dam, to meet downstream riparian water rights. The reach of the river between Gravelly Ford and Mendota is essentially dry, except when flood releases are being made.

As described in Section 5.3.1, the San Joaquin River gains waters as it flows toward the Sacramento–San Joaquin Delta from agricultural irrigation return flows and tributaries (see Figure 5.3.1-7). Stream flow gaging records for the period 1942 to 2004 indicate that flow in the San Joaquin River at Newman, upstream of the river's confluence with the Tuolumne River, averaged 1,789 cfs, and that flow in the San Joaquin River at Vernalis, upstream of the Delta and downstream of the Tuolumne River confluence, averaged 4,328 cfs. A substantial proportion of the increase in San Joaquin River flow between Newman and Vernalis is contributed by the Tuolumne River, which has an average annual flow of 1,265 cfs as measured at Modesto.

Stanislaus River. New Melones Reservoir was completed by the U.S. Army Corps of Engineers (Corps) in 1978 and approved for filling in 1983. The reservoir has a storage capacity of 2.4 million acre-feet per year (afy) and provides for both water supply and flood control. New Melones Reservoir, located approximately 60 miles upstream from the confluence of the Stanislaus and San Joaquin Rivers, is operated by the USBR as part of the Central Valley Project. The USBR provides water to Central Valley Project water supply contractors from this river. Flow in the lower Stanislaus River is primarily controlled by releases from the reservoir. The USBR makes releases from New Melones Reservoir to meet senior water-right obligations to Oakdale Irrigation District and South San Joaquin Irrigation District, to satisfy downstream riparian water rights, and to meet instream requirements for water quality, fisheries, and wildlife.

Under Section 3406 (b)(2) of the Central Valley Project Improvement Act (enacted by Congress in 1992), the DOI has the responsibility to dedicate and manage 800,000 afy of Central Valley Project water for fishery, wildlife, and habitat restoration purposes. Program objectives include improving habitat conditions for anadromous fish[2] in Central Valley Project rivers, streams, and the Bay-Delta to help meet the Anadromous Fish Recovery Program doubling goals. The Stanislaus River is one of the rivers controlled by the Central Valley Project. Under this program, the USBR releases water to the lower Stanislaus River to assist anadromous fish. The USBR has initiated an effort to revise its current interim plan of operation for New Melones Reservoir in consideration of changing conditions that have occurred in the basin and other directives.

Sacramento–San Joaquin Delta. One hundred fifty years ago, a network of levees was developed in the Sacramento–San Joaquin Delta to prevent flooding of the fertile farmland. While most of these islands continue to be used for agriculture, residential development is also occurring within and around the Delta. Delta farmers divert water directly from the Delta channels to irrigate their land. A portion of the diverted water is returned to the Delta channels as agricultural return.

California's two largest engineered water systems, the Central Valley Project and the State Water Project, also divert water from the Delta. The Central Valley Project diverts water from Old River

2 Anadromous fish hatch (rear) in freshwater, migrate to the ocean (saltwater) to grow and mature, and migrate back to freshwater to spawn and reproduce.

in the south Delta at the Tracy Pumping Plant and exports it to Central Valley Project contractors via the Delta-Mendota Canal. Contra Costa Water District, a Central Valley Project contractor, diverts its water from Old River and Rock Slough in the south Delta and Mallard Slough in the west Delta. The State Water Project diverts water from Old River at the Banks Pumping Plant and exports it to customers via the California Aqueduct, the South Bay Aqueduct, and the Central Coast Aqueduct. The State Water Project diverts smaller amounts of water from Barker Slough in the north Delta to serve customers in Napa and Solano Counties. Between 1995 and 2004, the State Water Project diverted an average of 2.6 million afy from the Delta. The Central Valley Project diverted an average of 2.5 million afy from the Delta.

Future Projects

There are numerous proposed programs and projects that, if implemented, could affect the San Joaquin or Stanislaus Rivers and/or the Delta and contribute to either beneficial and/or adverse cumulative effects on the water resources and/or the associated ecosystem resources. **Table 5.7-1** summarizes these programs and projects. These programs and projects are categorized by whether they would affect one or more of the three environmental issues affected by the WSIP: water supply/supply reliability, water quality, and/or aquatic resources (habitat and species). A few of these proposed programs and projects have been approved and are being implemented; many more are under study and may or may not be approved for implementation. As noted in the table, many of these programs are specifically designed to improve environmental conditions in the rivers or Delta and most of them could contribute to both beneficial and adverse cumulative effects on environmental resources in these rivers or the Delta.

San Joaquin River. As shown in Table 5.7-1, there are almost a dozen proposed future programs, projects, and actions that would directly affect surface waters, water quality, and related aquatic resources in the San Joaquin River, as well as others listed under the Delta Region that might indirectly affect the river depending on how they are implemented. As summarized in the table, several of these programs are intended to improve conditions in the river with respect to water quality and aquatic habitats, and some are also intended to improve water supply management and supply reliability. Notable among these potential projects is the recently established San Joaquin River Restoration Settlement, which is described in more detail below.

In September 2006, a settlement agreement among the USBR, the Friant Water Users Authority (Friant), and the Natural Resource Defense Council was approved to restore flows and salmon habitat in the San Joaquin River between Friant Dam and the confluence with the Merced River and to improve water reliability for water users. The settlement agreement provides opportunities for Friant Division long-term water contractors to mitigate water supply impacts resulting from water releases called for under the agreement. The settlement agreement requires specific releases of water from Friant Dam to the confluence of the Merced River, designed primarily to meet the various life-stage needs of spring- and fall-run Chinook salmon (USBR, 2007). The release schedule assumes continuation of the current average Friant Dam releases of 116,741 acre-feet, with additional flow requirements depending on the hydrologic year type. For example, approximately 247,000 acre-feet would be released in most dry years, whereas about 555,000 acre-feet would be released in wet years.

TABLE 5.7-1
PROJECTS THAT COULD CONTRIBUTE TO CUMULATIVE EFFECTS ON THE SAN JOAQUIN RIVER AND/OR DELTA

			Areas of Potential Effect Relevant to the WSIP (Adverse and/or Beneficial)			
Project Name	**Description**	**Project Sponsor / Partners**	**Water Supply / Reliability**	**Water Quality**	**Habitat / Species**	**Potential Effects / Status**
San Joaquin River Watershed						
San Joaquin River TMDL for salt and boron	Basin Plan amendment for control of salt and boron discharge into the lower San Joaquin River. Water quality objectives and implementation are yet to be completed.	Central Valley RWQCB		X		Would likely reduce saline discharges to the San Joaquin River, but may be deleterious to flow and salinity concentration conditions. Technical TMDL Report completed in January 2002. Notice of Determination (NOD) for the San Joaquin River at Vernalis Salt and Boron TMDL and Basin Plan Amendment submitted in 2006. Schedule has been deferred. (Central Valley RWQCB, 2007)
San Joaquin River TMDL for Dissolved Oxygen in the Stockton Deepwater Ship Channel	Basin Plan amendment containing a dissolved oxygen TMDL that apportions responsibility to parties attributable to the factors of cause. Implementation yet to be completed.	Central Valley RWQCB		X		Beneficial water quality effect. Removal of oxygen demanding substances, aeration and flow augmentation will likely be tools to meet TMDL.
New Melones Revised Operation Plan	Modify current interim operational plan in consideration of evolving San Joaquin and Stanislaus River conditions, directives and requirements.	USBR	X	X	X	May change priorities of New Melones Reservoir operation.
San Joaquin Valley Drainage Implementation Program	Management of agricultural drainage discharge to the San Joaquin River. Incorporated into the San Luis Drainage Feature Re-evaluation Program.	San Joaquin River Exchange Contractors, Panoche, Westlands and Broadview Water Districts		X		Intended to reduce water quality impacts on the San Joaquin River. Final report released in 2000 followed by a new Drainage Management Strategy in 2000 to implement the updated recommendations (DWR, 2007a).
San Luis Drainage Feature Re-evaluation Program	Intended to address drainage management and disposal from the San Luis Unit.	USBR	X	X		Will reduce various constituent discharges to the San Joaquin River. Final report released in 2006. Record of Decision (ROD) released in 2007 (USBR, 2007b).
Upper San Joaquin River Basin Storage Investigation (CALFED Program)	Evaluation of potential for increasing storage in the Upper San Joaquin Watershed to increase water supply, storage capacity, and flood control, as well as improve water quality and wildlife habitat.	USBR, DWR and partners	X	X	X	Could contribute to both beneficial and adverse environmental effects on the San Joaquin River. Environmental document and feasibility study anticipated in 2009 (USBR and DWR, 2006).

TABLE 5.7-1 (Continued)
PROJECTS THAT COULD CONTRIBUTE TO CUMULATIVE EFFECTS ON THE SAN JOAQUIN RIVER AND/OR DELTA

Project Name	Description	Project Sponsor / Partners	Areas of Potential Effect Relevant to the WSIP (Adverse and/or Beneficial)			Potential Effects / Status
			Water Supply / Reliability	Water Quality	Habitat / Species	
San Joaquin Valley Water Transfers	San Joaquin River Exchange Contractors Water Authority 2005 – 2014 transfer program of up to 130 TAF/year of substitute water to other CVP contractors. Water to be also transferred for delivery to San Joaquin Valley wetland habitat areas and/or to the EWA program as replacement water for CVP contracts.	USBR, San Joaquin River Exchange Contractors Water Authority	X	X	X	Could benefit Central Valley and Delta ecosystems. As of 2003, the feasibility studies and project identifications were still underway (CALFED, 2003).
San Joaquin River Restoration Settlement (Friant Settlement Legislation)	Agreement restoring water flow for salmon along with channel improvements in San Joaquin River downstream of Friant Dam to the confluence with the Merced River. Goal is to maximize flows for fish survival while meeting the supply obligations to San Joaquin River water users. Projects to restore flow will be implemented in phases.	USBR, DWR, Friant Users Water Authority, Natural Resources Defense Council	X		X	Intended to have a beneficial effect on fish habitat and fishery resources in the San Joaquin River. May incidentally increase Delta inflow and thus benefit Delta resources. Depending on how management goal is met, projects under this program might contribute in some ways to adverse effects on the Delta.
Delta-Mendota Canal Recirculation Feasibility Study	Feasibility study of recirculating/augmenting water from the Delta through CVP facilities to the San Joaquin River to enhance flow, reduce salinity, and reduce reliance on New Melones Reservoir for meeting water quality and fishery flow objectives.	USBR, DWR		X	X	This project is intended to contribute to beneficial effects on San Joaquin River water quality and fish habitat. A NOI/NOP was released in March 2007. The final feasibility report and EIS/EIR is expected in 2009 (USBR, 2007d).
Stockton Delta Water Supply Project	New supplemental water supply for Stockton diverted from the San Joaquin River. The project includes a new intake structure, pipelines and water treatment plant as well as a groundwater recharge / conjunctive use element.	City of Stockton	X	X		Would contribute to cumulative adverse effects of water diversion on the Delta. Stockton certified the Final EIR in 2005, and is currently designing and permitting the project for construction.
Lower San Joaquin River Flood Improvement Project	Improve flood control capacity on the lower San Joaquin River and enhance ecosystem structure and function on the lower river and south Delta.	DWR, USBR, South Delta Water Agency			X	Intended to provide environmental benefits to lower the San Joaquin River and south Delta; could also involve potential adverse effects on habitat depending on the nature of proposed actions. Project plan development to occur in 2007/2008. Environmental documents and feasibility study scheduled for completion in 2010.

TABLE 5.7-1 (Continued)
PROJECTS THAT COULD CONTRIBUTE TO CUMULATIVE EFFECTS ON THE SAN JOAQUIN RIVER AND/OR DELTA

			Areas of Potential Effect Relevant to the WSIP (Adverse and/or Beneficial)			
Project Name	**Description**	**Project Sponsor / Partners**	**Water Supply / Reliability**	**Water Quality**	**Habitat / Species**	**Potential Effects / Status**
Delta Region						
Shasta Reservoir Enlargement	Expand Shasta Reservoir to increase storage upstream of the Delta. Alternatives range from reservoir reoperation, and dam modification to raising the dam 6.5 feet. Project could increase water supplies available for export	USBR	X	X		Could contribute to both beneficial and adverse effects on the Delta by providing greater flexibility to release additional water from the reservoir for water quality and/or habitat or species benefit and by increasing potential supply exports from the Delta. Project is in the planning stages; environmental document anticipated in 2008.
Upstream of Delta Off-stream Storage (Sites Reservoir)	Develop new off-stream storage reservoir upstream of the Delta to increase water supply reliability, improve water quality in the Delta, and improve fish migration on the Sacramento River	DWR, USBR	X	X	X	Could contribute to both beneficial and adverse effects on the Delta by providing greater flexibility to release additional water from the reservoir for water quality and/or habitat or species benefit and by increasing potential supply exports from the Delta. NOP/NOI issued in November 2001; environmental document anticipated in late 2008.
In-Delta Storage Program (Delta Wetlands Project)	Develop storage in the Delta (on Delta islands). This could reduce flows in the Delta by capturing peak flow through the Delta during high flow periods and releasing it later in the year when exports are needed.	CALFED and DWR	X	X	X	Could contribute to both beneficial and adverse effects on the Delta by providing additional flexibility to release additional water from the reservoir for water quality and/or habitat or species benefit and by increasing potential supply exports from the Delta. EIR/EIS for Delta Wetlands Project completed in 2000. DWR issued 2004 Feasibility Report and 2006 supplemental report.
Los Vaqueros Reservoir Expansion Project	Expand the existing Los Vaqueros Reservoir to improve water supply reliability and water quality for Bay Area water users, while enhancing the Delta environment.	CCWD, USBR, DWR	X	X	X	Could contribute to both beneficial and adverse effects on the Delta by reducing impacts of water diversions on fish, providing environmental water, and improving water supply reliability. NOP/NOI released in 2006; Draft EIS/EIR anticipated early 2008.

TABLE 5.7-1 (Continued)
PROJECTS THAT COULD CONTRIBUTE TO CUMULATIVE EFFECTS ON THE SAN JOAQUIN RIVER AND/OR DELTA

Project Name	Description	Project Sponsor / Partners	Areas of Potential Effect Relevant to the WSIP (Adverse and/or Beneficial)			Potential Effects / Status
			Water Supply / Reliability	Water Quality	Habitat / Species	
South Delta Improvements Program (SDIP)	Series of actions: physical/structural improvements and operational changes to maximize SWP diversion capacity and improve conditions for fish, increase supply for downstream agriculture, and improve water quality and reliability of supply.	DWR, USBR	X	X	X	Could contribute to both beneficial and adverse effects on the Delta by increasing Delta water diversions and, at the same time, reducing impacts of water diversions on fish and improving water quality. Final EIS/EIR released in 2006. Stage 1 physical/structural improvements to be considered for approval first; then Stage 2 to consider increasing water deliveries.
Rock Slough and Old River Water Quality Improvement Projects	Two projects relocating agricultural drainage discharge points to improve water quality.	CALFED, CCWD		X		Would contribute to cumulative beneficial effects on Delta water quality.
Delta Cross Channel Reoperation and Through-Delta Facility (TDF)	Study of whether changes in operation of the Delta Cross Channel could benefit fish and water quality. Includes looking at a screened Through-Delta Facility for conveyance of up to 4,000 cfs.	CALFED, USBR, DWR	X	X	X	Could contribute to both beneficial and adverse effects on the Delta by altering Delta diversions and flow patterns to benefit fish and water quality and improve water supply reliability. A final report is anticipated in fall 2008 (Bagheban, 2007).
North Delta Flood Control and Ecosystem Restoration Project	Feasibility study of floodway improvements in the North Delta to provide conveyance, flood control, and ecosystem benefits.	DWR, U.S. Army Corps of Engineers			X	Would provide flood control and ecosystem benefits but could also contribute to some adverse effects on the Delta associated with construction of proposed projects such as bridge replacement, dredging, or island bypass systems. DWR and the Corps are conducting a feasibility study. An NOI/NOP was released in 2003. Final EIR/EIS anticipated in late spring 2008. Construction is expected to be complete by 2011 (DWR, 2007b).
Delta-Mendota Canal/California Aqueduct Intertie	Connection between the two facilities would increase water supply reliability for SWP and CVP.	DWR, USBR	X			Could increase average daily pumping for Delta water diversions into the Delta Mendota Canal. Project included in the USBR's Operations Criteria and Plan; Draft EIS anticipated in 2007 (USBR, 2007b).

TABLE 5.7-1 (Continued)
PROJECTS THAT COULD CONTRIBUTE TO CUMULATIVE EFFECTS ON THE SAN JOAQUIN RIVER AND/OR DELTA

Project Name	Description	Project Sponsor / Partners	Areas of Potential Effect Relevant to the WSIP (Adverse and/or Beneficial)			Potential Effects / Status
			Water Supply / Reliability	Water Quality	Habitat / Species	
Bay Area Water Quality and Supply Reliability Program	Program to work towards creating coordinated water delivery operations and regional exchange projects to improve water quality and supply reliability.	Various Bay Area water agencies	X	X		Several projects in various stages of development, as described in the *Bay Area Integrated Regional Management Plan*, released November 2006. Projects could contribute to both beneficial and adverse cumulative effects on the Delta.
South Bay Aqueduct Improvement and Enlargement Project	Project to upgrade and increase the size of the South Bay Aqueduct water delivery infrastructure.	DWR	X			Not expected to contribute to cumulative adverse Delta effects. Project EIR confirmed in June 2005; project under construction (DWR, 2005).
Sacramento Valley Water Management Program (Phase 8)	Program to resolve water quality and water rights issues arising from need to meet the flow-related water quality objectives of the 1995 Bay-Delta Water Quality Control Plan and the SWRCB's Phase 8 Water Rights hearing process. Short-term program includes actions and projects that would also improve water management and develop additional supplies.	USBR, DWR and agencies representing Sacramento River and Delta water users	X	X	X	Intended to benefit water quality in the Delta, and, in turn, ecosystem resources. This project would contribute to beneficial cumulative effects to the Delta. An NOI/NOP and Scoping Report were published in 2003 (DWR, 2007c).
Long-Term CVP and SWP Operations Criteria and Plan (OCAP) - ESA Reconsultation	Sets standards for operation of the integrated SWP and CVP. OCAP and associated Biological Opinions set operating terms and conditions, including the instream habitat conditions to be maintained. Due to both environmental and regulatory changes since the last OCAP update in 2004, the USBR has requested reinitiation of the Section 7 Endangered Species Act consultation with the USFWS and NMFS.	DWR, USBR	X	X	X	Could contribute to both beneficial and adverse cumulative effects on the Delta. The Biological Opinions are expected to be complete by mid-2008 (MWD, 2007).
Central Valley Project Long-Term Contract Renewals	Renewal of the CVP long-term service contracts. Process includes a current water needs assessment for each contractor. Decisions issued to date for Sacramento Division, Sacramento River Settlement Contracts, Delta-Mendota Canal Division, Friant Division and several individual contracts. Others ongoing, to be completed after the Long-term OCAP.	DWR, USBR	X			Could contribute to both beneficial and adverse cumulative effects on the Delta and San Joaquin River.

TABLE 5.7-1 (Continued)
PROJECTS THAT COULD CONTRIBUTE TO CUMULATIVE EFFECTS ON THE SAN JOAQUIN RIVER AND/OR DELTA

			Areas of Potential Effect Relevant to the WSIP (Adverse and/or Beneficial)			
Project Name	**Description**	**Project Sponsor / Partners**	**Water Supply / Reliability**	**Water Quality**	**Habitat / Species**	**Potential Effects / Status**
Sacramento River Water Reliability Study	Implementation of a water supply consistent with the Water Forum objectives of establishing a Sacramento River diversion to meet the Placer-Sacramento region's water supply needs and to promote ecosystem preservation along the American River.	Reclamation, Place County Water Agency (PCWA), cities of Roseville and Sacramento, Sacramento Suburban Water District	X		X	Could contribute to both beneficial and adverse cumulative effects on the Delta. Reclamation and PCWA issued NOI/NOP in 2003; environmental documentation in preparation.
Environmental Water Account (EWA) Water Purchase Program	The EWA provides protection to the fish of the Bay-Delta estuary at no uncompensated water cost to CVP or SWP water users. The program involves water supplies to replace water supply otherwise lost through changes in CVP or SWP operations	CALFED	X	X	X	Intended to contribute to beneficial effects on Delta fisheries. In a transitional phase as the short-term part sunsets at the end of 2007. Exploration of a transitional phase or long-term phase is underway. EIS/EIR is in preparation on the Long-term EWA program. Intended to contribute to cumulative beneficial effects on the Delta resources.
Freeport Regional Water Project	Partnership between the two agencies to build infrastructure for sharing of regional supply with a Sacramento River diversion. The project will supply EBMUD customers in dry years.	EBMUD and Sacramento County Water Agency (SCWA)	X			Could contribute to adverse effects on the Delta. The Final EIR certified in 2004; the USBR issued the ROD in 2005. Project beginning construction.
Oroville Facilities FERC Relicensing	Process required to renew the existing FERC license that expires in 2007 for DWR's Oroville Facilities (part of the SWP), operated primarily for water supply but also for power generation, flood control, environmental protection, recreation, and salinity control in the Delta.	DWR	X	X	X	This project has mitigation and license conditions intended to benefit fish and wildlife habitat and resources such that continued facilities operation should not contribute to adverse cumulative effects in the Delta. FERC issued Draft EIS in 2006. Final EIS issued in May 2007 (DWR, 2007d).
Monterey Amendment/Settlement Agreement	Amendments to DWR's SWP contracts. Notably, the Monterey Agreement revised water allocation procedures during shortages, transferred water from agricultural to municipal contractors and transferred the Kern Water Bank lands from state to local ownership.	DWR	X		X	Could contribute to adverse cumulative effects on the Delta. NOP was issued in 2003 and Draft EIR is expected to be released in 2007.
CVPIA Water Acquisition Program	This program provides water to protect federal wildlife habitat/reserves in the Central Valley.	USBR			X	Contributes to cumulative beneficial effects on fish and wildlife habitat in the Central Valley – wildlife refuges.

TABLE 5.7-1 (Continued)
PROJECTS THAT COULD CONTRIBUTE TO CUMULATIVE EFFECTS ON THE SAN JOAQUIN RIVER AND/OR DELTA

Project Name	Description	Project Sponsor / Partners	Areas of Potential Effect Relevant to the WSIP (Adverse and/or Beneficial)			Potential Effects / Status
			Water Supply / Reliability	Water Quality	Habitat / Species	
Delta Improvements Package	A set of programs under CALFED to improve water supply reliability, improve water quality, and increase environmental protection. It outlines the conditions under which the SWP would be allowed to increase permitted export pumping to 8,500 cfs.	CALFED		X	X	Intended to contribute to beneficial effects on the Delta and San Joaquin River.
Contra Costa Water District Alternative Intake Project	Drinking water quality project to relocate some of CCWD's existing water diversions to a new intake on Victoria Canal, which provides better water quality. No diversion increase.	CCWD		X		Project would not result in significant adverse effects on the Delta resources. Final EIS/EIR completed in 2006. This project is in the permitting and design phase.
CALFED Ecosystem Restoration Program	Program with actions to improve habitat and water quality in various regions of the Sacramento-San Joaquin water system.	CALFED		X	X	Could contribute to cumulative benefits for fish and wildlife species, habitats, and ecological processes.
Bay Delta Habitat Conservation Plan	Conservation planning process underway to develop a habitat conservation plan/natural resources conservation plan to cover species in the Bay-Delta region and secure permits from agencies.	Resources Agency			X	Intended to protect Delta species. A MOA was issued in 2006. The plan is expected to be complete by 2009 (Resources Agency, 2007).
Trinity River Mainstream Fishery Restoration Program	Program to alleviate fish impacts due to CVP deliveries from the Trinity River, by increasing flow in the Trinity River, resulting in less water being imported to the Central Valley	USBR			X	Intended to benefit fishery resources in the Trinity River. This program could contribute to adverse cumulative effects on the Delta. Final EIS and ROD were issued in 2000; following resolution of litigation the ROD is now being implemented.
Isolated Delta Facility	Facility to convey water around the Delta for local supply and export through a hydraulically isolated channel. Represents substantial changes in CVP/SWP operations to benefit Delta environmental resources, water quality and water reliability		X	X	X	This project includes elements intended to benefit the Delta environment, such as eliminating flow reversals in the south Delta. It could contribute to both beneficial and adverse effects on the Delta and San Joaquin River.

TABLE 5.7-1 (Continued)
PROJECTS THAT COULD CONTRIBUTE TO CUMULATIVE EFFECTS ON THE SAN JOAQUIN RIVER AND/OR DELTA

Project Name	Description	Project Sponsor / Partners	Areas of Potential Effect Relevant to the WSIP (Adverse and/or Beneficial)			Potential Effects / Status
			Water Supply / Reliability	Water Quality	Habitat / Species	
Dry Year Water Purchase Program	Instituted in 2001 to facilitate dry year water transfers among the CVP, SWP and third parties to reduce the hardship of water shortages and help public agencies throughout the state supplement their water supplies in dry years. The DWR provided transfers of 138.8 TAF from willing sellers in 2001, 22 TAF in 2002 and very little in 2003 and 2004. Mandatory reductions in California's use of Colorado River water could increase demand for water south of the Delta and increase acquisitions under the Dry Year Program	DWR	X			Could contribute to adverse effects in the Delta as a result of increased supply deliveries during dry years that would, in turn, reduce Delta inflow.
Davis-Woodland Water Supply Project	Provide a reliable water supply for future needs, improve water quality for drinking water purposes, and improve the quality of treated wastewater effluent discharged by the project partners. Project partners would divert up to 46.1 TAF/year of surface water from the Sacramento River and convey it for treatment and use in the cities of Davis and Woodland.	City of Davis, City of Woodland, University of California, Davis	X	X		Could contribute to adverse effects. The additional water provided by this project would be commingled with the cities' existing groundwater supply, which would subsequently improve drinking water quality. The DEIR was released April 2007.
Yuba River Accord	Three separate but interrelated agreements that would establish higher instream flow requirements to protect lower Yuba River fish species. Improved water supply reliability for the DWR and USBR, including a commitment of 60,000 acre-feet per year for the EWA and up to an additional 140,000 acre-feet of water in dry years for the SWP and CVP. Improved water supply reliability for Yuba County's farmers.	USBR, DWR, Yuba County Water Agency	X		X	Pilot program for 2007 is underway. NOI/NOP issued in 2005. Draft EIS/EIR due in 2007. (Yuba County Water Agency, 2007).

CCWD = Contra Costa Water District
CVP = Central Valley Project
CVPIA = Central Valley Project Improvement Act
DEIR = Draft Environmental Impact Report
DWR = California Department of Water Resources
EBMUD = East Bay Municipal Utility District
EIR/EIS = Environmental Impact Report / Environmental Impact Statement
EWA = Environmental Water Account
FERC = Federal Energy Regulatory Commission
NMFS = National Marine Fisheries Service
NOA = Notice of Availability
NOI = Notice of Intent
NOP = Notice of Preparation
OCAP = Operations Criteria and Plan
ROD = Record of Decision
RWQCB = Regional Water Quality Control Board
SWP = State Water Project
SWRCB = State Water Resources Control Board
TAF = thousand acre-feet
TMDL = total maximum daily load
USBR = U.S. Bureau of Reclamation
USFWS = U.S. Fish and Wildlife Service

Modeling studies completed by Friant concluded that implementation of the settlement agreement would be expected to reduce deliveries to Friant Division long-term water contractors by an average of about 170,000 afy (15 percent). Friant plans to develop and implement tools as part of the agreement to reduce or avoid water supply impacts by utilizing surplus water primarily to enhance groundwater programs, and also by developing programs to return water to Friant water users through recapture, recirculation, transfers, and exchanges. Thus, in the future, the San Joaquin River will carry more flow downstream toward the Delta than it does today, although some of the proposed releases might be recaptured and recirculated before they reach the Delta or even the confluence with the Tuolumne River.

The parties to the settlement agreement have filed a joint motion seeking U.S. District Court approval to implement the agreement. In addition, because the DOI will have primary responsibility for implementing the agreement, federal legislation is being proposed to authorize the DOI to implement the settlement agreement.

Stanislaus River. The USBR will continue to operate New Melones Reservoir for water supply and flood control purposes and to implement Central Valley Project Improvement Act Section 3406 (b)(2) water releases to improve habitat conditions for anadromous fish. Although no specific future projects were identified on this river, as noted in Table 5.7-1, projects such as the Delta-Mendota Canal Recirculation Feasibility Study might affect the Stanislaus River by reducing the need for the USBR to make releases from New Melones Reservoir to meet water quality and/or fisheries objectives downstream on the San Joaquin River or in the Delta.

Sacramento–San Joaquin Delta. As Table 5.7-1 illustrates, numerous future projects and activities affecting the Delta have been proposed—many sponsored under state and federal programs to improve and enhance the Delta for multiple objectives, including habitat and species protection and restoration, improved water quality, increased water supply and supply reliability, and Delta levee protection. Approximately 16 of these projects include enhancement of the Delta ecosystem resources as one of the key objectives. Twenty-seven of these programs target improving conditions to support water supply uses and reliability, while 26 projects are also specifically intended to improve water quality. Select relevant projects from among those listed on Table 5.7-1 are referenced below in the impact discussion to represent how these future projects might affect cumulative conditions in the Delta.

5.7.2.2 Cumulative Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to cumulative effects, but generally considers that implementation of the proposed program would have significant cumulative impacts if it were to:

- Have impacts that would be individually limited, but cumulatively considerable (“cumulatively considerable” means that the incremental effects of a project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects.)

Impacts associated with the proposed program that would be “individually limited” are based on the impact analyses presented in Section 5.3 and the significance criteria presented in that section for the various environmental resource topics.

Approach to Analysis and Impact Summary

Cumulative impacts are analyzed based on the CEQA guidance and approach described above in Section 5.7.1. Cumulative impacts are discussed below, and impact significance determinations are summarized in **Table 5.7-2**.

TABLE 5.7-2
SUMMARY OF CUMULATIVE IMPACTS IN THE TUOLUMNE RIVER SYSTEM AND DOWNSTREAM WATER BODIES RELATED TO WSIP WATER SUPPLY AND SYSTEM OPERATIONS

	Significance Determination						
Impact	Hydrology	Geomorphology	Surface Water Quality	Groundwater	Fisheries	Terrestrial Biology	Recreation / Visual Quality
5.7.2-1: Cumulative impacts on the Tuolumne River from Hetch Hetchy Reservoir to Don Pedro Reservoir	LS	LS	LS	LS	LS	LS	LS
5.7.2-2: Cumulative impacts on the Tuolumne River from Don Pedro Reservoir to the San Joaquin River	LS	LS	LS	LS	LS	LS	LS
5.7.2-3: Cumulative impacts on the San Joaquin River, Stanislaus River, and Delta	LS	LS	LS	LS	LS	LS	LS

NOTE: Significance determinations presented in this table assume implementation of all mitigation measures presented in Chapter 5, Section 5.3, and described in Chapter 6.

LS = Less than Significant, no mitigation required

Because impacts on stream flow and reservoir levels are related to effects on other environmental resources (see Section 5.1), the cumulative impacts in this section are organized by geographic area rather than by environmental topic in order to characterize the overall effects on the affected water body. In determining the significance of cumulative impacts, it is assumed that mitigation measures identified in Section 5.3 and described in Chapter 6 would be implemented, and any residual effects after mitigation are considered in combination with the effects of past, other current and probable future projects. The incremental contribution of the program’s residual effects to the overall cumulative impact is then examined to determine whether it would be “cumulatively considerable.”

Tuolumne River – Hetch Hetchy Reservoir to Don Pedro Reservoir

Impact 5.7.2-1: Cumulative impacts on the Tuolumne River from Hetch Hetchy Reservoir to Don Pedro Reservoir.

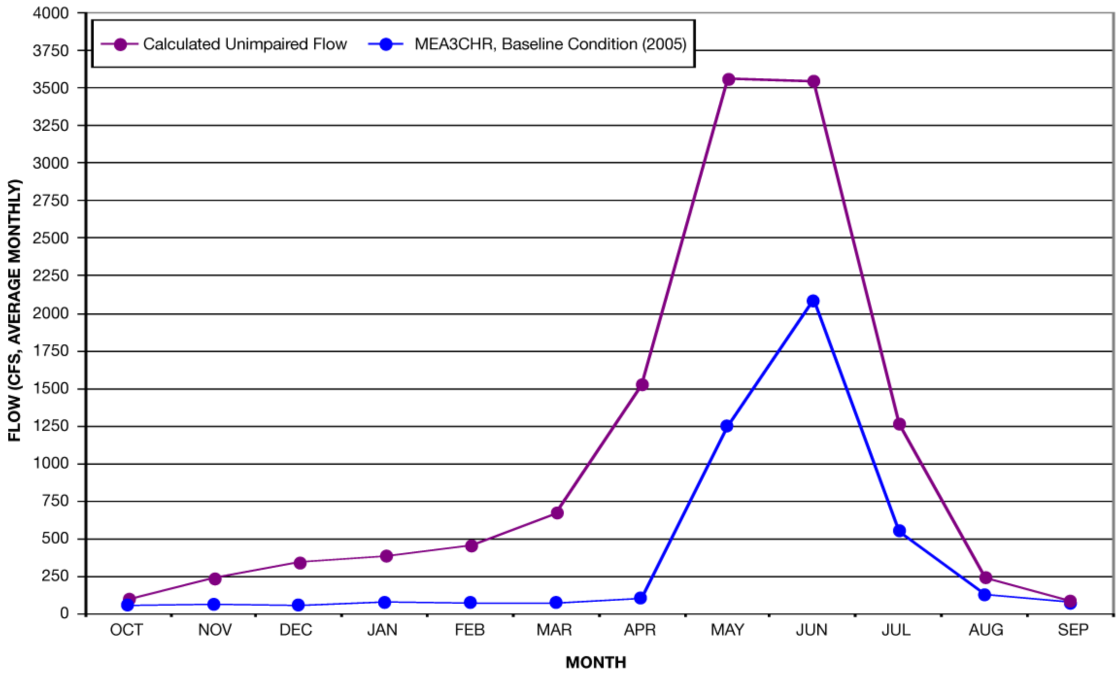
Effect of Past and Present Projects

Hydrology. Construction and operation of the SFPUC regional water system has substantially altered the hydrology of the Tuolumne River below Hetch Hetchy Reservoir. Average annual "unimpaired flow" in the Tuolumne River at Hetch Hetchy Reservoir is estimated to be about 750,000 acre-feet (Beck, 1992). Unimpaired flow is the flow in the river that would have occurred if there were no upstream water diversions or storage reservoirs. For the Tuolumne River, unimpaired flow is roughly equivalent to "natural flow"; that is, the flow that would have occurred prior to Euro-American settlement.

Currently, the SFPUC diverts about 63 percent of the average annual unimpaired flow of the river at Hetch Hetchy Reservoir (472,500 afy) for water supply and hydropower generation. About half of the water diverted at Hetch Hetchy Reservoir is conveyed to the Bay Area and used for municipal water supply. Most of the other half is used to generate electrical power at the Kirkwood Powerhouse and then is discharged back to the river at Early Intake, about 10 miles downstream of Hetch Hetchy Reservoir. About 5 percent of the water diverted at Hetch Hetchy Reservoir is discharged to Moccasin Creek, which flows to Don Pedro Reservoir. Thus, operation of the regional water system currently reduces average annual flow in the Tuolumne River immediately below Hetch Hetchy Reservoir to 37 percent of its historical value. The percentage reduction in flow decreases in a downstream direction as tributaries add flow and diverted water is returned to the river at Early Intake and Don Pedro Reservoir. Downstream, at Don Pedro Reservoir, the current SFPUC diversion represents approximately 13 percent of unimpaired flows. The relationship between the water supply facilities and the river is shown diagrammatically in Figure 5.3.1-2.

Operation of the regional water system has not only altered the total volume of flow in the river, but has also altered the pattern of flow. **Figure 5.7-1** shows the average monthly unimpaired and current flow in the Tuolumne River below Hetch Hetchy Reservoir. Operation of the reservoir has resulted in the delay of springtime flow increases and a reduction in peak flows.

The construction of Lake Lloyd and Lake Eleanor altered the hydrology of Cherry and Eleanor Creeks, respectively. Lake Lloyd retains snowmelt, which would have otherwise flowed downstream in Cherry Creek to the Tuolumne River. Most of the retained water is conveyed to Holm Powerhouse via the Cherry Power Tunnel and released to the creek just above its confluence with the Tuolumne River. Snowmelt stored in Lake Eleanor is conveyed in a tunnel to Lake Lloyd. The operations of the two reservoirs have resulted in decreases in both peak flow and total flow in Cherry and Eleanor Creeks below the dams.



SFPUC Water System Improvement Program ▪ 203287

Figure 5.7-1
Current and Unimpaired Average Monthly Flows
in the Tuolumne River Below Hetch Hetchy Reservoir

In summary, past construction and continued operation of the regional water system has had a substantial effect on the hydrology of Cherry Creek, Eleanor Creek, and the Tuolumne River between Hetch Hetchy and Don Pedro Reservoirs. A substantially smaller total annual volume of water flows down the rivers and creeks compared to unimpaired conditions. Peak flows have been much reduced, and seasonal flow patterns have been altered. The hydrologic changes have had an adverse effect on the river's aquatic and riparian wildlife habitat, as described below.

Geomorphology. River channels exist in a state of dynamic equilibrium with their watersheds. When conditions in the watershed change, the dynamic equilibrium is disturbed, and river channel geomorphology, or "form," adjusts to the new conditions. From the beginning of the 20th century to the present, the SFPUC has built new water system facilities and increased diversions to keep pace with municipal water and power demands; these facilities and operations have progressively altered conditions in the watershed, primarily by reducing river flow. The form of the river channel continues to adjust to the changing conditions.

Peak, or flood, flows are the predominant influence on river channel geomorphology. Hetch Hetchy Reservoir and the associated diversions have had a substantial effect on the magnitude, duration, and frequency of flood flows. **Table 5.7-3** shows the estimated magnitude of flood peaks in the Tuolumne River below Hetch Hetchy Reservoir before and after completion of the reservoir. The table shows that peak flows with a given frequency of occurrence were reduced by

TABLE 5.7-3
ESTIMATED FLOOD PEAKS IN THE TUOLUMNE RIVER BELOW HETCH HETCHY RESERVOIR
(cubic feet per second)

Recurrence Interval (Years)	Pre–Hetch Hetchy Reservoir	Post–Hetch Hetchy Reservoir[c]	Percent Change
1.5	8,294[a]	3,455	-58
2.33	8,500[a]	5,734	-33
5	10,147[a]	8,281	-18
10	15,660[b]	10,056	-36
25	31,795[b]	13,044	-59
50	33,504[b]	14,918	-55

[a] Calculated from measured flows at Hetch Hetchy (1911–1922).
[b] Estimated using data from the Merced River.

SOURCE: RMC Water and Environment and McBain and Trush, 2006.

18 to 59 percent following construction of the reservoir. For example, the peak flow expected to occur once in every 50 years without Hetch Hetchy Reservoir would be about 33,500 cfs, and with the reservoir in place is about 15,000 cfs, a reduction of 55 percent.

River channel form also depends on the free downstream movement of bedload (i.e., the silt, sand, gravel, and boulders transported by the stream). Hetch Hetchy Reservoir and Lakes Lloyd and Eleanor prevent the downstream movement of bedload. River channels deprived of bedload are subject to more erosion than those with a normal supply.

In summary, past construction and continued operation of the regional water system has had a substantial adverse effect on the geomorphology of the Tuolumne River and its tributaries. Channel-forming peak flows in the river are substantially smaller than under unimpaired conditions, and the reservoirs prevent the downstream movement of bedload, which leads to erosion in the river reaches below dams.

Surface Water Quality. Although past and present projects have had a substantial effect on stream flow and geomorphological conditions in the Tuolumne River between Hetch Hetchy and Don Pedro Reservoirs, they have probably not had much effect on water quality. Water quality in the Tuolumne River prior to construction and operation of the regional water system was excellent, and it remains so under existing conditions.

The capture and storage of water in Hetch Hetchy Reservoir and Lakes Lloyd and Eleanor affect the temperature of water in the reservoirs and in the streams below the reservoirs. It also reduces the dissolved oxygen content of water in the reservoirs, although any oxygen depletion is rapidly corrected by the release of turbulent water to the streams below the reservoirs, which enables rapid re-aeration. The temperature of surface waters in the reservoirs rises in the spring and summer with exposure to solar radiation, but the deeper waters remain cool. Almost all of the time, water is released from the reservoirs from the cooler pool of deep water, so water temperature in the streams below the reservoirs is probably similar to historical temperatures and may even be lower at times.

The reduction in flow in the river as a result of past and present projects causes water temperature to rise more rapidly in the early summer months than under unimpaired conditions. Solar radiation heats streams with low flows more rapidly than streams with greater flows. However, any changes in temperature attributable to past and present projects has not lessened the Tuolumne River's ability to support its beneficial uses, as designated by the Central Valley Regional Water Quality Control Board.

Groundwater. From Hetch Hetchy Reservoir to Don Pedro Reservoir, the Tuolumne River flows through a deep canyon in mountainous terrain. Most of the bed of the river is exposed rock. There are no large groundwater bodies, but small groundwater bodies are probably associated with limited alluvial deposits and a few riverside meadows, such as the meadow in the Poopenaut Valley. Changes in the surface water hydrology of the river attributable to past and present projects have probably had no effect on groundwater quality. By delaying the advent of large spring flows in the river and reducing the magnitude of peak flows, past and present projects have reduced the frequency and extent of flooding of the few riverside meadows, which has probably reduced groundwater levels underlying the meadows.

Fisheries. Past and present projects have substantially reduced stream flow in the Tuolumne River between Hetch Hetchy and Don Pedro Reservoirs in most months. The reduction in stream flow has reduced the extent of spawning habitat for resident trout. The variability of daily flows as a result of hydropower operations, and flow shaping to facilitate river rafting, has also reduced the suitability of the river as habitat for trout by increasing the risk of stranding and causing possible unintended downstream movement of juvenile fish. The construction of dams and reservoirs has decreased the ability of river fish to move upstream and downstream, but has increased the availability of habitat for fish that are adapted to life in lakes. Overall, past construction and continued operation of the regional water system has had a substantial adverse effect on the fishery resources of the Tuolumne River between Hetch Hetchy and Don Pedro Reservoirs.

Terrestrial Biology. When Hetch Hetchy Reservoir and Lakes Lloyd and Eleanor were built, a large area of terrestrial wildlife habitat within river canyons was inundated. Changes in river hydrology attributable to past and present projects probably damaged some riparian areas and streamside meadows, but other riparian habitats may have expanded as the river channel adjusted to the new flow regime. Overall, past construction and continued operation of the regional water system has had a substantial adverse effect on the terrestrial biological resources of the Tuolumne River corridor between Hetch Hetchy and Don Pedro Reservoirs.

Recreation and Visual Quality. Changes in river hydrology attributable to past and present projects may have improved whitewater recreation by reducing the magnitude of the unrunnable spring flood flows and extending the season in which the river can be run by commercial rafters. The changes in river hydrology that have reduced fish habitat may have also reduced angling success.

When the regional water system was built, sections of scenic river canyons were inundated to form artificial lakes. A vegetation-free zone extends around the perimeter of the lakes in the area and is visible when the reservoir is drawn down. The lakes provide a different visual experience than the canyons they replaced. The reduction in flow in the river as a result of past and present projects has also altered the appearance of the river corridor in some months. Dams and associated water and power facilities have introduced prominent man-made features into an entirely undeveloped scenic area. Overall, past construction and continued operation of the regional water system has had a substantial adverse effect on the visual resources of the Tuolumne River corridor between Hetch Hetchy and Don Pedro Reservoirs.

Potential Effects of Future Projects

This section describes the potential effects of the following projects: Hetch Hetchy Communications System Upgrade Project, the Hetch Hetchy Repair and Rehabilitation Program, discretionary fishery releases from Hetch Hetchy Reservoir, the SFPUC's Watershed and Environmental Improvement Program, the Don Pedro Pumped Storage Project, and the Tuolumne Wild and Scenic River Comprehensive Management Plan.

The Hetch Hetchy Communications System Upgrade Project is currently undergoing environmental review, and it is expected that the potential adverse impacts resulting from construction of the project would be reduced to a less-than-significant level through implementation of conventional construction mitigation measures. The communications upgrade project would not be expected to have long-term significant adverse effects on the environment.

The Hetch Hetchy Repair and Rehabilitation Program consists of a number of small projects that would be implemented over a several-year period. The projects could have short-term adverse impacts on water quality, fisheries, terrestrial biological, and other environmental resources during the construction period. However, adverse impacts would likely be reduced to a less-than-significant level through implementation of conventional construction mitigation measures, including the SFPUC standard construction measures. The project would not likely cause any long-term adverse environmental impacts.

The discretionary fishery releases from Hetch Hetchy Reservoir could have an effect on hydrology, water quality, fisheries, and terrestrial biological resources. However, the releases would be expected to have little or no effect on geomorphology, groundwater, and recreational and visual resources.

Even though no specific actions have been identified, it is expected that the Tuolumne Wild and Scenic River Comprehensive Management Plan would have a beneficial impact on hydrology, geomorphology, groundwater, surface water quality, fisheries, terrestrial biological resources, and visual resources. Similarly, the SFPUC's Watershed and Environmental Improvement Program would result in beneficial impacts on the same resources.

The Don Pedro Pumped Storage Project is defined only in concept, so its potential environmental impacts can only be described in general terms. The project would involve large-scale construction in the vicinity of Don Pedro Reservoir. Most, and perhaps all, of the short-term construction impacts would be reduced to a less-than-significant level through implementation of conventional construction mitigation measures. The project would inundate several hundred acres of undeveloped land and would require the construction of a dam several hundred feet high and more than 1,000 feet long, a combined powerhouse and pump station, pipelines, and electrical power transmission lines. Once complete, the project would likely be a prominent landscape feature and have long-term adverse impacts on visual quality. The project would have no effect on flow in the Tuolumne River and little effect on water levels in Don Pedro Reservoir.

Hydrology. The current daily minimum required releases from Hetch Hetchy Reservoir to the Tuolumne River are shown in Section 5.3.1, Table 5.3.1-2. As described in Section 5.3, the analysis of the direct impacts of the WSIP assumed that the same minimum releases would be required in 2030. For the cumulative impact analysis, it was also assumed that the discretionary flow releases would increase the required minimum releases from Hetch Hetchy Reservoir in July, August, and September.

Although USFWS did not establish the specific months for release, July through September are analyzed here as reasonable assumptions because they represent the summer season when trout could likely benefit from additional flow (as snowmelt releases from the reservoir diminish) and they represent the months when additional releases would have the greatest potential effect on water supply. The effect on water supply would reduce the amount of water in reservoir storage and require capture of more snowmelt the following spring to refill the reservoir. Additional flow releases in these three summer months were analyzed to assess the potential effects of such a release on top of WSIP operation.

Table 5.7-4 shows the estimated minimum required releases with the addition of the discretionary flow releases under three different hydrologic conditions. These hydrologic conditions are referred to as Type A, Type B, and Type C and are defined in Table 5.3.1-2 and the accompanying text. The assumption that the discretionary releases would be made in the summer was based on the fact that early discussions between the SFPUC and the USFWS envisaged a summer release. It is only an assumption, however, because the SFPUC and USFWS are currently engaged in studies designed to determine whether a release is needed to improve conditions for resident trout and, if needed, when the releases should be made.

A discretionary release from Hetch Hetchy Reservoir at any time of the year except in the spring would be made by drawing water from storage in the reservoir and thus would lower water levels in the reservoir compared to the existing condition (without the discretionary release). Water drawn as a result of the discretionary release would need to be replaced in the subsequent spring. If it is ultimately decided that the discretionary release should be made in the spring, then in some years, target flows below Hetch Hetchy Reservoir might be achievable without drawing the reservoir down, because enough snowmelt would be available in some years to both refill the reservoir and make the releases.

September	5,316	3,000	8,316	4,284	1,400	5,684	3,669	800	4,469
Total	**59,196**	**15,000**	**74,196**	**49,989**	**6,500**	**56,489**	**35,165**	**4,400**	**39,565**

[a] If the July 1 first-of-month storage at Hetch Hetchy Reservoir is less than 210,000 acre-feet, the fishery release schedule would not require a discretionary release.
[b] If diversion into Canyon Power Tunnel exceeds 920 cfs, the flow release is increased by 64 cfs, or up to 3,928 acre-feet per month. This is not included in this table.

Compared to the existing condition, the assumed discretionary flow releases would increase flow in the Tuolumne River immediately below Hetch Hetchy Reservoir by 22 to 78 percent in July, August, and September, with the percentage increase depending on hydrologic conditions. Because the release would increase drawdown of Hetch Hetchy Reservoir during the summer months (except during very dry or very wet years), it would increase the amount of water needed to refill the reservoir in a subsequent spring, thus delaying and reducing the duration of high spring flows in the river below the reservoir compared to the existing condition.

The effects of the assumed summertime discretionary release on the timing of spring releases from Hetch Hetchy Reservoir would be similar in kind to those of the WSIP. The assumed summertime discretionary flow releases would reduce spring releases to the Tuolumne River below Hetch Hetchy Reservoir by an annual average of about 4,100 acre-feet because more snowmelt would need to be captured to refill the reservoir after the previous years' summertime releases. Because more snowmelt would need to be captured to refill the reservoir after the previous years' summertime releases, the reduction in annual releases would range from zero in some years up to about 18,400 acre-feet. The reduction in release would manifest itself as a delay in spring releases of up to about three days, after which the release pattern would be the same as under the existing condition. A delay in spring releases of only up to three days would not represent a substantial change in the timing of spring flows in the river. Under existing conditions, the beginning of the higher spring releases varies by a few days from year to year depending on year type. This small delay in spring releases would result in less-than-significant hydrology effects compared to the existing condition.

It is expected that the SFPUC and USFWS will consider the findings of this impact analysis as they evaluate how and if to implement these discretionary flow releases to benefit resident fish. While a release of additional flow in summer months could benefit fish in that summer, it results in potentially adverse effects in the following spring. Although this adverse effect is found to be less than significant, the USFWS may want to modify the timing of such releases, if warranted, to minimize any potential adverse effects.

Surface Water Quality. Water for the assumed summertime discretionary flow releases would be drawn from the pool of cool water deep within Hetch Hetchy Reservoir. Water temperature in the stream increases in a downstream direction below the release point under the influence of solar radiation. Greater flow in the stream in the summer months would retard the rate of temperature increase. Overall, the discretionary fishery releases would have a modestly beneficial effect on water quality.

Fisheries. The increase in summer flow and decrease in water temperature that would result from the discretionary flow releases would likely benefit resident fish in the reach of the river below Hetch Hetchy Reservoir during the summer. The delay of a few days in large spring releases from Hetch Hetchy Reservoir that would occur as a result of the summertime discretionary flow releases would have a minor adverse effect on the availability of spawning habitat for resident trout. Overall, the assumed summertime discretionary fishery releases would likely have a beneficial effect on fish and fish habitat, although, as noted earlier, studies are in progress to determine whether the releases would be beneficial and, if so, how they should be implemented.

Terrestrial Biology. The Tuolumne River between Hetch Hetchy and Don Pedro Reservoirs lies within a deep canyon and flows primarily over a rock bed; nonetheless, there are a number of locations where alluvial materials have accumulated and riparian vegetation has become established. The vegetation depends on groundwater that is recharged during large springtime flows. As a result of the assumed summertime discretionary flow releases, the commencement of the large spring releases from Hetch Hetchy Reservoir would be delayed for a few days and reduced in duration in some years, which could adversely affect groundwater recharge and riparian vegetation in riverside meadows and alluvial deposits. Because of the sensitivity of plant species in riverside meadows, the adverse impacts of reduced groundwater recharge could be significant if the discretionary releases were implemented as modeled here based on the initial assumptions. However, adverse impacts on plant species in riverside meadows are unlikely to be acceptable to USFWS. It is expected that the USFWS will consider the findings of this impact analysis on the proposed discretionary releases and incorporate them into current studies regarding how and if to implement these releases. As discussed above, the USFWS did not previously specify that these releases must be made in July through September. Because of the potential effect that a delay in spring releases might have on riverside meadows along the Tuolumne River below Hetch Hetchy, it is assumed that the USFWS would modify the release schedule to avoid this potential impact or otherwise incorporate measures to reduce such effects to a less-than-significant level (such as the action proposed in WSIP Measure 5.3.7-2, Controlled Releases to Recharge Groundwater in Streamside Meadows and Other Alluvial Deposits). It is assumed that the USFWS would require that any discretionary releases be made in a manner that would not be injurious to special status plants. Therefore, it is assumed that the impacts of discretionary releases on meadow plants would be less than significant.

Recreation and Visual Quality. The Hetch Hetchy Communications System Upgrade Project would include three new microwave towers and equipment shelters at undeveloped sites. One site would be located on land owned by the CCSF below Cherry Dam, one at Burnout Ridge in the Stanislaus National Forest, and one at Poopenaut Pass in Yosemite National Park. The preliminary analysis indicates that the visual impact of the new towers in the Tuolumne River corridor can be reduced to a less-than-significant level through implementation of appropriate mitigation measures (SFPUC, 2007).

The assumed summertime discretionary flow release would make it slightly easier to maintain adequate flows between the Cherry Creek confluence and Don Pedro Reservoir for rafting. This could result in a slight increase in the length of the rafting season, a modestly beneficial effect. If it is ultimately determined that the discretionary releases should be made at some time other than the summer, then they would have no effect on the rafting season.

Cumulative Effects and WSIP Contribution

Table 5.7-5 summarizes the effects of past and present projects, the impacts of the WSIP, the effects of probable future projects, and the combined impacts of the WSIP plus probable future projects on the Tuolumne River between Hetch Hetchy Reservoir and La Grange Dam. Past and present projects have substantially altered the hydrology, geomorphology, fisheries, and terrestrial biology of this river reach compared to pre-Euro-American settlement conditions.

Water quality, groundwater, and visual and recreational resources have been moderately altered. The existing condition, which serves as the baseline for the analysis of the WSIP, reflects the substantial environmental changes that have occurred as a result of the past and present projects. Because past and present actions have altered this river reach, some of the reach’s environmental resources are more sensitive to small adverse changes than they would be if the reach had remained relatively unaltered from pre-Euro-American settlement conditions.

As described in Section 5.3, the WSIP would have a less-than-significant adverse impact on hydrology, geomorphology, surface water quality, groundwater, fisheries, and recreational and visual resources. It would have a less-than-significant impact on terrestrial biological resources after mitigation (Measure 5.3.7-2). As described in the previous section, probable future projects would have less-than-significant impacts on hydrology, geomorphology, surface water quality, groundwater, terrestrial biological resources, and recreation and visual resources. These projects would have beneficial impacts on fisheries.

TABLE 5.7-5
CUMULATIVE EFFECTS ON THE TUOLUMNE RIVER BETWEEN HETCH HETCHY AND DON PEDRO RESERVOIRS

Resource	Effects of Past and Present Projects	Impacts of WSIP (prior to mitigation/after mitigation)	Effects of Future Projects	Cumulative Impact (WSIP after mitigation + Future Projects)	WSIP Contribution Cumulatively Considerable?
Hydrology	SA	LS	LS	LS	No
Geomorphology	SA	LS	LS	LS	No
Surface Water Quality	MA	LS	LS	LS	No
Groundwater	MA	LS	LS	LS	No
Fisheries	SA	LS	B	LS	No
Terrestrial Biology	SA	PSM/LS	LS	LS	No
Recreation/Visual Quality	MA	LS	LS	LS	No

B = Beneficial impact
LS = Less than Significant, no mitigation required
PSM/LS = Potentially Significant but reduced to Less than Significant with mitigation
SA = Substantially Altered
MA = Moderately Altered

When the WSIP and foreseeable future projects are considered together, none of their cumulative effects would rise to a level of significance. Even though past and present projects have moderately to substantially altered the environmental resources along this reach of the Tuolumne River, the cumulative impacts of the WSIP after mitigation combined with the effects of future projects would not result in a substantial or noticeable change from the existing condition. In particular, the WSIP's impacts on terrestrial biology would be expected to be substantially avoided with implementation of Measure 5.3.7-2. Further, as described under Terrestrial Biology on the previous page, it is expected that the USFWS would require that future discretionary releases be made in a manner that is protective of biological resources. Thus, the cumulative impact on terrestrial biology would be considered less than significant. Because there are no significant cumulative impacts, no mitigation measures beyond Measure 5.3.7-2 would be necessary.

Tuolumne River – Don Pedro Reservoir to the San Joaquin River

Impact 5.7.2-2: Cumulative impacts on the Tuolumne River from Don Pedro Reservoir to the San Joaquin River.

Effect of Past and Present Projects

Hydrology. Construction and operation of the SFPUC regional water system and TID's and MID's water supply facilities, including Don Pedro Reservoir, La Grange Dam, and the Turlock and Modesto Canals, have substantially altered the hydrology of the Tuolumne River below La Grange Dam. Average annual unimpaired flow in the Tuolumne River at La Grange Dam is estimated to be about 1,850,000 acre-feet (Beck, 1992). Currently, the SFPUC, TID, and MID divert an average of about 63.8 percent of the unimpaired flow of the river at La Grange Dam for municipal and agricultural water supply. The SFPUC's upstream diversion reduces flow at La Grange Dam by about 298,500 afy, and TID and MID divert about 867,000 afy below the dam. Operation of the water supply facilities reduces average annual flow in the Tuolumne River below La Grange Dam to 36.2 percent of the unimpaired value. The percentage reduction in flow decreases in a downstream direction as groundwater infiltration, spills from irrigation canals, agricultural tailwater discharges, and tributaries add water to the river.

Operation of SFPUC, TID, and MID reservoirs and diversions has not only altered the total volume of flow in the river, but has also altered the pattern of flow. **Figure 5.7-2** shows the average monthly unimpaired and current flow in the Tuolumne River below La Grange Dam. The effect of upstream reservoirs and diversions is an overall reduction in flow, particularly in March through June, as well as a shifting in the seasonal occurrence of peak flows.

In summary, past construction and continued operation of the upstream reservoirs and diversions has had a substantial adverse effect on the hydrology of the Tuolumne River below La Grange Dam. The river is substantially smaller than under historical unimpaired conditions, and its flow regime is managed to provide water supply and hydropower.

Geomorphology. The river channel downstream of La Grange Dam has been modified by past gold and aggregate mining, agricultural and urban development within the river corridor, and past and present municipal and agricultural water supply operations. Gold mining involved dredging the sand and gravel from the riverbed and floodplain, extracting the gold, and piling the unwanted materials (referred to as tailings) along the river corridor. Mid- and late-19th century gold mining and the resulting tailings primarily affected a 10-mile reach of the river between La Grange Dam and Roberts Ferry. Some of the tailings were removed and used to construct Don Pedro Dam.

Instream and offstream gravel mining in a 16-mile reach of river corridor between Roberts Ferry and the community of Empire has created a number of water-filled pits. In addition, from Roberts Ferry to the confluence with the San Joaquin River, the Tuolumne River channel is confined by streamside agricultural and urban development and is often separated from the floodplain by privately owned levees. From the late 19th century to the present, the SFPUC, TID, and MID have built water system facilities and increased diversions to keep pace with water demand; these facilities and operations have progressively changed the magnitude and pattern of river flow. The channel of the Tuolumne River, greatly altered by mining and agricultural and urban development, is continually adjusting its form in response to these flow changes.

Peak, or flood, flows are the predominant influence on river channel geomorphology. The reservoirs and associated diversions on the Tuolumne River have had a substantial effect on the magnitude, duration, and frequency of flood flows. **Table 5.7-6** shows the estimated magnitude of flood peaks in the Tuolumne River below La Grange Dam before and after completion of Don Pedro Reservoir. The table shows that peak flows with a given frequency of occurrence were all reduced by 70 to 75 percent following construction of Don Pedro Reservoir. For example, the

1.5	8,360	2,400	-71
2.0	12,100	3,350	-72
5.0	25,000	6,700	-73
10	36,000	9,900	-73
25	54,000	15,200	-72

[a] Estimated from measured flows below La Grange Dam (1897–1969).
[b] Estimated from measured flows below La Grange Dam (1970–2002), but excluding the January 1997 flood.

SOURCE: RMC Water and Environment and McBain and Trush, 2006.

peak flow expected to occur once in every 25 years without Hetch Hetchy and Don Pedro Reservoirs would be about 54,000 cfs; with the reservoirs in place, it is about 15,200 cfs, a reduction of 72 percent.

River channel form also depends on the free downstream movement of bedload; that is, the silt, sand, gravel and boulders transported by the stream. Don Pedro Reservoir and La Grange Dam prevent the downstream movement of bedload from the watershed above Don Pedro Reservoir.

In summary, past construction and continued operation of water storage and diversion facilities has had a substantial adverse effect on the geomorphology of the Tuolumne River and its tributaries. Channel-forming peak flows in the river are substantially smaller than under historical unimpaired conditions, and the reservoirs prevent the downstream movement of bedload.

Surface Water Quality. Although past and present projects have had a substantially adverse effect on stream flow and geomorphological conditions in the Tuolumne River between Don Pedro Reservoir and the San Joaquin River confluence, they have probably not had much effect on water quality. Water quality in the Tuolumne River prior to construction and operation of the reservoirs and diversions was excellent, and it remains good under the existing condition. Surface runoff from agricultural fields and urban areas and the discharge of groundwater contaminated with agricultural chemicals has caused some deterioration, particularly below the river’s confluence with Dry Creek. The Central Valley Regional Water Quality Control Board has listed the lower Tuolumne River as impaired by diazanon and other pesticides. However, a recent study indicated that plant nutrient and pesticide concentrations are still very low (Stillwater Sciences, 2004).

As noted above, the capture and storage of water in reservoirs affects the temperature of water in both the reservoirs and the streams below the reservoirs. Because Don Pedro Reservoir is large, water is always released to the Tuolumne River from the cool pool of water deep within the reservoir. The water temperature in the river below La Grange Dam is probably similar to historical unimpaired conditions in the winter and spring, but may be cooler in the summer and early fall.

Because solar radiation heats small streams more rapidly than larger ones, the reduction in flow as a result of past and present projects and activities causes water temperatures under current conditions to rise more rapidly than under historical unimpaired conditions. In portions of the river, the past artificial widening of the river channel and the clearing of riparian vegetation has further accelerated the rate of temperature increase. The changes in water temperature attributable to past and present projects and activities have reduced but not eliminated the Tuolumne River’s ability to support coldwater fish species, as reflected in the COLD beneficial use designation. The changes have probably limited the length of the river reach below La Grange Dam that is suitable for coldwater fish.

Groundwater. Much of the Tuolumne River between La Grange Dam and the confluence with the San Joaquin River flows over water-bearing alluvial deposits. The Modesto Groundwater Subbasin lies to the north of the river, and the Turlock Groundwater Subbasin lies to the south. Historically, the river recharged the groundwater basins in a short reach below La Grange Dam, and elsewhere groundwater discharged to the river. The same overall pattern of groundwater recharge and discharge to the river occurs under current conditions, but groundwater levels and quality have been affected by agricultural and urban development. About half of the Tuolumne River’s unimpaired flow at Don Pedro Reservoir is diverted at La Grange Dam and applied to crops. A portion of the applied water percolates into the groundwater, raising levels in the upper aquifer and probably increasing discharge to the river. However, because some farmers and most municipalities obtain some or all of their water supplies from wells, groundwater levels have become depleted in some areas. As a result, in a five-mile-long reach of the river in Modesto, the river discharges to the groundwater basin rather than gaining from it.

Some of the fertilizers and pesticides applied to agricultural lands have percolated into the groundwater, and groundwater quality has deteriorated compared to historical conditions. Overall, past and present projects have both raised and lowered groundwater levels and caused groundwater quality to deteriorate substantially.

Fisheries. Past and present water projects prevent the downstream movement of bedload from the upper watershed to the Tuolumne River channel below La Grange Dam and have substantially reduced the volume and changed the pattern of stream flow in the river between the dam and the San Joaquin River confluence. Mining and agriculture have greatly altered the characteristics of the river channel. These changes have substantially reduced the extent and suitability of spawning and rearing habitat for migratory salmonids. The variability of daily flows as a result of hydropower operations has also reduced the suitability of habitat for fish by increasing the risk of stranding and causing unintended downstream movement of juvenile fish.

Prior to large-scale water development on the San Joaquin River and its tributaries, an estimated 300,000 to 500,000 salmon returned to the San Joaquin River watershed each year (Brown and Moyle, 1993). A substantial fraction of the salmon run probably returned to the Tuolumne River. In 1944, long after La Grange Dam had blocked access to the upper river, 130,000 spawners returned to the river (CDFG, 1946; Fry, 1961). Between 1971 and 2004, salmon runs averaged about 6,700 per year. The decline is probably due to many factors, including ocean conditions and increased levels of salmon fishing as well as cumulative habitat degradation as a result of water projects and other development in the Sacramento–San Joaquin Delta, the Tuolumne River drainage basin, and other parts of the San Joaquin River drainage basin. Overall, the past river channel modification and the construction and continued operation of the water supply facilities have had a substantial adverse effect on the fishery resources of the Tuolumne River between Don Pedro Reservoir and the San Joaquin River confluence.

Terrestrial Biology. When Don Pedro Reservoir was built (in 1923) and later expanded (in the late 1960s), large areas of terrestrial wildlife habitat within the canyons formed by the Tuolumne River and its tributaries upstream of the dam site were inundated. Gold mining more than a century ago and subsequent gravel mining and clearing of land for agriculture destroyed most of the riparian forest along the Tuolumne River corridor below La Grange Dam. Changes in river hydrology attributable to past and present water supply projects have also contributed to the destruction of the riparian forest. Overall, past mining, current agricultural activities, and the construction and continued operation of water supply facilities have had a substantial adverse effect on the terrestrial biological resources of the Tuolumne River corridor between La Grange Dam and the San Joaquin River.

Recreation and Visual Quality. When Don Pedro Reservoir was built and expanded, scenic river canyons were inundated to form an artificial lake. A vegetation-free zone extending around the perimeter of the reservoir is visible when the reservoir is drawn down. The reservoir has a different scenic value than the canyons it replaced.

Historically, a band of riparian forest up to five miles wide followed the Tuolumne River corridor from La Grange Dam to the confluence with the San Joaquin River. Almost all of the forest was destroyed by gold and gravel mining or cleared to make room for agriculture. The diminution of flow in the river as a result of past and present water supply projects has also contributed to the loss of riparian vegetation. Overall, past and present activities have altered the character and appearance of the river corridor from continuous riparian forest to a patchwork of open river channel, tailings, agricultural and urban lands, and forest remnants.

Potential Effects of Future Projects

This section describes the potential effects of the following projects: TID Infiltration Gallery Project, TID Regional Surface Water Supply Project, 1995 FERC Settlement Agreement, New Don Pedro Project FERC relicensing, and the expansion of the MID municipal water treatment plant.

The TID Infiltration Gallery Project and the TID Regional Surface Water Supply Project would result in an increase in flow in a 25-mile reach of the Tuolumne River below La Grange Dam that would likely have beneficial effects on biological resources. Flow requirements for the lower Tuolumne River below La Grange Dam will also be reexamined during the New Don Pedro Project FERC relicensing process in 2016; during this process, the current flow release schedules may be retained or modified. The 1995 FERC Settlement Agreement has led to the development of a habitat restoration plan which, if implemented, would benefit biological resources in the river corridor between La Grange Dam and the confluence with the San Joaquin River. None of these projects would be expected to have adverse environmental effects.

The existing 30-mgd capacity MID municipal water treatment plant is located adjacent to Modesto Reservoir, and it obtains its water supply from the reservoir. The Tuolumne River supplies water to Modesto Reservoir via the Modesto Canal. Water is diverted into the Modesto Canal at La Grange Dam. The supplemental EIR on the proposed expansion of the MID treatment plant indicates that the existing plant is operated in a way that does not increase the rate of diversion of water from the Tuolumne River at La Grange Dam. The supplemental EIR notes that this is possible because the increased use of water for municipal purposes in the MID service area is offset by a reduction in agricultural use as agricultural lands are converted to urban uses. The expanded treatment plant would be operated in the same way as the existing plant. Like the existing plant, the expanded plant would not alter the total volume of water diverted by MID at La Grange Dam, but it would slightly alter the seasonal pattern of diversions and releases to the Tuolumne River at La Grange. The supplemental EIR on the expansion project indicates that there would be no substantial changes in releases to the Tuolumne River from La Grange Dam as a result of the project (Jones and Stokes, 2004).

Hydrology. The Infiltration Gallery Project as originally envisaged would have changed the point of diversion for some of TID's agricultural water supply. Water that would otherwise have been diverted at La Grange Dam and conveyed to farmers in the Turlock Canal would be released at the dam and allowed to flow downstream in the Tuolumne River to the infiltration gallery near the Geer Road Bridge, at which point it would be pumped into the Ceres Main Canal. The Infiltration Gallery Project would have increased flow in the Tuolumne River between La Grange Dam and the Geer Road Bridge by about 100 cfs between mid-March and mid-October.

It is now likely that the original Infiltration Gallery Project will be modified to supply water to a TID-owned municipal water treatment plant that is a part of TID's Regional Surface Water Supply Project. With the modified project in place, water that would otherwise have been diverted at La Grange Dam and conveyed to farmers would be released at the dam and allowed to flow downstream in the Tuolumne River to the infiltration gallery. Up to 66 cfs would be diverted from the river and pumped to the new municipal water treatment plant year-round. Another 34 cfs might be diverted from mid-March to mid-October and pumped to the Ceres Main Canal for agricultural use. The Infiltration Gallery/Regional Surface Water Supply Project would increase flow in the reach of the Tuolumne River between La Grange Dam and the Geer Road Bridge by 66 cfs from mid-October to mid-March, and by 100 cfs from mid-March to mid-October.

Flow in the river under the existing condition and with the Infiltration Gallery/Regional Surface Water Supply Project in place, and the difference between the two, are shown in **Tables 5.7-7** and **5.7-8**. For Table 5.7-7, it was assumed that the additional flow would be 66 cfs year-round. For Table 5.7-8, it was assumed that there would be 66 cfs of additional flow from October through March, and 100 cfs of additional flow from April through September. The Infiltration Gallery/Regional Surface Water Supply Project would increase flow in this reach of the river every month compared to the existing condition. The greatest increases would occur during June, July, August, and September of average below-normal, dry, and critically dry years, when only the minimum required amount of water is currently released from La Grange Dam. In these months, assuming only municipal diversions, the Infiltration Gallery/Regional Surface Water Supply Project would about double the volume of flow in the river and thus would have a substantial beneficial impact on hydrology. If the Infiltration Gallery/Regional Surface Water Supply Project involves the diversion of water for both municipal and agricultural use, then it would more than double the volume of flow in the river in the summer of average below-normal, dry, and critically dry years.

The New Don Pedro Project is scheduled for relicensing by FERC in 2016. The current minimum fishery release requirements for the Tuolumne River below La Grange Dam will be reexamined during the relicensing process. The minimum required fishery releases could be retained or modified (it is unlikely they would be decreased). If summertime minimum releases are increased, then large spring releases could be delayed while TID and MID replenish storage in Don Pedro Reservoir. The impacts on overall hydrology would be minor and probably beneficial.

Geomorphology. The habitat restoration plan for the lower Tuolumne River, a part of the 1995 FERC Settlement Agreement, includes a number of recommendations which, if implemented, would improve stream channel geomorphology between La Grange Dam and the confluence with the San Joaquin River. As described above, past and present projects and actions have radically altered the flow regime of the river and the physical characteristics of the river channel. The dynamic equilibrium between river flow and channel characteristics has been thoroughly and continually disturbed over the past 140 years. The habitat restoration plan recommends a series of actions to accelerate the development of a river channel that is in balance with its current flow regime. These recommendations include shaping releases from La Grange Dam to provide specified peak flows every few years, adding gravel, removing levees and reconstructing the river channel, and restoring riparian vegetation. Overall, the habitat restoration plan would have a substantial beneficial impact on stream channel geomorphology.

NOTE: "Existing Condition (2005)" is based on model run MEA3CHR. An overview of the model runs is presented in Section 5.1. Detailed information on the models and underlying assumptions is provided in Appendix H.

Surface Water Quality. Water for the Infiltration Gallery/Regional Surface Water Supply Project would be drawn from the pool of cool water deep within Don Pedro Reservoir. Water temperature in the stream increases in a downstream direction below the release point from the reservoir under the influence of solar radiation. Greater flow in the stream in the summer months would retard the rate of temperature increase. Overall, the Infiltration Gallery/Regional Surface Water Supply Project would have a modestly beneficial effect on water quality.

Fisheries. The habitat restoration plan, a part of the 1995 FERC Settlement Agreement, and the Infiltration Gallery/Regional Surface Water Supply Project would both improve conditions for coldwater fish in the Tuolumne River between La Grange Dam and the San Joaquin River confluence. Construction of a more natural river channel that is in balance with its flow regime, the addition of gravel, and the restoration of the riparian forest as part of the habitat restoration plan would improve the quality of habitat for salmonids. Increases in river flow as a result of the Infiltration Gallery/Regional Surface Water Supply Project would increase the extent of spawning and rearing habitat for salmonids. Increased flow would also extend the length of the river reach in which water remains at a suitable temperature for salmonids. Increased flow in May would aid out-migration by juvenile Chinook salmon. Increased flow in June, July, August, and September would aid oversummering steelhead. Overall, future projects are likely to have a substantial beneficial effect on the fishery resources of the Tuolumne River between La Grange Dam and the San Joaquin River confluence.

Terrestrial Biology. The habitat restoration plan, a part of the 1995 FERC Settlement Agreement, would improve conditions for both terrestrial wildlife and vegetation in the Tuolumne River corridor between La Grange Dam and the San Joaquin River confluence. Construction of a more natural river channel that is in balance with its flow regime and the planting of native vegetation as part of the habitat management plan would help restore and maintain the riparian forest along the river corridor. The restored riparian forest would provide improved habitat for birds, mammals, and amphibians. Increased summertime flow in the river between La Grange Dam and Geer Road would have a modest beneficial effect on the survival of riparian vegetation. Overall, future projects are likely to have a substantial beneficial effect on the terrestrial biological resources of the Tuolumne River corridor between La Grange Dam and the San Joaquin River confluence.

Cumulative Effects and WSIP Contribution

Table 5.7-9 summarizes the effects of past and present projects, the impacts of the WSIP, the effects of probable future projects, and the combined impacts of the WSIP plus probable future projects on the Tuolumne River between La Grange Dam and the San Joaquin River confluence. Past and present projects have substantially altered the hydrology, geomorphology, groundwater, fisheries, terrestrial biology, and visual and recreational resources of this river reach compared to pre-Euro-American settlement conditions. Water quality has been moderately altered. The existing condition, which serves as the baseline for the analysis of the WSIP, reflects the substantial environmental changes that have occurred as a result of past and present projects. Because past and present actions have drastically altered this river reach, some of the reach’s environmental resources are more sensitive to small adverse changes than they would be if the reach had remained relatively unaltered from pre-Euro-American settlement conditions.

As described in Section 5.3, the WSIP would have a less-than-significant adverse impact on hydrology, geomorphology, surface water quality, groundwater, and recreational and visual resources. It would have less-than-significant impacts on fisheries and terrestrial biological resources after mitigation (Measure 5.3.6-4a, Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water, or Measures 5.3.6-4b, Fishery Habitat Enhancement, and 5.3.7-6, Lower Tuolumne River Riparian Habitat Enhancement). As described in the previous section, probable future projects would have potentially adverse but less-than-significant impacts or beneficial effects on hydrology, geomorphology, surface water quality, groundwater, fisheries, terrestrial biology, and recreational and visual resources.

TABLE 5.7-9
CUMULATIVE EFFECTS ON THE TUOLUMNE RIVER BETWEEN LA GRANGE DAM AND THE SAN JOAQUIN RIVER

Resource	Effects of Past and Present Projects	Impacts of WSIP (prior to mitigation/after mitigation)	Effects of Future Projects	Cumulative impact (WSIP after mitigation + Future Projects)	WSIP Contribution Cumulatively Considerable?
Hydrology	SA	LS	B	LS	No
Geomorphology	SA	LS	B	LS	No
Surface Water Quality	MA	LS	B	LS	No
Groundwater	SA	LS	LS	LS	No
Fisheries	SA	PSM/LS	B	LS	No
Terrestrial Biology	SA	PSM/LS	B	LS	No
Recreation/Visual Quality	SA	LS	B	LS	No

B = Beneficial impact
LS = Less than Significant, no mitigation required
PSM/LS = Potentially Significant but reduced to Less than Significant with mitigation
SA = Substantially Altered
MA = Moderately Altered

As noted above, many of the foreseeable future projects would have beneficial environmental effects. Two of the foreseeable future projects, the Infiltration Gallery Project and the Regional Surface Water Supply Project, would produce environmental benefits by increasing flow in the reach of the river between La Grange Dam and Roberts Ferry. **Tables 5.7-10** and **5.7-11** show the cumulative effects of the Infiltration Gallery/Regional Surface Water Supply Project and the WSIP on flow in the Tuolumne River below La Grange Dam. For Table 5.7-10, it was assumed that the Infiltration Gallery Project would add 66 cfs year-round. For Table 5.7-11, it was assumed that the Infiltration Gallery/Regional Surface Water Supply Project would add 66 cfs of flow from October through March, and 100 cfs of flow from April through September.

The WSIP would have no effect on flow in the river below La Grange Dam in critically dry years, but would result in infrequent reductions in flow in below-normal and dry years. The Infiltration Gallery/Regional Surface Water Supply Project and the WSIP together would increase flow in the river in almost every month of below-normal, dry, and critically dry years compared to the existing condition. The Infiltration Gallery/Regional Surface Water Supply Project would more than offset the infrequent WSIP-induced reductions in flow in below-normal and dry years.

The WSIP alone would reduce flows in the river in most months of average above-normal years, and in all months of average wet years, compared to the existing condition. The Infiltration Gallery/Regional Surface Water Supply Project and the WSIP together would result in flow reductions of a lesser magnitude in average above-normal and wet years than would the WSIP alone.

Thus, as shown in Table 5.7-9, when the WSIP and future projects are considered together, none of their cumulative effects would rise to a level of significance. Even though past and present projects have moderately to substantially altered the environmental resources along this reach of

the Tuolumne River, the cumulative impacts of the WSIP after mitigation combined with the effects of future projects would not result in a substantial or noticeable change from the existing condition. In particular, the WSIP's impacts on fisheries and terrestrial biology would be expected to be avoided with implementation of Measure 5.3.6-4a, or would be substantially reduced with implementation of Measures 5.3.6-4b and 5.3.7-6. Since the implementation of future projects would be expected to be beneficial to both fisheries and terrestrial biology, the combined cumulative impacts on fisheries and terrestrial biology would be considered less than significant. Because there are no significant cumulative impacts, no mitigation measures beyond Measure 5.3.6-4a or Measures 5.3.6-4b and 5.3.7-6 would be necessary.

Downstream Water Bodies: the San Joaquin River, Stanislaus River, and Delta

Impact 5.7.2-3: Cumulative impacts on the San Joaquin River, Stanislaus River, and Delta.

As discussed in Section 5.3, the WSIP would result in less-than-significant impacts on the San Joaquin River, Stanislaus River, and/or Delta in the areas of hydrology, water quality, water supply, and fisheries; therefore, these issue areas are discussed below. The WSIP would have no effect on these downstream water bodies in the areas of geomorphology, groundwater, terrestrial biology, recreation, or visual resources; therefore, these issue areas are not discussed further.

Effect of Past and Present Projects

Hydrology. Past water and flood control project development on the San Joaquin River has substantially altered the river hydrology. The river between Gravelly Ford and Mendota is essentially dry, except when flood releases are being made. Past water and flood control project developments on the major tributaries to the San Joaquin River, including the Merced, Tuolumne, and Stanislaus Rivers, have also affected the hydrology of the San Joaquin River. The past activities of hydraulic mining in the Sierra foothills, levee construction, major water supply project development and operation in the Delta and upstream of the Delta, and ship channel development and maintenance have in combination substantially altered Delta hydrology.

The diversion of water by the Central Valley Project, State Water Project, and others in the south Delta as well as upstream depletion of San Joaquin River flows affect the pattern of flow in the Delta channels. Historically, net flow in the Delta channels was toward the San Francisco Bay Estuary. Now, because freshwater inflow to the south Delta from the San Joaquin River is small relative to the diversions at the Banks and Tracy Pumping Plants, net flow in many south Delta channels reverses during summer and fall. Flow in the lower San Joaquin River and the south Delta channels is directed upstream toward the pumping plants rather than downstream toward the estuary (Miller, 1993).

The diminution of flow and flow reversals in the lower San Joaquin River as a result of water diversions by the State Water Project and Central Valley Project are harmful to migrating salmon. In 1990, the California Department of Water Resources (DWR) began installing temporary barriers in several waterways in the south Delta to improve conditions for migrating salmon. Temporary barriers have been placed across the Grant Line Canal, Middle River, and Old River. The purpose of the barriers is to control water levels for irrigators, improve water quality, and direct more water down the lower San Joaquin River for downstream migrating juvenile salmon in the spring and for upstream migrating adults in the fall. It is expected that permanent operable barriers will replace the temporary barriers in the next few years.

Water Quality. As described in Section 5.3.3, San Joaquin River water quality has been degraded by a combination of agricultural drainage, past mining activity, wastewater and urban stormwater runoff, wildlife refuge discharge, and flow depletion in some months of some years. Inadequate drainage and accumulating naturally-occurring salts have been persistent problems in parts of the San Joaquin Valley for more than a century. The San Joaquin River has levels of total dissolved solids and total organic carbon that are high for natural waters and are considerably higher than for Tuolumne River water. The river is listed as an impaired water body for mercury, boron, various pesticides, salinity, and unknown toxicity. Both the Tuolumne River and the Stanislaus River contribute higher quality water to the San Joaquin River as it flows into the Delta.

Water quality in the Delta is governed by the Delta's complex hydrodynamics, which mix the freshwater entering the system from upstream tributary rivers with the saline water that enters from Suisun Bay. When freshwater flow is small, tidal flow enables saline water to penetrate into the Delta. Under these circumstances, water quality in some parts of the Delta becomes brackish. The reversal of flow in the lower San Joaquin River and many south Delta channels as a result of water diversion by the State Water Project and Central Valley Project increases the tendency for saline water to penetrate into the Delta. Water quality in the Delta generally declines in a southerly and westerly direction. Delta water quality is also affected by agricultural drainage, urban runoff, wastewater discharges, and high organic carbon input from drainage off the peat soils on the Delta islands.

Fisheries. As described in Section 5.3.6, the lower San Joaquin River and Delta provide habitat to a diverse assemblage of resident and migratory estuarine organisms. The biological environment is a complex community of plants and animals inhabiting the saltwater, estuarine (brackish water), and freshwater habitats within the Bay-Delta estuary.

Fishery sampling within the Bay-Delta estuary has shown that 55 fish species inhabit the estuary (Baxter et al., 1999), of which approximately one-half are non-native, introduced species. Many of the fish species inhabiting the estuary, such as striped bass and American shad, were purposefully introduced to provide recreational and commercial fishing opportunities. A number of the fish species have been introduced accidentally into the estuary through movement among connecting waterways (e.g., threadfin shad and inland silversides). In recent years, a number of fish and macroinvertebrate species have been accidentally introduced into the estuary, primarily from the Orient, through ballast water discharges from commercial cargo ships (e.g., yellowfin and chameleon gobies). In addition, an estimated 100 macroinvertebrates have also been introduced, primarily through ballast water discharge, into the estuary (Carlton, 1979). These introductions of non-native fish and macroinvertebrates have contributed to a substantial change in the species composition, predator/prey interactions, and competitive interactions affecting the population dynamics of native species. Many of the introduced fish and macroinvertebrates have colonized and inhabit the lower San Joaquin River and Delta.

In recent years, the bottom-dwelling fish community, including delta and longfin smelt and other species, has experienced a significant decline in abundance. State and federal resource agencies are currently evaluating various factors that could be contributing to the decline. Hypotheses include the effects of losses at water diversions, changes in Delta hydrology, the effects of pollutants on survival, and the effects of introduced species on the Delta food web. The importance of these factors in the decline in fish abundance has not been determined.

A variety of special-status fish species, several of which have been listed for protection under the Federal and/or California Endangered Species Acts, are present in the Delta and the San Joaquin and Tuolumne Rivers. Special-status fish species that occur in the lower San Joaquin River and Delta include steelhead, green sturgeon, delta smelt, Chinook salmon, Sacramento splittail, and longfin smelt. Several special-status species use the Delta as a migratory corridor. The winter-run Chinook salmon is federally and state-listed as endangered. The spring-run Chinook salmon is federally and state-listed as threatened. The fall/late-fall-run Central Valley Chinook salmon is a federal candidate species and California species of special concern. The Distinct Population Segment of Central Valley steelhead is federally listed as threatened. Fall/late-fall-run Central Valley Chinook salmon use the lower San Joaquin River as a migratory corridor and spawn in the Tuolumne River below La Grange Dam. The Evolutionarily Significant Unit of Central Valley steelhead may also spawn in the Tuolumne River in small numbers. In addition, delta smelt, a federally and state-listed threatened species, and Sacramento splittail, a California species of special concern and formerly a federal threatened species, have been documented within the lower San Joaquin River and Delta (USFWS, 2003). The NMFS recently listed green sturgeon as a threatened species. Although the distribution of green sturgeon in the lower San Joaquin River is poorly understood, the species is known to reside within the Delta.

The Pacific Fisheries Management Council has designated Central San Francisco Bay, Suisun Bay, and the Delta as Essential Fish Habitat (EFH) to protect and enhance habitat for coastal marine fish and macroinvertebrate species that support commercial fisheries. The major rivers tributary to the Delta, including the San Joaquin and Tuolumne Rivers, have also been identified as EFH for Pacific salmon. The amended Magnuson-Stevens Fishery Conservation and Management Act, also known as the Sustainable Fisheries Act (Public Law 104-297), requires all federal agencies to consult with the Secretary of Commerce on activities or proposed activities authorized, funded, or undertaken by that agency that may adversely affect EFH of commercially managed marine and anadromous fish species.

Potential Effects of Future Projects

San Joaquin River. As shown in Table 5.7-1, above, of the 11 potential future projects affecting the San Joaquin River directly, five are proposed primarily to improve environmental conditions in the river, including water quality and habitat quality. These projects that will benefit the river environment include the TMDL (total daily maximum load) programs being implemented by the Regional Water Quality Control Board, the San Luis Drainage Feature Re-evaluation Program (which will reduce agricultural drainage to the river), the San Joaquin River Restoration Settlement, and the Delta-Mendota Canal Recirculation Feasibility Study. Other projects propose to improve water supply benefits and reliability, but also generally incorporate measures to protect or enhance the river's environmental resources. The projects could contribute to both adverse and beneficial cumulative effects on the San Joaquin River. Overall, future projects affecting the San Joaquin River could result in both beneficial and potentially significant adverse effects on the river's water resources, supply, quality, and aquatic fishery resources.

Stanislaus River. Existing water supply diversions for agricultural, municipal and industrial use will continue. Continuation of the USBR's water releases in compliance with the Central Valley Project Improvement Act Section (b)(2) water requirements as well as continued implementation of the Vernalis Adaptive Management Program (VAMP) (through 2012 with possible renewal/extension), both of which are intended to improve habitat conditions for anadromous fish, would provide overall environmental benefit in the areas of hydrology, water quality, fisheries and, potentially visual resources as well. The USBR's proposal to revise its operation plan for the New Melones Reservoir could modify current reservoir release patterns and quantities with potential adverse effects. It is expected that mitigation would be required for any potentially significant effects.

Sacramento-San Joaquin Delta. Implementation of the regulatory water quality and flow objectives for the Delta limits the potential for future cumulative flow impacts and water quality effects in the Delta and related impacts on biological resources that could be associated with these physical effects. The USBR and DWR, through the Central Valley Project and State Water Project, respectively, remain largely responsible for meeting these Delta environmental standards through adjustments in their diversions and/or reservoir operations. In addition, as shown on Table 5.7-1, several proposed future projects target improvement of Delta environmental conditions, such as the Environmental Water Account, the South Delta Improvements Program – Phase I, the OCAP ESA Reconsultation, the CVPIA Water Acquisition Program, and the Bay-Delta Habitat Conservation Plan, among others. Several other projects have multiple-purpose objectives to increase water supply and/or improve supply reliability while also improving environmental conditions in the Delta, such as the Delta Cross Channel Reoperation and Through-Delta Facility, the Los Vaqueros Reservoir Expansion Project, or the Upstream of Delta Offstream Storage (Sites Reservoir). These two types of projects are intended to result in beneficial effects to the Delta environment. Other projects are primarily water supply and water reliability projects, including the Freeport Regional Water Project, Stockton Delta Water Project, and Sacramento River Water Reliability Study Project; these could result in some additional adverse impacts on the Delta, although mitigation has been or is expected to be imposed to address these impacts.

The potential cumulative effects on the Delta are strictly limited by existing regulations that have established both water quality and flow objectives for the Delta that must be met. These regulatory requirements are described in the setting discussions in Sections 5.3.1 and 5.3.3, above. In summary, the State Water Resources Control Board (SWRCB) established water quality objectives for the Delta in the 1995 Water Quality Control Plan; it also established flow objectives and adopted Water Rights Decision 1641 and subsequent orders to update and clarify responsibilities among water-rights holders for implementing the flow objectives. In D-1641 and Order WR 2001-05, the SWRCB assigned responsibilities to water-rights holders for specified periods, including the USBR and DWR, in certain watersheds tributary to the Delta. The SWRCB accepted with modifications the proposals made by some water agencies and groups of water agencies with respect to their responsibilities for meeting flow objectives in the Delta. The responsibilities of various parties, including water users in the Sacramento, San Joaquin, Mokelumne, Calaveras, and Cosumnes River watersheds, were defined in D-1641. These responsibilities require that the water users in these watersheds contribute specified amounts of water to protect water quality, and that the USBR and/or DWR ensure the objectives are met in the Delta.

As a result of existing regulations coupled with future projects intended to benefit the Delta environment, future cumulative effects on the Delta would be both beneficial and adverse.

Cumulative Effects and WSIP Contribution

Table 5.7-12 summarizes the effects of past and present projects, the impacts of the WSIP, the effects of probable future projects, and the combined impacts of the WSIP plus probable future projects on the San Joaquin River, Stanislaus River, and Delta. Past and present projects have substantially altered the hydrology, geomorphology, water quality, groundwater, fisheries, terrestrial biology, and visual and recreational resources of these water bodies compared to pre-Euro-American settlement conditions. The existing condition, which serves as the baseline for the analysis of the WSIP, reflects the substantial environmental changes that have occurred as a result of the past and present projects.

TABLE 5.7-12
CUMULATIVE EFFECTS ON THE SAN JOAQUIN RIVER, STANISLAUS RIVER, AND DELTA

Resource	Effects of Past and Present Projects	Impacts of WSIP (prior to mitigation/after mitigation)	Effects of Future Projects	Cumulative Impact(WSIP after mitigation + Future Projects)	WSIP Contribution Cumulatively Considerable?
Hydrology	SA	LS	B/PSM	B/PSM	No
Surface Water Quality	SA	LS	B/PSM	B/PSM	No
Water supply	MA	LS	B/PSM	B/PSM	No
Fisheries	SA	LS	B/PSM	B/PSM	No

B = Beneficial impact
LS = Less than Significant, no mitigation required
PSM/LS = Potentially Significant but reduced to Less than Significant with mitigation
SA = Substantially Altered
MA = Moderately Altered

As discussed in Section 5.3, the WSIP would result in less-than-significant impacts on the San Joaquin River, Stanislaus River, and/or Delta in the areas of hydrology, water quality, water supply, and fisheries. The WSIP would have no effect on these downstream water bodies in the areas of geomorphology, groundwater, terrestrial biology, recreation or visual resources.

As described in the previous section, probable future projects would have both beneficial effects and potentially significant effects on hydrology, surface water quality, water supply, and fisheries. Some future projects could contribute further to significant adverse effects on the San Joaquin River and downstream to the Delta. The WSIP would have a less-than-significant effects on the San Joaquin and Stanislaus Rivers and the Delta. As summarized below, the WSIP's contribution to adverse cumulative effects would be less than cumulatively considerable.

As discussed in Impact 5.3.1-5, the WSIP would reduce flows in the lower Tuolumne River and, in turn, downstream in the San Joaquin River and to the Delta primarily between February and June in wet or above-normal years, when flow in the San Joaquin is at its seasonal maximum. Very infrequently (observed once over the modeled 82-year period of hydrologic record), following a protracted drought, flow reductions in the San Joaquin River attributable to the WSIP would be sufficient to cause flow in the river at Vernalis to fall below the flow objective established for that location. This would, in turn, cause salinity levels to increase above the objective established for that location. However, as required by regulation, under these circumstances, the USBR would increase flow releases from New Melones Reservoir on the Stanislaus River (or, in the future, implement an alternate means of providing additional flows) to meet the Vernalis flow and salinity objectives. Thus, flow and water quality objectives would continue to be met under the WSIP.

Similarly, with respect to the Delta, in most years, the flow reduction attributable to the WSIP would not be sufficient to cause Delta outflow to fall below the regulatory objective. Only very infrequently (observed once over the modeled 82-year period of hydrologic record), following a protracted drought, would the reduction in flow due to the WSIP have the potential to result in Delta outflow below the objective. However, in accordance with SWRCB regulation, the USBR and DWR would be required to decrease diversions or otherwise adjust their operations to maintain the Delta outflow standards. Thus, with WSIP implementation, both the San Joaquin River flow and salinity objectives and the Delta outflow objectives would be met. Therefore, the WSIP's contribution to potential cumulative flow effects on the San Joaquin or in the Delta would be less than cumulatively considerable.

As discussed in Impact 5.3.4-1, the WSIP would have a less-than-significant effect on water availability and water quality affecting water use by other diverters on the Stanislaus River or San Joaquin River. Very infrequently, following a protracted drought, the USBR might be required to release additional flows from New Melones Reservoir (or implement an alternate means of augmenting flow) to maintain flow and water quality objectives at Vernalis and in the Delta, but this would not have a significant effect on water supply. No other new significant diversions from the Tuolumne or Stanislaus Rivers have been proposed that would result in additional cumulative effects on water supply availability for existing users. On the San Joaquin River, additional water supply diversions are being implemented such as the Stockton Delta Water Supply Project, and studies such as the Upper San Joaquin Storage Investigation are underway to evaluate the potential for expanding supply storage. As indicated in Table 5.7-1, other projects are proposed to improve supply availability for San Joaquin River users through revised water management and other actions.

As discussed in Impact 5.3.4-2, under most conditions the WSIP would have no effect on water supply availability from the Delta, and only on rare occasions would the WSIP reduce Delta inflow during excess conditions[3] but when the export limits do affect State Water Project and Central Valley Project pumping. Rather than reducing pumping for supply deliveries in that same year to compensate for the WSIP effects, the USBR and/or DWR could release additional water from storage to maintain flow objectives and pumping for deliveries; however, this would contribute to an increased risk to water delivery reliability in a subsequent year, if reservoir storage did not refill and thus compensate for the additional release. The WSIP's contribution to this increased risk to supply availability is small and less than cumulatively considerable; the potential Delta inflow difference caused by the WSIP would be typically 20,000 afy, a fraction (less than 0.001 percent) of the total average inflow of about 21 million acre-feet.

The cumulative effect of other past and present projects and regulatory actions has reduced supply availability for Delta water users, primarily for the State Water Project contractors and Central Valley Project contractors, as they represent the more junior water rights holders to Delta water. Some future projects would contribute to this cumulative effect as more senior water rights holders exercise their rights, and as area-of-origin water rights claims to the Delta and tributaries

[3] Excess conditions refers to conditions when Delta outflow exceeds the maximum flow required to comply with SWRCB flow and water quality objectives for the San Francisco Bay / Sacramento-San Joaquin Delta Estuary.

are pursued. At the same time, other future projects, such as the South Delta Improvement Project, the Environmental Water Account, the Los Vaqueros Reservoir Expansion Project, the Delta Cross Channel Reoperation, and the Delta-Mendota Canal / California Aqueduct Intertie, seek to improve water supply reliability for Delta water users. As shown in Table 5.7-12, the cumulative effects of potential future projects on Delta water supply availability reflect a mix of both potentially beneficial and significant, adverse impacts.

As discussed in Impact 5.3.6-5, with mitigation, the WSIP would have a less-than-significant effect on fishery resources along the San Joaquin River and a negligible effect downstream in the Delta. For the San Joaquin River and its tributaries, a relationship has been established between spring flow and the subsequent survival and contribution of adults to the salmon population (USFWS, 1994). A reduction in river flow during the spring rearing and juvenile emigration period would result in an incremental contribution to reduced juvenile survival and a small incremental contribution to the cumulative reduction in juvenile survival and subsequent adult population abundance. Increased water temperatures, particularly during the late spring juvenile salmonid migration period (April–May), would also be expected to adversely affect juvenile salmon survival. The WSIP could contribute to flow reductions that would result in corresponding temperature increases in some summer flows following a protracted drought; however, these infrequent temperature increases would not be expected to result in significant adverse effects on salmon or steelhead migrating downstream within the San Joaquin River, since the migration would occur earlier in the year and ambient water temperatures within the river might already be elevated (as a result of low flow drought conditions).

In the future, implementation of TID's Infiltration Gallery Project would contribute additional flows to a segment of the lower Tuolumne River, but these flows would be recaptured upstream of the confluence with the San Joaquin River. Under the FERC relicensing process for the Don Pedro Project, scheduled to occur in 2016, fishery release requirements for the lower Tuolumne River will be reviewed. It is speculative, at this time, to assess how these flow requirements might change.

5.7.3 Cumulative Effects on Alameda Creek Watershed Streams and Reservoirs

5.7.3.1 Relevant Projects

Past and Present Projects

A number of existing facilities under the jurisdiction of the SFPUC, the Alameda County Water District (ACWD), Zone 7 Water Agency, the Alameda County Flood Control and Water Conservation District (ACFCWCD), and the California Department of Water Resources (DWR), among others, affect environmental conditions in the Alameda Creek watershed upstream, adjacent to, and downstream of the proposed WSIP projects. Although built in the past, these existing facilities continue to operate and thus affect current conditions. The major facilities, shown in **Figure 5.7-3**, include:

- Calaveras Dam and Reservoir
- Turner Dam and San Antonio Reservoir
- Del Valle Reservoir/South Bay Aqueduct
- Alameda Creek Diversion Dam and Tunnel
- BART weir
- Sunol infiltration galleries (refer to description in Section 5.4.4)
- ACWD's upper, middle, and lower inflatable dams
- ACWD and Sunol groundwater wells
- Gravel mining operations and quarries
- ACFCWCD channelization projects

Calaveras Dam was constructed between 1913 and 1925, while Turner and Del Valle Dams were constructed in the late 1960s. Calaveras Reservoir was operated at its full 96,800-acre-foot capacity for over 75 years before being restricted to a capacity of 37,800 acre-feet in late 2001. The Sunol infiltration galleries and Sunol Dam were constructed in 1901. The other listed facilities were constructed between 1910 and the present. Use of the water supply facilities, with the exception of the infiltration galleries, has increased over the same time period to keep pace with water demand in the Bay Area. Through mid-2006, the SFPUC owned two smaller dams on Alameda Creek, Niles and Sunol Dams, which were removed in 2006. Groundwater pumping and extraction via near-surface wells and infiltration facilities has been ongoing for many decades in both the Sunol area and the Niles Cone area downstream of the SFPUC facilities. Lands within the CCSF-owned Alameda watershed are managed in accordance with the SFPUC's *Alameda Watershed Management Plan* (Alameda WMP), as described in Sections 4.2 and 5.2 of this PEIR.

As described in Section 5.4, the roughly 175-square-mile Alameda Creek watershed upstream of Calaveras, San Antonio, and Del Valle Reservoirs has remained mostly undeveloped. However, urbanization, quarrying, and other land use activities have altered major portions of the Alameda Creek watershed. About 400 square miles of the overall 625-square-mile Alameda Creek watershed drains into Arroyo de la Laguna to the north and east of the SFPUC lands. This area has been heavily urbanized, resulting in significantly increased peak flows and major inputs of urban pollutants. Similarly, the Bay Plain downstream of Niles Canyon has also experienced extensive urbanization.

Future Projects

Reasonably foreseeable future projects affecting stream flow or related resources in the Alameda Creek watershed are listed in **Table 5.7-13** and shown in Figure 5.7-3. Table 5.7-13 presents other SFPUC projects in the watershed; even though the SFPUC's Alameda WMP is currently being implemented, it is included in this list because it encompasses numerous future sub-projects and activities. The replacement of Calaveras Dam just downstream from the current dam (Calaveras Dam, SV-2) and the recapture facility (Alameda Creek Fishery, SV-1) are considered part of the WSIP and therefore are not included on the cumulative projects table. In addition to the listed projects, the SFPUC would conduct routine maintenance on its facilities in the Alameda watershed. Table 5.7-13 also presents non-SFPUC projects planned or proposed by other agencies or organizations.

Most of the projects on both tables are habitat or watershed enhancement projects or plans intended to reverse some of the degradation of watershed resources resulting from a century of urban development. The list includes over a dozen projects that are in various stages of planning and implementation by public agencies, citizens' groups, and quarry operators. These projects range from removing dams, weirs, culverts, pipelines, and screens that block fish passage to restoring and protecting habitat and fish flows. The SFPUC's projects identified in the table include the Alameda WMP and related activities and two WSIP-related activities, the Watershed and Environmental Improvement Program and the Habitat Reserve Program (both described in Chapter 3, Section 3.12).

Many of the non-SFPUC projects are part of Zone 7's Stream Management Master Plan for Alameda Creek and ACWD's Alameda Creek steelhead restoration program. The list also includes a major flood detention project (the Chain of Lakes project, part of Zone 7's Master Plan) in the Arroyo de la Laguna watershed, levee improvements, and two quarries. Table 5.7-13 includes summary descriptions of each project, the affected watershed or water body, and the potential cumulative impact areas that could be compounded due to identified impacts of the WSIP.

5.7.3.2 Cumulative Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to cumulative effects, but generally considers that implementation of the proposed program would have significant cumulative impacts if it were to:

- Have impacts that would be individually limited, but cumulatively considerable ("cumulatively considerable" means that the incremental effects of a project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects)

Impacts associated with the proposed program that would be "individually limited" are based on the impact analyses presented in Section 5.4 and the significance criteria presented in that section for the various environmental resource areas.

Approach to Analysis and Impact Summary

Cumulative impacts are analyzed based on the CEQA guidance and approach described above in Section 5.7.1. Cumulative impacts are discussed below, and impact significance determinations are summarized in **Table 5.7-14**.

TABLE 5.7-13
FUTURE PROJECTS IN THE ALAMEDA CREEK WATERSHED CONSIDERED IN THE CUMULATIVE ANALYSIS

Cumulative Project No.	Plan/Project Name	Jurisdiction	Project Description	Affected Watershed/ Water Body	Potential Cumulative Impact Areas	Status/Schedule
OTHER SFPUC PROJECTS						
AP-1	Alameda Watershed Management Plan (WMP)[a]	SFPUC	Provides a policy framework for the SFPUC to make consistent decisions about the activities, practices, and procedures that are appropriate on SFPUC watershed lands. Included in the plan are several management actions designed to implement the established goals and policies for water quality, water supply, and ecological enhancement.	CCSF-owned lands in Alameda Creek watershed	Beneficial impacts on terrestrial biological resources, fisheries, and surface water quality	Plan adopted in 2000, implementation ongoing
AP-1a	Alameda Watershed Habitat Conservation Plan (sub-project of Alameda WMP)[a]	SFPUC	Develop a comprehensive, multi-species habitat conservation plan for species of concern in the watershed, including steelhead.	Alameda Creek watershed – Alameda Creek, San Antonio Creek, Calaveras Creek, Arroyo Hondo, and Arroyo de la Laguna and tributary streams and reservoirs	Beneficial impacts on terrestrial biological resources and fisheries	Phase 2 – indicates implementation within 10 years of adoption of Alameda WMP
AP-2	Watershed and Environmental Improvement Program (WSIP-related activity)	SFPUC	Protect and restore lands and natural resources critical to operation of the SFPUC's regional water system. The program could include water quality, ecosystem and habitat protection, improvements, and restoration and would address such issues as fish passage, riparian habitat degradation, and sensitive species recovery.	CCSF-owned lands in Alameda Creek watershed	Beneficial impacts on terrestrial biological resources, fisheries, and surface water quality	Program funded but still under development; includes implementation of actions in the WMP
AP-3	Habitat Reserve Program (WSIP-related activity)	SFPUC	Develop and enhance wetlands and other habitats to be applied toward mitigation of impacts on biological resources resulting from implementation of the WSIP.	CCSF-owned lands in the Alameda and Peninsula watersheds; also includes locations in the San Joaquin Valley	Beneficial long-term impacts on terrestrial biological resources, and surface water quality, but short-term construction impacts; possible impacts on agricultural resources depending on the site	Program in development, with environmental review scheduled from 2007 to 2008 and implementation between 2008 and 2010

FUTURE PROJECTS IN THE ALAMEDA CREEK WATERSHED CONSIDERED IN THE CUMULATIVE ANALYSIS

Cumulative Project No.	Plan/Project Name	Jurisdiction and/or Project Sponsor	Project Description	Affected Watershed/ Water Body	Potential Cumulative Impact Areas	Status/Schedule
NON-SFPUC PROJECTS						
AC-1	Zone 7 Stream Management Master Plan (SMMP)[a]	Zone 7 Water Agency	Involves 45 individual projects with the primary purpose of providing flood protection within arroyos, creeks, and streams in the greater Alameda Creek watershed in partnership with local agencies, including the SFPUC. In addition to flood control, the projects strive to meet regional resource area goals and objectives to the extent possible. Only SMMP projects with the potential to contribute to cumulative impacts are addressed in this analysis.	Alameda Creek watershed – Alameda Creek, Arroyo de la Laguna, Arroyo Mocho, Arroyo del Valle, Arroyo Las Positas, Alamo Canal	Beneficial impacts on surface water quality, hydrology (regional flooding), terrestrial biological resources, and fisheries	Varies by project
AC-1a	Arroyo de la Laguna Reach 10 Improvements (sub-project of Zone 7 SMMP)[a]	Zone 7 Water Agency	Improvements along Reach 10 of Arroyo de la Laguna include bank stabilization and protection features, enhancement of stream corridor and riparian habitat, and removal of barriers to steelhead fish migration along creeks.	Arroyo de la Laguna	Beneficial impacts on hydrology (flood protection and drainage), erosion, surface water quality, and habitat	Estimated construction schedule is 2008–2010
AC-1b	Chain of Lakes (sub-project of Zone 7 SMMP)[a]	Zone 7 Water Agency	Provides 5,000 acre-feet of flood retention and storage in the Sunol-Niles area and the Livermore Valley.	Arroyo Las Positas, Arroyo Mocho	Beneficial impacts on hydrology (flood protection and drainage), water supply, and surface water quality	Began operation in 2005, with total project completed in 2030
AC-1c	Lower Arroyo del Valle Restoration and Enhancement (sub-project of Zone 7 SMMP)[a]	Zone 7 Water Agency	Remove three fish barriers, modify flap gates, and improve riparian vegetation.	Lower Arroyo del Valle	Beneficial impacts on hydrology (flood protection and drainage), fisheries, and habitat	Unknown
AC-2	Alameda Creek Steelhead Restoration[b]	Alameda County Water District (ACWD)	In 2005, ACWD received $1 million from the National Fish and Wildlife Foundation to initiate two projects that will improve steelhead migration in Alameda Creek. ACWD's two projects are part of a much larger effort by multiple agencies, including the SFPUC, to improve fish passage in the Alameda Creek watershed. In June 2007, ACWD began installing a fish screen as part of this effort.	Alameda Creek watershed – Alameda Creek Flood Control Channel	Beneficial impacts on fisheries	Unknown
AC-2a	Rubber Dam 2 Decommissioning and Foundation Modification Project (sub-project of Alameda Creek Steelhead Restoration)[b]	ACWD	Remove the fabric portion of the Rubber Dam 2 and a section of the dam's foundation to improve steelhead migration in Alameda Creek. Located in Fremont within the Alameda Creek Flood Control Channel adjacent to the Quarry Lakes Regional Recreational Area.	Alameda Creek	Beneficial impacts on fisheries	Mitigated Negative Declaration (MND) adopted June 2006 Estimated construction schedule: 2007–2009

TABLE 5.7-13 (Continued)
FUTURE PROJECTS IN THE ALAMEDA CREEK WATERSHED CONSIDERED IN THE CUMULATIVE ANALYSIS

Cumulative Project No.	Plan/Project Name	Jurisdiction and/or Project Sponsor	Project Description	Affected Watershed/ Water Body	Potential Cumulative Impact Areas	Status/Schedule
NON-SFPUC PROJECTS (cont.)						
AC-2b	Alameda Creek Pipeline No. 1 Fish Screen (sub-project of Alameda Creek Steelhead Restoration)[b]	ACWD	Install a diversion screen to eliminate the potential for out-migrating juvenile steelhead at the intake location of Alameda Creek Pipeline No. 1.	Alameda Creek	Beneficial impacts on fisheries	MND adopted June 2006 Estimated construction schedule 2007–2009
AC-2c	BART Weir (sub-project of Alameda Creek Steelhead Restoration Efforts)	Alameda County Flood Control and Water Conservation District (ACFCWCD)	Modify flood control drop structure (the BART weir) to allow for fish passage.	Alameda Creek	Beneficial impacts on fisheries	Feasibility study completed in 2006; project currently in preliminary design phase.
AC-2d	Middle Inflatable Dam Modification (sub-project of Alameda Creek Steelhead Restoration)[c]	ACWD	Modify middle inflatable dam (adjacent to BART weir) to allow for fish passage. Could result in taking inflatable dam out of commission (used for redundancy).	Alameda Creek	Beneficial impacts on fisheries	Unknown
AC-3	Alameda Creek – Levee Reconfiguration[j]	ACFCWCD	Reconfigure levee at mouth of Alameda Creek.	Arroyo Las Positas – Alameda Creek watershed	Beneficial impacts on habitat and flood control	Unknown
AC-4	PG&E Gas Line Crossing[e]	PG&E	Modify the cement-armored PG&E gas pipeline crossing of Alameda Creek in the Sunol Valley above the confluence with San Antonio Creek, which likely poses a barrier to fish migration at most water flows. This project involves modification of the concrete mat or construction of a fish ladder to allow fish passage.	Alameda Creek	Beneficial impacts on fisheries	Scheduled for completion by 2009
AC-5	Stonybrook Creek Culvert Removal[f]	Caltrans	Remove culvert and design/install new creek crossing (two county-owned culverts and one Caltrans culvert).	Alameda Creek	Beneficial impacts on fisheries	Unknown
AC-6	Upper Inflatable Dam Fish Passage Project[g]	Alameda Creek Alliance	Install pool and weir ladder in the right north channel.	Alameda Creek	Beneficial impacts on fisheries	Unknown

TABLE 5.7-13 (Continued)
FUTURE PROJECTS IN THE ALAMEDA CREEK WATERSHED CONSIDERED IN THE CUMULATIVE ANALYSIS

Cumulative Project No.	Plan/Project Name	Jurisdiction and/or Project Sponsor	Project Description	Affected Watershed/ Water Body	Potential Cumulative Impact Areas	Status/Schedule
NON-SFPUC PROJECTS (cont.)						
AC-7	Sunol Valley Aggregate Quarry – SMP 30[h]	Sunol Valley Aggregate Quarry	Continued mining under current permit in the near term, with planned expansion to increase mining depth. Project would restore portions of the Alameda Creek and San Antonio Creek banks and install a slurry cutoff wall.	Alameda and San Antonio Creeks	Would affect groundwater flow pattern. Installation of the slurry cutoff wall is expected to benefit creek flow hydrology by reducing seepage to the quarry pits; no adverse impacts on creek flows expected. Planned creek bank restoration would also benefit riparian habitat.	Near-term continuation of quarry operations; expansion of quarry and other activities in 2009–2011
AC-8	Section 1135 Alameda Creek Flood Control Project Fish Passage Modifications[j]	U.S. Army Corps of Engineers, ACFCWCD	Study concepts include potential fishways at BART weir and middle and upper ACWD inflatable dams, and four fish screens at Shinn Pond Diversion 1 and 2, Kaiser Pond Diversion, and Alameda Creek Pipeline Intake.	Alameda Creek, approximately 1.25 miles downstream of Niles Dam site and 4.75 miles downstream of Sunol Dam site	Beneficial impacts on fisheries	Project schedule unknown
AC-9	Apperson Ridge Quarry[i]	Oliver de Silva, Inc.	Surface mining permit for the operation of 680-acre hard rock quarry and associated manufacturing facilities located on the Apperson Ranch (a.k.a. Diamond A. Ranch) on Apperson Ridge in the Sunol area.	East of Sunol Valley, midway between Sunol Regional Wilderness and San Antonio Reservoir	EIR identified potential impacts on water quality due to increased erosion and sedimentation, detrimental impacts on wildlife habitat (i.e., San Antonio tule elk herd); and potential impacts on well yields in the Welch Creek area	EIR prepared in 1984; project approved by Alameda County in 1984; implementation schedule unknown

TABLE 5.7-14
SUMMARY OF CUMULATIVE IMPACTS IN THE ALAMEDA CREEK WATERSHED RELATED TO WSIP WATER SUPPLY AND SYSTEM OPERATIONS

	Significance Determination						
Impact	Hydrology	Geomorphology	Surface Water Quality	Groundwater	Fisheries	Terrestrial Biology	Recreational / Visual Quality
5.7.3-1: Cumulative effects on the Alameda Creek watershed	N/A	LS	LS	LS	LS	LS	LS

NOTE: Significance determinations presented in this table assume implementation of all mitigation measures presented in Chapter 5, Section 5.4, and described in Chapter 6.

LS = Less than Significant, no mitigation required
N/A = Not Applicable

Because impacts on stream flow and reservoir levels are related to effects on other environmental resources (see Section 5.1), the cumulative impacts in this section are organized by geographic area rather than by environmental topic in order to characterize the overall effects on the affected water body. In determining the significance of cumulative impacts, it is assumed that mitigation measures identified in Section 5.4 and described in Chapter 6 would be implemented, and any residual effects after mitigation are considered in combination with the effects of past, other current, and probable future projects. The incremental contribution of the program's residual effects to the overall cumulative impact is then examined to determine whether it would be "cumulatively considerable."

The WSIP would increase summer flow releases from Calaveras Reservoir, reduce rainy season flows in upper Alameda Creek below the diversion dam, and substantially raise the water level in Calaveras Reservoir compared to existing conditions. However, as described below, the proposed program, in combination with the cumulative projects identified in the tables above, would not have significant adverse environmental effects beyond the program effects already described for the WSIP in Section 5.4.

Alameda Creek Watershed

Impact 5.7.3-1: Cumulative effects on the Alameda Creek watershed.

Effect of Past and Present Projects

Hydrology. Construction and operation of the SFPUC regional water system and the State of California's Del Valle Reservoir have substantially altered the hydrology of the Alameda Creek watershed. Peak flows in the various upstream tributaries to Alameda Creek have been substantially reduced by reservoir operations.

Development has also greatly altered the Alameda Creek watershed. Major alterations include channelization of the lower 12 miles of the creek for flood control; construction of Turner, Calaveras, and Del Valle Dams for water supply; and construction of a concrete drop structure to stabilize the channel around the Fremont BART weir. As described above, the Arroyo de la Laguna watershed, which constitutes nearly two-thirds of the entire Alameda Creek watershed, has been extensively altered by urbanization and quarrying.

Since 1931, following construction of the Alameda Creek Diversion Dam and Tunnel, the SFPUC has diverted flows and drainage from the southern Alameda Creek watershed into Calaveras Reservoir for municipal water supply. For about 70 years, from 1931 to 2001, the SFPUC diverted substantial flows from Alameda Creek above the diversion dam to Calaveras Reservoir. However, as described in Section 5.4.1, the SFPUC reduced the diversions from Alameda Creek into Calaveras Reservoir in December 2001 due to interim California Division of Safety of Dams (DSOD) operational restrictions on Calaveras Reservoir. The SFPUC currently diverts a small percentage of the unimpaired flow of Alameda Creek above the diversion dam, as well as nearly all of the flow of Arroyo Hondo, to Calaveras Reservoir. The DWR also diverts a substantial portion of the flow from Arroyo del Valle. The water diverted from the Alameda Creek watershed is conveyed to the Bay Area and used for municipal water supply.

Flows to Alameda Creek from portions of the watershed upstream of Arroyo del Valle and from the Arroyo de la Laguna watershed have been affected by urban development and groundwater withdrawal, but are not diverted to any large dams/reservoirs. The lower reach of the creek is characterized by extensive urban development and has been channelized (rip-rapped) for floodwater conveyance.

In summary, past construction and continued operation of the regional water system have had a substantial adverse effect on the hydrology of portions of Alameda Creek, Arroyo Hondo, Calaveras Creek, and San Antonio Creek. These streams are managed for water supply and flood control and carry flows that are substantially reduced compared to historical conditions.

Geomorphology. Stream channels exist in a state of dynamic equilibrium with their watersheds. When conditions in the watershed change, the dynamic equilibrium is disturbed, and the river channel form will adjust to the new watershed condition. Water resources development, flood control structures, gravel mining, and urbanization have progressively changed conditions in the Alameda Creek watershed; only the headwater watersheds (above the dams) and Niles Canyon stream reaches retain any semblance of pre-Euro-American settlement conditions.

The SFPUC reservoirs served as catchments for sediments from the San Antonio and Arroyo Hondo/Calaveras Creek upper watersheds; however, these watersheds contribute a small percentage of the sediment supply to Alameda Creek. Extensive quarrying and urban development have also interrupted sediment flow to the creek. The recent removal of Niles and Sunol Dams in 2006 will allow for the release of small amounts of additional sediments to the lower portion of Alameda Creek over time. The ACFCWCD periodically removes accumulated sediments from the lower, channelized reach of Alameda Creek.

Surface Water Quality. Water quality in the headwater areas of Alameda Creek and its tributaries, above the water development facilities, has likely been minimally affected relative to natural conditions. However, urban development has introduced large quantities of urban runoff pollutants such as oil and grease, herbicides, and pesticides into Alameda Creek and its tributaries both north and east of the Sunol Valley (i.e., in the San Ramon and Livermore Valleys) and in the main stem of Alameda Creek downstream of SFPUC facilities. Increased runoff in the Arroyo de la Laguna watershed resulting from urbanization has also resulted in increased sediment generation. In addition, the diminution of flow in the creeks immediately downstream of the dams as a result of past and present projects causes water temperature and dissolved oxygen to rise more rapidly than under historical conditions. On occasion, the SFPUC also stores and mixes Tuolumne River water with local water in San Antonio Reservoir, and the State of California mixes South Bay Aqueduct water with local sources in Del Valle Reservoir, altering the water quality characteristics of the local watershed but not necessarily degrading water quality.

In summary, past construction and continued operation of the regional water system combined with urban development in the watershed have had a substantial adverse effect on water quality in Alameda Creek downstream of the SFPUC facilities.

Groundwater. As described in Section 5.4.4, primary groundwater resources in the Alameda Creek watershed are in the Livermore and Sunol Valleys, downstream of the major SFPUC facilities. Major groundwater withdrawal projects managed by the ACWD (in the Niles Cone) and Zone 7 Water Agency (in the Sunol and Arroyo de la Laguna groundwater basins) have been developed in the Pleasanton area, the Sunol Valley, and the Niles Cone. Groundwater withdrawal in these areas has lowered water tables and resulted in groundwater quality degradation. The ACWD and Zone 7 have implemented groundwater recharge projects in these areas to assist in restoring groundwater conditions.

Fisheries. Section 5.4.5 provides a detailed description of the existing condition of fishery resources in the Alameda Creek watershed, depicting the effects of past and present projects. Alameda Creek historically hosted a steelhead run, with spawning occurring in the upper reaches of the watershed. This steelhead run was eliminated over the past century by the placement of several obstructions to migration within the Alameda Creek channel. Major alterations to Alameda creek and its tributaries (including the channelization of the lower 12 miles of the creek for flood control; the construction of San Antonio, Calaveras, and Del Valle Reservoirs for water supply; and the construction of a concrete drop structure to stabilize the channel around the Fremont BART weir) have made spawning habitat within the watershed inaccessible for some returning anadromous fishes such as steelhead and Chinook salmon (Gunther et al., 2000). Construction and operation of dams, diversions, and other structures that function as fish migration barriers (e.g., the Sunol and Niles Dams and the grade control structure at the BART weir) have prevented anadromous fishes migrating into Alameda Creek and through Niles Canyon from reaching coldwater habitat farther upstream within the watershed (Gunther et al., 2000). The Sunol and Niles Dams were partially removed in September 2006, eliminating them as obstacles to fish passage. Despite the recent removal of these structures, steelhead can currently migrate upstream only as far as the BART weir.

The upper reach of Alameda Creek supports a reproductive population of resident rainbow trout. Arroyo Hondo, a tributary to Calaveras Creek upstream from Calaveras Reservoir, is known to contain self-sustaining populations of resident rainbow trout. Populations of resident rainbow trout have been reported above Calaveras Reservoir on several occasions since 1905, in Arroyo Hondo, Isabel Creek, and Smith Creek (Leidy, 1984; cited in ESA, 2005). Young-of-year trout have been observed in Stonybrook Creek and Sinbad Creek, tributaries to Alameda Creek (Gunther et al., 2000). There is some evidence that a native, locally adapted trout stock survives in the Alameda Creek watershed (Gunther et al., 2000).

Terrestrial Biology. Construction of the regional water system combined with urban development in the lower watershed has had a substantial adverse effect on terrestrial biological resources in the Alameda Creek watershed. The creation of reservoirs in the upper watershed of Alameda Creek and its major tributaries as part of the regional water system and other water systems resulted in the inundation of substantial areas of land. These areas were probably occupied by native grassland, chaparral and scrub, mixed evergreen forest, and riparian forest. However, development of the reservoirs has resulted in replacement of upland habitats with creation of riparian, wetlands and freshwater marsh habitat around the periphery of the reservoirs. The characteristics and extent of the wetlands and related habitats have varied historically due to changes in the operating levels of the reservoirs.

The lower watershed was historically occupied by grassland, oak woodland forest, and riparian forest. However, urban development, gravel mining, grazing, and flood control projects have affected much of the terrestrial biological resources of the lower watershed, except in Niles Canyon; at present, non-native grassland is the most common natural community on the SFPUC Alameda watershed. The current status of wildlife and natural communities is described in more detail in Section 5.4.6.

Recreational and Visual Quality. Changes in stream hydrology attributable to past and present projects have affected visual quality due to reduced flows in scenic areas of the watershed (i.e., Little Yosemite); in addition, water supply facilities, mining, flood control projects, and urbanization have changed the entire visual character of the lower reaches of Alameda Creek. Upstream of the dams on Alameda, Calaveras, and Del Valle Creeks, the watersheds retain much of their predevelopment visual character. The East Bay Regional Park District has enhanced recreational resources in the watershed by constructing trails and visitor facilities (including major park facilities at Del Valle Reservoir).

Potential Effects of Future Projects

The planned and reasonably foreseeable future projects in the watershed would have primarily beneficial effects on the environmental resources of the watershed. As described above, many of the proposed projects (shown as Projects AC-1, 1a, 1c, 2, 2a, 2b, 2c, 2d, 3, 4, 5, 6, and 8, and AP-1, 1a, 2, and 3 on Figure 5.7-3) would remove fish migration barriers from Alameda Creek and its major tributaries, enhance fish and riparian habitat, reduce sedimentation, and increase infiltration and retention of unnaturally high peak runoff resulting from urbanization. The proposed Chain of Lakes project (AC-1b) would provide recharge for Zone 7's Arroyo de la

Laguna groundwater basin and would both reduce peak flows and capture substantial quantities of sediments, thereby preventing their transport downstream. The Sunol Valley Aggregate Quarry project (AC-7) would continue current mining but would include a slurry cutoff wall that is expected to reduce seepage from Alameda and San Antonio Creeks to the quarry pits, thereby benefiting riparian habitats and fisheries. Project AC-9, the Apperson Ridge Quarry, would permit a hard-rock mine in the ridges in the upper end of the San Antonio Creek watershed. Depending on how this project is implemented, it could adversely affect water quality downstream, although implementation of conventional mitigation measures would likely mitigate water quality impacts to a less-than-significant level. Overall, the future cumulative projects would not substantially affect hydrology, geomorphology, water quality, groundwater, fisheries, riparian habitat, or visual quality/recreational resources.

Cumulative Effects and WSIP Contribution

Table 5.7-15 summarizes the effects of past and present projects, the impacts of the WSIP, the effects of probable future projects, and the combined impacts of the WSIP plus probable future projects on the Alameda Creek watershed. Past and present projects have substantially altered the hydrology, geomorphology, surface water quality, groundwater, fisheries, and terrestrial biology of this portion of the Alameda Creek watershed compared to pre-Euro-American settlement conditions. Visual and recreational resources have been moderately altered. The existing condition, which serves as the baseline for the analysis of the WSIP, reflects the substantial environmental changes that have occurred as a result of the past projects. Because past and present actions have drastically altered the Alameda Creek watershed, some of the environmental resources are more sensitive to small adverse changes than they would be if the watershed had remained relatively unaltered from pre-Euro-American settlement conditions.

TABLE 5.7-15
CUMULATIVE EFFECTS ON THE ALAMEDA CREEK WATERSHED

Resource	Effects of Past and Present Projects	Impacts of WSIP (prior to mitigation/ after mitigation)	Effects of Other Future Projects	Cumulative Impact (WSIP after mitigation + Future Projects)	WSIP Contribution Cumulatively Considerable?
Hydrology	SA	SU/SU[a]	N/A	N/A	No
Geomorphology	SA	LS	LS	LS	No
Surface Water Quality	SA	LS	LSM	LS	No
Groundwater	SA	LS	LS	LS	No
Fisheries	SA	PSM/LS[a]	B	LS	No
Terrestrial Biology	SA	PSM/LS[a]	B	LS	No
Recreational/Visual Quality	MA	LS	LS	LS	No

[a] Pertains to impacts on Alameda Creek downstream of the diversion dam. No other future project would add to this impact.

B = Beneficial impact
LS = Less than Significant, no mitigation required
LSM = Less than Significant with standard mitigation
PSM/LS = Potentially Significant impact, but reduced to Less than Significant with mitigation
SU = Significant, Unavoidable impact, even with implementation of mitigation measures
N/A = Not Applicable
SA = Substantially Altered
MA = Moderately Altered

As described in Section 5.4, the WSIP would have a less-than-significant adverse effect on geomorphology, surface water quality, and groundwater levels. However, because the proposed program would substantially reduce and alter flow patterns in Alameda Creek below the diversion dam, the WSIP itself could have significant adverse effects on hydrology, fisheries, and terrestrial biological resources in this stretch of the creek. With the exception of the hydrological impact in Alameda Creek below the diversion dam (and below the Calaveras Creek confluence), which would remain significant even with mitigation, the program impacts would be reduced to a less-than-significant level with implementation of mitigation measures described in Chapter 6 (Measures 5.4.5-3a, Minimum Flows for Resident Trout on Alameda Creek; 5.4.5-3b, Alameda Diversion Dam Restrictions or Fish Screens; 5.4.6-1, Compensation for Impacts on Terrestrial Biological Resources; and 5.4.6-3, Operational Procedures for Calaveras Dam Releases). As described above, most other foreseeable future projects are likely to have beneficial or less-than-significant impacts on geomorphology, surface water quality, groundwater levels and quality, fisheries, terrestrial biological resources, and recreational and visual resources in the Alameda Creek watershed.

The Apperson and Sunol quarry projects could create adverse water quality effects downstream in San Antonio Creek and Reservoir, but compliance with applicable water quality regulations coupled with implementation of conventional mitigation measures is expected to reduce these efforts to less than significant. Similarly, implementation of the physical components of many of the watershed and fish passage improvement projects could result in temporary increases in sedimentation and short-term water quality effects. Such short-term impacts are typically mitigated to a less-than-significant level by project-specific mitigation measures and best management practices. In the long term, these improvement projects, in combination with the WSIP fishery releases from Calaveras Reservoir, would result in beneficial cumulative effects on geomorphology, surface water quality, groundwater, fisheries, terrestrial biological resources, and recreational/visual resources and would likely offset any adverse effects from the proposed quarry projects.

Implementation of the WSIP would substantially reduce flows in the reach of Alameda Creek from the diversion dam to below its confluence with Calaveras Creek compared to existing conditions (Impact 5.4.1-2). This impact was determined to be significant and unavoidable, even with implementation of Measure 5.4.1-2 (Diversion Tunnel Operation) and bypass flows included as part of the protective measures in the Calaveras Dam Replacement project (SV-2). However, no other past, present, or future projects were identified that would further reduce the stream flow in this reach of Alameda Creek, and some of the projects listed in Table 5.7-13 could enhance the flow. Thus, there would be no adverse cumulative impact on hydrology associated with past, present, and future projects, and the WSIP's contribution to the cumulative impact on hydrology is not applicable.

Due to agreements and ongoing actions regarding the implementation of fish passage improvement projects in lower Alameda Creek (as described in Section 5.4.5 of the PEIR), it is possible that steelhead will be restored to the Alameda Creek watershed reaches upstream of the BART weir by 2030. More specifically, steelhead may be restored during construction or operation of the Calaveras Dam Replacement project (SV-2) under the WSIP. In response to this scenario, the SFPUC has modified the WSIP program description—mainly that of the Alameda Creek Fishery Enhancement (SV-1) and Calaveras Dam Replacement (SV-2) projects—to incorporate protective measures for steelhead in the event that man-made barriers in Alameda Creek have been successfully removed and that steelhead migration, spawning, and rearing have been restored in Alameda Creek above the BART weir. The protective measures incorporated into the operations of the Calaveras Dam Replacement project would address future-occurring steelhead and would provide for a range of minimum bypass flows and releases at the Alameda Creek Diversion Dam and Calaveras Dam to support steelhead migration, spawning, and rearing. The program as revised, and with implementation of mitigation measures identified in the PEIR, which together include minimum bypass flows to support the various life stages and habitat requirements for steelhead, would have a less-than-significant contribution to cumulative impacts on fishery resources in the Alameda Creek watershed. Please refer to Chapter 14, Section 14.9, of the PEIR for further discussion.

In summary, when the WSIP and future projects are considered together, none of their cumulative effects would rise to a level of significance. Even though past and present projects have moderately to substantially altered the environmental resources along this reach of Alameda Creek, the cumulative impacts of the WSIP after mitigation combined with the effects of future projects would not result in a substantial or noticeable change from the existing condition.

As stated previously, the WSIP's impacts on fisheries, terrestrial biology, and recreational/visual resources would be substantially reduced with implementation of Measures 5.4.5-3a, 5.4.5-3b, 5.4.6-1, and 5.4.6-3. Since the implementation of future projects would be expected to be beneficial to fisheries, terrestrial biology, and recreational/visual resources, the combined cumulative impacts on these resources with the WSIP after mitigation would be considered less than significant. Because there are no significant cumulative impacts, no mitigation measures beyond Measures 5.4.1-2, 5.4.5-3a, 5.4.5-3b, 5.4.6-1, and 5.4.6-3 would be necessary.

5.7.4 Cumulative Effects on San Francisco Peninsula Streams and Reservoirs

5.7.4.1 Relevant Projects

Past and present projects have affected streams, stream flow, and related environmental resources on the San Francisco Peninsula. The WSIP and other foreseeable future projects could also affect streams, stream flow, and related environmental resources. Foreseeable future projects, other than facility improvement projects included in the WSIP, are listed in **Table 5.7-16** and shown in **Figure 5.7-4**. They include both SFPUC and non-SFPUC projects.

San Mateo Creek Watershed

Past and Present Projects

Components of the SFPUC regional water system have substantially affected environmental quality in the San Mateo Creek watershed (shown in Section 5.5, Figure 5.5.1-1). Although built in the past, these components continue to operate and thus affect current conditions. These and other past projects and activities that affect the San Mateo Creek watershed include:

- San Andreas Reservoir
- Crystal Springs Reservoir
- Creek modifications in the lower watershed
- Urban development in the lower watershed
- Jefferson Martin Transmission Line

San Andreas Dam impounds San Andreas Reservoir and was built in 1870. Upper and Lower Crystal Springs Dams were built in 1877 and 1890 and together impound Crystal Springs Reservoir. The dams were built by the Spring Valley Water Company and later purchased by the CCSF. Various improvements to the reservoirs and associated conveyance and water treatment facilities have been made to accommodate increased demand for water and more stringent drinking water standards.

Land use in the San Mateo Creek watershed (which drains to San Andreas and Crystal Springs Reservoirs) has not changed much from conditions that existed prior to Euro-American settlement. The CCSF owns most of the land that drains to the two reservoirs; this land is almost

TABLE 5.7-16
FUTURE PROJECTS IN THE PENINSULA WATERSHED CONSIDERED IN THE CUMULATIVE ANALYSIS

San Mateo Creek	Potential impact on hydrology (flood control) and biological resources	Needs funding

[a] SFPUC, *Peninsula Watershed Management Plan*, 2001.
[b] San Mateo Resource Conservation District, Personal telephone communication between Kelly Nelson, of San Mateo Resource Conservation District, and Kelly White, of ESA. November 22, 2006.

entirely undeveloped and public access is very limited. The CCSF's watershed lands in the San Mateo Creek watershed are managed in accordance with the *Peninsula Watershed Management Plan* (Peninsula WMP), as described in Sections 4.2 and 5.2 of this PEIR. In 2006, Pacific Gas and Electric Company constructed an electrical power transmission line, the Jefferson Martin Transmission Line, along the eastern side of Crystal Springs Reservoir.

In the last 150 years, land use in the portion of the creek's watershed below Lower Crystal Springs Dam has been almost completely converted to urban uses. With the exception of a two-mile-long reach immediately below the dam, the San Mateo Creek channel has been progressively modified over many years to accommodate urban runoff and prevent flooding of lands adjacent to the creek. In the last five years, the City of San Mateo and Caltrans have completed several projects that enable the creek to convey the 100-year flood flows[4] without damage. These projects include the construction of two sections of floodwall near the Highway 101 crossing and replacement of the culverts at Norfolk Street and Highway 101 (Chan, 2006).

Future Projects

Reasonably foreseeable future projects by the SFPUC or others that could affect stream flow or related resources in the San Mateo Creek watershed are shown in Table 5.7-16. They include the Peninsula Watershed Habitat Conservation Plan, the Watershed and Environmental Improvement Program, and the Habitat Reserve Program. The SFPUC is preparing the habitat conservation plan for the watershed lands on the Peninsula, pursuant to the Federal Endangered Species Act. It will specify the actions necessary to protect listed species that are present within Peninsula watershed lands. Even though the Peninsula WMP is currently being implemented, it is included in the list of future SFPUC projects because it encompasses future sub-projects and activities. In addition, the SFPUC would conduct routine maintenance on its facilities in the Peninsula watershed.

One future project by another agency has been identified that would affect the upper San Mateo Creek watershed. San Mateo County plans to reconstruct the roadway that crosses Crystal Springs Dam. In the lower San Mateo Creek watershed, one project has been identified—the City of San Mateo's proposed project to raise the levees near the mouth of the creek (Chan, 2006). This flood control project would be designed to meet the requirements of the Federal Emergency Management Agency, but funding for the project has yet to be obtained, and the construction schedule for the project is unknown. Implementation of the CS/SA Transmission (PN-2), Lower Crystal Springs Dam (PN-4), and Pulgas Balancing Reservoir (PN-5) projects are considered part of the WSIP and are therefore not included in the list of cumulative projects.

Pilarcitos Creek Watershed

Past and Present Projects

Components of the SFPUC regional water system have substantially affected environmental quality in the Pilarcitos Creek corridor. Although built in the past, these components continue to

Future Projects in the Peninsula Watershed Considered in the Cumulative Analysis

THIS PAGE INTENTIONALLY LEFT BLANK

operate and thus affect current conditions. These and other projects and activities that affect Pilarcitos Creek include:

- Pilarcitos Reservoir
- Stone Dam
- Pilarcitos wells
- Highway 92
- Urban and agricultural development in the lower watershed

The Spring Valley Water Company built Pilarcitos Reservoir and Stone Dam in 1864 and 1871, respectively. They were subsequently purchased by the CCSF. The SFPUC uses Pilarcitos Reservoir to store and divert water from the Pilarcitos Creek watershed to the San Mateo Creek watershed. Stone Dam is used to divert water to the San Mateo Creek watershed and to the Coastside County Water District (Coastside CWD).

Land use in the Pilarcitos Creek watershed draining to Pilarcitos Reservoir and above Stone Dam has not changed much from conditions that existed prior to Euro-American settlement. The CCSF owns most of the Pilarcitos Creek watershed lands; these lands are undeveloped, and public access is very limited. The CCSF's lands in the Pilarcitos Creek watershed are managed in accordance with the Peninsula WMP, as described in Sections 4.2 and 5.2 of this PEIR.

Most land in the Pilarcitos Creek watershed downstream of Pilarcitos Reservoir remains undeveloped, but some floodplain lands near Half Moon Bay are used for agriculture, and portions of the watershed near the creek's mouth are used for urban purposes. Pilarcitos Creek itself has been adversely affected by the construction and improvement of Highway 92, which parallels about five miles of the creek, and by adjacent urban and agricultural development. A recent Caltrans project restored fish passage at two locations along the Highway 92 alignment. The Coastside CWD obtains some of its water supply from wells in the Pilarcitos Creek corridor.

Future Projects

Reasonably foreseeable future projects by the SFPUC or others that could affect stream flow or related resources in the Pilarcitos Creek watershed are shown in Table 5.7-16. They include the Peninsula Watershed Habitat Conservation Plan, the Watershed and Environmental Improvement Program, the Habitat Reserve Program, and the Peninsula WMP.

As shown in Table 5.7-16, several agencies in addition to the SFPUC have expressed interest in improving Pilarcitos Creek and its migratory fishery. The San Francisco Bay Regional Water Quality Control Board and CDFG commissioned a creek restoration plan in 1996 (Phillip Williams and Associates, 1996). The San Mateo Resource Conservation District is also preparing an integrated watershed plan for the Pilarcitos Creek watershed (Nelson, 2006).

Coastside CWD has evaluated the possibility of installing more wells in the Pilarcitos Creek corridor. Although the installation of additional wells was shown to be technically and economically feasible, Coastside CWD is not currently planning to move forward with the project (Schmidt, 2006).

5.7.4.2 Cumulative Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to cumulative effects, but generally considers that implementation of the proposed program would have significant cumulative impacts if it were to:

- Have impacts that would be individually limited, but cumulatively considerable ("cumulatively considerable" means that the incremental effects of a project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects)

Impacts associated with the proposed program that would be "individually limited" are based on the impact analyses presented in Section 5.5 and the significance criteria presented in that section for the various environmental resource areas.

Approach to Analysis and Impact Summary

Cumulative impacts are analyzed based on the CEQA guidance and approach described above in Section 5.7.1. Cumulative impacts are discussed below, and impact significance determinations are summarized in **Table 5.7-17**.

TABLE 5.7-17
SUMMARY OF CUMULATIVE IMPACTS IN THE PENINSULA WATERSHED RELATED TO WSIP WATER SUPPLY AND SYSTEM OPERATIONS

	Significance Determination						
Impact	Hydrology	Geomorphology	Surface Water Quality	Groundwater	Fisheries	Terrestrial Biology	Recreation / Visual Quality
5.7.4-1: Cumulative effects on the San Mateo Creek watershed	LS	LS	LS	LS	LS	LS	LS
5.7.4-2: Cumulative effects on the Pilarcitos Creek watershed	LS	LS	LS	LS	LS	LS	LS

NOTE: Significance determinations presented in this table assume implementation of all mitigation measures as they are presented in Chapter 5, Section 5.5, and described in Chapter 6.

LS = Less than Significant, no mitigation required

Because impacts on stream flow and reservoir levels are related to effects on other environmental resources (see Section 5.1), the cumulative impacts in this section are organized by geographic area (i.e., San Mateo Creek watershed and Pilarcitos Creek watershed) rather than by environmental topic in order to characterize the overall effects on the affected water body. In determining the significance of cumulative impacts, it is assumed that mitigation measures identified in Section 5.5 and described in Chapter 6 would be implemented, and any residual effects after mitigation are considered in combination with the effects of past, other current, and probable future projects. The incremental contribution of the program's residual effects to the overall cumulative impact is then examined to determine whether it would be "cumulatively considerable."

San Mateo Creek Watershed

Impact 5.7.4-1: Cumulative effects on the San Mateo Creek watershed.

Effect of Past and Present Projects

Hydrology. Components of the SFPUC regional water system in the San Mateo Creek watershed, including construction and operation of dams and reservoirs, have substantially altered the hydrology of San Mateo Creek. Construction of Lower Crystal Springs Dam separated the lower reaches of San Mateo Creek from about 80 percent of its tributary watershed in all but the wettest months of wet years. Under pre-Euro-American settlement conditions, some flow from the upper watershed probably reached the lower reaches in all but the driest months of the driest years. Under current conditions, releases from Lower Crystal Springs Dam occur only in the wettest months of wet years. The average annual release of water from the upper watershed to the lower reaches of San Mateo Creek is about one-tenth of the discharge that would occur if Crystal Springs and San Andreas Reservoirs did not exist.

Most of the time, flow into the reach of San Mateo Creek below Lower Crystal Springs Dam consists of seepage around the dam, infiltration from groundwater and, during and after storms, surface water runoff. Urban development in the watershed of the lower creek has probably increased the volume and speed of runoff into the creek compared to historical conditions. The replacement of vegetation and permeable soils with impermeable roofs, roads, and parking lots increases the volume of runoff in a given storm, and the replacement of natural tributary drainage channels with underground storm sewers reduces the time stormwater runoff takes to get to the mainstream channel.

In summary, past construction and continued operation of the regional water system combined with urban development in the lower watershed has had a substantial adverse effect on the hydrology of San Mateo Creek. Creek flow has been substantially reduced from historical conditions, and the creek's flow regime is managed for water supply in the upper watershed and for flood control and storm drainage purposes in the lower watershed.

Geomorphology. Crystal Springs and San Andreas Reservoirs and their associated diversions have substantially altered the magnitude, duration, and frequency of flood flows, which are the predominant influence on channel form. Currently, the 100-year return-period flow in San Mateo Creek immediately below Lower Crystal Springs Dam is estimated to be 1,320 cfs and would consist of a release from the dam and uncontrolled flow over the spillway. Under undeveloped conditions, it is estimated that the 100-year return-period flow in the creek was between 4,000 and 5,000 cfs. For more than 100 years, lower San Mateo Creek has been adjusting its channel form in response to the flow regime created by the regional water system and the lack of bedload transport from the upper watershed.

Channel adjustment in response to the altered flow regime is primarily occurring in the first two miles of San Mateo Creek below Lower Crystal Springs Dam. The channel in this reach of creek retains it natural form, much of it lying within a canyon. Below this reach, the creek channel has been modified to accommodate and accelerate the downstream movement of flood flows to San Francisco Bay. The creek consists of an earthen channel, with concrete floodwalls in places, and two long culverts under El Camino Real and Highway 101.

In summary, past construction and continued operation of the regional water system and channel modification to reduce flood hazards has had a substantial adverse effect on the geomorphology of San Mateo Creek. Channel-forming peak flows in the creek are substantially smaller than under historical conditions, the reservoirs prevent the downstream movement of bedload, and the lower reaches of the creek are confined within a flood control channel.

Surface Water Quality. The creation of reservoirs in the upper watershed as part of the regional water system and the blending of local and Tuolumne River water in the reservoirs have altered the chemical characteristics of water in the upper San Mateo Creek watershed. Although the water has been altered from its historical character, water quality in the upper watershed remains very good and is sufficient to support all designated beneficial uses.

Water quality in the lower reaches of San Mateo Creek has been adversely affected by the hydrologic changes attributable to the regional water system. Most of the time under the existing condition, flow in the creek below Lower Crystal Springs Dam is limited to seepage around the dam. Water quality in the creek below the dam site was undoubtedly better under historical conditions, since at least some flow reached the lower creek from the upper watershed in all but the driest months of the driest years. When no water reaches the creek from its upper watershed, detention time in the creek becomes extended and water is confined in pools, which causes water temperature to rise and dissolved oxygen levels to decline.

Water quality in the lower reaches of the creek has also been adversely affected by the discharge of urban runoff into the creek. Rainfall on roofs, streets, and parking lots washes accumulated debris and chemicals into the city storm sewers, which drain to San Mateo Creek. Water in urban creeks, such as the lower reaches of San Mateo Creek, typically contains higher levels of metals, plant nutrients, and pesticides than creeks in undeveloped areas.

In summary, past construction and continued operation of the regional water system combined with urban development in the lower watershed has had a substantial adverse effect on water quality in lower San Mateo Creek. Creek flow has been substantially reduced from historical conditions; this reduced flow coupled with the discharge of polluted urban runoff into the creek has caused water quality to deteriorate.

Groundwater. The creation of reservoirs in the upper watershed as part of the regional water system has raised groundwater levels in the vicinity of the reservoirs. Urban development overlies much of the lower San Mateo Creek watershed. Groundwater quality has probably declined relative to historical conditions because chemicals associated with residential, commercial, and industrial activities have percolated into the shallow groundwater basin.

Fisheries. San Mateo Creek historically supported resident rainbow trout populations. Small numbers of anadromous steelhead may have used the creek downstream of Lower Crystal Springs Dam for spawning and juvenile rearing habitat. The construction of reservoirs between 1860 and 1890 inundated instream fish habitat, created a complete barrier to fish migration, and excluded steelhead from the upper watershed. The reduction in flow in lower San Mateo Creek as a result of the regional water system has reduced the extent and quality of habitat for resident trout and steelhead in the canyon below Lower Crystal Springs Dam.

Downstream of the canyon, channel modifications designed to reduce flood hazards have introduced barriers to fish migration. Channel modifications and the discharge of contaminants in urban runoff have greatly reduced the quality of instream habitat.

In summary, past construction and continued operation of the regional water system combined with urban development in the lower watershed has had a substantial adverse effect on fish habitat in San Mateo Creek. The current extent and quality of fish habitat is reduced relative to historical conditions.

Terrestrial Biology. Construction of the regional water system combined with urban development in the lower watershed has had a substantial adverse effect on terrestrial biological resources in the San Mateo Creek watershed. The creation of reservoirs in the upper watershed of San Mateo Creek as part of the regional water system inundated about 2.5 square miles of land, which was probably occupied by native grassland, chaparral and scrub, mixed evergreen forest, and riparian forest. The lower watershed was occupied grassland, mixed evergreen forest, and riparian forest and, close to San Francisco Bay, tidal salt marsh. Urban development has destroyed most of the terrestrial biological resources of the lower watershed, except in the canyon immediately downstream of Lower Crystal Springs Dam. However, development of the reservoirs has resulted in the replacement of upland habitats with riparian, wetland, and freshwater marsh habitat around the periphery of the reservoir. The characteristics and extent of the wetlands and related habitats have varied historically due to the changes in operating levels of Crystal Springs Reservoir.

Recreation and Visual Quality. Construction of regional water system components combined with urban development in the lower watershed has had a substantial effect on visual quality in the San Mateo Creek watershed. When the components of the regional water supply system were built, parts of the natural landscape in the upper San Mateo Creek watershed were inundated to form artificial lakes. A muddy, vegetation-free zone extending around the perimeter of the lakes is inundated at times and becomes visible when the reservoir is drawn down. These artificial lakes have a different scenic value than the natural grassland and forest they replaced. Similarly, the grassland, riparian forest, and wetlands of the lower San Mateo Creek watershed have been largely converted to an urban landscape, which has less scenic value than the natural landscape it replaced.

Potential Effects of Future Projects

The SFPUC's Peninsula Watershed Habitat Conservation Plan, Watershed and Environmental Improvement Program, Habitat Reserve Program, and Peninsula WMP would have beneficial impacts on the biological resources in the upper San Mateo Creek watershed. The only other identified future project that could adversely affect the upper San Mateo Creek watershed is San Mateo County's planned reconstruction of the roadway on Lower Crystal Springs Dam. It is expected that mitigation measures implemented during construction of the project would avoid significant impacts to environmental resources. Ongoing repair and maintenance activities for the SFPUC's water supply facilities will be necessary in the future, but these activities would be conducted consistent with management guidelines in the Peninsula WMP as well as in compliance with environmental regulations and the recently adopted Water Enterprise Environmental Stewardship Policy (SFPUC, 2006). Consequently, future projects would not be expected to have a significant adverse effect on hydrology, geomorphology, surface water quality, groundwater levels and quality, fisheries, terrestrial biological resources, or recreation and visual resources in the upper San Mateo Creek watershed.

Urban development and redevelopment is likely to continue in the lower San Mateo Creek watershed in accordance with city and county general plans. The creek channel may be further modified to reduce flooding in the future. One future flood control project has been identified. Although current regulations limit the environmental impacts of flood reduction projects and urban development/redevelopment compared to levels permitted in the past, some minor incremental impacts are likely to result from the increasingly dense urban environment and a more confined creek.

Cumulative Effects and WSIP Contribution

Table 5.7-18 summarizes the effects of past and present projects, the impacts of the WSIP, the effects of probable future projects, and the combined impacts of the WSIP plus probable future projects on the San Mateo Creek watershed. Past and present projects have substantially altered the hydrology, geomorphology, surface water quality, groundwater, fisheries, and terrestrial biology of the watershed compared to pre-Euro-American settlement conditions. Visual and recreational resources have been moderately altered. The existing condition, which serves as the baseline for the analysis of the WSIP, reflects the substantial environmental changes that have occurred as a result of the past projects. Because past and present actions have altered the watershed, some of the watershed's environmental resources are more sensitive to small adverse changes than they would be if the reach had remained relatively unaltered from pre-Euro-American settlement conditions.

As described in Section 5.5, the WSIP would have a less-than-significant adverse impact on hydrology, geomorphology, surface water quality, groundwater, and recreational and visual resources. It would have a less-than-significant impact on terrestrial biological resources after mitigation (Measures 5.5.6-1a, Adaptive Management of Freshwater March and Wetlands at Upper and Lower Crystal Springs Reservoirs; 5.5.6-1b, Compensation for Impacts on Terrestrial Biological Resources; and 5.5.6-1c, Compensation for Serpentine Seep-Related Special-Status Plants). Most aspects of the WSIP would have less than significant effects on fisheries in

TABLE 5.7-18
CUMULATIVE EFFECTS ON THE SAN MATEO CREEK WATERSHED

Resource	Effects of Past and Present Projects	Impacts of WSIP (prior to mitigation/after mitigation)	Effects of Future Projects	Cumulative Impacts of WSIP (after mitigation) + Future Projects	WSIP Contribution Cumulatively Considerable?
Hydrology	SA	LS	LS	LS	No
Geomorphology	SA	LS	LS	LS	No
Surface Water Quality	SA	LS	LS	LS	No
Groundwater	SA	LS	LS	LS	No
Fisheries	SA	PSU[a]/unknown	LS	B/LS	No
Terrestrial Biology	SA	PSM/LS	B	LS	No
Recreation/Visual Quality	MA	LS	LS	LS	No

[a] Pertains to potential inundation of trout spawning habitat in tributaries to Crystal Springs Reservoir. No other future project would add to this impact.

B = Beneficial impact
LS = Less than Significant, no mitigation required
PSM/LS = Potentially Significant but reduced to Less-than-Significant with mitigation
PSU = Potentially Significant and Unavoidable
SA = Substantially Altered
MA = Moderately Altered

the San Mateo Creek watershed except one. Increasing the water level in Crystal Springs Reservoir would inundate trout spawning habitat in segments of two creeks tributary to the reservoir. It is expected that mitigation to provide compensatory replacement habitat will be feasible, but until site-specific evaluation of this measure is completed (as part of the project-level CEQA review now in progress for the Lower Crystal Springs Replacement Project, PN-4), this impact is considered potentially significant and unavoidable. No other future project would add to this impact, thus, there is no cumulative impact. As described in the previous section, probable future projects would have overall beneficial effects and possibly some less-than-significant impacts associated with specific projects on hydrology, geomorphology, surface water quality, groundwater, fisheries, terrestrial biological resources, and recreational and visual resources.

When the WSIP and foreseeable future projects are considered together, none of their cumulative effects would rise to a level of significance. Even though past and present projects have moderately to substantially altered the environmental resources along San Mateo Creek, the cumulative impacts of the WSIP after mitigation combined with the effects of future projects would not result in a substantial or noticeable change from the existing/historical condition. Because there are no significant cumulative impacts, no mitigation measures beyond Measures 5.5.6-1a, 5.5.6-1b, and 5.5.6-1c would be necessary.

Pilarcitos Creek Watershed

Impact 5.7.4-2: Cumulative effects on the Pilarcitos Creek watershed.

Effect of Past and Present Projects

Hydrology. Construction and operation of SFPUC regional water system components have substantially altered the hydrology of Pilarcitos Creek. The construction of Pilarcitos Reservoir and Stone Dam effectively reduced the size of the Pilarcitos Creek watershed by about 25 percent. Runoff from the 25 percent of the watershed above Stone Dam is diverted to the San Mateo Creek watershed and to Coastside CWD rather than flowing down Pilarcitos Creek to the Pacific Ocean.

Prior to construction of Pilarcitos Reservoir and its associated diversion, flow in the reach of Pilarcitos Creek between the reservoir and the future Stone Dam site was likely considerable in the rainy months. Flow probably declined through the summer and may have dried up completely at times. Currently, the reservoir and diversion reduce flow in the rainy months relative to historical conditions. Releases from the reservoir through the summer to supply water to Coastside CWD probably increase flow relative to unimpaired conditions.

Prior to construction of Stone Dam, flow in the reach of Pilarcitos Creek below the dam site was likely considerable in the rainy season and minimal in the dry summer months. Most of the time and under the existing condition, flow in the creek immediately below Stone Dam consists only of leakage and seepage around the dam. The creek gains flow from tributaries beginning a few hundred yards below the dam. In wet months of wet years, water occasionally spills over Stone Dam to Pilarcitos Creek and flows to the Pacifica Ocean.

Flow in Pilarcitos Creek has also been affected by the installation of wells in the downstream end of the creek corridor. Creeks in rocky terrain often flow over beds of sand and gravel that have been deposited by the creek over time. The deposits of sand and gravel are saturated with water and are hydraulically connected to the overlying stream. The groundwater flowing in these deposits is referred to as underflow. Coastside CWD operates several wells close to the lower reaches of Pilarcitos Creek that pump water from the underflow. Because surface flow in the creek and underflow are hydraulically connected, operation of the wells has the potential to reduce stream flow.

Coastside CWD obtains an average of 53 million gallons per year, 3 percent of its water supply, from its wells adjacent to Pilarcitos Creek. Operation of the wells is only permitted between November and March, when creek flow is at its seasonal maximum, and the total extraction volume is limited to 117 million gallons per year (Coastside CWD, 2006). Average annual flow in Pilarcitos Creek is 3.7 billion gallons per year (USGS, 2006). Because of the small quantities involved and the prohibition on pumping in the low-flow months, the wells have a minimal effect on the hydrology of Pilarcitos Creek.

Geomorphology. As noted above, peak or flood flows are the predominant influence on channel geomorphology. Pilarcitos Reservoir and Stone Dam and their associated diversions have substantially altered the magnitude, duration, and frequency of flood flows in the reaches of the creek downstream of these structures. Peak flows in Pilarcitos Creek between Pilarcitos Reservoir and Stone Dam have been substantially reduced. Peak flows in Pilarcitos Creek immediately below Stone Dam have also been substantially reduced, but the effects diminish in a downstream direction as tributaries add flow to the main stem of the creek.

In addition to reducing peak flows, Pilarcitos and Stone Dams also prevent the downstream movement of sediment. For more than 100 years, Pilarcitos Creek has been adjusting its channel form in response to the flow regime created by the regional water system and the lack of bedload transport from the upper watershed.

Surface Water Quality. Pilarcitos Reservoir and Stone Dam and their associated diversions have affected the flow regime in Pilarcitos Creek, which has in turn affected water quality. Reductions in stream flow typically result in increased water temperature. Storage in reservoirs increases water temperature in the upper portion of the water column and preserves a pool of cool water in the summer. Storage may also reduce dissolved oxygen concentrations, particularly near the bottom of reservoirs. Although it has been altered from its historical character, water quality in the Pilarcitos Creek watershed remains good and is sufficient to support all designated beneficial uses. Some deterioration in water quality has probably occurred in the farthest downstream reaches of the creek due to runoff from agricultural fields and urban areas.

Groundwater. The creation of reservoirs in the upper watershed as part of the regional water system has raised groundwater levels in the vicinity of the reservoirs. Urban development and agricultural fields overlie the farthest downstream reaches of the Pilarcitos Creek watershed. Groundwater quality has probably declined in this area relative to historical conditions because chemicals associated with residential and agricultural activities have percolated into the shallow groundwater basin.

Fisheries. Construction of Pilarcitos Reservoir in 1864 inundated instream fish habitat in the upper reaches of Pilarcitos Creek, and construction of Stone Dam in 1871 created a complete barrier to fish migration into the upper watershed. With Stone Dam in place, anadromous salmonids were excluded from the upper reaches of the creek, which led to the development of two separate fish populations: resident trout in the creek above Stone Dam and anadromous salmonids below the dam. The current summertime releases from Pilarcitos Reservoir to Pilarcitos Creek to supply water to Coastside CWD probably increase flow relative to unimpaired conditions and thus may benefit resident trout in the reach of the creek between Pilarcitos Reservoir and Stone Dam.

The reduction in flow in Pilarcitos Creek below Stone Dam as a result of the regional water system has reduced the extent and quality of habitat for resident trout and steelhead. In addition to these adverse effects on fish habitat, fish passage may be limited at times by road culverts. The discharge of sediment into the creek due to highway maintenance and agricultural activities has degraded the quality of spawning habitat.

Terrestrial Biology. Construction of the regional water system combined with urban development and agricultural activities in the lower watershed has had an adverse effect on terrestrial biological resources in the upper Pilarcitos Creek watershed. The creation of Pilarcitos Reservoir inundated upland, riparian, and other wetland habitats along the historical creek channel, but resulted in the creation of riparian, freshwater marsh, and other wetlands around the periphery of the reservoir. Operation of the regional water system has increased summertime flows in Pilarcitos Creek between Pilarcitos Reservoir and Stone Dam, which may have contributed to the development of the white alder riparian forest along this reach of the creek. Operation of the regional water system has also reduced and altered the seasonal pattern of flow below Stone Dam, which in turn has probably reduced the extent and quality of riparian vegetation, although these effects diminish downstream as tributaries add water to the creek. Road construction, agriculture, and urban development in the lower watershed of the creek have reduced the extent and quality of riparian vegetation, and associated wildlife habitat, from their historical condition.

Recreation and Visual Quality. Construction of the regional water system combined with urban development has had some adverse effect on visual quality in parts of the Pilarcitos Creek watershed. When the regional water system was built, a small area of natural landscape in the upper Pilarcitos Creek watershed was inundated to form an artificial lake. A muddy, vegetation-free zone extending around the perimeter of the lake is inundated at times and becomes visible when the reservoir is drawn down. Pilarcitos Reservoir has a different scenic value than the landscape of coastal scrub it replaced. Road construction, agriculture, and urban development have reduced the visual quality of the lower Pilarcitos Creek watershed.

Potential Effects of Future Projects

The SFPUC's Peninsula Watershed Habitat Conservation Plan, Watershed and Environmental Improvement Program, Habitat Reserve Program, and Peninsula WMP would have beneficial impacts on the biological resources in the upper Pilarcitos Creek watershed. No other future projects have been identified that would affect the upper Pilarcitos Creek watershed above Stone Dam (within CCSF-owned watershed lands). Ongoing repair and maintenance activities for the SFPUC's facilities will be necessary in the future, but these activities would be conducted consistent with management guidelines in the Peninsula WMP as well as in compliance with environmental regulations and the recently adopted Water Enterprise Environmental Stewardship Policy (SFPUC, 2006). Consequently, future projects would not be expected to have a significant adverse effect on hydrology, geomorphology, surface water quality, groundwater levels and quality, fisheries, terrestrial biological resources, or recreational and visual resources in the upper San Mateo Creek watershed.

Urban development and redevelopment is likely to continue in the lower Pilarcitos Creek watershed below Stone Dam (outside of CCSF-owned watershed lands) in accordance with city and county general plans. Although current regulations limit the environmental impacts of development and redevelopment projects compared to levels permitted in the past, some minor incremental impacts are likely to result from the increasingly dense urban coastal zone.

As shown in Table 5.7-16, several future projects address habitat improvement and restoration in the lower Pilarcitos Creek watershed, including improving Pilarcitos Creek and its migratory fishery. These projects or activities resulting from associated planning activities are likely to be beneficial to the environment.

Cumulative Effects and WSIP Contribution

Table 5.7-19 summarizes the effects of past and present projects, the impacts of the WSIP, the effects of probable future projects, and the combined impacts of the WSIP plus probable future projects on the Pilarcitos Creek watershed. Past and present projects have substantially altered the hydrology, geomorphology, fisheries, and terrestrial biology of the watershed compared to pre-Euro-American settlement conditions. Surface water quality, groundwater, and visual and recreational resources have been moderately altered. The existing condition, which serves as the baseline for the analysis of the WSIP, reflects the substantial environmental changes that have occurred as a result of the past projects. Because past and present actions have altered the watershed, some of the watershed's environmental resources are more sensitive to small adverse changes than they would be if the reach had remained relatively unaltered from pre-Euro-American settlement conditions.

TABLE 5.7-19
CUMULATIVE EFFECTS ON THE PILARCITOS CREEK WATERSHED

Resource	Effects of Past and Present Projects	Impacts of WSIP (prior to mitigation/after mitigation)	Effects of Future Projects	Cumulative Impacts of WSIP (after mitigation) + Future Projects	WSIP Contribution Cumulatively Considerable?
Hydrology	SA	LS	LS	LS	No
Geomorphology	SA	LS	LS	LS	No
Surface Water Quality	MA	PSM/LS	B/LS	LS	No
Groundwater	MA	LS	B/LS	LS	No
Fisheries	SA	PSM/LS	B	LS	No
Terrestrial Biology	SA	PSM/LS	B	LS	No
Recreation/Visual Quality	MA	LS	LS	LS	No

B = Beneficial impact
LS = Less than Significant, no mitigation required
PSM/LS = Potentially Significant but reduced to Less-than-Significant with mitigation
SA = Substantially Altered
MA = Moderately Altered

As described in Section 5.5, the WSIP would have a less-than-significant adverse impact on hydrology, geomorphology, groundwater, and recreational and visual resources. It would have a less-than-significant impact on surface water quality, fisheries, and terrestrial biological resources after mitigation (Measure 5.5.3-2, Revised Operations Plan for Pilarcitos Watershed Facilities). As described in the previous section, probable future projects would have primarily beneficial effects on hydrology, geomorphology, surface water quality, groundwater, fisheries, terrestrial biology, and recreational and visual resources.

When the WSIP and foreseeable future projects are considered together, none of their cumulative effects would rise to a level of significance. Even though past and present projects have moderately to substantially altered environmental resources along Pilarcitos Creek, the cumulative impacts of the WSIP after mitigation, combined with the effects of future projects, would not result in a substantial or noticeable change from the existing condition. Because there are no significant cumulative impacts, no mitigation measures beyond Measure 5.5.3-2 would be necessary.

5.7.5 Cumulative Effects on Westside Groundwater Basin Resources

This section describes the cumulative effects on groundwater resources in the Westside Groundwater Basin due to implementation of past, present, and reasonably foreseeable future projects or activities in combination with the WSIP water supply and system operations, including operations associated with the Local and Regional Groundwater Projects (SF-2) and Recycled Water Projects (SF-3) evaluated in Section 5.6. These are the only components of the proposed program expected to affect this groundwater basin.

5.7.5.1 Relevant Projects

North Westside Groundwater Basin

Past and Present Projects

As discussed in Section 5.6, San Francisco has intermittently used groundwater from the North Westside Groundwater Basin as a drinking water and irrigation supply since the early 1900s (Luhdorff & Scalmanini, 2006). By the early 1900s, wells had been constructed to the north, east, and south of Lake Merced for farming and drinking water supply. During that time, the Spring Valley Water Company had two wells located near the Lake Merced outlet that pumped about 0.1 mgd, or 100 afy, and the total of Lake Merced, Sunset District, and Golden Gate Park pumping averaged 0.4 mgd (400 to 500 afy). In the early 1930s, the San Francisco Board of Public Works installed production wells in the Sunset District as an emergency water supply. These wells pumped an average of about 5 mgd between 1930 and 1935, but were discontinued after Hetch Hetchy water became available in the mid-1930s.

In 2005, groundwater was used for irrigation and other nonpotable uses, primarily 1.0 mgd (1,100 afy) at Golden Gate Park[5] and 0.4 mgd (400 afy) at the San Francisco Zoo. In addition, less than 0.02 mgd (13 afy) is used for other purposes, including 8 afy at Edgewood School and 5 afy in Stern Grove (Luhdorff & Scalmanini, 2006). As of 2005, there are no other substantial users of North Westside Groundwater Basin water.

---

[5] Historical pumping rates for the Golden Gate Park wells were estimated for this analysis. The recent installation of flow meters on two of the wells will allow for more accurate measurement of pumping rates in the future.

Future Projects

In addition to two of the WSIP facility improvement projects, the only identified probable future project in the North Westside Groundwater Basin is the San Francisco Public Works Department's restoration of Pine Lake using groundwater from the primary production aquifer (Pine Lake is described in Section 5.6.1.6). The Pine Lake project calls for pumping of up to 0.08 mgd (90 afy) of groundwater from an existing well for restoration of Pine Lake beginning in May 2007 (Mosqueda, 2007).

The two WSIP facility improvement projects that would affect the North Westside Groundwater Basin are the Recycled Water Projects (SF-3) and Local Groundwater Projects (part of SF-2). Under the Recycled Water Projects, described in Chapter 3, Section 3.8, approximately 1.4 mgd (1,500 afy) of groundwater pumping would be replaced by recycled water for irrigation at the San Francisco Zoo and Golden Gate Park. Once this project is implemented, up to 0.5 mgd (560 afy) of pumping for nonpotable uses would continue in the North Westside Groundwater Basin for such purposes as irrigation of sensitive plants in Golden Gate Park and water for some animal exhibits at the San Francisco Zoo.[6] Under the Local Groundwater Projects, also described in Chapter 3, Section 3.8, up to 4 mgd (4,500 afy) would be pumped for municipal supply, including development of 2 mgd of groundwater from new wells, and use or replacement of existing irrigation and nonpotable wells for an additional 2 mgd. The Local Groundwater Projects also includes the addition of treated stormwater, recycled water, groundwater, and/or dechlorinated SFPUC system water to Lake Merced.

South Westside Groundwater Basin

Past and Present Projects

As discussed in Section 5.6, historical groundwater pumping in the South Westside Groundwater Basin resulted in a decline in groundwater levels to more than 100 feet below sea level from Daly City (immediately south of Lake Merced) to San Bruno. This decline contributed to a change in the direction of groundwater flow in the vicinity of Lake Merced from a northwesterly to a southwesterly direction. Although saltwater intrusion and land subsidence have not been observed, there has been public concern that this decline in water levels contributed to decreased water levels in Lake Merced. Efforts to restore groundwater levels in the South Westside Groundwater Basin and reduce potential effects on Lake Merced water levels have included the In-Lieu Recharge Demonstration Study implemented by the SFPUC, Daly City, California Water Service Company (Cal Water) in South San Francisco, and San Bruno, and the replacement of irrigation pumping in the vicinity of Lake Merced with recycled water from northern San Mateo County (Daly City), as discussed below.

Groundwater in the South Westside Groundwater Basin is primarily used for municipal and irrigation purposes. As indicated in Section 5.6, Figure 5.6-3, the total estimated and metered pumping for these uses reached a combined maximum of approximately 12.8 mgd (14,300 afy)[7]

---

[6] Pumping rates for nonpotable purposes may actually be less than estimated if recycled water is found to be of suitable quality for these uses.

[7] This pumping level has been adjusted to exclude pumping in Golden Gate Park, which is located in the North Westside Groundwater Basin.

in the 1960s (Luhdorff & Scalmanini, 2006). In addition, there are some private wells within the basin. As discussed below, total pumping from the South Westside Groundwater Basin (including municipal and irrigation uses) was about 4.1 mgd (4,600 afy) by 2005 because nearly all irrigation pumping around Lake Merced was replaced with recycled water and because of a temporary reduction in municipal pumping as part of the In-Lieu Recharge Demonstration Study.

Municipal Pumping. Historical municipal groundwater pumping by Daly City, Cal Water, and San Bruno, as shown in Figure 5.6-3, reached a high of approximately 8 mgd (9,000 afy) in the mid-1960s and ranged between approximately 5.4 mgd (6,000 afy) and 7.1 mgd (8,000 afy) from the mid-1970s until 2001 (Luhdorff & Scalmanini, 2006). During implementation of the In-Lieu Recharge Demonstration Study from 2002 to 2005, as described in Section 5.6, total municipal pumping was decreased to an average of approximately 1.8 mgd (2,000 afy), as shown in Figure 5.6-3 (Luhdorff & Scalmanini, 2006). As a result of this demonstration study, the total increase in groundwater storage in the South Westside Groundwater Basin was approximately 13,000 acre-feet, including 6,300 acre-feet in the Daly City area, 3,600 acre-feet in the South San Francisco area, and 3,000 acre-feet in the San Bruno area (Luhdorff & Scalmanini, 2005).

Although the In-Lieu Recharge Demonstration Study ended in 2005, Daly City did not resume full-scale pumping and continued to receive system water from the SFPUC in lieu of groundwater pumping. In 2005, Daly City pumped approximately 0.6 mgd (700 afy) of groundwater. As of 2006, Cal Water had not resumed pumping since cessation of the In-Lieu Recharge Demonstration Study, and San Bruno had resumed pumping at rates of approximately 1.5 mgd (1,700 afy).

Irrigation Pumping. Historical golf course and cemetery irrigation in the 1960s was previously estimated at about 4.7 mgd (5,300 afy) of groundwater,[8] and irrigation for three golf courses in the vicinity of Lake Merced (the Olympic Club, San Francisco Golf Club, and Lake Merced Golf Club) accounted for approximately 2.1 mgd (2,235 afy) of this amount. In 2005, irrigation pumping at these three golf courses was reduced to approximately 0.04 mgd (45 afy) when recycled water was made available from north San Mateo County (Daly City) as a substitute irrigation supply.

Other irrigation pumping rates in the South Westside Groundwater Basin in 2005 are consistent with historical pumping rates and are estimated at up to 2.1 mgd (2,400 afy) for cemeteries in Colma, 0.1 mgd (120 to 150 afy) for the California Golf Club[9] in San Bruno, and an undetermined amount for the Golden Gate National Cemetery in San Bruno (Luhdorff & Scalmanini, 2006).

In all, irrigation pumping in the South Westside Groundwater Basin has recently been estimated at 2.3 mgd (2,600 afy) in 2005—a reduction of 2.4 mgd (2,700 afy) from a high of approximately

[8] Historical irrigation pumping amounts were estimated for this analysis. Recent metered use of recycled water at the Lake Merced area golf courses indicates that actual usage may have been less than previously estimated. Therefore, estimates of historical unmetered irrigation pumping may be high.

[9] 2005 estimated pumping rates for the California Golf Club were reduced, from the historical estimate of 665 afy to 120–150 afy, based on information on actual water use rates at the Lake Merced area golf courses obtained when metered recycled water was provided to these golf courses.

4.7 mgd (5,300 afy) in the 1960s—primarily due to the replacement of recycled water for irrigation purposes at the Lake Merced area golf courses.

Pumping from Private Wells. There are over 90 backyard wells in Hillsborough residential areas; most were installed during the 1987–1992 drought and serve multiple adjoining lots. In 2003, total pumping from these wells was estimated at 0.27 mgd (300 afy) (Yates, 2003). There are not likely a large number of private wells in the San Bruno to Daly City portion of the South Westside Groundwater Basin, which typically has small lot sizes with limited irrigation areas. Also, San Mateo County requires well setbacks from sewer lines, which make small lots more difficult to permit for water wells.

Future Projects

In the future, the South Westside Groundwater Basin would continue to be used for municipal and irrigation uses, as well as by private well owners, as described below. With the exception of these uses, the proposed WSIP conjunctive-use program associated with the Regional Groundwater Projects (part of SF-2), and negligible irrigation pumping by the City of Burlingame, no other reasonably foreseeable future projects were identified in the South Westside Groundwater Basin.

Municipal Pumping. Planned groundwater uses for municipal purposes through 2030 are described in the urban water management plans (UWMPs) prepared for each municipality in the South Westside Groundwater Basin, as summarized below:

- In its 2005 UWMP, the City of Daly City estimates that future municipal groundwater pumping under the WSIP conjunctive-use program (Regional Groundwater Projects, SF-2) would range from 1.34 mgd (1,501 afy) during a nondrought year when surface water is supplied by the SFPUC to 3.76 mgd (4,212 afy) during a drought year when the city is also allowed to pump its banked groundwater (City of Daly City, 2005). These projected pumping volumes are presented in Table 4-4 of the 2005 UWMP.

- The 2006 UWMP for the South San Francisco Water District does not yet reflect long-term participation in the SFPUC's proposed conjunctive-use program, but participation in this program is expected to be included in the next revision of its UWMP. In its 2006 UWMP, Cal Water estimates that groundwater usage will be 1.37 mgd per year (1,534 afy) between 2010 and 2030 (California Water Service Company, 2006).

- The 2007 UWMP for the San Bruno does not yet reflect long-term participation in the SFPUC's proposed conjunctive-use program, but, if approved, participation in this program is expected to be included in the next revision of its UWMP. In its 2007 UWMP, the City of San Bruno estimates that overall, groundwater usage will decrease from 2.5 mgd (2,800 afy) in 2010 to zero in 2030 through implementation of conservation measures and increased purchases from the SFPUC. In a drought year, groundwater use between 2010 and 2030 is projected to range from 0.80 mgd (896 afy) to a maximum of 2.5 mgd (2,800 afy) (City of San Bruno, 2007).

- In its 2006 UWMP, the City of Burlingame estimates that it may use less than 0.01 mgd (11 afy) of groundwater for irrigation purposes between 2010 and 2030 (City of Burlingame, 2005). This amount would have negligible effects on the groundwater basin during nondrought or drought years compared to pumping by Daly City, South San Francisco, and San Bruno.

- Hillsborough and Millbrae do not currently utilize or plan to utilize groundwater as a water source (BAWSCA, 2006; City of Millbrae, 2005).

Irrigation Pumping. It is expected that the existing irrigation uses of South Westside Groundwater Basin groundwater described above would continue in the future at approximately 2.3 mgd (2,600 afy). As described further in Chapter 7 (see Table 7.2), there are no planned recycled water projects in South San Francisco, San Bruno, Burlingame, Millbrae, or Daly City that would replace groundwater for irrigation (other than Daly City's replacement of irrigation pumping at the Lake Merced area golf courses with recycled water, as described above).

Pumping from Private Wells. At a minimum, water usage by private well owners would continue at the current rate of approximately 0.27 mgd (300 afy), and it is possible that new private wells could be permitted in the future.

5.7.5.2 Cumulative Impacts

Significance Criteria

The CCSF has not formally adopted significance standards for impacts related to cumulative effects, but generally considers that implementation of the proposed program would have significant cumulative impacts if it were to:

- Have impacts that would be individually limited, but cumulatively considerable ("cumulatively considerable" means that the incremental effects of a project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects.)

Impacts associated with the proposed program that would be "individually limited" are based on the impact analyses presented in Section 5.6 and the significance criteria presented in that section for the various environmental resource areas.

Approach to Analysis and Impact Summary

Cumulative impacts are analyzed based on the CEQA guidance described above in Section 5.7.1. For this groundwater analysis, as described in Section 5.6, a potentially significant effect would occur if withdrawal of groundwater would result in overdraft conditions and related adverse effects, including saltwater intrusion, land subsidence, and/or effects on interrelated surface water features, or if it would adversely affect groundwater quality. The analysis describes the effects of past and present projects on the groundwater basin, and since many projects are still in operation today, the existing environmental conditions reflect the cumulative effects of these past projects and their present operations. These existing conditions form the basis for analysis of the WSIP impacts described in Section 5.6 as well as the basis for assessing the effects of probable future projects and cumulative impacts. The analysis then describes the cumulative impacts on groundwater resources of past, present, and probable future projects together with impacts of the

WSIP. The WSIP's contribution to cumulative impacts is considered prior to mitigation, but the effects of mitigation measures identified in Section 5.6 and described in Chapter 6 are assessed in determining the significance of overall cumulative impacts. Based on this analysis, the WSIP's contribution to the cumulative effect is then evaluated to determine if it is "cumulatively considerable." Impacts are discussed separately for the North and South Westside Groundwater Basins.

Cumulative impacts are discussed below, and impact significance determinations are summarized in **Table 5.7-20**.

TABLE 5.7-20
SUMMARY OF CUMULATIVE IMPACTS IN THE WESTSIDE GROUNDWATER BASIN RELATED TO WSIP WATER SUPPLY AND SYSTEM OPERATIONS

Impact	Significance Determination
5.7.5-1: Cumulative impacts on the North Westside Groundwater Basin	LS
5.7.5-2: Cumulative impacts on the South Westside Groundwater Basin	LS

NOTE: Significance determinations presented in this table assume implementation of all mitigation measures as they are presented in Chapter 5, Section 5.6 and described in Chapter 6.

LS = Less than Significant, no mitigation required

North Westside Groundwater Basin

Impact 5.7.5-1: Cumulative impacts on the North Westside Groundwater Basin.

As discussed above, future groundwater pumping in the North Westside Groundwater Basin would include up to 0.5 mgd (560 afy) of pumping for nonpotable uses once the Recycled Water Projects (SF-3) are implemented, up to 4 mgd (4,500 afy) of pumping for municipal supply under the Local Groundwater Projects (SF-2), and up to 0.08 mgd (90 afy) of groundwater from an existing well to restore water levels in Pine Lake. The Local Groundwater Projects also include the addition of treated stormwater, recycled water, groundwater, and/or dechlorinated SFPUC system water to Lake Merced to achieve the desired lake level, or range of levels.

With implementation of the WSIP projects and pumping for restoration of Pine Lake in combination with ongoing pumping in the basin, total future, cumulative groundwater withdrawals from the North Westside Groundwater Basin would be up to approximately 4.6 mgd (5,150 afy). This cumulative, maximum level of pumping would be within the range of recharge to the basin (4,850 afy to 6,950 afy), but would exceed the lower end of the range. However, cumulative impacts related to the potential for basin overdraft and associated adverse effects on surface water resources, saltwater intrusion, and land subsidence in the North Westside Groundwater Basin would be considered less than significant, assuming implementation of Measure 5.6-1 (Groundwater Monitoring to Determine Basin Safe Yield) and Measure 5.6-2 (Implementation of a Lake Level Management Plan). Measure 5.6-1 requires the SFPUC to continue ongoing studies (including groundwater and lake level monitoring programs to determine the safe yield of the North Westside Groundwater Basin) and to use this monitoring data to inform decisions regarding appropriate pumping patterns to avoid overdraft and the related undesirable effects. Measure 5.6-2 requires the SFPUC to prepare and implement a lake level management plan identifying strategies to alter pumping patterns or lake level augmentation to maintain Lake Merced within the desired long-term range, should monitoring conducted under Measure 5.6-1 indicate the potential for adverse effects on lake levels due to groundwater pumping. With implementation of these measures, to be coordinated by the SFPUC and subject to separate project-level CEQA review prior to implementation of the Local Groundwater Projects (SF-2) and Recycled Water Projects (SF-3), groundwater pumping attributable to the proposed program and the Pine Lake project would not result in overdraft of the North Westside Groundwater Basin or related adverse effects. Therefore, the WSIP in combination with the Pine Lake project would have less-than-significant cumulative impacts on the groundwater basin. No additional mitigation beyond Measures 5.6-1 and 5.6-2 would be necessary.

In addition, the San Francisco Department of Public Health, the agency responsible for permitting water wells in San Francisco, would not grant a permit for a new well unless measures were in place to avoid adverse effects on the groundwater basin. In accordance with Article 12B of the San Francisco Health Code, as discussed in Section 5.6, the Department of Public Health would ensure that any permit application for a water well would undergo CEQA environmental review and receive SFPUC approval prior to issuance of the permit. The operator of the well would be required to comply with any conditions or restrictions on use of the water well imposed by the SFPUC and/or as mitigation measures under CEQA. With implementation of these well permitting requirements, including review by the SFPUC, potential cumulative impacts on groundwater resources and interrelated surface water features of the North Westside Groundwater Basin would be less than significant.

South Westside Groundwater Basin

Impact 5.7.5-2: Cumulative impacts on the South Westside Groundwater Basin.

Future and continuing projects identified in the northern portion of the South Westside Groundwater Basin include the WSIP conjunctive-use program (the regional component of SF-2), municipal pumping by the participating pumpers, and continued irrigation pumping at 2,600 afy. To the south of this area, future pumping includes up to approximately 0.27 mgd (300 afy) of pumping from private wells and negligible irrigation pumping by the City of Burlingame. As discussed in Section 5.6, impacts related to the potential for basin overdraft, saltwater intrusion, and land subsidence would be less than significant for the conjunctive-use program under the Regional Groundwater Projects (SF-2) because, under the WSIP, the SFPUC, Daly City, Cal Water, and San Bruno would enter into an operating agreement(s) that would restrict pumping under the conjunctive-use program to water banked as a result of reductions in pumping in nondrought years. With implementation of the proposed operating agreement(s):

- Groundwater levels would increase and there would be a larger quantity of water in the South Westside Groundwater Basin during nondrought years due to the in-lieu recharge resulting from deliveries of SFPUC system water and correspondingly reduced groundwater pumping.
- Under the proposed conjunctive-use program, the participating pumpers collectively would not be allowed to pump more than the quantity of banked groundwater resulting from the in-lieu delivery of SFPUC system water.

Although in a drought year, pumping under the Regional Groundwater Projects, in combination with municipal pumping by the participating pumpers could temporarily exceed historic high groundwater withdrawal rates, the proposed operating agreement(s), executed between the SFPUC and the participating pumpers, would outline allowable operating parameters for pumping during drought years to avoid adverse long-term conditions; an operating committee would be formed to develop annual operating maintenance plans as well as an annual operating schedule; and groundwater monitoring and modeling would be conducted to identify the potential for adverse conditions and inform decisions to modify the recharge or pumping strategy in response to changing conditions over time.

Implementation of the proposed conjunctive-use program should result in higher average groundwater levels in the northern portion of the South Westside Groundwater Basin as a result of the coordinated use of surface water and groundwater. Implementation of the operating agreement(s) would ensure that impacts related to basin overdraft, saltwater intrusion, and land subsidence would be less than significant. Because there are no other planned future uses of groundwater in this portion of the basin, other than the those existing uses described above that would continue, and impacts of the WSIP would be less than significant due to implementation of the proposed operating agreement(s), cumulative groundwater impacts would be less than significant.

Furthermore, as discussed in Section 5.6, the San Mateo County Environmental Health Division would not grant a well permit for a large well[10] that could potentially cause overdraft of the South Westside Groundwater Basin or be located in an area subject to a specific and localized groundwater problem. Thus, groundwater pumping under the WSIP would not contribute to cumulative impacts related to basin overdraft and associated adverse conditions and no mitigation would be necessary. Therefore, WSIP effects on groundwater resources in the South Westside Groundwater Basin would not be cumulatively considerable and would be considered *less than significant*.

---

10 A large well means any individual well that pumps an amount equal to or greater than 50 gallons per minute or 1,000 gallons per day, or multiple small wells on the same land use parcel which cumulatively pump an amount equal to or greater the 50 gallons per minute or 1,000 gallons per day.

5.7.6 Climate Change and Global Warming

The issue of global warming/climate change has become an important factor in water resources planning in California, and it is being considered during planning for the SFPUC regional water system. There is evidence that increasing concentrations of greenhouse gases[11] have caused and will continue to cause a rise in temperatures around the world, which will result in a wide range of changes in climate patterns. Climate scientists agree that a warming trend occurred during the latter part of the 20th century and will likely continue through the 21st century. These changes will have a direct effect on water resources in California, and numerous studies on climate and water in California have been conducted to determine the potential impacts.

A literature review of recent studies on global warming was conducted for this PEIR to identify the current status of available information and to determine potential impacts of global warming on implementation of the WSIP. **Table 5.7-21** summarizes the major articles reviewed that are relevant to global warming and the SFPUC regional water system.

Based on these articles, global warming could result in the following types of water resources impacts in California, including impacts on the SFPUC regional water system and associated watersheds:

- Reductions in the average annual snowpack due to a rise in the snowline and a shallower snowpack in the low- and medium-elevation zones, such as in the Tuolumne River basin, and a shift in snowmelt runoff to earlier in the year
- Changes in the timing, intensity, and variability of precipitation, and an increased amount of precipitation falling as rain instead of as snow
- Long-term changes in watershed vegetation and increased incidence of wildfires that could affect water quality
- Sea level rise and an increase in saltwater intrusion
- Increased water temperatures with accompanying adverse effects on some fisheries
- Increases in evaporation and concomitant increased irrigation need
- Changes in urban and agricultural water demand

However, other than the general trends listed above, there is no clear scientific consensus on exactly how global warming will quantitatively affect California water supplies, and current models of California water systems generally do not reflect the potential effects of global warming. The Hetch Hetchy/Local Simulation Model (HH/LSM) used in the PEIR for the water supply and system operations analysis remains the best available tool for assessing the impacts of the WSIP.

[11] Greenhouse gases are gaseous constituents in the atmosphere that contribute to the “greenhouse effect,” and include carbon dioxide, methane, nitrous oxide, ozone, and water vapor. The greenhouse effect occurs when greenhouse gases absorb radiant energy from the sun, trap the radiation reflected back from the earth’s surface, and warm the surrounding atmosphere. Human activities such as deforestation and the burning of fossil fuels have increased the levels of greenhouse gases in the atmosphere, particularly carbon dioxide, resulting in a warming trend in atmospheric temperatures around the world.

TABLE 5.7-21
ANNOTATED BIBLIOGRAPHY ON CLIMATE CHANGE/GLOBAL WARMING

Author, Title, Date	Summary and Relevance to Regional Water System
California Department of Water Resources, *Technical Memorandum Report: Progress on Incorporating Climate Change into Management of California's Water Resources,* July 2006.	This report is DWR's response to the governor's 2005 order establishing targets for greenhouse gas emissions and requiring biennial reporting by state agencies. This report describes progress made in the effort to incorporate climate change into water resources planning and management tools and methodologies.
California Department of Water Resources, *California Water Plan Update 2005*, Volume 4, Maurice Roos, "Accounting for Climate Change," 2005.	Evidence that climate change will have significant effects on water resources in California has continued to accumulate in recent years. Some of the more important changes would arise from temperature increases, which would raise snow elevations in temperate zones and change the pattern of runoff from mountain watersheds, thereby affecting reservoir operation. Other consequences include: a rise in sea level, which could adversely affect the Sacramento–San Joaquin River Delta, a major source of water supply for the state; possibly more extreme precipitation and flood events; changes in water consumption by crops and wildlands; and water temperature problems for anadromous fish.
California Energy Commission, California Climate Change Center, *Climate Warming and Water Supply Management in California,* March 2006.	A modeled future dry climate scenario is compared with a future normal climate scenario that follows historical trends for population growth through 2050. Effects on the overall economy from the drier scenario would not be drastic for urban areas but would severely affect rural and agricultural regions.
California Energy Commission, *Climate Change Impacts and Adaptation in California,* June 2005.	This report presents a short review of literature on climate change impacts and adaptation options for California. Future changes in precipitation cannot be accurately determined at this time. However, it is predicted that precipitation will shift towards falling more as rain than as snow, which would increase flood frequencies. Runoff/snowpack melting would increase in the winter season and decrease in the spring and summer due to general atmospheric warming. Many sources reviewed came from the California Energy Commission's Public Interest Energy Research program.
California Energy Commission, prepared by the University of California, Berkeley, *Climate Change and Water Supply Reliability,* March 2005a.	The purpose of the study was to assess impacts of climate change on urban and agricultural water agencies. It describes preliminary work on methods for measuring current water supply reliability and methods for projecting changes in supply reliability caused by climate change. This research differs from other studies in that researchers gathered and analyzed data from individual water districts. This analysis is relevant because there is considerable heterogeneity among water districts in California with regard to source of water, the nature and age of water rights, cost of operations, finances, price structures, and other terms of service.
California Energy Commission, prepared by Pacific Institute, *Climate Change and California Water Resources: A Survey and Summary of the Literature,* August 2005b.	This study surveyed existing literature related to impacts of climate change on California water resources. It provides recommendations for future water management under warming conditions.
California Energy Commission, Center for Environmental and Water Resource Engineering, Department of Civil and Environmental Engineering, Department of Agricultural and Resource Engineering, University of California, Davis, *Climate Warming & California's Water Future,* March 20, 2003.	Effects of climate change on the long-term performance and management of California's water system are examined. Modeling took into account potential changes in the water management system, including changes in population, land use, and agricultural practices.
California Environmental Protection Agency, California Climate Change Center, *Our Changing Climate, Assessing the Risks to California,* August 2006.	This study summarizes recent findings of the California Climate Change Center's "Climate Scenarios," a project analyzing a range of impacts that projected warming would have on California. One section focused specifically on water resources.

TABLE 5.7-21 (Continued)
ANNOTATED BIBLIOGRAPHY ON CLIMATE CHANGE/GLOBAL WARMING

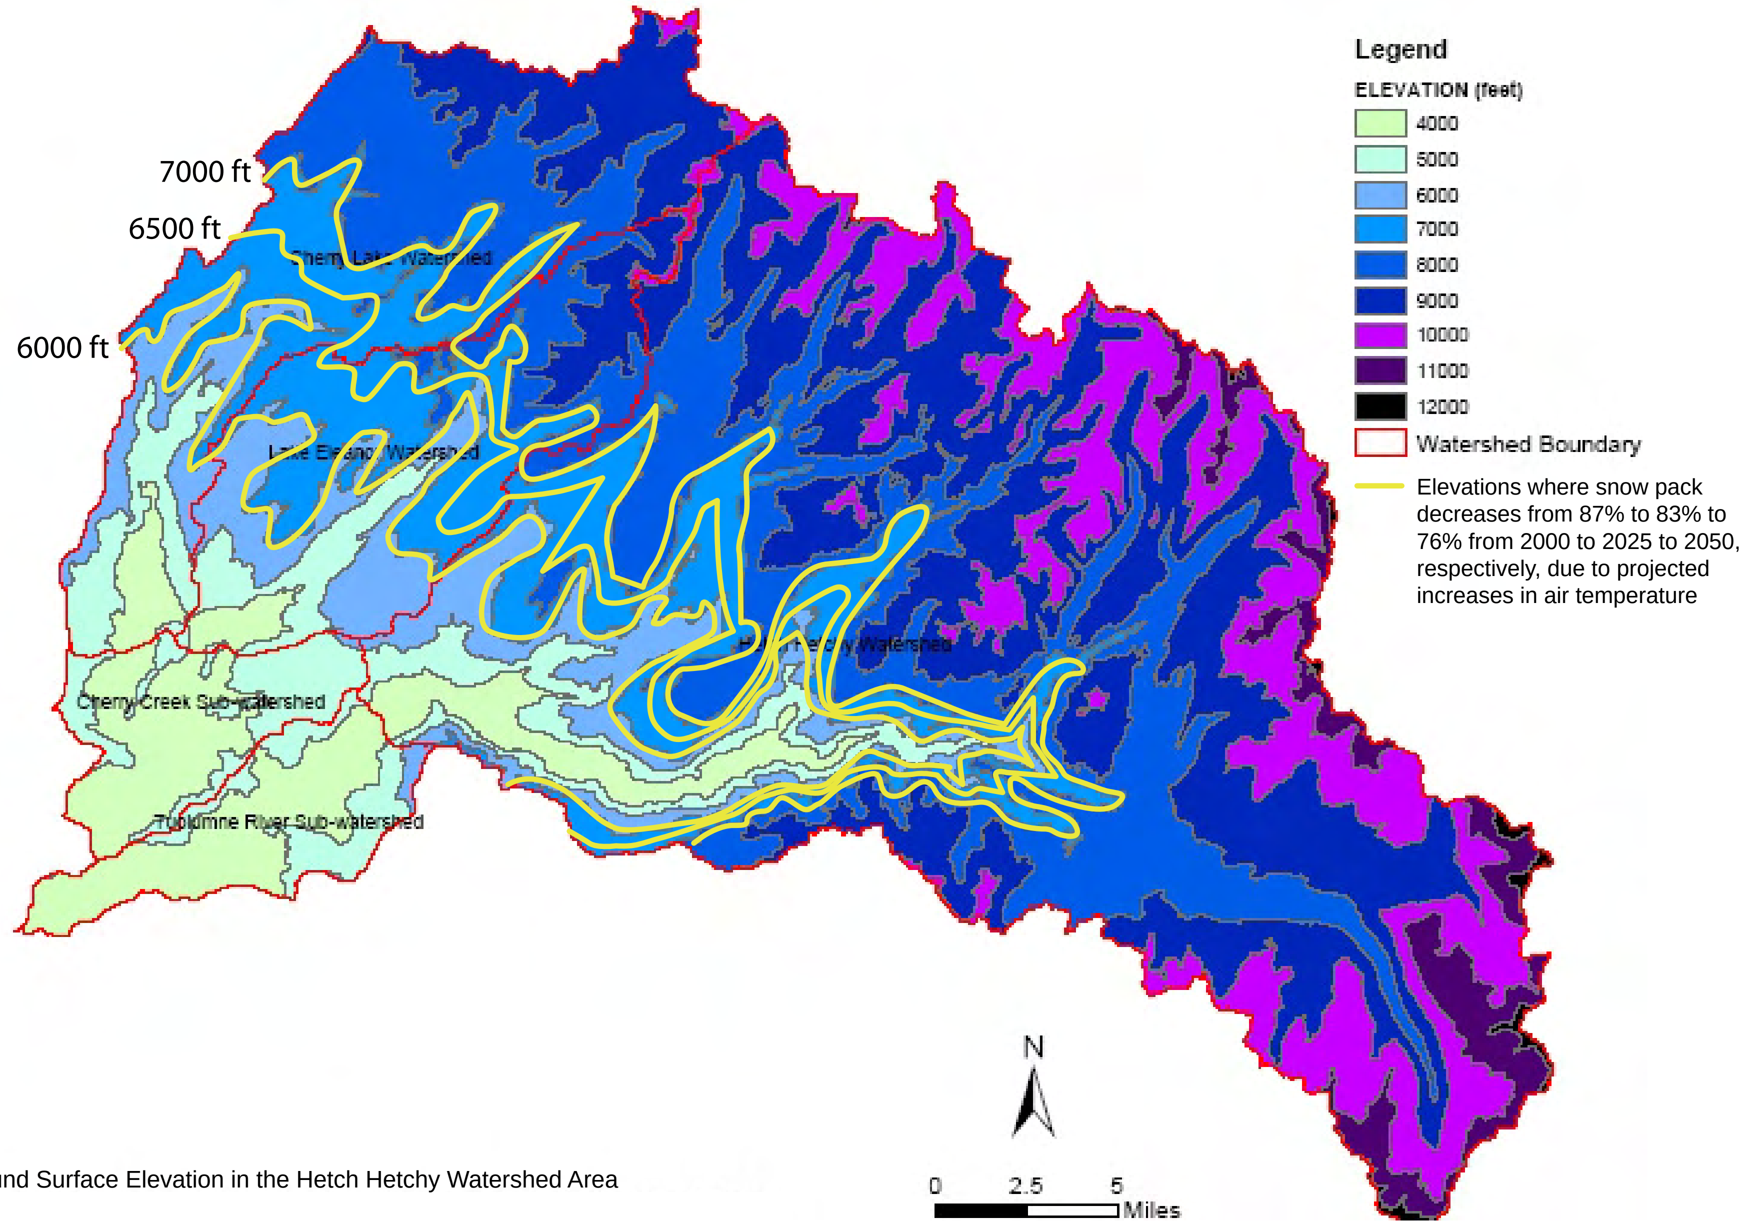
Author, Title, Date	Summary and Relevance to Regional Water System
Hayhoe, Katharine et al., "Emission Pathways, Climate Change, and Impacts on California," Proceedings of the National Academy of Sciences, August 24, 2004.	This study looked at the magnitude of future climate change in California using the highest and lowest United Nations Intergovernmental Panel on Climate Change emissions pathways.
Miller, Norman et al., *Journal of the American Water Resources Association,* "Potential Impacts of Climate Change on California Hydrology," August 2003.	Hydrologic calculations were performed for a set of California river basins that extend from the coastal mountains and Sierra Nevada northern region to the southern Sierra Nevada region. Results indicate that for all snow-producing cases, a larger proportion of the stream flow volume will occur earlier in the year. The amount and timing is dependent on the characteristics of each basin, particularly the elevation. Increased temperatures lead to a higher freezing line, and therefore less snow accumulation and increased melting below the freezing height.
San Francisco Public Utilities Commission, Special Commission Meeting, "Discussion of Global Warming Impacts: San Francisco Water System," available online at http://sanfrancisco.granicus.com/ViewPublisher.php?view_id=22, August 8, 2006.	Introductory discussion of global warming by the commission. Three main topics were discussed: (1) impacts on SFPUC water supply storage due to possible loss of snowpack; (2) impacts related to a rise in sea level and effects on sewage treatment plants in San Francisco; and (3) effects due to changes in the intensity and duration of storms and potential flooding. The SFPUC has established climate change as an area for discussion for years to come. Current operation of the Hetch Hetchy system is able to accommodate a range of climate conditions; however, the SFPUC has started preliminary studies to look at warming patterns and effects on the system.

SOURCE: ESA+Orion, 2006.

Nevertheless, independent of the HH/LSM, SFPUC staff performed an initial evaluation of the effect on the regional water system of a 1.5-degree Celsius (^{o}C) temperature rise between 2000 and 2025 (SFPUC, 2006a). The temperature rise of 1.5 ^{o}C is based on a consensus among many climatologists that current global climate modeling suggests a 3 ^{o}C rise will occur between 2000 and 2050 and a rise of 6 ^{o}C will occur by 2100. The evaluation predicts that an increase in temperature of 1.5 ^{o}C will raise the snowline approximately 500 feet every 25 years.

The elevation of the watershed draining into Hetch Hetchy Reservoir ranges from 3,800 to 12,000 feet above mean sea level, with about 87 percent of the watershed area above 6,000 feet, as shown in **Figure 5.7-5**. In 2000 (a normal hydrologic year in the 82-year period of historical record), the average snowline in this watershed was approximately 6,000 feet during the winter months. Therefore, the SFPUC evaluation indicates that a rise in temperature of 1.5 ^{o}C between 2000 and 2025 will result in less or no snowpack between 6,000 and 6,500 feet and faster melting of the snowpack above 6,500 feet. Similarly, a temperature rise of 1.5 ^{o}C between 2025 and 2050 will result in less or no snowpack between 6,500 and 7,000 feet and faster melting of the snowpack above 7,000 feet. The change in snowline that would result from the projected rise in temperature between 2000 and 2050 is highlighted in Figure 5.7-5.

The SFPUC climate change modeling indicates that about 7 percent of the runoff currently draining into Hetch Hetchy Reservoir will shift from the spring and summer seasons to the fall and winter seasons in the Hetch Hetchy basin by 2025. This percentage is within the current



Ground Surface Elevation in the Hetch Hetchy Watershed Area

SOURCE: SFPUC, 2006

Figure 5.7-5
Projected Decreases in Snow Pack in the Hetch Hetchy Watershed Due to Climate Change, 2000 to 2050

interannual variation in runoff and is within the range accounted for during normal runoff forecasting and existing reservoir management practices. The additional change between 2025 and 2030 will not be detectible. The predicted shift in runoff timing is similar to the results found by other researchers modeling water resource impacts in the Sierra Nevada due to warming trends associated with climate change.

Based on these preliminary studies and the results of the literature review, the potential impacts of global warming on the regional water system are not expected to affect the proposed WSIP operations through 2030, either directly or in combination with the cumulative projects previously described. This is because the predicted changes in stream flow and reservoir water levels in the Hetch Hetchy watershed attributable to climate change during this period are within the same range that occurs under both the existing and proposed operations and management of the system. SFPUC hydrologists are involved in ongoing monitoring and research regarding climate change trends and will continue to monitor the changes and predictions, particularly as these changes relate to the proposed operations and management of the regional water system.

ATTACHMENT 5-A
Mitigation for Chapter 5 Impacts

Introduction

This attachment is an excerpt from Chapter 6, Mitigation Measures, that presents all mitigation measures for impacts described in Chapter 5. Mitigation measures for PSM, PSU, and SU impacts identified in Sections 5.3 through 5.6 are presented under the respective environmental resource topic, such as Fisheries or Terrestrial Biological Resources. No PSM, PSU, or SU cumulative impacts related to WSIP water supply and system operations were identified (Section 5.7). All mitigation measures are numbered to correspond to the same impact numbers, although in some cases, the same measure would mitigate more than one impact and the numbering corresponds to the first impact identified and cross-referenced so that measures are not duplicated.

Mitigation Measures to Minimize Water Supply and System Operations Impacts

Plans and Policies (Section 5.2)

System Measures

None required.

Tuolumne River System and Downstream Water Bodies

Stream Flow and Reservoir Water Levels (Section 5.3.1)

Groundwater (Section 5.3.5)

System Measures

None required.

Fisheries (Section 5.3.6)

System Measures

Overview of Measures 5.3.6-4a, 5.3.6-4b, and 5.3.7-6

The SFPUC will attempt to implement Measure 5.3.6-4a as described below, which could mitigate both Impacts 5.3.6-4 and 5.3.7-6 to a less than significant level. Measure 5.3.6-4a involves some uncertainty because its implementation depends on the SFPUC negotiating and reaching agreement with MID/TID and possibly other water agencies. If Measure 5.3.6-4a proves to be infeasible, the SFPUC will implement Measure 5.3.6-4b to lessen fisheries impacts and Measure 5.3.7-6 to lessen impacts on riparian vegetation.

Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water

Measure 5.3.6-4a: The SFPUC will pursue a water transfer arrangement with MID/TID and/or other water agencies such that the water acquired is developed through actions that result in reduction of demand on Don Pedro Reservoir as a result of conservation, improved delivery efficiency, inter-agency transfer of conserved water, or use of an alternative supply such as groundwater. The TID and MID would deliver less water from Don Pedro Reservoir. The consequent increase in water storage in Don Pedro Reservoir would offset the reduction in inflow to Don Pedro Reservoir attributable to the WSIP. The release pattern from La Grange Dam would be the same or similar to the existing condition thus lessening or eliminating Impacts 5.3.6-4 and 5.3.7-6. The actions necessary to reduce demand for Don Pedro Reservoir water may themselves have environmental effects. See Section 6.5 for a review of potential environmental effects associated with the expected actions of this mitigation measure. Further environmental review would be undertaken prior to approving a specific water transfer agreement.

Fishery Habitat Enhancement

Measure 5.3.6-4b: If Measure 5.3.6-4a is not implemented, then the SFPUC will mitigate potential fishery effects on the lower Tuolumne River by implementing (or funding) one of the following two habitat enhancement actions that are designed to sustain fishery resources under the river's flow regime, which are consistent with the Habitat Restoration Plan for the Lower Tuolumne River Corridor: gravel augmentation/habitat enhancement to provide salmonid spawning and rearing habitat, or isolating or filling a captured former gravel quarry pit along the river that provides habitat for salmonid predators.

The gravel augmentation/habitat enhancement project will be implemented to increase salmonid spawning success and to improve the survival of rearing salmonids in the reach of the river downstream of La Grange Dam. Spawning success will be improved by the addition of suitable gravel to the stream channel. Other habitat features will be created to provide cover for juvenile salmonids and to increase the availability of substrate for macroinvertebrates that would be used as food by rearing juvenile salmon and steelhead. The gravel augmentation/habitat enhancement project will involve the planning, design, permitting, purchase, placement, and monitoring of suitable gravel and associated habitat enhancements at three riffle locations within the spawning reach between Basso Bridge and La Grange Dam. The three locations will meet the criteria for suitable habitat as described in the Habitat Restoration Plan for the Lower Tuolumne River Corridor. The gravel will preferentially be rounded river rock of native origin that would be sized and pre-washed before placement into the river. The gravel augmentation/habitat enhancement project will also involve the addition of large woody debris and boulders to create increased habitat complexity and diversity at each of the three enhancement sites. After construction of the gravel augmentation/habitat enhancement project, it will be surveyed to establish its baseline condition. A survey of the three sites will be made at a minimum of five-year intervals by a qualified fisheries biologist. The fisheries biologist will determine whether the three sites continue to meet established criteria for salmonid spawning and rearing habitat. If the sites do not meet the criteria, as part of its long-term operations, the SFPUC will make the improvements necessary to return it to the baseline conditions.

As an alternative to the gravel augmentation project, the SFPUC will remove from the lower river channel one of the former gravel quarry pits that has been "captured" by the river and acts as predator zones for fish such as largemouth and striped bass to prey on rearing and emigrating juvenile salmonids. Removal could be accomplished by filling the pit or installing a levee berm around the pit to isolate it permanently from the river channel. The SFPUC could implement this action directly or fund implementation by another entity involved in river restoration.

The performance standard for gravel pit removal would be an established permanent reduction in area of salmonid predator habitat. The SFPUC will monitor the pit removal project at five-year intervals. If floods have eroded the fil1 or damaged the levees in a manner that restores salmonid predator habitat, the SFPUC will make the necessary repairs. The SFPUC will continue periodic monitoring and repair as part of long-term system operations.

Terrestrial Biological Resources (Section 5.3.7)

System Measures

Controlled Releases to Recharge Groundwater in Streamside Meadows and Other Alluvial Deposits

Measure 5.3.7-2: To mitigate for potential WSIP effects on meadow resources along the Tuolumne River below Hetch Hetchy Reservoir, the SFPUC will manage releases from Hetch Hetchy Reservoir during the spring to recharge groundwater in the riverside meadows in the Poopenaut Valley and streamside alluvial deposits. The goal of the release pattern will be to approximate conditions characteristic of most Sierra meadows, which are mainly wetlands or semi-wetlands supporting a cover of both emergent wetlands plants and upland vegetation (Ratliff, 1982), and which depend on precipitation and upslope flows to recharge the upper soil layers with water (Ratliff, 1985). The performance standard to be achieved by this measure is no net loss of the extent, diversity, and condition of the existing meadow and wetland vegetation types in the Poopenaut Valley.

The SFPUC will manage reservoir releases for this purpose by releasing the expected available volume of water in the reservoir in a pattern that provides flows of a magnitude that inundate the meadows and streamside alluvial deposits for as long as possible. For example, rather than making releases at a constant rate each day (e.g., releasing 1,000 cfs for seven days), the SFPUC could release the same volume of water but with varying cfs rates, creating flow pulses to meet the objective.

As part of this measure the SFPUC will gather baseline data regarding the extent, species composition and condition of the existing meadow vegetation within the Poopenaut Valley. Some of these environmental baseline data may be available as a result of current study efforts in the Poopenaut Valley.[1] As needed, the SFPUC will augment this information by carrying out vegetation composition surveys in the meadow before implementing the WSIP and at 5 year intervals after WSIP implementation to assess the efficacy of mitigation releases in maintaining or improving the percentage cover of meadow species as described by Ratliff (1985). The basic methodology for baseline vegetation survey and subsequent mitigation monitoring will be generally accepted quantitative vegetation sampling methods to permit statistical comparison of vegetation composition over time, as well as mapping the meadow vegetation in the Poopenaut Valley. The SFPUC will retain the services of a qualified biologist to assist in shaping the releases from Hetch Hetchy Reservoir in consideration of baseline and future meadow vegetation data. If a significant decline in the extent or diversity of native meadow vegetation occurs, releases will be modified as needed to achieve the mitigating effect of sustaining the existing meadow communities.

Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water

See **Measure 5.3.6-4a** in the Fisheries section, above. This measure also addresses impact 5.3.7-6 Impacts on biological resources along the Tuolumne River below La Grange. The SFPUC will attempt to implement Measure 5.3.6-4a as described above, which could mitigate both Impacts 5.3.6-4 and 5.3.7-6 to a less than significant level. Measure 5.3.6-4a involves some uncertainty because its implementation depends on the SFPUC negotiating and reaching agreement with MID/TID and possibly other water agencies. If Measure 5.3.6-4a proves to be infeasible, the SFPUC will implement Measure 5.3.6-4b to lessen fisheries impacts and Measure 5.3.7-6 to lessen impacts on riparian vegetation.

Lower Tuolumne River Riparian Habitat Enhancement

Measure 5.3.7-6: To mitigate the WSIP effects on riparian vegetation, the SFPUC will both protect and enhance one mile of riparian vegetation along the contemporary floodplain of the lower Tuolumne River. This will include funding the acquisition of fee title to or a conservation easement over riparian land totaling one mile (consisting of one or multiple sites) in order to permanently protect that land, and also funding riparian enhancement and on-going vegetation management to maintain the enhanced riparian values in perpetuity along one mile of river. The enhancement and management may be carried out along one river mile either on the land acquired by the SFPUC as described above or on land already under the permanent management of a public agency or conservation organization.

The SFPUC will implement this measure consistent with the Habitat Restoration Plan for the Lower Tuolumne River Corridor (McBain and Trush, 2000) and in coordination with the Tuolumne River Technical Advisory Committee. The SFPUC will also strive to

[1] In 2006 the SFPUC, National Park Service (and USFWS) began a collaborative study effort in the Poopenaut Valley. The effort has led to geomorphology test releases in May 2006, fieldwork in the channel in 2006 and 2007 to examine sediment transport and deposition relationships with flow. Two transects with ten recording piezometers have been installed across the meadow to measure groundwater recharge and drainage patterns. Supplementary stream staff gages have been installed to allow manual readings during high flows. Surveys have been done of the meadow to define the topography and the location and elevation of the piezometers. Infiltration of water from the stream to the meadow soils will be monitored during high flows to develop a better understanding of groundwater dynamics in the meadow so that reservoir operations, flow pulses, and minimum streamflow releases can be managed to improve meadow conditions within the constraints of water supply and facility limitations.

implement these projects in partnership with those groups currently working to restore riparian floodplains on the lower Tuolumne River.

The SFPUC may implement riparian enhancement in accordance with site locations and plans already developed as part of the Habitat Restoration Plan for the Lower Tuolumne River Corridor or on other appropriate sites along the river. For sites that haven't already had plans developed, a riparian enhancement plan will be prepared for each. The plan shall include, but not be limited to, the following:

- Clearly stated objectives and goals consistent with the Habitat Restoration Plan for the Lower Tuolumne River Corridor (McBain and Trush, 2000).
- Location, size, and type of mitigation actions proposed.
- Documentation of performance and monitoring standards.
- Performance and monitoring standards shall indicate success criteria to be met within 5 years for vegetation, removal of exotic species, etc. Adaptive management standards shall include contingency measures that shall outline clear steps to be taken if and when it is determined, through monitoring or other means, that the enhancement or restoration techniques are not meeting success criteria.
- Documentation of the necessary long-term management and maintenance requirements, and provisions for sufficient funding.

System Measures

None required.

Alameda Creek Watershed Streams and Reservoirs

Stream Flow and Reservoir Water Levels (Section 5.4.1)

System Measures

Diversion Tunnel Operation

Measure 5.4.1-2: The SFPUC will establish and implement written operational criteria for the Alameda Creek Diversion Dam that directs that the diversion dam and tunnel shall be operated to pass flows down Alameda Creek when diversion of those flows is not required to maintain desired levels in Calaveras Reservoir in order to provide the maximum possible days of winter and spring flows in Alameda Creek below the diversion dam.

This measure reinforces the way the SFPUC generally operates the diversion tunnel now: that diversion gates are closed in the spring once desired Calaveras Reservoir storage have been reached. However, at times additional flows have been diverted from Alameda Creek after reservoir storage levels have been achieved such that the “excess” water has subsequently been released from the reservoir to maintain the appropriate water level. This measure would formalize Alameda Creek diversion procedures to maintain flows in Alameda Creek to the extent they are not needed to achieve required reservoir storage. This measure would reduce the flow reduction impact but not to a level that is less than significant.

Fisheries (Section 5.4.5)

System Measures

Minimum Flows for Resident Trout on Alameda Creek

Measure 5.4.5-3a: The SFPUC shall develop and carry out as part of the implementation of the Calaveras Dam Replacement (SV-2) project, an operational plan to implement minimum bypass flows when precipitation generates runoff into the creek below the diversion dam to the Calaveras Creek confluence from December 1 through April 30 to support spawning and egg incubation for resident trout as well as breeding habitat for other native stream-dependent amphibians. This is the period when winter precipitation typically would produce flows for spawning and egg incubation and breeding habitat for other native stream-dependent species. The operational plan will identify the specific minimum flow requirements to support resident trout spawning and egg incubation, and a detailed monitoring plan to survey and document trout spawning and egg incubation and any diversion facility modifications that are needed to implement the minimum stream flows. This measure will be implemented in conjunction with the proposed bypass flows at the diversion dam to meet the 1997 CDFG MOU flow requirements.

Minimum flow requirements to support resident trout spawning and egg incubation vary depending on stream reach conditions. Although site-specific studies are needed to determine an appropriate minimum flow requirement for each specific creek reach, based on the general size and characteristics of the Alameda Creek channel immediately downstream of the diversion structure it has been suggested that a minimum flow on the order of 10 cfs may be needed to support trout spawning and egg incubation. The SFPUC's Natural Resources Division will complete the site-specific studies needed to determine the appropriate minimum stream flow for this reach of the creek; studies may show that the minimum flow requirement is more or less than 10 cfs. This minimum flow requirement would be met when precipitation would naturally generate runoff in the creek (below the diversion dam) under unimpaired conditions between December 1 and April 30. When precipitation generates runoff in the creek, the SFPUC shall provide for bypass of flow up to the required minimum flow amount. The operational plan will allow for adapting minimum flow amounts to support resident trout spawning and egg incubation and other native stream-dependent species based on the monitoring results and best available scientific information.

The monitoring plan will be provided to appropriate resource agencies for review and comment and will subsequently be implemented by the SFPUC's Natural Resources Division staff. Monitoring results shall be provided to the resource agencies as requested. Monitoring shall occur for a minimum of five years and a maximum of ten years following completion of the Calaveras Dam Replacement project. At the completion of the monitoring period the SFPUC shall produce a draft comprehensive report describing the methods, data collected, and results used to assess the performance of the minimum streamflow in providing suitable habitat for resident trout spawning and egg incubation.

The Alameda Creek Fisheries Restoration Workgroup is currently overseeing collaborative studies to better characterize the flow-habitat relationships for trout spawning within Alameda Creek, and the SFPUC is providing staff and funding to support this effort. Information from these studies will also be used in developing the specific range of minimum stream flows needed to support suitable habitat within the reach below the diversion dam to the Calaveras Creek confluence.

This measure addresses two areas of impact to the resident trout fishery in Alameda Creek below the diversion dam. First, it addresses the decrease in flow below the diversion dam that would occur under the WSIP as a result of re-instituting flow diversions to Calaveras Reservoir once the dam is replaced (WSIP Project SV-2) and current DSOD storage capacity restrictions are removed. Second, it addresses the loss of fish from the lower creek system that would result from fish entrainment through the unscreened diversion tunnel to Calaveras Reservoir. Providing for minimum stream flows in Alameda Creek below the diversion dam, as required by the mitigation measure, would support resident trout spawning and egg incubation and it is expected that this measure would be sufficient to sustain the trout population in this reach of the creek. This would fully address/mitigate for both areas of WSIP impact to the resident trout fishery below the diversion dam. If monitoring indicates that this measure is adequate to sustain the resident trout population below the diversion dam, then no additional mitigation action would be required. If monitoring indicates that this measure does not sustain the resident trout fishery in this reach, then the SFPUC shall either modify the minimum stream flow to enhance downstream habitat conditions to fully meet the mitigation requirement or also implement Measure 5.4.5-3b Diversion Restrictions or Fish Screens.

Alameda Diversion Dam Diversion Restrictions or Fish Screens

Measure 5.4.5-3b: If, after 10 years of monitoring results for Measure 5.4.5-3a, Minimum Flows for Resident Trout in Alameda Creek, indicate that the measure does not sustain the resident trout population in Alameda Creek below the diversion dam, then the SFPUC shall also implement additional measures as follows: either implement seasonal restrictions on Alameda Creek diversions to Calaveras Reservoir to protect the downstream resident trout fishery during the critical spawning period (December 1 through April 30) or install and operate a fish passage barrier to “screen” the diversion facility (screening could consist of a behavioral barrier, such as electrical or sound barrier that deters fish, or a physical barrier – such as a screen facility).

SFPUC shall consult with the appropriate resource agencies, including CDFG, to first review the monitoring results for Measure 5.4.5-3a and determine the need for any further mitigation actions. If needed, SFPUC will consult with the appropriate resource agencies to develop appropriate seasonal restrictions on diversions. This could involve establishing a set annual time period for diversion restrictions or annual monitoring of fishery conditions that would then trigger implementation of diversion restrictions.

Alternatively, the SFPUC will implement a fish passage barrier if determined to be feasible. During the 10-year monitoring and evaluation period for Measure 5.4.5-3a, the SFPUC will evaluate the feasibility of installing and operating a fish passage barrier. The feasibility study will include an engineering evaluation of the existing site and diversion structure, access for construction and power supplies to the site, the application of various alternative designs, and identification of a preferred design if determined to be feasible. If it is determined that a fish passage barrier is needed to protect resident trout at the diversion structure then engineering design will be completed and be sufficiently detailed to allow permitting and completion of construction within a period of 24 months after the date that the additional mitigation is determined to be required.

Terrestrial Biological Resources (Section 5.4.6)

System Measures

Compensation for Impacts on Terrestrial Biological Resources

Measure 5.4.6-1: This measure mitigates for water supply and systemwide operation effects on resources within the Alameda Creek watershed. These impacts would occur primarily through operation of the Calaveras Dam Replacement project (SV-2).

The SFPUC will compensate for sensitive wetland, riparian and upland habitats and habitats which support key special-status species or other species of concern lost as a result of WSIP system operation. Similar habitat will be identified, protected, restored, enhanced, created and managed off-site[2] to ensure no net loss of habitat extent or function. A qualified biologist will quantify the magnitude and extent of impacts to wetlands, sensitive habitats, and key special-status species and other species of concern, and the SFPUC will develop and implement mitigation and compensation plans that meet the appropriate regulatory requirements and permit conditions with respect to compensation ratios, other

2 Off-site means the compensatory action is located other than within the project construction footprint, but could be on lands already under SFPUC ownership. Measure 4.6-2 addresses compensatory actions to be taken within the construction footprint.

conservation measures and management requirements to mitigate project impacts to less than significant levels.

The SFPUC will obtain required permits and comply with applicable environmental regulations addressing sensitive habitats and species. Compensatory lands—including those restored or enhanced as well as those acquired or designated as protected as part of program mitigation--will be established in perpetuity with a commitment that such lands will not be used for any purpose that conflicts with the primary purpose of maintaining intact wildlife and plant habitat.

One alternative for implementing such habitat compensation is the Habitat Reserve Program (HRP) currently being developed by the SFPUC. The purpose of the HRP is to provide a comprehensive, coordinated approach to mitigation and related regulatory compliance for WSIP projects and operations. This related SFPUC project is described further in Chapter 3.0, Section 3.12.3. Under the proposed HRP, the SFPUC would proceed as soon as possible with identifying, securing (through designation, management agreement, conservation easement, or acquisition of fee title) and improving lands to be used for habitat compensation so that mitigation is underway concurrent with habitat loss related to WSIP program activities, further ensuring no net loss of resources. The proposed HRP is scheduled for CEQA environmental review in 2007 and is targeted for implementation as soon as possible thereafter. Once the HRP is approved and implemented, the SFPUC will use this as one vehicle or method for implementing the mitigation requirements for individual WSIP projects. Otherwise, where appropriate and necessary, the SFPUC will develop and implement appropriate habitat compensation mitigation for individual WSIP projects and their associated operational impacts.

Operational Procedures for Calaveras Dam Releases

Measure 5.4.6-3: During project-level CEQA review on the Calaveras Dam Replacement project (SV-2), the SFPUC will develop operational procedures for managing planned releases from Calaveras Dam to minimize habitat impacts on amphibians, their egg masses, and tadpoles. The goal of such releases, apart from benefits to fish, is to mimic a more natural pattern of hydrology regime as much as possible. The procedures will specify the minimum amount and frequency of planned releases and the rate of the increase and decrease of any individual release event. One of the specific goals of such releases would be to reduce the risk of mortality to breeding amphibians. Such operational procedures will be developed prior to completion of construction of the Calaveras Dam Replacement project. In addition, instream flow releases required under CDFG agreement with SFPUC (see Table 5.4.1-9) would begin upon completion of construction.

Surface Water Quality (Section 5.5.3)

[Paragraph has been deleted per responses to comments or staff-initiated text changes (Vol. 7, Chapter 16).]

System Measures

Low-head Pumping Station at Pilarcitos Reservoir

Measure 5.5.3-2a: The SFPUC shall install a permanent low-head pumping station at Pilarcitos Reservoir which would enable the SFPUC to access and use an additional 350 acre-feet of water from Pilarcitos Reservoir. In years when the WSIP would cause releases from Pilarcitos Reservoir to Pilarcitos Creek to be reduced to reservoir inflow earlier in the summer than under the existing condition (about 25 percent of years in the hydrologic record), the SFPUC will use the pumping station to augment flow in Pilarcitos Creek with water from the reservoir. The pumping station will draw water from the cool pool of water below the thermocline during times when the reservoir is stratified. The pumping station outlet will be designed to ensure that water discharged to the creek is adequately aerated.

Aeration System at Pilarcitos Reservoir

Measure 5.5.3-2b: The SFPUC shall install a permanent aeration system at Pilarcitos Reservoir. The SFPUC will operate the aeration system as necessary to avoid anoxic conditions and maintain good water quality conditions at the reservoir.

Groundwater (Section 5.5.4)

System Measures

None required.

Fisheries (Section 5.5.5)

System Measures

Create New Spawning Habitat Above Crystal Springs Reservoir

Measure 5.5.5-1: The SFPUC will survey the extent and quality of fish spawning habitat that could potentially be lost due to inundation and, if feasible, create new spawning habitat at a higher elevations. The specifics of this mitigation measure will be determined as part of project-level CEQA review for the Lower Crystal Springs Dam Improvements project (PN-4).

Establish Flow Criteria, Monitor and Augment Flow

Measure 5.5.5-5: The SFPUC shall develop a monitoring and operations plan for Stone Dam to ensure WSIP-related flow reductions downstream of Stone Dam do not impair steelhead passage and spawning during the winter months of normal and wetter hydrologic years. This operational plan will provide for minimum stream flows to support existing adult steelhead passage and spawning downstream of Stone Dam, in the reach between Stone Dam and the confluence with the tributary at Albert Canyon, approximately 3.5 miles downstream. Downstream of Albert Canyon, WSIP flow reductions are unlikely to cause a significant impact to steelhead migration and spawning due to contributing flows from numerous downstream tributaries being sufficient to maintain adult upstream passage and spawning conditions within the creek. Monitoring and implementation of the operational plan will occur when precipitation generates runoff into Pilarcitos Creek below Stone Dam from December 1 through April 30 of normal and wetter years. This monitoring and operations plan will be established within five years of the approval of the PEIR.

Specific instream flows needed to support anadromous steelhead downstream of Stone Dam have not yet been identified. Suitable instream flows for steelhead passage on Pilarcitos Creek may be defined as providing a water depth of at least 0.6 feet over 25 percent of the total wetted channel cross-sectional area with 10 percent being contiguous. In cooperation with CDFG and NMFS, the SFPUC will identify up to five critical riffles, downstream of Stone Dam and upstream of Albert Canyon that may cause a passage impediment/barrier to steelhead migration at reduced flows as defined by the water depth criterion above. Such habitat types will be selected for survey because they represent the shallowest habitat type and thus would most likely represent low flow passage barriers under WSIP-related reduced flow scenarios. This monitoring plan will survey and document the critical riffles identified to determine physical conditions (e.g., depth, velocity, and top width of the channel) present at various flow levels. The SFPUC will measure the stage-discharge relationship at each of the five critical riffles and identify the minimum stream flow that meets the steelhead passage criterion at the most restrictive of the five riffle locations.

The SFPUC will calibrate and validate the flow measurements made at the existing flow monitoring gage (USGS Gage 11162620) located immediately downstream of Stone Dam. The SFPUC will then develop a statistical relationship between the flow measurements at the existing gage and the flow at the most restrictive critical riffle downstream of Stone Dam to establish minimum average daily flows necessary to meet steelhead passage criterion. The SFPUC will monitor average daily flows at the stream flow gage during the period from December 1 through April 30 each year. If average daily flow, as measured at the gage, indicates that the minimum stream flow at the downstream critical riffle is not met, the SFPUC will release bypass flows from Stone Dam at a rate sufficient to meet the minimum stream flow for steelhead passage at a release rate up to, but not exceeding, the average daily inflow into Pilarcitos Reservoir as determined by SFPUC operators.

The SFPUC's Natural Resources Division will complete the site-specific studies needed to determine the appropriate minimum stream flow for the most restrictive critical riffle identified during monitoring. This minimum flow criterion will be met when WSIP diversions occur between December 1 and April 30 of normal and wetter hydrologic years. The operational plan will allow for adapting minimum flow amounts to support steelhead migration based on the monitoring results and best available scientific information. Monitoring and flow management will be continued for a minimum period of five years and a maximum period of ten years, at which time the SFPUC will prepare a technical report describing results of the stream flow monitoring, identifying whether or not operation of Stone Dam reduced passage flows below the minimum criteria, and identifying, if needed, an appropriate bypass flow for future operations at Stone Dam (a minimum flow below which water could not be diverted to storage between December and April 30). The technical report will be provided to CDFG and NMFS.

Terrestrial Biological Resources (Section 5.5.6)

System Measures

Habitat Monitoring and Compensation

Measure 5.5.3-2c The SFPUC shall compensate for reduced productivity and diversity of San Francisco garter snake (SFGS) and California red-legged frog (CRLF) wetland habitat which could occur as a result of greater variability, extent and duration in drawdowns at Pilarcitos Reservoir as a result of implementation of Revised Measure 5.5.3-2a (Low-head Pumping Station at Pilarcitos Reservoir). To offset the potential loss of habitat quality, the SFPUC will develop an adaptive management plan for managing and maintaining freshwater marsh and other wetlands around the periphery of Pilarcitos Reservoir. This adaptive management plan would include pre- implementation monitoring and post-implementation monitoring for up to 10 years to ensure that habitat is sustained at Pilarcitos Reservoir, to achieve no net loss of habitat and value for SFGS and CRLF habitat and document changes (if any) in extent or quality of the habitat attributable to operation of the low-head pumping station.

In the event that habitat is reduced, one alternative for implementing such habitat compensation is the Habitat Reserve Program (HRP) currently being developed by the SFPUC. The purpose of the HRP is to provide a comprehensive, coordinated approach to mitigation and related regulatory compliance for WSIP projects and operations. The HRP is described further in the PEIR, Chapter 3.0, Section 3.12.3. Under the proposed HRP, the SFPUC would proceed as soon as possible with identifying, securing (through designation, management agreement, conservation easement, or acquisition of fee title) and improving lands to be used for habitat compensation so that mitigation is underway concurrent with habitat loss related to WSIP program activities, further ensuring no net loss of resources. The proposed HRP is undergoing CEQA environmental review in 2008 and 2009 and is targeted for implementation as soon as possible thereafter. Once the HRP is approved and implemented, the SFPUC will use this as one vehicle or method for implementing the mitigation requirements for WSIP-related activities. Otherwise, where appropriate and necessary, the SFPUC will develop and implement appropriate habitat compensation mitigation for WSIP system operational effects on Pilarcitos Reservoir, independent of the HRP.

Adaptive Management of Freshwater Marsh and Wetlands at Upper and Lower Crystal Springs Reservoirs

Measure 5.5.6-1a: To offset the loss of wetlands, a qualified professional will develop an adaptive management plan for managing and maintaining freshwater marsh and other wetlands around the periphery of Upper Crystal Springs, and Lower Crystal Springs Reservoirs. This adaptive management plan may include the following:

- Gradually raise the reservoir elevations at appropriate times of year to maintain continuous freshwater marsh and riparian habitat along the shorelines to reduce potentially adverse effects to San Francisco garter snakes and California red-legged frogs.

- Identify feasible measures to help to moderate the effects of reservoir drawdown, increase the extent of reservoir margins with the potential to support freshwater marsh vegetation, and investigate the effectiveness for the management and control of predatory aquatic species such as largemouth bass and bullfrogs.

- Perform monitoring and review to ensure that habitat is sustained at Upper and Lower Crystal Springs Reservoirs and elsewhere, as appropriate, to achieve no net loss of habitat and value for freshwater marsh, wetlands, and special-status species.
- Observe all appropriate protective measures to avoid "take" of San Francisco garter snake. In the event that the mitigation measures above cannot be followed, the SFPUC will prepare a sensitive species relocation plan, which would be approved by both the CDFG and USFWS. Such a plan would detail how underground refugia would be excavated, identify suitable relocation areas, etc.

Compensation for Impacts on Terrestrial Biological Resources

Measure 5.5.6-1b: This measure mitigates for water supply and systemwide operation effects on resources within the Peninsula watershed. These impacts would occur primarily through operation of the Upper and Lower Crystal Springs Reservoir facilitated by the Crystal Springs Dam Improvements project (PN-9).

The SFPUC will compensate for sensitive wetland, riparian and upland habitats and habitats which support key special-status species or other species of concern lost as a result of WSIP system operation. Similar habitat will be identified, protected, restored, enhanced, created and managed off-site[3] to ensure no net loss of habitat extent or function. Similarly, in the event of the loss of large, mature oaks and oak woodland, creation and/or restoration of oak woodland elsewhere will be implemented to compensate for the loss of these common upland habitats. A qualified biologist will quantify the magnitude and extent of impacts to wetlands, sensitive habitats, other upland habitats, and key special-status species and other species of concern, and the SFPUC will develop and implement mitigation and compensation plans that meet the appropriate regulatory requirements and permit

[3] Off-site means the compensatory action is located other than within the project construction footprint, but could be on lands already under SFPUC ownership. Measure 4.6-2 addresses compensatory actions to be taken within the construction footprint.

conditions with respect to compensation ratios, other conservation measures and management requirements to mitigate project impacts to less than significant levels.

The SFPUC will obtain required permits and comply with applicable environmental regulations addressing sensitive habitats and species. Compensatory lands—including those restored or enhanced as well as those acquired or designated as protected as part of program mitigation--will be established in perpetuity with a commitment that such lands will not be used for any purpose that conflicts with the primary purpose of maintaining intact wildlife and plant habitat.

One alternative for implementing such habitat compensation is a Habitat Reserve Program (HRP) currently being developed by the SFPUC. The purpose of the HRP is to provide a comprehensive, coordinated approach to mitigation and related regulatory compliance for WSIP projects and operations. This related SFPUC project is described further in Chapter 3.0, Section 3.11. Under the proposed HRP, the SFPUC would proceed as soon as possible with identifying, securing (through designation, management agreement, conservation easement, or acquisition of fee title) and improving lands to be used for habitat compensation so that mitigation is underway concurrent with habitat loss related to WSIP program activities, further ensuring no net loss of resources. The proposed HRP is scheduled for CEQA environmental review in 2007 and targeted for implementation as soon as possible thereafter. Once the HRP is approved and implemented, the SFPUC will use this as one vehicle or method for implementing the mitigation requirements for individual WSIP projects. Otherwise, where appropriate and necessary, the SFPUC will develop and implement appropriate habitat compensation mitigation for individual WSIP projects and operational effects.

Compensation for Serpentine Seep-Related Special Status Plants

Measure 5.5.6-1c: The SFPUC will develop and implement a plan to protect, create, and restore habitat for plant species adapted to serpentine seeps, particularly fountain thistle, around Upper and Lower Crystal Springs Reservoirs. The plan will also include control of pampas grass and any other invasive plant species within the serpentine seep habitat.

Recreational and Visual Resources (Section 5.5.7)

System Measures

None required.

Westside Groundwater Basin Resources (Section 5.6)

System Measures

Groundwater Monitoring to Determine Basin Safe Yield

Measure 5.6-1: The SFPUC will continue ongoing studies, including the existing groundwater and lake level monitoring programs, to determine the safe yield of the North Westside Groundwater Basin in order to avoid overdraft and associated effects including adverse effects on surface water features and seawater intrusion. Using this data, the SFPUC will develop and implement a plan identifying appropriate pumping patterns to avoid overdraft and the undesirable effects associated with overdraft. The plan will establish both a regular (average annual) and an intermittent (dry year or emergency) yield as well as a strategy for modifying pumping patterns such that the pumping levels can be sustained as an ongoing reliable water supply without depletion of groundwater storage or degradation of water quality.

Implementation of a Lake Level Management Plan

Measure 5.6-2: The SFPUC will develop and implement a lake level management plan identifying strategies for altering pumping patterns or lake augmentation to maintain Lake Merced water levels within the desired long-term range should monitoring conducted under Measure 5.6-1 indicate the potential for adverse effects on lake levels due to groundwater pumping. The SFPUC will coordinate the implementation of this measure with Measure 5.6-1.

Drinking Water Source Assessments for Groundwater Wells

Measure 5.6-5: As required by the California Department of Health Services and incorporated as part of the WSIP, the SFPUC will prepare drinking water source assessments for groundwater wells constructed under the Local and Regional Groundwater Projects (SF-2) and will update these assessments every five years. If the assessment indicates no potential for contamination, then no mitigation is required. However, for wells that are considered vulnerable to contamination on the basis of the drinking water source assessment, the SFPUC will develop and implement a source water protection program specifying actions and a program to be implemented to prevent contamination of the drinking water source.

The source water protection program could include nonregulatory components such as watershed restoration, stormwater monitoring, groundwater monitoring, and public education to protect drinking water quality. Land use planning, permitting, and possibly more restrictive regulatory methods may also be implemented by the local municipality where a threat to drinking water quality is indicated, and management of potential sources of microbiological or direct chemical contamination to eliminate or reduce the risk of contamination of the water supply may be considered. The SFPUC will encourage public participation in the development of the program and will update the program every five years along with the drinking water source assessments.

Cumulative Projects and Impacts Related to WSIP Water Supply and System Operations (Section 5.7)

Cumulative System Measures

None required.

6 Mitigation Measures

CHAPTER 6
Mitigation Measures

6.1 Introduction

This chapter presents mitigation measures for impacts associated with implementation of the proposed program as identified in Chapters 4 and 5 of this PEIR. Chapter 4 identifies impacts that would be associated with construction and operation of WSIP facility improvement projects, while Chapter 5 identifies impacts that would result from the proposed water supply and system operations. In these chapters, the level of significance is indicated for each impact; these determinations are one of the following: N/A (not applicable), B (Beneficial, no mitigation required), LS (Less than Significant, no mitigation required), PSM/SM (Potentially Significant/Significant, can be mitigated to less than significant), LSM (Less than Significant, since it would be mitigated with program-level mitigation measures) PSU/SU (Potentially Significant Unavoidable/Significant and Unavoidable, where mitigation would not necessarily reduce the impact to less than significant). The significance determinations are based on the potential effects of the proposed program as they relate to the significance criteria listed in Chapters 4 and 5, with consideration of how SFPUC construction measures and regulatory requirements may reduce the severity of the effect. Mitigation measures are then identified for all impacts determined to be PSM as well as for impacts determined to be PSU or SU, to the extent that any feasible mitigation would be available. The detailed descriptions of all mitigation measures are included in this chapter.

Section 6.2 of this chapter presents the SFPUC construction measures that will be applied to all WSIP facility improvement projects; Section 6.3 describes the mitigation measures to minimize facilities-related impacts; and Section 6.4 describes the mitigation measures to minimize water supply and system operations impacts. All mitigation measures are numbered to correspond to impact numbers presented in Chapters 4 and 5; in some cases where the same measure would mitigate more than one impact, the measure number corresponds to the first impact identified. In a few cases, implementation of the mitigation measures in and of themselves could result in additional environmental effects, and therefore, Section 6.5 includes a general description of impacts of those mitigation measures. Section 6.6 presents summary tables of all impacts and mitigation measures, showing which measures apply to which impact.

For the facilities-related mitigations, Section 6.3 presents the detailed text of the mitigation measures by environmental topic for all PSM/SM and PSU/SU impacts identified in the Chapter 4 analysis. The summary tables in Section 6.6 list all impacts analyzed in Chapter 4 and provides the mitigation information as applicable to each facility improvement project, including the impact statement, the significance determination, applicable SFPUC construction measure, PEIR mitigation measure, and regulations that reduce the severity of the impact. For some projects, an identified impact would not apply (N/A). For some projects, the impact would be LS with implementation of applicable SFPUC construction measures, though in a few cases, the identified impact would be LS without implementation of the SFPUC construction measures. For impacts determined to be PSM/SM, the mitigation measures described in Section 6.3 must be implemented to reduce potentially significant impacts to a less-than-significant level. For impacts determined to be PSU or SU, implementation of mitigation measures would still be required, but it has been determined that these measures would not reduce the identified impact to a less-than-significant level.[1] Section 6.3 identifies the appropriate program-level mitigation measures in general terms, referred to as “Program Measures,” that would apply to impacts identified for individual facilities improvement projects. Section 6.3 also presents “Collective Measures” and “Cumulative Measures,” which would reduce collective and cumulative impacts, respectively, and would apply to the WSIP by region or as a whole.

For the water supply/system operations mitigations, Section 6.4 presents the detailed text of the mitigation measures by watershed/groundwater basin for all PSM/SM and PSU/SU impacts identified in the Chapter 5 analysis. The summary tables in Section 6.6 list all impacts analyzed in Chapter 5 together with the significance determinations and the mitigation measures for PSM, PSU, and SU impacts. Similar to the facilities impact analysis, for impacts determined to be PSM, the mitigation measures described in Section 6.4 must be implemented to reduce potentially significant impacts to a less-than-significant level. For impacts determined to be PSU and SU, implementation of mitigation measures would still be required, but it has been determined that these measures would not reduce the identified impact to a less-than-significant level.[2] Section 6.4 identifies water supply/system operations mitigation measures which apply to the WSIP as a whole and are referred to as “System Measures.”

CEQA Section 15126.4 states that an EIR shall distinguish between the mitigation measures which are proposed by project sponsor to be included in the project and the measures that are identified in the EIR as proposed by the lead agency. At this time, the SFPUC intends to incorporate all mitigation measures presented in this PEIR into the implementation of the WSIP, if approved, and therefore all measures are considered to be proposed by the project sponsor except in the following cases:

- If any of the project-level EIRs completed on WSIP facility improvement projects finds a different impact determination and deems a PEIR mitigation measures unnecessary

- If any of the project-level EIRs determines that a project-specific mitigation measure would be more appropriate than a PEIR mitigation measure once the impact is more fully analyzed with additional project-level details

In the above cases, the SFPUC may not need to provide mitigation due to less-than-significant impact findings, or may chose to implement alternative mitigation measures identified in the project-level EIRs.

---

1 In some cases, a mitigation measure may reduce an impact but because there is no definitive threshold, a less-than-significant determination cannot be made.
2 *Ibid*.

6.2 SFPUC Construction Measures

The following SFPUC standard construction measures apply to all proposed WSIP facility improvement projects. The SFPUC standard construction measures are aimed at minimizing disruptions to surrounding neighborhoods, resources, and land uses during any SFPUC construction, maintenance, or repair activity or project that requires CEQA review. As required by the SFPUC, each project must include the SFPUC standard construction measures in the construction contract or project implementation procedures, as appropriate.

Some of the SFPUC standard construction measures may not be appropriate for certain kinds of projects, but each of the measures must be addressed, either by explaining why the measure is not applicable to the particular site, undertaking the activities listed, or undertaking further investigation and developing a more detailed work plan to address the issue.

1. *Neighborhood Notice*: The SFPUC will provide reasonable advance notification to the businesses, owners and residents of adjacent areas potentially affected by the Water System Improvement Program (WSIP) projects about the nature, extent and duration of construction activities. Interim updates should be provided to such neighbors to inform them of the status of the construction.

   Where schools would be affected, the SFPUC will coordinate with school facility managers to schedule construction for time periods with the least impact on school activities and facilities to ensure student safety and to minimize disruption to educational and recreational uses of the school property.

2. *Seismic and Geotechnical Studies*: Projects will incorporate review of existing information and, if necessary, new engineering investigations to provide relevant geotechnical information about the particular site and project, including a characterization of the soils at the site, and the potential for subsidence and other ground failure. Construction will address any recommendations by such geotechnical reports to ensure seismic stability and reliability of the proposed project. All SFPUC projects must be designed for seismic reliability and minimum potential water loss and property damage. All components of the water system improvement program must be designed to continue water service during a major earthquake.

3. *On-Site Air and Water Quality Measures during Construction*: All construction contractors must take measures to minimize fugitive dust and dirt emissions resulting from the construction, and implement measures to minimize any construction effects on local air and water quality, including a local storm drain system or watercourse. These measures could include preparation of a Stormwater Pollution Prevention Plan (SWPPP), if required by the California Regional Water Quality Control Board. At a minimum, construction contractors should undertake the following measures, as applicable, to minimize any adverse effects:

   - Erosion and sedimentation controls tailored to the site and project
   - Dust control plan
   - Placement of straw rolls around each of the nearby stormwater inlets;
   - Preservation of existing vegetation;
   - Installation of silt fences;

- Use of wind erosion control (e.g. – geotextile or plastic covers on stockpiled soil);
- Sweeping of nearby streets at least once a day; and/or;
- Stabilization of site ingress/egress locations to minimize erosion.
- Spraying the disturbed areas of the site, or any stockpiled soil, with water to minimize fugitive dust emissions.

4. *Groundwater*: If groundwater is encountered during any excavation activities, the construction contractor shall prepare a dewatering plan so that water is discharged to the stormwater system in compliance with the local standards and discharge permit requirements.

5. *Traffic*: Each contractor shall prepare a traffic control plan which will minimize the impacts on traffic and on-street parking on any streets affected by construction of the proposed project. As appropriate, SFPUC or the contractor will consult with local traffic and transit agencies.

6. *Noise*: The contractor will comply with local noise ordinances regulating construction noise to the extent feasible, and will undertake efforts to minimize any noise disruption to nearby neighbors and sensitive receptors during construction.

7. *Hazardous Materials*: Appropriate measures will be implemented to characterize and dispose of hazardous materials should they be encountered during excavation and construction. Contract specifications will mandate full compliance will all applicable local, state and federal regulations related to the identification, transportation and disposal of hazardous materials/soils. As necessary, a spill prevention and countermeasure plan will be prepared.

   A qualified environmental professional will conduct any necessary site assessment. The site assessment would include a regulatory database review to identify permitted hazardous materials and environmental cases in the vicinity of each project no more than three months before construction, and a review of appropriate standard information sources to determine the potential for soil or groundwater contamination to occur. Follow-up sampling would be conducted as necessary to characterize soil and groundwater quality prior to construction and, if needed, site investigations or remedial activities would e performed in accordance with applicable laws. The environmental professional would prepare a report documenting the activities performed, summarize the results and make recommendations for appropriate handling of any contaminated materials during construction. A contingency plan would also be prepared identifying measures to be taken should unanticipated contamination be identified during construction. Construction contractors will conduct asbestos and lead abatement in accordance with established regulations.

8. *Biological Resources*: As an initial matter, SFPUC project managers will screen the project site and area to determine whether biological resources may be affected by construction activities. In the event further investigation is necessary, the SFPUC will comply with all requirements for investigation, analysis and protection of biological resources. A qualified biologist must conduct any required biological screening survey. The biologist will review standard information sources to determine special status species with the potential to occur on the project site. The biologist would carry out a site survey by walking or driving over the project site, as appropriate, to note the general resources and whether any habitat for special-status species is present. The biologist would then document the survey with a brief letter report or memo, setting forth the date of the visit, whether habitat for special-status

species is present, providing a map or description showing where sensitive areas exist within the site, and identifying any appropriate avoidance measures.

9. *Cultural Resources*: As an initial matter, SFPUC project managers will screen the project site and area to determine whether cultural resources, including archaeological and other historical resources, may be affected by construction activities. In the event further investigation is necessary, the SFPUC will comply with all requirements for investigation, analysis and protection of cultural resources.

CEQA considers paleontological resources to be "cultural resources." Any screening for cultural resources would include screening for archaeological, paleontological and historic resources. For projects requiring excavation, deep grading, well drilling or tunneling into geologic material at sites identified as having high potential for encountering paleontological resources, a state-registered professional geologist or qualified professional paleontologist will conduct a site-specific evaluation of the paleontological sensitivity. The assessment will include a report of findings for the SFPUC.

A qualified archaeologist, historian or paleontologist will conduct all cultural resources survey and screening work. Screening surveys for cultural resources would include a cultural resources records search to be conducted at the appropriate office member of the California Historical Resources Information System. A field survey will be conducted if determined necessary after the cultural resources records search. Any impacts on identified cultural resources will be avoided to the extent feasible.

Any initial historic resource screening will identify historic resources on the project site as well as adjacent to the project site.

It is possible that project work may affect accidentally discovered buried or submerged cultural resources. Any contractor must distribute the Planning Department archaeological resource “ALERT” sheet to any person involved in soil-disturbing activities. If there is any indication of an archaeological or a paleontological resource during the soils disturbing activity of the project, the contractor shall immediately suspend any soils disturbing activities in the area and notify the SFPUC of such discovery. The SFPUC will then work with the Planning Department’s Environmental Review Officer to determine what additional measures should be implemented, based on reports from a qualified archaeological or paleontological consultant.

10. *Project Site*: The SFPUC will conduct construction activities on SFPUC-owned lands to the extent feasible and minimize the need for use of non-SFPUC-owned land during construction. In cases where construction easement or staging areas are needed on non-SFPUC land, the SFPUC will restore these areas to their prior condition so that the owner may return them to their prior use, unless otherwise arranged with the property owner. The site will be maintained to be clean and orderly. Construction staging areas will be sited away from public view where possible. Nighttime lighting will be directed away from residential areas.

Upon project completion, the construction contractor will return the SFPUC project site to its general condition before construction, including re-grading of the site and re-vegetation of disturbed areas.

6.3 Mitigation Measures to Minimize Facilities Impacts

This section presents all mitigation measures for PSM/SM and PSU/SU impacts described in Chapter 4. Mitigation measures for impacts identified in Sections 4.2 through 4.15 are presented under the respective environmental resource topic, such as Land Use or Biological Resources. Mitigation measures for collective and cumulative impacts (Sections 4.16 and 4.17) are also presented under the appropriate environmental resource topic, rather than under a separate heading, so that similar measures are grouped together. As stated above, all mitigation measures are numbered to correspond to the same impact numbers, although in some cases, the same measure would mitigate more than one impact and the numbering corresponds to the first impact identified and cross-referenced so that measures are not duplicated.

6.3.1 Plans and Policies

None applicable.

6.3.2 Land Use and Visual Resources

Program Measures

Facility Siting Studies

Measure 4.3-2: It is the policy of the SFPUC to construct and operate its facilities on SFPUC-owned lands to the extent feasible. When use of SFPUC-owned land is not feasible, and where additional permanent easement or land acquisition is required, the SFPUC will conduct project-specific facility siting studies and implement these studies' recommendations to avoid or minimize impacts on existing land uses to the maximum extent feasible. Siting studies will identify and evaluate alternative site locations, access roads, building configurations and facility operations to minimize or avoid land use impacts. The studies will also consider existing and planned land uses on and adjacent to proposed facility sites and rights-of-way on non-SFPUC-owned land. To the extent feasible, the SFPUC will implement the recommendations in the siting studies.

Architectural Design

Measure 4.3-4a: The design of permanent new, above-ground facilities will consider the existing visual character of the site and surrounding area, including the visibility of facilities and related structures from scenic highways and scenic roads. Structures will be designed to incorporate building features and design elements that are compatible with the surroundings.

Landscaping Plans

Measure 4.3-4b: The SFPUC will prepare and implement landscaping plans to restore project sites to their pre-construction condition such that short-term construction disturbance does not result in long-term visual impacts. To retain the existing visual character of the site and surrounding area, disturbed areas will be recontoured and revegetated and recontoured to pre-construction condition. Landscape vegetation will include noninvasive, and where possible, native grasses, shrubs, and trees similar to existing landscaping. The SFPUC will monitor landscape plantings annually for five years after project completion to ensure that sufficient ground coverage has developed and will implement additional measures, such as replanting or modifying irrigation systems, as determined necessary.

Landscape Screens

Measure 4.3-4c: In addition to revegetation of disturbed areas, the landscaping plans will include new plantings and landscape berms to screen views of new structures and equipment from scenic roads to the extent possible, provided that such landscaping does not affect security of SFPUC facilities.

Minimize Tree Removal

Measure 4.3-4d: The SFPUC will minimize or avoid the removal of existing trees that currently screen existing and proposed sites of WSIP facilities by modifying the proposed alignments of new temporary and permanent roads to the extent feasible. The SFPUC will consult with a qualified arborist regarding the minimum buffer zones required to prevent root damage to remaining trees and to provide the SFPUC with any necessary maintenance requirements for remaining trees. Also, the arborist will develop and assist the SFPUC in implementing an appropriate landscaping plan (see Measure 4.3-4b, above), including tree replacement, that is compatible with project operation and maintenance.

Reduce Lighting Effects

Measure 4.3-5: To the extent possible, all permanent exterior lighting will incorporate cutoff shields and non-glare fixture design. All permanent exterior lighting will be directed onsite and downward. In addition, new lighting will be oriented to ensure that no light source is directly visible from neighboring residential areas and will be installed with motion-sensor activation. In addition, highly reflective building materials and/or finishes will not be used in the designs for proposed structures, including fencing and light poles. Vegetation selected for landscaping will be selected, placed and maintained to minimize offsite light and glare in surrounding areas as part of the landscaping plans described in Measure 4.3-4b.

Collective Measures

Construction Coordination at Irvington Portal

Measure 4.16-1a: If construction schedules of multiple WSIP projects occurring at and near Irvington Portal coincide or overlap, the SFPUC will coordinate with construction contractor(s) and neighbors to minimize disturbance of residents in the adjacent neighborhood to the extent practicable. Such coordination will need to balance the duration of construction with the magnitude of construction-related impacts on the same sensitive receptors.

6.3.3 Geology, Soils and Seismicity

Program Measures

Quantified Landslide Analysis

Measure 4.4-1: If the screening analysis conducted in accordance with SFPUC Construction Measure #2 identifies any landslide hazards, affected WSIP facilities will, to the extent feasible, be located away from known landslides, very steep hillsides, debris-flow source areas, the mouths of steep sidehill drainages, and the mouths of canyons that drain steep terrain. However, where these landslide hazard areas cannot be avoided, a more quantified analysis (including a site-specific geologic investigation and a slope stability analysis to determine the potential for landsliding) should be performed as part of the geotechnical investigation. Recommendations identified in the site-specific geotechnical report regarding the potential for landsliding, including appropriate construction measures, will be incorporated into the project designs to minimize the potential for damage to project facilities.

Subsidence Monitoring Program

Measure 4.4-4: As part of the project-specific CEQA review for the New Irvington Tunnel (SV-4) and BDPL Reliability Upgrade (BD-1), the SFPUC will analyze the potential for ground subsidence to occur during tunneling, and will identify project-specific trigger levels that would require corrective action should subsidence occur. As determined to be necessary, the tunnel contractor will implement a subsidence monitoring program during tunneling to detect subsidence, including measurements of groundwater levels, surface and subsurface settlement, ground movement and displacement, and movement in existing infrastructure as needed. The SFPUC will implement corrective actions, such as increased tunnel support, if measured displacement reaches the specified trigger levels.

Characterize Extent of Expansive and Corrosive Soil

Measure 4.4-9: If the screening analysis conducted in accordance with SFPUC Construction Measure #2 identifies a potential for expansive or corrosive soils, the site-specific geotechnical investigation will include a characterization of the presence and extent of expansive and corrosive soil at the project facility site. The results and recommendations of the investigation will be incorporated into the final project design.

6.3.4 Surface Water Hydrology and Water Quality

Program Measures

Site-Specific Groundwater Analysis and Identified Measures

Measure 4.5-2: As part of the project-specific CEQA review for the New Irvington Tunnel project (SV-4), the SFPUC will inventory springs and wells in the area of the planned tunnel and conduct a project-specific analysis of the potential for tunnel dewatering to stop or decrease spring flow, lower groundwater levels in nearby wells, or to otherwise cause adverse effects on groundwater resources and beneficial uses of the groundwater. If a significant impact is identified, then measures such as altering groundwater withdrawal rates and/or providing an alternate water supply for affected users will be implemented to ensure that groundwater resources or beneficial uses are not adversely affected.

Flood Flow Protection Measures

Measure 4.5-4a: In construction contract specifications, the SFPUC will require the contractor(s) to include, in their erosion control measures or SWPPP prepared for the project, a measure prohibiting the stockpiling of soil, storage of hazardous materials, and stockpiling of construction materials in flood zones, where practical. Where construction would occur in large flood zones, making it impractical to implement this requirement, the erosion control measures or SWPPP will include measures for protecting stockpiled soil, sources of hazardous materials, and stockpiled construction materials from exposure to flood waters.

Site-Specific Flooding Analysis and Identified Measures

Measure 4.5-4b: As part of the project-specific CEQA review for the Alameda Creek Fishery (SV-1) and New Irvington Tunnel (SV-4) projects, the SFPUC will conduct a site-specific analysis of the potential for flooding as a result of project implementation. If a dam or concrete weir is installed in Alameda Creek under the Alameda Creek Fishery project, the analysis will include, at a minimum, the stream flow data and planned design and operation of the dam or weir to prevent flooding impacts. For the New Irvington Tunnel project, the analysis will include design measures needed to ensure that upstream water levels are not affected, bridge abutments are protected from damage due to flood flows and would not adversely redirect flood flows, and that bridge pilings are protected from scour.

Stormwater Treatment and Groundwater Monitoring

Measure 4.5-5: If treated stormwater is used to augment Lake Merced water levels, the project-level CEQA analysis for the Local Groundwater Projects (SF-2) will include measures to ensure that use of stormwater does not promote eutrophication of the lake and provisions for implementing these measures. The project-level CEQA analysis will also evaluate the potential for groundwater quality degradation due to the use of treated stormwater to augment lake levels. If necessary, the SFPUC will implement a groundwater monitoring program in the vicinity of Lake Merced to monitor for degradation of groundwater quality. Monitoring will include water quality sampling for total coliform bacteria, total nitrogen, nitrate, nitrite, total organic carbon, parameters for which drinking water quality criteria have been established, and any other potential pollutants of concern. The project-level CEQA documentation will identify corrective actions that would be implemented should groundwater quality degradation be identified, such as additional treatment of water used to augment water levels in Lake Merced.

Appropriate Source Control and Site Design Measures

Measure 4.5-6: For projects located in areas not covered by a municipal stormwater permit and disturbing less than one acre of land during construction, the SFPUC will implement appropriate source control and site design measures that 1) minimize the stormwater flow rate and quantity to prevent off-site erosion and flooding; and 2) minimize stormwater pollutant discharges to the maximum extent possible. These measures will ensure compliance with applicable water quality criteria and goals and protect the beneficial uses of the receiving water.

6.3.5 Biological Resources

Program Measures

Wetlands Assessment

Measure 4.6-1a: As part of project-specific CEQA review, a qualified wetland scientist will review project plans, airphotos, and topographic maps and conduct a site visit to determine whether wetlands are present and could be affected by the project. If the review shows that wetlands could be affected, the wetland scientist will perform a formal wetland delineation and develop mitigation as per Measure 4.6-1b, below.

Compensation for Wetlands and Other Biological Resources

Measure 4.6-1b: If the wetland delineation indicates that the WSIP project will affect jurisdictional wetlands or aquatic resources, then, in accordance with state and federal permit requirements, the SFPUC will avoid and minimize direct and indirect impacts such as erosion and sedimentation, alteration of hydrology, and degradation of water quality. As a first priority, the SFPUC will implement (1) avoidance measures. For unavoidable impacts, the SFPUC will implement (2) minimization of unavoidable impacts, (3) restoration procedures, and (4) compensatory creation or enhancement to ensure no net loss of wetland extent or function.

In addition to wetlands, the SFPUC will compensate for sensitive riparian and upland habitats and habitats which support key special-status species or other species of concern lost as a result of WSIP project construction and operation. Similar habitat will be identified, protected, restored, enhanced, created and managed off-site[3] to ensure no net loss of habitat extent or function. For each WSIP project, a qualified biologist will quantify the magnitude and extent of impacts to wetlands, sensitive habitats, and key special-status species and other species of concern, and the SFPUC will develop and implement restoration and/or compensation plans that meet the appropriate regulatory requirements and permit conditions with respect to restoration and/or compensation ratios. Compensation ratios typically range from a minimum of 1:1 for common habitats to 2:1 or higher for rare and sensitive habitats. If individual project requirements of the RWQCB, CDFG, or USFWS differ somewhat from these ratios, they are still intended to achieve the same purpose of full restoration and/or compensation, to mitigate project impacts to less-than-significant levels, and to ensure no net reduction in the populations of any species listed as threatened or endangered by the state or federal resource agencies.

The SFPUC will obtain required permits for each project and comply with applicable environmental regulations addressing sensitive habitats and species. Compensatory lands, including those restored or enhanced as well as those acquired or designated as protected as part of program or project mitigation, will be established in perpetuity with a commitment that such lands will not be used for any purpose that conflicts with the primary purpose of maintaining intact wildlife and plant habitat.

3 Off-site means the compensatory action is located other than within the project construction footprint, but could be on lands already under SFPUC ownership. Measure 4.6-2 addresses compensatory actions to be taken within the construction footprint.

One alternative for implementing off-site habitat compensation is the Habitat Reserve Program (HRP) currently being developed by the SFPUC. The purpose of the HRP is to provide a comprehensive, coordinated approach to mitigation and related regulatory compliance for WSIP projects. This related SFPUC project is described further in Chapter 3.0, Section 3.11. Under the proposed HRP, the SFPUC would proceed as soon as possible with securing (through designation, management agreement, conservation easement, or acquisition of fee title) and improving lands to be used for habitat compensation so that mitigation is underway before or concurrent with habitat loss related to WSIP project activities, further ensuring no net loss of resources. CEQA environmental review for the proposed HRP will commence in 2007 and is targeted for implementation as soon as possible thereafter. Once the HRP is approved and implemented, the SFPUC will use this as one vehicle or method for implementing the mitigation requirements for individual WSIP projects. Otherwise, where appropriate and necessary, the SFPUC will develop and implement appropriate habitat compensation mitigation for individual WSIP projects.

Habitat Restoration/Tree Replacement

Measure 4.6-2: If the biological screening survey identifies sensitive habitats or heritage trees, the following measures, as modified and applied to WSIP projects, will be implemented:

- Temporarily-impacted sensitive habitats (natural communities identified as sensitive by CDFG, and USFWS-designated critical habitat) would be restored to their pre-project condition.

- If specific trees to be removed are designated as heritage trees (or similar local designation), then SFPUC will replace the trees, consistent with requirements in local ordinances. If such heritage trees occur near extensive areas of sensitive habitats, locally collected, native species will be used as replacement trees where possible.

- Where possible, the loss of sensitive habitats will be minimized by coordinating WSIP projects to make repeated use of staging/construction areas and access roads. For example, tunnel spoils could be considered for borrow material for other projects.

Protection Measures During Construction for Key Special-Status Species and Other Species of Concern

Measure 4.6-3a: The following general practice measures, as modified and applied to the WSIP projects, will be implemented if the initial biological screening survey (SFPUC Construction Measure #8) indicates the potential for the presence of key special-status species and other species of concern:

- Preconstruction surveys for key special-status species and other species of concern will be conducted by a qualified biologist to verify their presence or absence. Surveys will occur during the portion of the species' life cycle when the species is most likely to be identified within the appropriate habitat. Key special-status species and other species of concern will be avoided during construction when possible.

- A worker awareness program (environmental education) will be developed and implemented to inform project workers of their responsibilities in regards to sensitive biological resources.

- An environmental inspector will be appointed to serve as a contact for issues that may arise concerning implementation of mitigation measures, and to document and report on adherence to these measures during construction.

- Loss of habitat will be minimized through the following measures: (1) the number and size of access routes and staging areas and the total area of the project activity will be limited to the minimum necessary to achieve the project goal; (2) the introduction or spread of invasive non-native plant species and plant pathogens will be avoided or minimized by developing and implementing a weed control plan; and (3) all areas temporarily disturbed by construction will be revegetated to pre-project or native conditions, as specified in project-specific revegetation plans.

Standard Mitigation Measures for Specific Plants and Animals

Measure 4.6-3b: Table 6.1 identifies the key special-status species mitigation measures that the program analysis indicates would apply to each WSIP project. Measures listed in **Table 6.2** (listed by species) are generic measures and will be modified to fit site-specific conditions and applied to each WSIP project wherever special-status species could be affected by the projects. Surveys required under Measure 4.6-3a will refine the list of species that could be affected by a project. Table 6.1 is intended as the minimum necessary actions. In addition to adopting the generic measures, as more site-specific information is available, project-specific CEQA analysis may identify additional measures for key special-status species and additional measures for other species.

Pipeline and Water Treatment Plant Treated Water Discharge Restrictions

Measure 4.6-4: Planned discharges of regional system water from the WSIP pipelines and water treatment plants (such as crossover facilities) to creeks, rivers or other natural water bodies will be designed to minimize impacts to riparian and aquatic resources to the extent feasible. This will include dechlorination and/or pH adjustment facilities and energy dissipation structures that avoid or reduce bank erosion. In addition, the facilities should include design features to avoid or minimize temperature effects on aquatic resources; or alternatively, whenever possible, planned discharges should be scheduled to occur in the winter, when stream flows are high and temperatures low in the receiving waters to avoid or minimize temperature effects.

Collective Measures

Bioregional Habitat Restoration Measures

Measure 4.16-4a: Bioregional effects (those beyond the level of individual plants or animals and impacts not readily associated with any particular project) could result from the collective construction of WSIP facilities and the cumulative effects of implementing WSIP projects along with other proposed projects. Combined collective and cumulative bioregional effects that will need to be addressed as part of future mitigation efforts include the following:

- Compound impacts on functional units of habitat as WSIP projects simplify vegetation structure and increase “edge” (the boundary between two different habitats);
- Increased habitat impacts due to the spread of weedy, non-native plant species;
- Genetic diversity impacts on small populations that become reduced and isolated by development;

TABLE 6.1 (SEE MEASURE 4.6-3b)
MITIGATION MEASURES FOR KEY SPECIAL-STATUS SPECIES

No.	Project Name Notes: 1. This table is for guidance only and is not intended as a complete list of mitigations for all projects, which must be assessed individually at the project-specific level. 2. Standard measure B.4 (general surveys for raptors and protection of raptor nests) apply to all projects.	Suites of Key Special-Status Species						Individual Special-Status Species								
		Vernal Pool Invertebrates	Vernal Pool Plants	Riparian and Reservoir Species	Native Grassland Species	Salt Marsh Species	Fishes	Large-Flowered Fiddleneck	Foothill yellow-legged frog	California Red-Legged Frog	California Tiger Salamander	San Francisco Garter Snake	Alameda Whipsnake	Swainson's Hawk	Western Burrowing Owl	San Joaquin Kit Fox
SJ-1	Advanced Disinfection	I.2								RA.1	RA.2			B.1	B.2, B.3	M.2

SF-2	Groundwater Projects				P.4, I.3					RA.1		RA.3				
SF-3	Recycled Water Projects				P.4, I.3					RA.1		RA.3				

Note: Project-specific CEQA documents would review recent special-status species lists relevant to the habitats present.

All codes are defined in Table 6-2.

Vernal pool invertebrates:
- Vernal pool fairy shrimp
- Conservancy fairy shrimp
- Vernal pool tadpole shrimp

Vernal pool species:
- Succulent owl's-clover
- Hoover's spurge
- Colusa grass
- San Joaquin Valley Orcutt grass
- Hairy Orcutt grass
- Greene's tuctoria

Salt marsh species:
- Western snowy plover
- California clapper rail
- California black rail
- Salt marsh harvest mouse

Riparian and Reservoir species:
- Least Bell's vireo
- Valley elderberry longhorn beetle
- Riparian woodrat
- Delta button-celery
- Bald eagle

Fishes:
- Green sturgeon (San Joaquin Valley only)
- Chinook salmon
- Central Valley DPS steelhead
- Central California Coast DPS steelhead
- Rainbow trout (Alameda watershed)

Native grassland species:
- Bay checkerspot butterfly
- Callippe silverspot butterfly
- Fountain thistle (Peninsula)
- Marin dwarf flax (Peninsula)
- San Mateo woolly sunflower (Peninsula)

TABLE 6-2 (MEASURE 4.6-3b) STANDARD PROGRAMMATIC BIOLOGICAL RESOURCES MITIGATION MEASURES

Biological Resource Species and Status	Standard Mitigation Measures for Specific Plants and Animals
Invertebrates	
Valley Elderberry Longhorn Beetle (FT/--)	**I.1:** A biological monitor will accompany tree/brush clearing crews. The monitor will flag all elderberry shrubs in the tree clearing zone and be present during tree clearing operations in the vicinity of flagged shrubs to ensure that elderberry shrubs are not cut. If avoidance is not feasible, habitat impacts will be mitigated in accordance with the Programmatic Biological Opinion (PBO) for Valley elderberry longhorn beetle, issued by the USFWS Sacramento Field Office in 1996.
Vernal Pool Crustaceans Vernal pool fairy shrimp (FT/--) Conservancy fairy shrimp (FE/--) Vernal pool tadpole shrimp (FE/--)	**I.2:** Suitable habitat for vernal pool invertebrates will be avoided. If infeasible, impacts will be mitigated in accordance with the PBO for vernal pool invertebrates, issued by the USFWS Sacramento Field Office in 1995. Surveys may be conducted, with USFWS approval, to establish whether or not listed invertebrates are present.
Bay Checkerspot Butterfly (FT/--), Callippe Silverspot Butterfly (FE/--)	**I.3:** Suitable habitat for Bay checkerspot and Callippe silverspot butterflies will be avoided
Fishes	
Central Valley fall- and late-fall run DPSChinook salmon (FC/--) Central Valley DPS steelhead (FT/--) Green sturgeon Southern District DPS (FT/--) Central Coast DPS Steelhead (FT/--) Rainbow trout (--/--)	**F1:** For construction activity in anadromous fish-bearing streams, a biological monitor with appropriate permits will be present during all construction activities to relocate fish as necessary.
Reptiles and Amphibians	
California Red-Legged Frog (FT/CSC) Foothill yellow-legged frog (--/CSC)	**RA.1:** A PBO for construction impacts on red-legged frog was prepared by the USFWS (Federal Register, 1999). The general mitigation measures, above, and the measures listed below, are taken largely from the PBO and may be modified by a project-specific BO. The foothill yellow-legged frog has no legal protection under FESA; however, all potential FYLF habitat is also considered potential habitat for CRLF and these protection measures would be applied in any case. • The name and credentials of a biologist qualified to act as a construction monitor will be submitted to the USFWS for approval at least 15 days prior to commencement of work. • The USFWS-approved biologist will survey the site two weeks prior to the onset of work activities and immediately prior to commencing work. If frog adults, tadpoles, or eggs are found, the approved biologist will contact the USFWS to determine whether relocating any life stages is appropriate. • If worksites require dewatering, the intakes will be screened with a maximum mesh size of 5 millimeters. • The USFWS-approved biologist will remove and destroy from within the project area any individuals of non-native species, such as bullfrogs, crayfish, and centrarchid fishes, to the maximum extent possible.

TABLE 6-2 (MEASURE 4.6-3b) (Continued)
STANDARD PROGRAMMATIC BIOLOGICAL RESOURCES MITIGATION MEASURES

Biological Resource Species and Status	Standard Mitigation Measures for Specific Plants and Animals
Reptiles and Amphibians (cont.)	
California Tiger Salamander (FT/CSC)	**RA.2:** In addition to measures described for California red-legged frog, which would serve to protect California tiger salamander, the following measures will minimize adverse effects to California tiger salamander. • A preconstruction survey will be conducted at each site to identify suitable burrow aestivation areas. Aestivation habitat will be defined as the presence of two or more small mammal burrows greater than 1 inch in diameter within a 10-foot-diameter area and within 10 feet of proposed construction sites (i.e., the presence of a single isolated gopher hole would not be considered habitat). As feasible within the context of the work area, aestivation areas will be temporarily fenced and avoided. • At locations where aestivation burrows are identified and cannot be avoided, aestivation burrows will be excavated by hand prior to construction and individual animals moved to natural burrows or artificial burrows constructed of PVC pipe within 0.25 mile of the construction site. • To ensure compliance with these measures and minimize California tiger salamander take, a qualified biological monitor will be present during all construction operations at locations with suitable aestivation burrows. Construction sites where potential habitat has been identified will be surveyed by a qualified biologist for California tiger salamander. Surveys would be appropriately timed with respect to salamander activity and proposed construction activities. • Surveys would include drift fences and pitfall traps within construction sites to identify and relocate animals. Following removal of individuals, construction areas will be fenced with temporary silt fencing.
San Francisco Garter Snake (FE/CE/CP)	**RA.3:** San Francisco garter snake is a California fully protected species, and incidental taking must be avoided. Therefore, in addition to measures RA.1 and RA.2, above, for construction activities in occupied habitat the work area will be fenced with frog- and snake-proof mesh fence, or 4- x 8-foot plywood panels joined lengthwise, with escape funnels to allow egress, but not access, by San Francisco garter snake.
Alameda Whipsnake (FT/CT)	**RA.4:** Construction-related impacts on individual Alameda whipsnakes will be minimized and/or avoided through the development and implementation of an Alameda whipsnake protection and monitoring plan, to be approved by the USFWS during informal consultation under FESA. Protective measures outlined in RA.1 will apply to all areas of known or potential habitat for Alameda whipsnake. In addition, it will include: • Sites within Alameda whipsnake habitat will be hand-cleared, or a qualified biologist will do surveys and relocate the snake immediately prior to equipment clearing. • Activities that could harm or harass Alameda whipsnake will be avoided or minimized. • Upland habitats used by Alameda whipsnake will be restored as feasible, and lost habitat will be compensated according to an agreed-upon ratio.
Birds	
Swainson's Hawk (FSC/CT)	**B.1:** To avoid disrupting nesting Swainson's hawks, construction activities at known nesting locations will occur prior to the nesting season (March 1 through September 15). Alternatively, if construction activities take place during the nesting season, a qualified biologist will conduct a preconstruction survey no more than two weeks before the start of construction and report whether or not there are nesting Swainson's hawks within 1,320 feet of any project (access permitting). If there are nesting Swainson's hawks within the 1,320-foot buffer areas, construction will be delayed until the CDFG has been consulted to determine suitable avoidance measures. A potential avoidance measure may include delaying all construction activity within 1,320 feet of an active Swainson's hawk nest until the adult and/or juvenile hawks are no longer using the nest as the center of their activity.

TABLE 6-2 (MEASURE 4.6-3b) (Continued)
STANDARD PROGRAMMATIC BIOLOGICAL RESOURCES MITIGATION MEASURES

Biological Resource Species and Status	Standard Mitigation Measures for Specific Plants and Animals
Birds (cont.)	
Western Burrowing Owl (FSC/CSC)	**B.2:** No more than two weeks before construction, a survey for burrows and burrowing owls will be conducted by a qualified biologist within 500 feet of the project (access permitting). The survey will conform to the protocol described by the California Burrowing Owl Consortium (1995), which includes up to four surveys on different dates if there are suitable burrows present. **B.3:** If occupied owl burrows are found within the survey area, a determination will be made by a qualified biologist, in consultation with the CDFG, as to whether or not work will affect the occupied burrows or disrupt reproductive behavior. If it is determined that construction will not affect occupied burrows or disrupt breeding behavior, construction will proceed without any restriction or mitigation measures. If it is determined that construction will affect occupied burrows during August through February, the subject owls will be passively relocated from the occupied burrow(s) using one-way doors. There will be at least two unoccupied burrows suitable for burrowing owls within 300 feet of the occupied burrow before one-way doors are installed. Artificial burrows will be in place at least one-week before one-way doors are installed on occupied burrows. One-way doors will be in place for a minimum of 48 hours before burrows are excavated. If it is determined that construction will physically affect occupied burrows or disrupt reproductive behavior during the nesting season (March through July), then avoidance is the only mitigation available. Construction will be delayed within 300 feet of occupied burrows until it is determined that the subject owls are not nesting or until a qualified biologist determines that juvenile owls are self-sufficient or are no longer using the natal burrow as their primary source of shelter.
Raptors including bald eagle (FD/CE/CFP)	**B.4: Raptor nests:** • In consultation with CDFG and USFWS trees with unoccupied raptor nests (stick nests or cavities) may only be removed prior to March 1, or following the nesting season. • A survey to identify active nests will be conducted by a qualified biologist no more than two weeks before the start of construction at project sites from February 1 through July 30. • Construction activities within 0.5 mile of an active bald eagle nest may not occur between February 1 and July 31. • Active raptor nests located within 500 feet of the project will be mapped, to the extent allowed by access. • If an active raptor nest is found within 500 feet of the project, a determination will be made by a qualified biologist, in consultation with the CDFG, as to whether or not construction work will affect the active nest or disrupt reproductive behavior. • If it is determined that construction will not affect an active nest or disrupt breeding behavior, construction will proceed without any restriction or mitigation measure. • If it is determined that construction will affect an active raptor nest or disrupt reproductive behavior, then avoidance is the only mitigation available. Construction will be delayed within 300 feet of such a nest until a qualified biologist determines that the subject raptors are not nesting or until any juvenile raptors are no longer using the nest as their primary day and night roost.
Least Bell's vireo (FE/CE)	**B.5:** Protection for least Bell's vireos depend principally on seasonal avoidance of habitat during the nesting season and protection of suitable habitat. To avoid working during the active breeding season, construction activities in suitable habitat (dense willows [*Salix* sp.], mulefat [*Baccharis glutinosa*], or California wild rose [*Rosa californica*] may not proceed until July 15 unless approved by the USFWS and CDFG, as appropriate.
California Black Rail (FE/CE), California Clapper Rail (FSC/CT/CFP)	**B.6:** When working within 100 feet of salt or brackish marshland (e.g., the BDPL Reliability Upgrade, BD-1), presume presence for either species during the period from February 1 to August 31, and schedule construction to begin no earlier than September 1 and end no later than January 31.

TABLE 6-2 (MEASURE 4.6-3b) (Continued)
STANDARD PROGRAMMATIC BIOLOGICAL RESOURCES MITIGATION MEASURES

Biological Resource Species and Status	Standard Mitigation Measures for Specific Plants and Animals
Birds (cont.)	
Western Snowy Plover (FT/CSC)	**B.7:** When project activities are in or adjacent to suitable habitat (e.g., portions of the BDPL Reliability Upgrade, BD-1) no earlier than September 1 and no later than January 31, no measures are necessary; however, between March 15 and August 31 the following will be observed: • A qualified biologist will conduct preconstruction surveys two weeks and one week before the start of work. If western snowy plovers or their nests are not observed, then the project activity may proceed; or • If a western snowy plover is observed within a 50-foot perimeter of the location of the construction activity two weeks or one week before, a qualified biologist will observe the activities of the bird(s) to determine if nesting behavior is exhibited. If either nesting behavior or a nest is observed within a 50-foot perimeter of the location of the activity, then the activity will be delayed until either nesting is abandoned or completed.
Mammals	
Salt Marsh Harvest Mouse (FE/CE/CFP)	**M.1:** When project activities are in or adjacent to suitable habitat (e.g., portions of the BDPL Reliability Upgrade, BD-1), vehicles will be confined to existing roads where possible, and disturbed areas will be revegetated with brackish marsh species. Crews will use matting, pontoon boards, or other comparable methods whenever feasible to minimize impacts on vegetation. The placement of mats will be verified by a qualified biologist before their placement to minimize habitat impacts. Crews will work exclusively from mat boards and boardwalks to minimize the trampling of vegetation. A qualified biologist will be available during the course of the maintenance work. In situations where habitat is to be permanently disturbed, project-specific take avoidance measures (such as fencing and trapping to exclude salt marsh harvest mouse) will be developed, since the mouse is a California fully protected species, and incidental taking must be avoided.
San Joaquin Kit Fox (FE/CT)	**M.2:** The following reasonable and prudent measures will be followed to avoid direct or indirect project-related disturbances and impacts on San Joaquin kit fox. Prior to the commencement of construction activities, a qualified biologist will survey for potential kit fox dens within the area to be disturbed and will photograph, mark, and map the dens. Disturbance of all known San Joaquin kit fox dens will be avoided. Limited destruction of potential dens may be allowed, provided the following procedures are implemented: • Potential dens occurring within the construction area will be monitored for three days with tracking medium or an infrared beam camera to determine current usage. If no kit fox activity is observed during this period, the den would be destroyed immediately to preclude subsequent use. If kit fox activity is observed, the den will be considered a known den. • Project-related vehicles will observe a 20-mph speed limit in habitat areas except as posted on county roads and state and federal highways. Off-road traffic outside the designated project area will be prohibited. • To prevent accidental entrapment of kit fox or other animals during construction, all excavated or deep-walled holes or trenches greater than 2 feet will be covered at the end of each workday by plywood or similar materials, or provided with escape routes constructed of earth fill or wooden planks. Before such holes are filled they will be thoroughly inspected for trapped animals. • Kit foxes are attracted to den-like structures such as pipes and may enter stored pipe and become trapped or injured. All construction pipes, culverts, or similar structures with a diameter of 4 inches or greater that are stored at construction sites for one or more overnight periods will be thoroughly inspected for kit foxes before the pipe is subsequently buried, capped, or otherwise used or moved in any way.

TABLE 6-2 (MEASURE 4.6-3b) (Continued)
STANDARD PROGRAMMATIC BIOLOGICAL RESOURCES MITIGATION MEASURES

Biological Resource Species and Status	Standard Mitigation Measures for Specific Plants and Animals
Mammals (cont.)	
Riparian Woodrat (FE/CSC)	**M.3:** If construction will involve surface disturbance or vegetation removal in riparian habitat in the San Joaquin Region, a biologist will carry out a preconstruction survey to determine the presence or any signs of riparian woodrat, such as stick nests. Such areas will be avoided if feasible. If avoidance is not feasible, a protection and monitoring plan will be developed and approved by the USFWS during formal consultation under FESA.
Plants	
Vernal Pool Plants Succulent Owl's-Clover ((FE/CE) Hoover's Spurge (FT/--) Colusa Grass (FT/CE) San Joaquin Valley Orcutt grass (FT/CE) Greene's Tuctoria (FE/CR) Hairy Orcutt Grass (FE/CE)	**P.1:** The avoidance measures for vernal pool crustaceans will also apply to vernal pool special-status plants. Surveys to ascertain presence are highly recommended, and if first-year surveys occur during unusually low rainfall conditions, a second year of surveys, if possible, will help to establish whether avoidance measures are needed.
Riparian Plants Delta button-celery (FSC/CE)	**P.2:** The state endangered Delta button-celery occurs on clay soils on the sparsely vegetated margins of seasonally flooded floodplains and swales. Periodic flooding maintains the species' habitat through sustenance of seasonal wetlands and reduction of competition due to scouring. If a population of this species is located in an area proposed for construction, the preferred action is to avoid it if possible. The CDFG might allow salvage and restoration of the site, since this is a species that depends on ongoing disturbance to maintain its habitat. However, such strategies generally involve several years of treatment and post-treatment monitoring, so the simplest approach is to avoid impacts if possible.
Large-Flowered Fiddleneck (FE/CE)	**P.3:** Surveys for large-flowered fiddleneck will be carried out at an appropriate time of year for projects located within the known range of the species (Corral Hollow and hills immediately to the west). Any populations found will be avoided. An approved biological monitor will be present during all surface clearing activities.
San Mateo Woolly Sunflower (FE/CE), Marin Western Flax (FT/CT) Fountain thistle (FE/CE)	**P.4:** Surveys for San Mateo woolly sunflower, fountain thistle and Marin western flax will be carried out at an appropriate time of year for projects located within the known range of the species. Any populations found will be avoided. An approved biological monitor will be present during all construction activities. A plan will be developed to protect populations located along Crystal Springs and Polhemus Roads where project-related construction vehicle traffic will occur. Where populations cannot be avoided, salvage of plants or seed will be implemented, along with a program to compensate for losses.

Status Codes: FE-Federal Endangered; FT-Federal Threatened; FC-Federal Candidate; FSC-Federal Species of Concern. FD-Federal Delisted; CE-California Endangered; CT-California Threatened; CR-California Rare; CFP-California Fully Protected

- Impacts on wildlife movement due to habitat fragmentation;

- Suppression of natural disturbance regimes (e.g., fire, flood) as projects are constructed, operated, and maintained; and

- Reduced population recovery opportunities from stochastic events (e.g., random events such as disease).

When implementing habitat compensation mitigation required for individual WSIP facility projects, the SFPUC shall do so in a manner that addresses the above bioregional effects and includes the following conservation principles:

- The parcels are either contiguous with other areas of relatively undisturbed habitat or are themselves large enough to support most of the species associated with the habitat;

- The distribution of mitigation lands will allow movement of plants and animals between them or from them to habitats otherwise conserved (e.g. as described in The Wilderness Society, 2001); and

- Implementation of habitat compensation mitigation for individual WSIP facility projects will be combined and implemented through a coordinated program with other mitigation efforts, such as through the Habitat Reserve Program (HRP), and shall meet these standards:

    - Long-term management of these lands stipulates maintaining natural disturbance regimes (e.g., through prescribed burning);

    - Long-term control actions for non-native species are applied; and

    - Contingencies are considered which address sharing biological materials and information with other conservation land stewards.[4] This might include restoring suitable sites with plants brought from another protected area once a weed infestation has been brought under control, or animal relocation if done strictly for the purpose of genetic diversity or recovery, and with the approval of the regulatory agencies.

Coordination of Construction Staging and Access

Measure 4.16-4b: When construction schedules for WSIP projects affecting the same areas overlap, the SFPUC will coordinate construction contractor(s) to the extent practicable to minimize surface disturbance associated with access roads, laydown areas, and staging areas.

[4] For example, the California Department of Parks and Recreation (CDPR), East Bay Regional Parks District (EBRPD), and the Midpeninsula Regional Open Space District (MROSD).

6.3.6 Cultural Resources

Program Measures

Suspend Construction Work if Paleontological Resource is Identified

Measure 4.7-1: This mitigation measure builds on SFPUC Construction Measure # 9 for cultural resources, which requires that construction work will be suspended immediately if there is any indication of a paleontological resource. When a paleontological resource (fossilized invertebrate, vertebrate, plant or micro-fossil) is discovered at any of the project sites, an appointed representative of the SFPUC will notify a qualified paleontologist, who will document the discovery as needed, evaluate the potential resource, and assess the significance of the find under the criteria set forth in Section 15064.5 of the CEQA Guidelines. When a fossil is found during construction, excavations within 50 feet of the find will be temporarily halted or diverted until the discovery is examined by a qualified paleontologist, in accordance with Society of Vertebrate Paleontology standards (SVP 1995, 1996). The paleontologist will notify the SFPUC to determine procedures to be followed before construction is allowed to resume at the location of the find. If the SFPUC determines that avoidance is not feasible, the paleontologist will prepare an excavation plan for mitigating the effects of the project.

Archaeological Testing, Monitoring, and Treatment of Human Remains

Measure 4.7-2a: SPFUC Construction Measure #9 for cultural resources requires that a pre-construction screening be conducted by a qualified archaeologist. Based on the results of this screening, the Environmental Review Officer (ERO) shall determine if implementation of an archaeological testing or archaeological monitoring program or both is the appropriate strategy for avoidance of potential adverse effects to significant archaeological resource. For those projects that require a federal permit and compliance with the NHPA, Section 106, the ERO will review the SHPO-approved requirements in the permit conditions and consider protective approaches that limit undue duplication of efforts.

Archaeological Testing Program. The archaeological consultant shall prepare and submit to the ERO for review and approval an archaeological testing plan (ATP). The archaeological testing program shall be conducted in accordance with the approved ATP. The ATP shall identify the property types of the expected archaeological resource(s) that potentially could be adversely affected by the proposed project, the testing method to be used, and the locations recommended for testing. The purpose of the archaeological testing program will be to determine to the extent possible the presence or absence of any expected archaeological resources and to identify and to preliminarily evaluate the integrity and significance of the resource.

At the completion of the archaeological testing program, the archaeological consultant shall submit a written report of the findings to the ERO. If based on the archaeological testing program the archaeological consultant finds that significant archaeological resources may be present, the ERO in consultation with the archaeological consultant shall determine if additional measures are warranted. Additional measures that may be undertaken include additional archaeological testing, archaeological monitoring, preparation of an archaeological research design and treatment plan, or an archaeological data recovery program.

Archaeological Monitoring Program. The archaeological consultant shall prepare and submit to the ERO for review and approval an archaeological monitoring plan (AMP). The archaeological monitoring program shall be conducted in accordance with the approved AMP. The AMP shall specify what project activities in areas sensitive for buried resources shall be archaeologically monitored. Project activities that may require monitoring may include the installation of pipelines and crossover facilities and certain soils-altering activities such as grading and access road construction associated with construction or improvement of water storage facilities. The archaeological monitoring program shall include the following:

- All project contractors shall be advised to be on the alert for evidence of the presence of the expected resource(s), of how to identify the evidence of the expected resource(s), and of the appropriate protocol in the event of apparent discovery of an archaeological resource;

- The archaeological monitor(s) shall be present on the project site according to a schedule agreed upon by the archaeological consultant and the ERO until the ERO has, in consultation with project archaeological consultant, determined that project construction activities are unlikely to have effects on significant archaeological deposits;

- The archaeological monitor shall record and be authorized to collect soil samples and artifactual/ecofactual material as warranted for analysis;

- If an intact archaeological deposit is encountered, all soils-disturbing activities within the area specified in the AMP of the deposit shall cease. The archaeological monitor shall be empowered to temporarily redirect demolition/excavation/pile driving/construction activities and equipment until the deposit is evaluated. The archaeological consultant shall immediately notify the ERO of the encountered archaeological deposit. The archaeological consultant shall make a reasonable effort to assess the identity, integrity, and significance of the encountered archaeological deposit, and present the findings of this assessment to the ERO.

Whether or not significant archaeological resources are encountered, the archaeological consultant shall submit a written report of the findings of the monitoring program to the ERO.

Additional Requirements: the following requirements, as applicable, are requisite in implementation of either an archaeological testing or monitoring program.

Archaeological Data Recovery Program. The archaeological data recovery program shall be conducted in accord with an archaeological data recovery plan (ADRP). The archaeological consultant, project sponsor, and ERO shall meet and consult on the scope of the ADRP prior to preparation of a draft ADRP. The archaeological consultant shall submit a draft ADRP to the ERO. The ADRP shall identify how the proposed data recovery program will preserve the significant information the archaeological resource is expected to contain. That is, the ADRP will identify what scientific/historical research questions are applicable to the expected resource, what data classes the resource is expected to possess, and how the expected data classes would address the applicable research questions. Data recovery, in general, should be limited to the portions of the historical property that could be adversely affected by the proposed project. Destructive data recovery methods shall not be applied to portions of the archaeological resources if nondestructive methods are practical.

The scope of the ADRP shall include the following elements:

- *Field Methods and Procedures*. Descriptions of proposed field strategies, procedures, and operations.
- *Cataloguing and Laboratory Analysis*. Description of selected cataloguing system and artifact analysis procedures.
- *Discard and Deaccession Policy*. Description of and rationale for field and post-field discard and deaccession policies.
- *Interpretive Program*. Consideration of an on-site/off-site public interpretive program during the course of the archaeological data recovery program.
- *Security Measures*. Recommended security measures to protect the archaeological resource from vandalism, looting, and non-intentionally damaging activities.
- *Final Report*. Description of proposed report format and distribution of results.
- *Curation*. Description of the procedures and recommendations for the curation of any recovered data having potential research value, identification of appropriate curation facilities, and a summary of the accession policies of the curation facilities.

Human Remains and Associated or Unassociated Funerary Objects. The treatment of human remains and of associated or unassociated funerary objects discovered during any soils disturbing activity shall comply with applicable State laws. This shall include immediate notification of the coroner of the county within which the project is located and in the event of the coroner's determination that the human remains are Native American remains, notification of the California State Native American Heritage Commission (NAHC) who shall appoint a Most Likely Descendant (MLD) (Pub. Res. Code Sec. 5097.98). The archaeological consultant, project sponsor, and MLD shall make all reasonable efforts to develop an agreement for the treatment of, with appropriate dignity, human remains and associated or unassociated funerary objects (CEQA Guidelines. Sec. 15064.5(d)). The agreement should take into consideration the appropriate excavation, removal, recordation, analysis, custodianship, curation, and final disposition of the human remains and associated or unassociated funerary objects. State law allows 24 hours to reach agreement on these matters. If the MLDs do not agree on the reburial method, the Project will follow Section 5097.98(b) of the California Public resources code which states, "the landowner or his or her authorized representative shall reinter the human remains and items associated with Native American burials with appropriate dignity on the property in a location not subject to further subsurface disturbance."

Final Archaeological Resources Report. The archaeological consultant shall submit a Draft Final Archaeological Resources Report (FARR) to the ERO that evaluates the historical significance of any discovered archaeological resource and describes the archaeological and historical research methods employed in the archaeological testing/monitoring/data recovery program(s) undertaken. Information that may put at risk any archaeological resource shall be provided in a separate removable insert within the final report. Once approved by the ERO, copies of the FARR shall be distributed as follows: the relevant California Historical Resources Information System Information Center shall receive one (1) copy and the ERO shall receive a copy of the transmittal of the FARR to the Information Center. The Major Environmental Analysis division of the Planning Department (MEA) shall receive three copies of the FARR along with copies of any formal site recordation forms (CA DPR 523 series) and/or documentation for evaluation under National Register of Historic Places/California Register of Historical Resources criteria. The SFPUC shall receive copies of the FARR as requested in number. In instances of high public interest in or the high interpretive value of the resource, the ERO may require a different final report content, format, and distribution than that presented above.

Accidental Discovery Measures

Measure 4.7-2b: SFPUC Construction Measure # 9 for cultural resources requires that construction activities be suspended immediately if there is any indication of an archaeological resource.

To avoid any potential adverse effect from the proposed project on accidentally discovered buried or submerged historical resources as defined in CEQA Guidelines Section 15064.5(a)(c), the project sponsor shall distribute the Planning Department archaeological resource “ALERT” sheet to the project prime contractor; to any project subcontractor (including demolition, excavation, grading, foundation, pile driving, etc. firms); or utilities firm involved in soil disturbing activities within the project site. Prior to any soil disturbing activities being undertaken, each contractor is responsible for ensuring that the “ALERT” sheet is circulated to all field personnel including, machine operators, field crew, pile drivers, supervisory personnel, etc. The project sponsor shall provide the Environmental Review Officer (ERO) with a signed affidavit from the responsible parties (prime contractor, subcontractor(s), and utilities firm) to the ERO confirming that all field personnel have received copies of the “ALERT” sheet.

If the ERO determines that an archaeological resource may be present within the project site, the project sponsor shall retain the services of a qualified archaeological consultant. The archaeological consultant shall advise the ERO as to whether the discovery is an archaeological resource, retains sufficient integrity, and is of potential scientific/historical/cultural significance. If an archaeological resource is present, the archaeological consultant shall identify and evaluate the archaeological resource. The archaeological consultant shall make a recommendation as to what action, if any, is warranted. Based on this information, the ERO may require, if warranted, specific additional measures to be implemented by the project sponsor.

Measures might include: preservation in situ of the archaeological resource; an archaeological monitoring program; or an archaeological testing program. If an archaeological monitoring program or archaeological testing program is required, it shall be consistent with the MEA guidelines for such programs. The ERO may also require that the project sponsor immediately implement a site security program if the archaeological resource is at risk from vandalism, looting, or other damaging actions.

The project archaeological consultant shall submit a Final Archaeological Resources Report (FARR) to the ERO that evaluates the historical significance of any discovered archaeological resource and describing the archaeological and historical research methods employed in the archaeological monitoring/data recovery program(s) undertaken. Information that may put at risk any archaeological resource shall be provided in a separate removable insert within the final report. Once approved by the ERO, copies of the FARR shall be distributed as follows: the relevant California Historical Resources Information System Information Center shall receive one (1) copy and the ERO shall receive a copy of the transmittal of the FARR to the Information Center. The MEA shall receive three copies of the FARR along with copies of any formal site recordation forms (CA DPR 523 series) and/or documentation for nomination to the National Register of Historic Places/California Register of Historical Resources. The SFPUC shall receive copies of the FARR as requested in number. In instances of high public interest in or the high interpretive value of the resource, the ERO may require a different final report content, format, and distribution than that presented above.

Protection of Historic Districts

Measure 4.7-3: The city's water system facilities affected by WSIP facility projects will be assessed by a qualified historian for their potential contribution to an historic district, following the guidelines identified under Impact 4.7-3. To qualify as an historic district, each resource within that potential district would need to be reliant upon the other resources within the district to be historically significant. Impacts on one resource within the potential district may or may not affect the others, and this conclusion would determine the ultimate significance of the impact.

If an historic district would be affected by one or more proposed WSIP facility projects, the SFPUC, in consultation with the ERO, will develop mitigation measures for effects with attention to the potential district as a whole, with utmost effort made to maintain the district's function, appearance, cohesive site organization, and ability to convey historic significance. Appropriate measures may also include but not be limited to: refinement of facility sites to minimize effects on district appearance and site organization as well as visual screening efforts to reduce the impact of adding new facilities or otherwise modifying the landscape.

Should an historic district be identified at the project level, it should be recorded as such, using the four National/California Register criteria of significance to explain its historical importance as a cohesive group of resources. The district should be documented by completing the State of California Department of Parks and Recreation 523 forms, using a 523D (District) form as an umbrella record to unify the 523A (Primary Record) and 523B (Building, Structure, Object) forms completed for each individual resource within the potential district, and submitting them to SHPO.

Alternatives Identification and Resource Relocation

Measure 4.7-4a: If a project proposes to demolish or remove a historical resource, including individual historic resources and/or historic districts, the SFPUC will attempt to identify feasible project alternatives that eliminate or reduce the need for demolition or removal to the greatest extent possible. The SFPUC will pursue and implement these project alternatives to the extent feasible, consistent with the goals and objectives of the WSIP.

Relocation of a resource will always be preferable to demolition, although relocation might not mitigate impacts to a less-than-significant level. If preservation of the affected historical resource at the current site is determined to be infeasible, the structure shall, if feasible, be stabilized and relocated to other nearby sites appropriate to their historic setting and general environment. This may not be possible in some cases, like in the replacement of Calaveras Dam (if it were identified as a historical resource for the purposes of CEQA). After relocation, the resource shall be treated according to preservation, rehabilitation, or restoration standards, as appropriate, that follow the Secretary of the Interior's *Standards*. This will ensure that the building, structure, object, site, or district retains historic integrity and its historic significance (Measure 4.7-4c). If the affected historical resource can neither be preserved at its current site nor moved to an alternative site and is to be demolished, the SFPUC shall consult with local historical societies and governmental agencies regarding salvage of materials from the affected historical resource for public information or reuse in other locations. Demolition may proceed only after any significant historic features or materials have been identified, preserved (as feasible), and their removal completed.

Representative features such as aqueduct/pipe sections, valves subject to replacement, decorative elements, or plaques/inscriptions from buildings or other portions of structures demolished as a part of the WSIP projects could be preserved and displayed. Most of these types of structures are of sufficient size that they would form "monumental" commemorative structures. For example, an original pipeline valve replaced by modern equipment might be mounted and displayed on publicly accessible SFPUC property with informative placards. Such displays, if located in other jurisdictions, might be subject to those jurisdiction's requirements related to public art, safety, and liability considerations.

Historical Resources Documentation

Measure 4.7-4b: Documentation of a historical resource, including resources identified as contributors to a historic district or as individually significant, prior to demolition or removal is a standard mitigation measure. Such documentation is often tied to meeting the documentation standards of the Historic American Buildings Survey/Historic American Engineering Record (HABS/HAER). The publication *Recording Historic Structures: Historic American Buildings Survey/Historic American Engineering Record* (Burns, 1989) provides four levels of documentation corresponding to the level of importance of the historic resource to be documented. For the purpose of this PEIR, the standards for photography in Documentation Levels III and IV have been modified to allow for the use of digital photographs instead of large-format negatives.

Documentation Level I:

1. Drawings: a full set of measured drawings depicting existing or historic conditions.
2. Photographs: photographs with large-format negatives of exterior and interior views; photocopies with large-format negatives of select existing drawings or historic views where available. Photographs would follow the HABS/HAER Photographic Specifications.
3. Written data: history and description.

Documentation Level II:

1. Drawings: select existing drawings, where available, should be photographed with large-format negatives or photographically reproduced on Mylar.

2. Photographs: photographs with large-format negatives of exterior and interior views, or historic views, where available. Photographs would follow the HABS/HAER Photographic Specifications.
3. Written data: history and description.

Documentation Level III:

1. Drawings: sketch plan.

2. Photographs: digital photographs of exterior and interior views.
3. Written data: architectural data form.

Documentation Level IV:

1. Drawings: sketch plan.
2. Photographs: digital photographs of exterior and interior views.
3. HABS/HAER inventory cards.

Digital photography will follow the standards in the National Register of Historic Places and National Historic Landmarks Survey, Photo Policy Expansion, March 2005 (Table VV). Digital image files would be burned to archival-quality disks, such as the eFilm Archival Gold CD-R or DVD-R; or MAM-A Mitsui Gold Archive CD-R or DVD-R.

The SFPUC will prepare, or retain a consultant to prepare, documentation of historical resources prior to any construction work associated with demolition or removal. The appropriate level of documentation will be selected by a qualified professional who meets the standards for history, architectural history, and/or architecture (as appropriate) set forth by the Secretary of the Interior (*Secretary of the Interior's Professional Qualification Standards*, 36 CFR 61) in consultation with a preservation specialist assigned by the San Francisco Planning Department and the local jurisdiction if deemed appropriate by the Planning Department. In addition to the four levels of documentation listed above, salvage and/or interpretive display may also be required if determined appropriate. The professional in history, architectural history and/or architecture (as appropriate) will prepare the documentation and submit it for review and approval by the Planning Department's preservation specialist. One set of the documentation will be archived at each of the following repositories: San Francisco Planning Department, SFPUC, the History Room of the San Francisco Public Library and the Water Resources Center Archive at the University of California Berkeley. Additional dissemination of documentation to local historical societies or historic preservation organizations may be appropriate. The San Francisco Planning Department will identify additional appropriate recipients of historical documentation during the project-level analysis.

Secretary of the Interior's Standards for Treatment of Historic Properties

Measure 4.7-4c: Compliance with the *Secretary of the Interior's Standards for the Treatment of Historic Properties* would reduce potential impacts associated with the alteration or modification of a historical resource (including historic districts and individually eligible resources) to a less-than-significant level. (In accordance with CEQA Section 15064.5(b)(3), a project that follows the *Secretary of the Interior's Standards for the Treatment of Historic Properties with Guidelines for Preserving, Rehabilitating, Restoring, and Reconstructing Historic Buildings* or the *Secretary of the Interior's Standards for Rehabilitation and Guidelines for Rehabilitating Historic Buildings* is generally considered to have impacts of a less-than-significant level.)

The SFPUC will prepare materials describing and depicting the proposed project, including but not limited to plans, drawings, and photographs of existing conditions (digital, following the standards in Measure 4.7-4a as well as proposed project plans, drawings, specifications, and description). Prepared materials will be submitted to the San Francisco

Planning Department. The Planning Department will review the proposed project, for compliance with the *Secretary of the Interior's Standards for the Treatment of Historic Properties*.

If a project is determined to be inconsistent with the *Secretary of the Interior's Standards for the Treatment of Historic Properties*, the SFPUC will pursue and implement redesign of the project to the extent feasible, consistent with the goals and objectives of the WSIP, such that consistency with the standards is achieved.

Historic Resources Survey and Redesign

Measure 4.7-4d: The SFPUC will undertake a historic resources survey within a designated area of potential effect that encompasses the proposed project to identify and evaluate potential historical resources, including districts, which may exist within or partially within the project's study area or area of potential effect. The survey will be conducted by a qualified professional who meets the *Secretary of the Interior's Professional Qualification Standards* for architectural history, history, or architecture (36 CFR 61).

If a survey identifies one or more historical resources in the projects' study area, or area of potential effect (i.e. historically significant resources), the qualified professional will then assess the impact the project may have on those historical resources. If the project will cause a substantial adverse change to a historical resource, the SFPUC will prepare materials describing and depicting the proposed project, including but not limited to plans, drawings, and photographs of existing conditions (digital, following the standards in Measure 4.7-1a) as well proposed project plans, drawings, specifications, and description. Prepared materials will be submitted to the San Francisco Planning Department. The San Francisco Planning Department will assign a preservation specialist to review the proposed project, for compliance with the *Secretary of the Interior's Standards for the Treatment of Historic Properties*.

If a project is determined to be inconsistent with the *Secretary of the Interior's Standards for the Treatment of Historic Properties*, the SFPUC will pursue and implement redesign of the project to the extent feasible, consistent with the goals and objectives of the WSIP, such that consistency with the standards is achieved.

Historic Resources Protection Plan

Measure 4.7-4e: A qualified historian will prepare a plan that specifies procedures for protecting historical resources and a monitoring method to be employed by the contractor while working near these resources. At a minimum, the plan will address the operation of construction equipment near adjacent historical resources, storage of construction materials away from adjacent resources, and education/training of construction workers about the significance of the historical resources.

Preconstruction Surveys and Vibration Monitoring

Measure 4.7-4f: If vibration-related impacts could impact historical resources, one or more geotechnical investigations by a California-licensed geotechnical engineer will be included as part of the proposed project. The SFPUC and its contractors will follow the recommendations of the final geotechnical reports regarding any excavation and construction for the project. The SFPUC will ensure that the construction contractor conducts a preconstruction survey of existing conditions and monitors the adjacent buildings for damage during construction, if recommended by the geotechnical engineer. Any preconstruction surveys and construction monitoring would include the services of a professional meeting the *Secretary of the Interior's Professional Qualification Standards* for architecture.

6.3.7 Traffic, Transportation, and Circulation

Program Measures

Traffic Control Plan Measures

Measure 4.8-1a: SFPUC Construction Measure #5 for traffic requires each contractor to prepare a traffic control plan to minimize traffic and on-street parking impacts on any streets affected by construction of the proposed program. SFPUC and construction contactor(s) will prepare and implement a traffic control plan, and coordinate with Caltrans and local jurisdictions, as appropriate, for affected roadways and intersections. Each project may require the implementation of different measures, depending on the project's site-specific construction details, the characteristics of the transportation network, and daily and peak hour vehicle, pedestrian and bicycle volumes. As applicable, elements of the traffic control plan could include, but are not necessarily limited to, the following:

- Circulation and detour plans will be developed to minimize impacts on local street circulation. Flaggers and/or signage will be used to guide vehicles through and/or around the construction zone.
- Truck routes designated by cities and counties will be identified in the traffic control plan. Haul routes that minimize truck traffic on local roadways and residential streets will be utilized to the extent possible.
- Sufficient staging areas will be provided for trucks accessing construction zones to minimize disruption of access to adjacent land uses, particularly at entries to onsite pipeline construction within residential neighborhoods.
- Access to driveways and private roads will be maintained by using steel trench plates. If access must be restricted for brief periods, property owners will be notified in advance.
- Construction vehicle movement will be controlled and monitored through the enforcement of standard construction specifications by onsite inspectors.
- Along major arterials, truck trips will be scheduled outside of the peak morning and evening commute hours to the extent possible.
- Lane closures will be limited during peak hours to the extent possible. Outside of allowed working hours or when work is not in progress, roads will be restored to normal operations, with all trenches covered with steel plates.

- Where possible, pipeline construction work in roadways will be limited to a width that, at a minimum, maintains alternate one-way traffic flow past the construction zone. Parking may be prohibited if necessary to facilitate construction activities or traffic movement. If the work zone width will not allow a 10-foot-wide paved travel lane, then the road will be closed to through-traffic (except emergency vehicles), and detour signing on alternative access roads will be used.

- Pedestrian and bicycle access and circulation will be maintained during project construction where safe to do so. If construction activities encroach on a bicycle lane, warning signs will be posted that indicate bicycles and vehicles are sharing the lane.

- Detours will be included for bicycles and pedestrians in all areas potentially affected by project construction.

- All equipment and materials will be stored in designated contractor staging areas on or adjacent to the worksite, in such a manner to minimize obstruction of traffic.

- Locations will be identified for parking by construction workers, either within the construction zone or, if necessary, at a nearby location with transport provided between the parking location and the worksite.

- Roadside safety protocols will be implemented. Advance “Road Work Ahead” warning signs and speed control (including signs informing drivers of state-legislated double fines for speed infractions in a construction zone) will be provided to achieve required speed reductions for safe traffic flow through the work zone.

- Construction will be coordinated with facility owners or administrators of sensitive land uses such as police and fire stations (including all fire protection agencies), transit stations, hospitals, and schools. Facility owners or operators will be notified in advance of the timing, location, and duration of construction activities and the locations of detours and lane closures.

- Construction will be coordinated with local transit service providers, including temporary relocation of bus routes or bus stops in work zones as necessary.

- Roadway right-of-ways will be repaired or restored to their original conditions or better upon completion of construction.

- To the extent applicable, the traffic control plan will conform to the *California Manual on Uniform Traffic Control Devices for Streets and Highways: Part 6 Temporary Traffic Control* and *Caltrans’ 2006 Standard Plans*.

Coordination of Individual Traffic Control Plans

Measure 4.8-1b: To the extent that the adopted SFPUC Construction Measure #5 does not contain such provisions already, or the provisions are not required for a project as a result of local encroachment or right-of-way permit conditions, the contract specifications for individual contracts within a single WSIP project will include the following:

- In the event that more than one construction contract is issued for work along existing or new pipelines, and where construction could occur within and/or across multiple streets in the same vicinity, the SFPUC and construction contractor(s) will coordinate the traffic control plans in order to mitigate the impact of traffic disruption. The coordinated plan will include measures that address overlapping construction schedules and activities, truck arrivals and departures, lane closures and detours, and the adequacy of on-street staging requirements.

Accommodation of Displaced Public Parking Supply for Recreational Visitors

Measure 4.8-4: Due to the potential displacement of designated parking areas where limited parking is available for adjacent public uses, traffic control plans prepared as part of SFPUC Construction Measure #5 and Measure 4.8-1a will include an additional measure to accommodate any anticipated visitor parking demand that would be displaced by proposed projects at public recreational facilities.

Collective Measures

SFPUC WSIP Projects Construction Coordinator

Measure 4.16-6a: Due to the potential for overlapping project activities and construction vehicles to affect travel within and across the five regions, the SFPUC will identify a qualified construction coordinator responsible for coordinating the project-specific traffic control plans developed as part of Measure 4.8-1a, and for developing a public information campaign (e.g., internet website, radio and newspaper updates) to inform the public of construction activities, detour routes, and alternate routes. Throughout the seven-year construction schedule for the WSIP projects, the SFPUC construction coordinator will work with local and regional agencies to pursue additional traffic mitigation measures to minimize local and regional traffic impacts and will incorporate these measures into the project-specific traffic control plans, as appropriate.

Combined San Joaquin Traffic Control Plan

Measure 4.16-6b: Due to the potential for overlapping project schedules in the San Joaquin Region near Tesla Portal, the SFPUC will develop [or the SFPUC's construction contractor(s) will be required to develop] a San Joaquin Traffic Control Plan that coordinates the project-specific traffic control plans developed as part of Measure 4.8-1a and identifies additional measures to minimize the combined impacts of multiple WSIP project construction traffic on I-580, Chrisman Road, and Vernalis Road. As applicable, these measures will be developed consistent with the standards of San Joaquin County, Stanislaus County, and Caltrans and could include:

- Additional traffic control devices, such as traffic signals at key intersections providing access to local roadways and land uses
- Additional traffic control personnel at key locations to facilitate vehicular traffic flow during peak periods of truck activity
- Adjustments in truck arrival and departure schedules for the various facilities (e.g., staggering departures)

Combined Sunol Valley Traffic Control Plan

Measure 4.16-6c: Due to the potential for overlapping project schedules in the Sunol Valley Region as well as for construction traffic to use Calaveras Road as an access route to all projects sites, the SFPUC or its construction contractor(s) will develop a Sunol Valley Traffic Control Plan that coordinates the project-specific traffic control plans developed as part of Measure 4.8-1a and identifies additional measures to minimize the impacts of construction traffic on Calaveras Road and I-680. As applicable, these measures will be developed consistent with the standards of Alameda County and Caltrans and could include:

- Additional traffic control devices, such as traffic signals at key intersections providing access to local roadways and land uses. Traffic signals could facilitate access onto Calaveras Road at intersections and also allow for gaps in truck traffic flow to facilitate access from driveways along Calaveras Road.
- Additional traffic control personnel at key locations to facilitate vehicular traffic flow during peak periods of truck activity.
- Adjustments in truck arrival and departure schedules for the various facilities (e.g., staggering departures).
- Public information regarding periods when construction traffic on Calaveras Road would be greatest.
- Working with Caltrans to determine if warning signs, such as a “Slow Trucks” sign (California Code W51), would be appropriate to inform drivers that slow-moving trucks may interfere with the flow of traffic on I-680.

Cumulative Measures

SFPUC WSIP Projects Construction Coordinator – Other Agencies

Measure 4.17-6: As required in Measure 4.8-1, contractors will be required to submit traffic control plans to the SFPUC, and in Measure 4.16-6a, the SFPUC will be required to identify a WSIP construction coordinator who will be responsible for coordinating the project-specific traffic control plans. The SFPUC WSIP construction coordinator will also consider the effects of any traffic generated by SFPUC maintenance activities and other SFPUC projects (as listed in Tables 4.17-1 through 4.17-6). The SFPUC WSIP construction coordinator will also coordinate with Caltrans, other county agencies, and local jurisdictions responsible for reviewing and/or approving the construction of other identified private and public development projects (as listed in Tables 4.17-1 through 4.17-6) so as to minimize traffic impacts on local access roads, particularly local streets where sensitive receptors (e.g., schools, residences, or hospitals) are located.

6.3.8 Air Quality

Program Measures

SJVAPCD Dust Control Measures

Measure 4.9-1a: In the San Joaquin Region, the SJVAPCD has determined that compliance with the following Regulation VIII (Fugitive PM_{10} Prohibitions) and Regulation IX (Mobile and Indirect Sources, Rule 9510, where applicable) control measures would mitigate PM_{10} impacts to a less-than-significant level. The SFPUC will include these measures, where applicable, in contract specifications:

SJVAPCD Basic Control Measures (applies to all construction sites)

- All disturbed areas, including storage piles, that are not being actively utilized for construction purposes, shall be effectively stabilized of dust emissions using water, chemical stabilizer/suppressant, covered with a tarp or other suitable cover, or vegetative ground cover.
- All onsite unpaved roads and offsite unpaved access roads shall be effectively stabilized of dust emissions using water or chemical stabilizer/suppressant.
- All land clearing, grubbing, scraping, excavation, land leveling, grading, cut and fill, and demolition activities shall be effectively controlled of fugitive dust emissions utilizing application of water or by presoaking.
- When materials are transported offsite, all material shall be covered, or effectively wetted to limit visible dust emissions, and at least 6 inches of freeboard space from the top of the container shall be maintained.
- All operations shall limit or expeditiously remove the accumulation of mud or dirt from adjacent public streets at the end of each workday. The use of dry rotary brushes is expressly prohibited except where preceded or accompanied by sufficient wetting to limit the visible dust emissions. Use of blower devices is expressly forbidden.
- Following the addition of materials to, or the removal of materials from, the surface of outdoor storage piles, said piles shall be effectively stabilized of fugitive dust emissions utilizing sufficient water or chemical stabilizer/suppressant.
- Within urban areas, trackout shall be immediately removed when it extends 50 or more feet from the site and at the end of each workday.
- Any site with 150 or more vehicle trips per day shall prevent carryout and trackout.

SJVAPCD Enhanced Control Measures (also applies when required to mitigate significant PM_{10} impacts)

- Traffic speeds on unpaved roads shall be limited to 15 mph.
- Sandbags or other erosion control measures shall be installed to prevent silt runoff to public roadways from sites with a slope greater than 1 percent.

<u>SJVAPCD Additional Control Measures</u> (also applies to construction sites that are large in area, located near sensitive receptors, or which for any other reason warrant additional emissions reductions)

- Wheel washers shall be installed for all exiting trucks, or all trucks and equipment leaving the site shall be washed off.
- Wind breaks shall be installed at windward side(s) of construction areas.
- Excavation and grading activity shall be suspended when winds exceed 20 mph and, regardless of windspeed, an owner/operator must comply with Regulation VIII's 20 percent opacity limitation.
- The area subject to excavation, grading, and other construction activity at any one time shall be limited.

<u>SJVAPCD Rule 9510, Indirect Source Review, Section 6.1, Construction Equipment Emissions</u> (applies to any project subject to discretionary approval by a public agency that ultimately results in the construction of a new building, facility, or structure or reconstruction of a building, facility, or structure for the purpose of increasing capacity or activity and also involving 9,000 square feet of space).

- 6.1.1: The exhaust emissions for construction equipment greater than fifty (50) horsepower used or associated with the development project shall be reduced by the following amounts from the statewide average as estimated by the ARB:
  - 6.1.1.1: 20% of the total NO_x emissions, and
  - 6.1.1.2: 45% of the total PM_{10} exhaust emissions.
- 6.1.2: An applicant may reduce construction emissions on-site by using less-polluting construction equipment, which can be achieved by utilizing add-on controls cleaner fuels, or newer lower emitting equipment.
- 6.3: The requirements listed in Section 6.1 above can be met through any combination of on-site emission reduction measures or off-site fees.

SJVAPCD Exhaust Control Measures

Measure 4.9-1b: To limit exhaust emissions within the San Joaquin Region, the SJVAPCD specifies the following exhaust controls for heavy-duty equipment (scrapers, graders, trenchers, earthmovers, etc.). The SFPUC will include these measures, where applicable, in contract specifications:

- Alternative-fueled or catalyst-equipped diesel construction equipment shall be used.
- Idling time (e.g., 10-minute maximum) shall be minimized.
- The hours of operation of heavy-duty equipment and/or the amount of equipment in use shall be limited.

- Fossil-fueled equipment shall be replaced with electrically driven equivalents (provided they are not run via a portable generator set).
- Construction shall be curtailed during periods of high ambient pollutant concentrations; this may include ceasing construction activity during the peak hour of vehicular traffic on adjacent roadways.
- Activity management (e.g., rescheduling activities to reduce short-term impacts) shall be implemented.

BAAQMD Dust Control Measures

Measure 4.9-1c: In the Sunol Valley, Bay Division, Peninsula, and San Francisco Regions, the BAAQMD has determined that implementation of the following control measures would mitigate PM_{10} impacts to a less-than-significant level. The SFPUC will include these measures, where applicable, in contract specifications:

BAAQMD Basic Control Measures (applies to all construction sites)

- All active construction areas shall be watered at least twice daily.
- All trucks hauling soil, sand, and other loose debris shall be covered *or* all trucks shall be required to maintain at least 2 feet of freeboard on public roads.
- All unpaved access roads, parking areas, and staging areas at construction sites shall either be paved, watered three times daily, or nontoxic soil stabilizers shall be applied.
- All paved access roads, parking areas, and staging areas at construction sites shall be swept daily (with water sweepers).
- If visible soil material is carried onto adjacent public streets, adjacent streets shall be swept daily (with water sweepers).

BAAQMD Enhanced Control Measures (also applies to sites over four acres)

- All inactive construction areas (previously graded areas inactive for 10 days or more) shall be hydroseeded or nontoxic soil stabilizers shall be applied.
- Exposed stockpiles (dirt, sand, etc.) shall be enclosed, covered, and watered, or nontoxic soil binders shall be applied.
- As feasible, traffic speeds on unpaved roads shall be limited to 15 mph.
- Sandbags or other erosion control measures shall be installed to prevent silt runoff to public roadways.
- Disturbed areas shall be replanted as quickly as possible.

BAAQMD Optional Control Measures (also applies to construction sites that are large in area, located near sensitive receptors, or which for any other reason warrant additional emissions reductions)

- Wheel washers shall be installed for all exiting trucks, or all trucks and equipment leaving the site shall be washed off.
- Wind-breaks or trees/vegetative wind-breaks shall be installed at windward side(s) of construction areas.
- Excavation and grading activity shall be suspended when winds exceed 25 mph.
- The area subject to excavation, grading, and other construction activity at any one time shall be limited.

BAAQMD Exhaust Control Measures

Measure 4.9-1d: To limit exhaust emissions within the Sunol Valley, Bay Division, Peninsula, and San Francisco Regions, the SFPUC will implement the following exhaust controls, where applicable:

- Grid power will be used instead of diesel generators at all construction sites where it is feasible to connect to grid power. While it may not be practical to connect to grid power for pipeline projects (since construction sites keep moving along the alignments), grid power shall be used for projects with fixed locations, such as tunnel entry and exit shafts/portals.
- All WSIP contracts specifications shall include Sections 2480 and 2485, Title 13, California Code of Regulations, which limit the idling of all diesel-fueled commercial vehicles (weighing over 10,000 pounds, both California- or non-California-based trucks) to 30 seconds at a school or five minutes at any location. In addition, the use of diesel auxiliary power systems and main engines shall be limited to five minutes when within 100 feet of homes or schools while the driver is resting.
- All WSIP contracts specifications shall include Section 93115, Title 17, California Code of Regulations, Airborne Toxic Control Measure for Stationary Compression Ignition Engines, which specifies fuel and fuel additive requirements; emission standards for operation of any stationary, diesel-fueled, compression-ignition engines; and operation restrictions within 500 feet of school grounds when school is in session.
- A schedule of low-emissions tune-ups shall be developed and such tune-ups shall be performed on all equipment, particularly for haul and delivery trucks. A log of required tune-ups shall be maintained and a copy of the log shall be submitted to the SFPUC on a monthly basis for review.
- Low-sulfur fuels shall be used in all stationary and mobile equipment.

Health Risk Screening or Use of Soot Filters

Measure 4.9-2a: If truck volumes associated with a particular project along a particular haul route exceed 40,000 truck trips over the entire construction period, a health risk screening will be completed. If a potentially significant impact is indicated, a site-specific health risk assessment (HRA) will be completed for the project. Any subsequent project-level analysis will consider DPM emission rates at the time of construction since emission rates are expected to decline in the future. Based on the site-specific HRA, a mitigation program will be developed implementing one or more the following methods of reducing DPM emission or exposure to a less-than-significant level:

- Modify haul routes to reduce exposure.
- Require use of biodiesel fuel, which reduces DPM emissions.
- Require new construction equipment to be utilized. Newer construction equipment is far cleaner than old equipment.
- Require that the vehicle fleet include trucks with soot filters (particulate traps) within the equipment fleet.
- Temporarily vacate affected receptors.
- Any other effective means of reducing DPM emissions or exposure.

Vacate SFPUC Land Managers’ Residences in Sunol Valley

Measure 4.9-2b: The two SFPUC Land Managers’ residences in the Sunol Valley will be vacated during construction of the Calaveras Dam (SV-2) or Treated Water Reservoirs (SV-5) projects. Alternatively, a health risk screening could be completed to determine health risks at these residences from either of these two projects. If a potentially significant impact is indicated, a health risk assessment will be completed, and measures will be implemented, as set forth in Measure 4.9-2a.

Tunnel Gas Odor Control

Measure 4.9-3: For any projects that would require a tunnel ventilation system, if hydrogen sulfide gas or any other odorous gases (including diesel exhaust) are encountered during tunnel excavation and become a nuisance odor problem (i.e., odor complaints are received), water scrubbers will be added to the ventilation system and appropriate chemicals will be added to remove the nuisance odors.

Collective Measures

Dust and Exhaust Control Measures for All WSIP Projects

Measure 4.16-7a: Measures 4.9-1a through 4.9-1d requires specific projects to implement dust and exhaust control measures. To address collective construction-related air quality impacts, these measures will be required for all WSIP projects as applicable and required by SJVAPCD and BAAQMD.

Health Risk Screening or Use of Soot Filters for All Projects in the San Joaquin and Sunol Valley Regions

Measure 4.16-7b: Measure 4.9-2a requires specific projects to either conduct a health risk assessment or use soot filters to reduce DPM emissions associated with haul trucks. To address collective DPM impacts, this measure will be required for all WSIP projects in the

San Joaquin and Sunol Valley Regions. This measure would only apply in the Sunol Valley Region if, under Measure 4.9-2b, the SFPUC elects not to vacate the two SFPUC Land Managers' residences in the Sunol Valley. If this requirement is applied to the New Irvington Tunnel project (SV-4), it shall be applied to both the Sunol Valley and Fremont tunnel portals, taking into account truck traffic from other WSIP projects in the vicinity of both portals.

Vacate SFPUC Land Managers' Residences for All Projects in the Sunol Valley Region

Measure 4.16-7c: Measure 4.9-2b requires the two SFPUC Land Managers' residences in the Sunol Valley to be vacated during construction of the Calaveras Dam (SV-2) and Treated Water Reservoirs (SV-5) projects. Alternatively, a health risk screening could be completed to determine health risks at these residences. If a potentially significant impact is indicated, a health risk assessment will be completed. To address collective DPM impacts, this measure will be required for all WSIP projects in the Sunol Valley Region.

6.3.9 Noise and Vibration

Program Measures

Noise Controls

Measure 4.10-1a: SFPUC Construction Measure #6 for noise requires compliance with local noise ordinances to the extent feasible. Many of these ordinances restrict hours when construction can occur, but do not specify noise limits for construction noise. For most projects, the SFPUC will conduct construction activities during the daytime hours to the extent feasible. However, if nighttime construction cannot be avoided, noise generated by these activities will be required to comply with applicable noise ordinance nighttime limits or not exceed 50-dBA sleep interference criterion (with windows open at night) to the extent feasible.

To ensure that construction noise impacts are mitigated to a less-than-significant level, all WSIP projects located within 500 feet of any noise-sensitive receptors (e.g., residences, schools, childcare centers, churches, hospitals, and nursing homes) will be required to implement appropriate noise controls to reduce daytime construction noise levels to meet the 70-dBA daytime speech interference criterion to the extent feasible. For nighttime construction, all WSIP projects located within 3,000 feet of any noise-sensitive receptors will be required to implement appropriate noise controls to maintain noise levels at or below any applicable ordinance nighttime noise limits or the 50-dBA nighttime sleep interference criterion to the extent feasible. Such controls could include any of the following, as appropriate:

- Best available noise control techniques (including mufflers, intake silencers, ducts, engine enclosures, and acoustically attenuating shields or shrouds) will be used for all equipment and trucks in order to minimize construction noise impacts. If feasible, construction equipment noise will not exceed the mitigated noise levels listed in **Table 4.10-4** (see measure below for limits on impact equipment).

- If impact equipment (e.g., jack hammers, pavement breakers, and rock drills) is used during project construction, hydraulically or electric-powered equipment will be used wherever feasible to avoid the noise associated with compressed-air exhaust from pneumatically powered tools. However, where use of pneumatically powered tools is unavoidable, an exhaust muffler on the compressed-air exhaust will be used (a

- muffler can lower noise levels from the exhaust by up to about 10 dBA). External jackets on the tools themselves will be used, where feasible, which could achieve a reduction of 5 dBA. Quieter procedures, such as drilling rather than impact equipment, will be used whenever feasible.

- Pile holes will be pre-drilled wherever feasible to reduce potential noise and vibration impacts. Where feasible, sonic or vibratory pile drivers will be used instead of impact pile drivers (sonic pile drivers are only effective in some soils).

- Pile driving activities shall be prohibited during the evening and nighttime hours (7 p.m. to 7 a.m.).

- Operation of equipment requiring use of back-up beepers will be avoided near sensitive receptors to the extent feasible during nighttime hours (10 p.m. to 7 a.m.).

- Stationary noise sources will be located as far from sensitive receptors as feasible. If they must be located near receptors, adequate muffling (with enclosures where feasible and appropriate) will be used to ensure local noise ordinance limits are met to the extent feasible. Enclosure opening or venting will face away from sensitive receptors. If any stationary equipment (e.g., ventilation fans, generators, dewatering pumps) is operated beyond the time limits specified by the pertinent noise ordinance, this equipment will conform to the affected jurisdiction’s pertinent day and night noise limits to the extent feasible.

- Material stockpiles as well as maintenance/equipment staging and parking areas will be located as far as feasible from residential and school receptors.

- Wherever feasible, pipeline alignments will be located at least 100 feet away from sensitive receptors.

- Where pipeline construction zones are within 100 feet of school classrooms or childcare facilities, pipeline construction activities (or at least the noisier phases of construction) will be scheduled on weekend or school vacation days to the extent feasible, avoiding weekday hours when schools are in session. If construction must occur when school is in session, interior noise levels in classrooms will not exceed 60 dBA if possible to avoid speech interference problems, which would allow for a maximum exterior noise level of 70 to 80 dBA, depending on whether windows are open or closed.

- Given the long duration of construction activities at tunnel shafts/portals and proposed nighttime activities, tunnel-related construction activities will be designed to comply with nighttime noise limits specified in local noise ordinances. Measures that could be implemented to comply with these limits include: using quiet ventilation fans (pure tone components of fan noise will be considered), using line power instead of generators, erection of temporary sound barriers, restricting heavy equipment operation during the nighttime hours, using nonmetallic containers in the muck removal system to prevent clanging/banging noises, limiting controlled detonations in the tunnel shaft/portal vicinities to the daytime hours, retrofitting windows/doors of affected homes, and/or prohibiting use of backup alarms on equipment during the nighttime hours.

- Where controlled detonation activities will occur, surrounding cities and residents should be notified of the blasting schedule, indicating the time range when blasting could occur (hours and duration).

- Proposed jack-and-bore pits will be located as far from sensitive receptors as technically feasible. If ventilation fans, dewatering pumps, or generators are required as part of this type of pipeline crossing, such equipment will comply with daytime and nighttime noise limits specified in pertinent noise ordinances to the extent feasible (also see Measure 4.9-1d in Section 4.9, Air Quality, for additional restrictions on generator operation).

- Wherever necessary, temporary or permanent noise barriers will be erected to maintain construction noise levels at or below the 70-dBA daytime speech interference criterion and the 50-dBA nighttime sleep interference criterion.

- A designated project liaison will be responsible for responding to noise complaints during the construction phases. The name and phone number of the liaison will be conspicuously posted at construction areas and on all advanced notifications. This person will take steps to resolve complaints, including periodic noise monitoring, if necessary. Results of noise monitoring will be presented at regular project meetings with the project contractor, and the liaison will coordinate with the contractor to modify any construction activities that generated excessive noise levels to the extent feasible.

- A reporting program will be required for each project that documents complaints received, actions taken to resolve problems, and effectiveness of these actions.

Vacate SFPUC Caretaker's Residence at Tesla Portal

Measure 4.10-1b: The SFPUC caretaker's residence at Tesla Portal will be vacated during construction of the Advanced Disinfection (SJ-1) and Tesla Portal Disinfection (SJ-5) projects as well as those portions of the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects located at Tesla Portal.

Limit Hourly Truck Volumes

Measure 4.10-2a: In addition to SFPUC Construction Measure #6 for noise, which requires compliance with local noise ordinances to the extent feasible, haul and delivery truck routes for all WSIP projects will avoid local residential streets and will follow local designated truck routes to the extent feasible. Total project-related haul and delivery truck volumes on any particular haul truck route will be limited to 80 trucks per hour.

Restrict Truck Operations

Measure 4.10-2b: Haul and delivery trucks will be prohibited from operating within 200 feet of any residential uses during the nighttime hours (10 p.m. to 7 a.m.). If there are receptors, but they are beyond 200 feet from the haul route, limited truck operations will be allowed during the more sensitive nighttime hours, but noise generated by these operations cannot exceed the 50-dBA sleep interference criterion at the closest receptors. If trucks must operate during these hours and residential uses are located within 200 feet of the haul route, deliveries will be made to staging areas outside residential areas, then transferred to the construction site during daytime hours (7 a.m. to 7 p.m.).

Vacate SFPUC Land Manager's Residence

Measure 4.10-2c: To minimize nighttime noise impacts, the SFPUC Land Manager's residence adjacent to Alameda East Portal will be vacated during off-site truck operations associated with the New Irvington Tunnel project (SV-4), if truck operations occur during the nighttime hours (10 p.m. to 7 a.m.) and are estimated to exceed the 50-dBA sleep interference criterion at this residence.

Vibration Controls to Prevent Cosmetic or Structural Damage

Measure 4.10-3a: To prevent cosmetic or structural damage to adjacent or nearby structures, the SFPUC will incorporate restrictions into all contract specifications (primarily for sheetpile driving, pile driving, or tunnel construction activities), whereby surface vibration will be limited to 0.2 in/sec PPV for continuous vibration (e.g., vibratory equipment and impact pile drivers) and 0.5 in/sec PPV for controlled detonations at the closest receptors to ensure that cosmetic or structural damage does not occur.

Limit Vibration Levels at or Below Vibration Perception Threshold

Measure 4.10-3b: For nighttime construction activities, the SFPUC will maintain vibration levels at or below the vibration perception threshold (0.012 in/sec PPV) at adjacent properties (or in accordance with local ordinances) to the extent feasible. If vibration complaints are received during facility construction, operational adjustments will be made (e.g., restricting use of equipment causing vibration disturbance during the nighttime hours or slowing the pace of its operation), as necessary, to reduce vibration annoyance effects.

Limit Tunnel-Related Detonation to Daylight Hours

Measure 4.10-3c: The SFPUC will limit controlled detonation associated with tunnel construction to the daylight hours, Monday through Saturday.

Collective Measures

Limiting Hourly Truck Volumes and Restricting Truck Operations on Haul Routes for Multiple WSIP Projects

Measure 4.16-8a: Measures 4.10-2a and 4.10-2b outline restrictions and guidelines for daytime and nighttime truck operations on local roadways. To address collective truck-related noise impacts, these measures will be applied to total haul and delivery truck volumes on any particular haul truck route that are attributable to all WSIP projects, including the Tesla Portal, Irvington Portal, Lower Crystal Springs Dam vicinities as well as haul routes in San Francisco Region. Therefore, total truck volumes from all WSIP projects on a particular route will not exceed 80 trucks per hour (so as not to exceed the 70-dBA speech interference criterion during the daytime hours) and will be restricted near sensitive receptors (to meet the 50-dBA sleep interference criterion) during the nighttime hours.

Vacate Land Manager's Residence for All Projects in Sunol Valley Region

Measure 4.16-8b: Measure 4.10-2c requires the SFPUC Land Manager's residence adjacent to Alameda East Portal to be vacated during construction truck operations associated with the New Irvington Tunnel project (SV-4). To address collective noise impacts, this residence will be vacated during construction truck operations associated with all WSIP projects in this region, if collective daytime truck volumes exceed the 70-dBA speech interference criterion (7 a.m. to 10 p.m.) or nighttime truck volumes exceed the 50-dBA sleep interference criterion (10 p.m. to 7 a.m.).

Cumulative Measures

Coordination of Truck Traffic on Local Streets

Measure 4.17-8: The SFPUC WSIP construction coordinator designated in Measure 4.17-6 will also be responsible for coordinating truck traffic generated on these same streets by SFPUC maintenance activities and other SFPUC projects (as listed in Tables 4.17-1 through 4.17-6) so that SFPUC-related truck noise increases are maintained at or below threshold levels specified in Measures 4.10-2a and 4.10-2b to the extent feasible (80 trucks per hour along a haul/delivery route and restricted nighttime truck operations).

6.3.10 Public Services and Utilities

Program Measures

Notify Neighbors of Potential Utility Service Disruption

Mitigation 4.11-1a: As part of the neighborhood notice, the SFPUC will notify residents and businesses in project area of potential utility service disruption two to four days in advance of construction.

Locate Utility Lines Prior to Excavation

Measure 4.11-1b: Prior to excavation, the SFPUC or its contractors will locate overhead and underground utility lines, such as natural gas, electricity, sewer, telephone, fuel, and water lines, that may be encountered during excavation work prior to opening an excavation.

Confirmation of Utility Line Information

Measure 4.11-1c: The SFPUC or its contractors will find the exact location of underground utilities by safe and acceptable means. Information regarding the size, color, and location of existing utilities must be confirmed before construction activities commence.

Safeguard Employees from Potential Accidents Related to Underground Utilities

Measure 4.11-1d: While any excavation is open, the SFPUC or its contractors will protect, support, or remove underground utilities as necessary to safeguard employees.

Notify Local Fire Departments

Measure 4.11-1e: The SFPUC or its contractors will notify local fire departments any time damage to a gas utility results in a leak or suspected leak, or whenever damage to any utility results in a threat to public safety.

Emergency Response Plan

Mitigation 4.11-f: The SFPUC will develop an emergency response plan in the event of a leak or explosion prior to commencing construction activities.

Prompt Reconnection of Utilities

Measure 4.11-2g: The SFPUC or its contractors will promptly reconnect any disconnected utility lines.

Coordinate Final Construction Plans with Affected Utilities

Measure 4.11-1h: The SFPUC or its contractors will coordinate final construction plans and specifications with affected utilities.

Waste Reduction Measures

Measure 4.11-2: The following requirements will be incorporated into contract specifications for each WSIP project:

The contractor(s) will obtain any necessary waste management permits prior to construction and will comply with conditions of approval attached to project implementation. As part of the waste management permit process, the contractor(s) will submit a solid waste recycling plan to the affected agencies. Elements of the plan will likely include, but are not necessarily limited to, the following:

- Identification of the types of debris that will be generated by the project and identify how all waste streams will be handled.
- Actions to reuse or recycle construction debris and clean excavated soil to the extent possible.
- Actions to divert at least 50% of inert solids (asphalt, brick, concrete, dirt, fines, rock, sand, soil, and stone) from disposal in a landfill.

6.3.11 Recreational Resources

Program Measures

Coordination with Golf Course/Recreational Facility Managers

Measure 4.12-1: Where golf courses or other recreational facilities would be directly affected by pipeline construction, the SFPUC will coordinate with facility managers to minimize adverse impacts on golfers and other recreational users.

Appropriate Siting of Proposed Facilities

Measure 4.12-2: The SFPUC will locate WSIP project facilities on park and recreation properties in consultation with park planning staff to minimize the direct loss of recreation and play space and to minimize any inconvenience to park, playground, or golf course users associated with the installation of non-recreational facilities within recreational areas.

6.3.12 Agricultural Resources

Program Measures

Supplemental Noticing and Soil Stockpiling

Measure 4.13-1a: For the San Joaquin Pipeline projects (SJPL System, SJ-3, and SJPL Rehabilitation, SJ-4), as part of the SFPUC Construction Measure #1 for neighborhood notice, advanced notification will include the name and number of an SFPUC staff person who can be contacted to discuss special needs and to work out accommodations to minimize temporary disruption to agricultural activities. The SFPUC will stockpile and replace topsoil in mapped areas of Prime and Unique Farmland and Farmland of Statewide Importance that would be temporarily disturbed by pipeline construction, unless other actions are required under specific agreements with individual land owners. (The SFPUC typically holds easements for work on its projects, but prior owners may have residual rights to use the rights-of-way for agricultural purposes. The SFPUC will work with farmers under the terms of these agreements.)

Avoidance or Soil Stockpiling

Measure 4.13-1b: The SFPUC will minimize any potential impacts on agricultural lands in the Sunol Valley by avoiding these resources wherever possible. Where this is not possible, topsoil along the pipeline right-of-way will be stockpiled, replaced, and hydroseeded to prevent erosion, unless other actions are required as a result of contracts affecting use of the property or under specific agreements with individual land owners.

Siting Facilities to Avoid Prime Farmland

Measure 4.13-2: The SFPUC will avoid areas identified as Prime Farmland, Unique Farmland, or Farmland of Statewide Importance in the siting of facilities for the 40-mgd Treated Water project (SV-3), Treated Water Reservoirs project (SV-5), and ancillary power supply facilities for the SJPL System project (SJ-3). If avoidance is not feasible, the SFPUC will adopt a permanent set-aside for an equivalent acreage of similarly-valued farmland in the area.

6.3.13 Hazards

Program Measures

Site Health and Safety Plan

Measure 4.14-1a: For all projects requiring excavation where the site assessment conducted in accordance with SFPUC Construction Measure #7 indicates the potential to encounter hazardous materials in the soil or groundwater, the contractor will prepare a site health and safety plan identifying the chemicals present, potential health and safety hazards, monitoring to be performed during site activities, soils-handling methods required to minimize the potential for exposure to harmful levels of any chemicals identified in the soil, appropriate personnel protective equipment, and emergency response procedures.

Materials Disposal Plan

Measure 4.14-1b: For all projects requiring excavation where the site assessment conducted in accordance with SFPUC Construction Measure #7 indicates the potential to encounter hazardous materials in the soil, the contractor will prepare a materials disposal plan that specifies the disposal method and approved disposal site for the soil and will provide written documentation that the disposal site will accept the waste.

Coordination with Property Owners and Regulatory Agencies

Measure 4.14-1c: Based on regulatory agency file reviews conducted in accordance with SFPUC Construction Measure #7, the SFPUC will assess the potential to encounter unacceptable levels of hazardous materials at known environmental cases, for construction activities to cause groundwater plume migration or interfere with ongoing remediations at known environmental cases, and for increased water levels in reservoirs or lakes to inundate known environmental cases. Should the review indicate that the project could encounter unacceptable levels of hazardous materials or interfere with a remediation, the SFPUC will contact the site owner (or responsible SFPUC department for the Peninsula Sportsmen's Club and Pacific Rod and Gun Club) and responsible regulatory agency to determine appropriate construction modifications or remediation necessary to avoid adverse effects during construction and operation of the project. Construction modifications will be designed to reduce groundwater plume migration or interference with the remediation; alternatively, modifications will be made to the remediation activities during construction to reduce interference with remediation activities to avoid encountering unacceptable levels of hazardous materials. The SFPUC will implement the requirements of the responsible regulatory agency.

Health Risk Screening and Airborne Asbestos Monitoring Plan

Measure 4.14-2: For tunneling projects where soil or rock containing naturally occurring asbestos has been identified, the SFPUC will conduct a health risk screening assessment to identify acceptable levels of asbestos in tunnel emissions based on site conditions and proximity to receptors. Prior to operation of the tunnel exhaust system, the contractor will be required to prepare an airborne asbestos monitoring plan for approval by the BAAQMD. The plan will specify the identified asbestos criterion, monitoring that will be conducted to identify asbestos concentrations in tunnel emissions, sampling methods, analytical methods, and corrective actions that will be taken if the asbestos criterion is exceeded. Additional dust filtration will be added to the tunnel exhaust system if the criterion is exceeded.

Hazardous Building Materials Surveys and Abatement

Measure 4.14-5: For all WSIP projects involving demolition or renovation of existing facilities, the SFPUC will retain a registered environmental assessor or a registered engineer to perform a hazardous building materials survey for each structure prior to demolition or renovation activities. If any friable asbestos-containing materials, lead-containing materials, or hazardous components of building materials are identified, adequate abatement practices, such as containment and/or removal, will be implemented prior to demolition or renovation. Any PCB-containing equipment or fluorescent lights containing mercury vapors will also be removed and disposed of properly.

6.3.14 Energy Resources

Program Measures

Incorporation of Energy Efficiency Measures

Measure 4.15-2: Consistent with the Energy Action Plan II priorities for reducing energy usage, the SFPUC will ensure that energy efficient equipment is used in all WSIP projects. A repair and maintenance plan will also be prepared for each facility to minimize power use. The potential for use of renewable energy resources (such as solar power) at facility sites will be evaluated during project-specific design.

6.4 Mitigation Measures to Minimize Water Supply and System Operations Impacts

This section presents all mitigation measures for impacts described in Chapter 5. Mitigation measures for impacts identified in Sections 5.3 through 5.6 are presented under the respective geographic area (i.e., watershed or groundwater basin). In some cases, a mitigation measure would mitigate more than one impact, and the mitigation measure numbering corresponds to the first impact identified. Impact and mitigation summary tables for Section 5.3, Tuolumne River Watershed and Downstream Waterbodies; Section 5.4, Alameda Creek Watershed Streams and Reservoirs; Section 5.5, San Francisco Peninsula Streams and Reservoirs; and Section 5.6, Westside Groundwater Basin, are presented in Section 6.6.

System Measures

Overview of Measures 5.3.6-4a, 5.3.6-4b, and 5.3.7-6

The SFPUC will attempt to implement Measure 5.3.6-4a as described below, which could mitigate both Impacts 5.3.6-4 and 5.3.7-6 to a less than significant level. Measure 5.3.6-4a involves some uncertainty because its implementation depends on the SFPUC negotiating and reaching agreement with MID/TID and possibly other water agencies. If Measure 5.3.6-4a proves to be infeasible, the SFPUC will implement Measure 5.3.6-4b to lessen fisheries impacts and Measure 5.3.7-6 to lessen impacts on riparian vegetation.

Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water

Measure 5.3.6-4a: The SFPUC will pursue a water transfer arrangement with MID/TID and/or other water agencies such that the water acquired is developed through actions that result in reduction of demand on Don Pedro Reservoir as a result of conservation, improved delivery efficiency, inter-agency transfer of conserved water, or use of an alternative supply such as groundwater. The TID and MID would deliver less water from Don Pedro Reservoir. The consequent increase in water storage in Don Pedro Reservoir would offset the reduction in inflow to Don Pedro Reservoir attributable to the WSIP. The release pattern from La Grange Dam would be the same or similar to the existing condition thus lessening or eliminating Impacts 5.3.6-4 and 5.3.7-6. The actions necessary to reduce demand for Don Pedro Reservoir water may themselves have environmental effects. See Section 6.5 for a review of potential environmental effects associated with the expected actions of this mitigation measure. Further environmental review would be undertaken prior to approving a specific water transfer agreement.

Fishery Habitat Enhancement

Measure 5.3.6-4b: If Measure 5.3.6-4a is not implemented, then the SFPUC will mitigate potential fishery effects on the lower Tuolumne River by implementing (or funding) one of the following two habitat enhancement actions that are designed to sustain fishery resources under the river's flow regime, which are consistent with the Habitat Restoration Plan for the Lower Tuolumne River Corridor: gravel augmentation/habitat enhancement to provide salmonid spawning and rearing habitat, or isolating or filling a captured former gravel quarry pit along the river that provides habitat for salmonid predators.

The gravel augmentation/habitat enhancement project will be implemented to increase salmonid spawning success and to improve the survival of rearing salmonids in the reach of the river downstream of La Grange Dam. Spawning success will be improved by the addition of suitable gravel to the stream channel. Other habitat features will be created to provide cover for juvenile salmonids and to increase the availability of substrate for macroinvertebrates that would be used as food by rearing juvenile salmon and steelhead. The gravel augmentation/habitat enhancement project will involve the planning, design, permitting, purchase, placement, and monitoring of suitable gravel and associated habitat enhancements at three riffle locations within the spawning reach between Basso Bridge and La Grange Dam. The three locations will meet the criteria for suitable habitat as described in the Habitat Restoration Plan for the Lower Tuolumne River Corridor. The gravel will preferentially be rounded river rock of native origin that would be sized and pre-washed before placement into the river. The gravel augmentation/habitat enhancement project will also involve the addition of large woody debris and boulders to create increased habitat complexity and diversity at each of the three enhancement sites. After construction of the gravel augmentation/habitat enhancement project, it will be surveyed to establish its baseline condition. A survey of the three sites will be made at a minimum of five-year intervals by a qualified fisheries biologist. The fisheries biologist will determine whether the three sites continue to meet established criteria for salmonid spawning and rearing habitat. If the sites do not meet the criteria, as part of its long-term operations, the SFPUC will make the improvements necessary to return it to the baseline conditions.

As an alternative to the gravel augmentation project, the SFPUC will remove from the lower river channel one of the former gravel quarry pits that has been "captured" by the river and acts as predator zones for fish such as largemouth and striped bass to prey on rearing and emigrating juvenile salmonids. Removal could be accomplished by filling the pit or installing a levee berm around the pit to isolate it permanently from the river channel. The SFPUC could implement this action directly or fund implementation by another entity involved in river restoration.

The performance standard for gravel pit removal would be an established permanent reduction in area of salmonid predator habitat. The SFPUC will monitor the pit removal project at five-year intervals. If floods have eroded the fil1 or damaged the levees in a manner that restores salmonid predator habitat, the SFPUC will make the necessary repairs. The SFPUC will continue periodic monitoring and repair as part of long-term system operations.

Terrestrial Biological Resources

System Measures

Controlled Releases to Recharge Groundwater in Streamside Meadows and Other Alluvial Deposits

Measure 5.3.7-2: To mitigate for potential WSIP effects on meadow resources along the Tuolumne River below Hetch Hetchy Reservoir, the SFPUC will manage releases from

Hetch Hetchy Reservoir during the spring to recharge groundwater in the riverside meadows in the Poopenaut Valley and streamside alluvial deposits. The goal of the release pattern will be to approximate conditions characteristic of most Sierra meadows, which are mainly wetlands or semi-wetlands supporting a cover of both emergent wetlands plants and upland vegetation (Ratliff, 1982), and which depend on precipitation and upslope flows to recharge the upper soil layers with water (Ratliff, 1985). The performance standard to be achieved by this measure is no net loss of the extent, diversity, and condition of the existing meadow and wetland vegetation types in the Poopenaut Valley.

The SFPUC will manage reservoir releases for this purpose by releasing the expected available volume of water in the reservoir in a pattern that provides flows of a magnitude that inundate the meadows and streamside alluvial deposits for as long as possible. For example, rather than making releases at a constant rate each day (e.g., releasing 1,000 cfs for seven days), the SFPUC could release the same volume of water but with varying cfs rates, creating flow pulses to meet the objective.

As part of this measure the SFPUC will gather baseline data regarding the extent, species composition and condition of the existing meadow vegetation within the Poopenaut Valley. Some of these environmental baseline data may be available as a result of current study efforts in the Poopenaut Valley[5]. As needed, the SFPUC will augment this information by carrying out vegetation composition surveys in the meadow before implementing the WSIP and at 5 year intervals after WSIP implementation to assess the efficacy of mitigation releases in maintaining or improving the percentage cover of meadow species as described by Ratliff (1985). The basic methodology for baseline vegetation survey and subsequent mitigation monitoring will be generally accepted quantitative vegetation sampling methods to permit statistical comparison of vegetation composition over time, as well as mapping the meadow vegetation in the Poopenaut Valley. The SFPUC will retain the services of a qualified biologist to assist in shaping the releases from Hetch Hetchy Reservoir in consideration of baseline and future meadow vegetation data. If a significant decline in the extent or diversity of native meadow vegetation occurs, releases will be modified as needed to achieve the mitigating effect of sustaining the existing meadow communities.

Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water

See **Measure 5.3.6-4a** in the Fisheries section, above. This measure also addresses impact 5.3.7-6 Impacts on biological resources along the Tuolumne River below La Grange. The SFPUC will attempt to implement Measure 5.3.6-4a as described above, which could mitigate both Impacts 5.3.6-4 and 5.3.7-6 to a less than significant level. Measure 5.3.6-4a involves some uncertainty because its implementation depends on the SFPUC negotiating and reaching agreement with MID/TID and possibly other water agencies. If Measure 5.3.6-4a proves to be infeasible, the SFPUC will implement Measure 5.3.6-4b to lessen fisheries impacts and Measure 5.3.7-6 to lessen impacts on riparian vegetation.

Lower Tuolumne River Riparian Habitat Enhancement

Measure 5.3.7-6: To mitigate the WSIP effects on riparian vegetation, the SFPUC will both protect and enhance one mile of riparian vegetation along the contemporary floodplain of the lower Tuolumne River. This will include funding the acquisition of fee title to or a conservation easement over riparian land totaling one mile (consisting of one or multiple sites) in order to permanently protect that land, and also funding riparian enhancement and on-going vegetation management to maintain the enhanced riparian values in perpetuity along one mile of river. The enhancement and management may be carried out along one river mile either on the land acquired by the SFPUC as described above or on land already under the permanent management of a public agency or conservation organization.

The SFPUC will implement this measure consistent with the Habitat Restoration Plan for the Lower Tuolumne River Corridor (McBain and Trush, 2000) and in coordination with the Tuolumne River Technical Advisory Committee. The SFPUC will also strive to

5 In 2006 the SFPUC, National Park Service (and USFWS) began a collaborative study effort in the Poopenaut Valley. The effort has led to geomorphology test releases in May 2006, fieldwork in the channel in 2006 and 2007 to examine sediment transport and deposition relationships with flow. Two transects with ten recording piezometers have been installed across the meadow to measure groundwater recharge and drainage patterns. Supplementary stream staff gages have been installed to allow manual readings during high flows. Surveys have been done of the meadow to define the topography and the location and elevation of the piezometers. Infiltration of water from the stream to the meadow soils will be monitored during high flows to develop a better understanding of groundwater dynamics in the meadow so that reservoir operations, flow pulses, and minimum streamflow releases can be managed to improve meadow conditions within the constraints of water supply and facility limitations.

implement these projects in partnership with those groups currently working to restore riparian floodplains on the lower Tuolumne River.

The SFPUC may implement riparian enhancement in accordance with site locations and plans already developed as part of the Habitat Restoration Plan for the Lower Tuolumne River Corridor or on other appropriate sites along the river. For sites that haven't already had plans developed, a riparian enhancement plan will be prepared for each. The plan shall include, but not be limited to, the following:

- Clearly stated objectives and goals consistent with the Habitat Restoration Plan for the Lower Tuolumne River Corridor (McBain and Trush, 2000).
- Location, size, and type of mitigation actions proposed.
- Documentation of performance and monitoring standards.
- Performance and monitoring standards shall indicate success criteria to be met within 5 years for vegetation, removal of exotic species, etc. Adaptive management standards shall include contingency measures that shall outline clear steps to be taken if and when it is determined, through monitoring or other means, that the enhancement or restoration techniques are not meeting success criteria.
- Documentation of the necessary long-term management and maintenance requirements, and provisions for sufficient funding.

6.4.3 Alameda Creek Watershed Streams and Reservoirs

Stream Flow and Reservoir Water Levels

System Measures

Diversion Tunnel Operation

Measure 5.4.1-2: The SFPUC will establish and implement written operational criteria for the Alameda Creek Diversion Dam that directs that the diversion dam and tunnel shall be operated to pass flows down Alameda Creek when diversion of those flows is not required to maintain desired levels in Calaveras Reservoir in order to provide the maximum possible days of winter and spring flows in Alameda Creek below the diversion dam.

This measure reinforces the way the SFPUC generally operates the diversion tunnel now: that diversion gates are closed in the spring once desired Calaveras Reservoir storage have been reached. However, at times additional flows have been diverted from Alameda Creek after reservoir storage levels have been achieved such that the “excess” water has subsequently been released from the reservoir to maintain the appropriate water level. This measure would formalize Alameda Creek diversion procedures to maintain flows in Alameda Creek to the extent they are not needed to achieve required reservoir storage. This measure would reduce the flow reduction impact but not to a level that is less than significant.

Fisheries

System Measures

Minimum Flows for Resident Trout on Alameda Creek

Measure 5.4.5-3a: The SFPUC shall develop and carry out as part of the implementation of the Calaveras Dam Replacement (SV-2) project, an operational plan to implement minimum bypass flows when precipitation generates runoff into the creek below the diversion dam to the Calaveras Creek confluence from December 1 through April 30 to support spawning and egg incubation for resident trout as well as breeding habitat for other native stream-dependent amphibians. This is the period when winter precipitation typically would produce flows for spawning and egg incubation and breeding habitat for other native stream-dependent species. The operational plan will identify the specific minimum flow requirements to support resident trout spawning and egg incubation, and a detailed monitoring plan to survey and document trout spawning and egg incubation and any diversion facility modifications that are needed to implement the minimum stream flows. This measure will be implemented in conjunction with the proposed bypass flows at the diversion dam to meet the 1997 CDFG MOU flow requirements.

Minimum flow requirements to support resident trout spawning and egg incubation vary depending on stream reach conditions. Although site-specific studies are needed to determine an appropriate minimum flow requirement for each specific creek reach, based on the general size and characteristics of the Alameda Creek channel immediately downstream of the diversion structure it has been suggested that a minimum flow on the order of 10 cfs may be needed to support trout spawning and egg incubation. The SFPUC's Natural Resources Division will complete the site-specific studies needed to determine the appropriate minimum stream flow for this reach of the creek; studies may show that the minimum flow requirement is more or less than 10 cfs. This minimum flow requirement would be met when precipitation would naturally generate runoff in the creek (below the diversion dam) under unimpaired conditions between December 1 and April 30. When precipitation generates runoff in the creek, the SFPUC shall provide for bypass of flow up to the required minimum flow amount. The operational plan will allow for adapting minimum flow amounts to support resident trout spawning and egg incubation and other native stream-dependent species based on the monitoring results and best available scientific information.

The monitoring plan will be provided to appropriate resource agencies for review and comment and will subsequently be implemented by the SFPUC's Natural Resources Division staff. Monitoring results shall be provided to the resource agencies as requested. Monitoring shall occur for a minimum of five years and a maximum of ten years following completion of the Calaveras Dam Replacement project. At the completion of the monitoring period the SFPUC shall produce a draft comprehensive report describing the methods, data collected, and results used to assess the performance of the minimum streamflow in providing suitable habitat for resident trout spawning and egg incubation.

The Alameda Creek Fisheries Restoration Workgroup is currently overseeing collaborative studies to better characterize the flow-habitat relationships for trout spawning within Alameda Creek, and the SFPUC is providing staff and funding to support this effort. Information from these studies will also be used in developing the specific range of minimum stream flows needed to support suitable habitat within the reach below the diversion dam to the Calaveras Creek confluence.

This measure addresses two areas of impact to the resident trout fishery in Alameda Creek below the diversion dam. First, it addresses the decrease in flow below the diversion dam that would occur under the WSIP as a result of re-instituting flow diversions to Calaveras Reservoir once the dam is replaced (WSIP Project SV-2) and current DSOD storage capacity restrictions are removed. Second, it addresses the loss of fish from the lower creek system that would result from fish entrainment through the unscreened diversion tunnel to Calaveras Reservoir. Providing for minimum stream flows in Alameda Creek below the diversion dam, as required by the mitigation measure, would support resident trout spawning and egg incubation and it is expected that this measure would be sufficient to sustain the trout population in this reach of the creek. This would fully address/mitigate for both areas of WSIP impact to the resident trout fishery below the diversion dam. If monitoring indicates that this measure is adequate to sustain the resident trout population below the diversion dam, then no additional mitigation action would be required. If monitoring indicates that this measure does not sustain the resident trout fishery in this reach, then the SFPUC shall either modify the minimum stream flow to enhance downstream habitat conditions to fully meet the mitigation requirement or also implement Measure 5.4.5-3b Diversion Restrictions or Fish Screens.

Alameda Diversion Dam Diversion Restrictions or Fish Screens

Measure 5.4.5-3b: If, after 10 years of monitoring results for Measure 5.4.5-3a, Minimum Flows for Resident Trout in Alameda Creek, indicate that the measure does not sustain the resident trout population in Alameda Creek below the diversion dam, then the SFPUC shall also implement additional measures as follows: either implement seasonal restrictions on Alameda Creek diversions to Calaveras Reservoir to protect the downstream resident trout fishery during the critical spawning period (December 1 through April 30) or install and operate a fish passage barrier to "screen" the diversion facility (screening could consist of a behavioral barrier, such as electrical or sound barrier that deters fish, or a physical barrier – such as a screen facility).

SFPUC shall consult with the appropriate resource agencies, including CDFG, to first review the monitoring results for Measure 5.4.5-3a and determine the need for any further mitigation actions. If needed, SFPUC will consult with the appropriate resource agencies to develop appropriate seasonal restrictions on diversions. This could involve establishing a set annual time period for diversion restrictions or annual monitoring of fishery conditions that would then trigger implementation of diversion restrictions.

Alternatively, the SFPUC will implement a fish passage barrier if determined to be feasible. During the 10-year monitoring and evaluation period for Measure 5.4.5-3a, the SFPUC will evaluate the feasibility of installing and operating a fish passage barrier. The feasibility study will include an engineering evaluation of the existing site and diversion structure, access for construction and power supplies to the site, the application of various alternative designs, and identification of a preferred design if determined to be feasible. If it is determined that a fish passage barrier is needed to protect resident trout at the diversion structure then engineering design will be completed and be sufficiently detailed to allow permitting and completion of construction within a period of 24 months after the date that the additional mitigation is determined to be required.

Terrestrial Biological Resources

System Measures

Compensation for Impacts on Terrestrial Biological Resources

Measure 5.4.6-1: This measure mitigates for water supply and systemwide operation effects on resources within the Alameda Creek watershed. These impacts would occur primarily through operation of the Calaveras Dam Replacement project (SV-2).

The SFPUC will compensate for sensitive wetland, riparian and upland habitats and habitats which support key special-status species or other species of concern lost as a result of WSIP system operation. Similar habitat will be identified, protected, restored, enhanced, created and managed off-site[6] to ensure no net loss of habitat extent or function. A qualified biologist will quantify the magnitude and extent of impacts to wetlands, sensitive habitats, and key special-status species and other species of concern, and the SFPUC will develop and implement mitigation and compensation plans that meet the appropriate regulatory requirements and permit conditions with respect to compensation ratios, other

[6] Off-site means the compensatory action is located other than within the project construction footprint, but could be on lands already under SFPUC ownership. Measure 4.6-2 addresses compensatory actions to be taken within the construction footprint.

conservation measures and management requirements to mitigate project impacts to less than significant levels.

The SFPUC will obtain required permits and comply with applicable environmental regulations addressing sensitive habitats and species. Compensatory lands—including those restored or enhanced as well as those acquired or designated as protected as part of program mitigation--will be established in perpetuity with a commitment that such lands will not be used for any purpose that conflicts with the primary purpose of maintaining intact wildlife and plant habitat.

One alternative for implementing such habitat compensation is the Habitat Reserve Program (HRP) currently being developed by the SFPUC. The purpose of the HRP is to provide a comprehensive, coordinated approach to mitigation and related regulatory compliance for WSIP projects and operations. This related SFPUC project is described further in Chapter 3.0, Section 3.12.3. Under the proposed HRP, the SFPUC would proceed as soon as possible with identifying, securing (through designation, management agreement, conservation easement, or acquisition of fee title) and improving lands to be used for habitat compensation so that mitigation is underway concurrent with habitat loss related to WSIP program activities, further ensuring no net loss of resources. The proposed HRP is scheduled for CEQA environmental review in 2007 and is targeted for implementation as soon as possible thereafter. Once the HRP is approved and implemented, the SFPUC will use this as one vehicle or method for implementing the mitigation requirements for individual WSIP projects. Otherwise, where appropriate and necessary, the SFPUC will develop and implement appropriate habitat compensation mitigation for individual WSIP projects and their associated operational impacts.

Operational Procedures for Calaveras Dam Releases

Measure 5.4.6-3: During project-level CEQA review on the Calaveras Dam Replacement project (SV-2), the SFPUC will develop operational procedures for managing planned releases from Calaveras Dam to minimize habitat impacts on amphibians, their egg masses, and tadpoles. The goal of such releases, apart from benefits to fish, is to mimic a more natural pattern of hydrology regime as much as possible. The procedures will specify the minimum amount and frequency of planned releases and the rate of the increase and decrease of any individual release event. One of the specific goals of such releases would be to reduce the risk of mortality to breeding amphibians. Such operational procedures will be developed prior to completion of construction of the Calaveras Dam Replacement project. In addition, instream flow releases required under CDFG agreement with SFPUC (see Table 5.4.1-9) would begin upon completion of construction.

Recreational and Visual Resources

System Measures

None required.

6.4.4 San Francisco Peninsula Streams and Reservoirs

Stream Flow and Reservoir Water Levels

System Measures

None identified.

Geomorphology

System Measures

None required.

Surface Water Quality

System Measures

Low-head Pumping Station at Pilarcitos Reservoir

Measure 5.5.3-2a: The SFPUC shall install a permanent low-head pumping station at Pilarcitos Reservoir which would enable the SFPUC to access and use an additional 350 acre-feet of water from Pilarcitos Reservoir. In years when the WSIP would cause releases from Pilarcitos Reservoir to Pilarcitos Creek to be reduced to reservoir inflow earlier in the summer than under the existing condition (about 25 percent of years in the hydrologic record), the SFPUC will use the pumping station to augment flow in Pilarcitos Creek with water from the reservoir. The pumping station will draw water from the cool pool of water below the thermocline during times when the reservoir is stratified. The pumping station outlet will be designed to ensure that water discharged to the creek is adequately aerated.

Aeration System at Pilarcitos Reservoir

Measure 5.5.3-2b: The SFPUC shall install a permanent aeration system at Pilarcitos Reservoir. The SFPUC will operate the aeration system as necessary to avoid anoxic conditions and maintain good water quality conditions at the reservoir.

Groundwater

System Measures

None required.

Fisheries

System Measures

Create New Spawning Habitat Above Crystal Springs Reservoir

Measure 5.5.5-1: The SFPUC will survey the extent and quality of fish spawning habitat that could potentially be lost due to inundation and, if feasible, create new spawning habitat at a higher elevations. The specifics of this mitigation measure will be determined as part of project-level CEQA review for the Lower Crystal Springs Dam Improvements project (PN-4).

Establish Flow Criteria, Monitor and Augment Flow

Measure 5.5.5-5: The SFPUC shall develop a monitoring and operations plan for Stone Dam to ensure WSIP-related flow reductions downstream of Stone Dam do not impair steelhead passage and spawning during the winter months of normal and wetter hydrologic years. This operational plan will provide for minimum stream flows to support existing adult steelhead passage and spawning downstream of Stone Dam, in the reach between Stone Dam and the confluence with the tributary at Albert Canyon, approximately 3.5 miles downstream. Downstream of Albert Canyon, WSIP flow reductions are unlikely to cause a significant impact to steelhead migration and spawning due to contributing flows from numerous downstream tributaries being sufficient to maintain adult upstream passage and spawning conditions within the creek. Monitoring and implementation of the operational plan will occur when precipitation generates runoff into Pilarcitos Creek below Stone Dam from December 1 through April 30 of normal and wetter years. This monitoring and operations plan will be established within five years of the approval of the PEIR.

Specific instream flows needed to support anadromous steelhead downstream of Stone Dam have not yet been identified. Suitable instream flows for steelhead passage on Pilarcitos Creek may be defined as providing a water depth of at least 0.6 feet over 25 percent of the total wetted channel cross-sectional area with 10 percent being contiguous. In cooperation with CDFG and NMFS, the SFPUC will identify up to five critical riffles, downstream of Stone Dam and upstream of Albert Canyon that may cause a passage impediment/barrier to steelhead migration at reduced flows as defined by the water depth criterion above. Such habitat types will be selected for survey because they represent the shallowest habitat type and thus would most likely represent low flow passage barriers under WSIP-related reduced flow scenarios. This monitoring plan will survey and document the critical riffles identified to determine physical conditions (e.g., depth, velocity, and top width of the channel) present at various flow levels. The SFPUC will measure the stage-discharge relationship at each of the five critical riffles and identify the minimum stream flow that meets the steelhead passage criterion at the most restrictive of the five riffle locations.

The SFPUC will calibrate and validate the flow measurements made at the existing flow monitoring gage (USGS Gage 11162620) located immediately downstream of Stone Dam. The SFPUC will then develop a statistical relationship between the flow measurements at the existing gage and the flow at the most restrictive critical riffle downstream of Stone Dam to establish minimum average daily flows necessary to meet steelhead passage criterion. The SFPUC will monitor average daily flows at the stream flow gage during the period from December 1 through April 30 each year. If average daily flow, as measured at the gage, indicates that the minimum stream flow at the downstream critical riffle is not met, the SFPUC will release bypass flows from Stone Dam at a rate sufficient to meet the minimum stream flow for steelhead passage at a release rate up to, but not exceeding, the average daily inflow into Pilarcitos Reservoir as determined by SFPUC operators.

The SFPUC's Natural Resources Division will complete the site-specific studies needed to determine the appropriate minimum stream flow for the most restrictive critical riffle identified during monitoring. This minimum flow criterion will be met when WSIP diversions occur between December 1 and April 30 of normal and wetter hydrologic years. The operational plan will allow for adapting minimum flow amounts to support steelhead migration based on the monitoring results and best available scientific information.

Monitoring and flow management will be continued for a minimum period of five years and a maximum period of ten years, at which time the SFPUC will prepare a technical report describing results of the stream flow monitoring, identifying whether or not operation of Stone Dam reduced passage flows below the minimum criteria, and identifying, if needed, an appropriate bypass flow for future operations at Stone Dam (a minimum flow below which water could not be diverted to storage between December and April 30). The technical report will be provided to CDFG and NMFS.

Terrestrial Biological Resources

System Measures

Habitat Monitoring and Compensation

Measure 5.5.3-2c The SFPUC shall compensate for reduced productivity and diversity of San Francisco garter snake (SFGS) and California red-legged frog (CRLF) wetland habitat which could occur as a result of greater variability, extent and duration in drawdowns at Pilarcitos Reservoir as a result of implementation of Revised Measure 5.5.3-2a (Low-head Pumping Station at Pilarcitos Reservoir). To offset the potential loss of habitat quality, the SFPUC will develop an adaptive management plan for managing and maintaining freshwater marsh and other wetlands around the periphery of Pilarcitos Reservoir. This adaptive management plan would include pre- implementation monitoring and post-implementation monitoring for up to 10 years to ensure that habitat is sustained at Pilarcitos Reservoir, to achieve no net loss of habitat and value for SFGS and CRLF habitat and document changes (if any) in extent or quality of the habitat attributable to operation of the low-head pumping station.

In the event that habitat is reduced, one alternative for implementing such habitat compensation is the Habitat Reserve Program (HRP) currently being developed by the SFPUC. The purpose of the HRP is to provide a comprehensive, coordinated approach to mitigation and related regulatory compliance for WSIP projects and operations. The HRP is described further in the PEIR, Chapter 3.0, Section 3.12.3. Under the proposed HRP, the SFPUC would proceed as soon as possible with identifying, securing (through designation, management agreement, conservation easement, or acquisition of fee title) and improving lands to be used for habitat compensation so that mitigation is underway concurrent with habitat loss related to WSIP program activities, further ensuring no net loss of resources. The proposed HRP is undergoing CEQA environmental review in 2008 and 2009 and is targeted for implementation as soon as possible thereafter. Once the HRP is approved and implemented, the SFPUC will use this as one vehicle or method for implementing the mitigation requirements for WSIP-related activities. Otherwise, where appropriate and necessary, the SFPUC will develop and implement appropriate habitat compensation mitigation for WSIP system operational effects on Pilarcitos Reservoir, independent of the HRP.

Adaptive Management of Freshwater Marsh and Wetlands at Upper and Lower Crystal Springs Reservoirs

Measure 5.5.6-1a: To offset the loss of wetlands, a qualified professional will develop an adaptive management plan for managing and maintaining freshwater marsh and other wetlands around the periphery of Upper Crystal Springs, and Lower Crystal Springs Reservoirs. This adaptive management plan may include the following:

- Gradually raise the reservoir elevations at appropriate times of year to maintain continuous freshwater marsh and riparian habitat along the shorelines to reduce potentially adverse effects to San Francisco garter snakes and California red-legged frogs.
- Identify feasible measures to help to moderate the effects of reservoir drawdown, increase the extent of reservoir margins with the potential to support freshwater

marsh vegetation, and investigate the effectiveness for the management and control of predatory aquatic species such as largemouth bass and bullfrogs.

- Perform monitoring and review to ensure that habitat is sustained at Upper and Lower Crystal Springs Reservoirs and elsewhere, as appropriate, to achieve no net loss of habitat and value for freshwater marsh, wetlands, and special-status species.
- Observe all appropriate protective measures to avoid "take" of San Francisco garter snake. In the event that the mitigation measures above cannot be followed, the SFPUC will prepare a sensitive species relocation plan, which would be approved by both the CDFG and USFWS. Such a plan would detail how underground refugia would be excavated, identify suitable relocation areas, etc.

Compensation for Impacts on Terrestrial Biological Resources

Measure 5.5.6-1b: This measure mitigates for water supply and systemwide operation effects on resources within the Peninsula watershed. These impacts would occur primarily through operation of the Upper and Lower Crystal Springs Reservoir facilitated by the Crystal Springs Dam Improvements project (PN-9).

The SFPUC will compensate for sensitive wetland, riparian and upland habitats and habitats which support key special-status species or other species of concern lost as a result of WSIP system operation. Similar habitat will be identified, protected, restored, enhanced, created and managed off-site[7] to ensure no net loss of habitat extent or function. Similarly, in the event of the loss of large, mature oaks and oak woodland, creation and/or restoration of oak woodland elsewhere will be implemented to compensate for the loss of these common upland habitats. A qualified biologist will quantify the magnitude and extent of impacts to wetlands, sensitive habitats, other upland habitats, and key special-status species and other species of concern, and the SFPUC will develop and implement mitigation and compensation plans that meet the appropriate regulatory requirements and permit

[7] Off-site means the compensatory action is located other than within the project construction footprint, but could be on lands already under SFPUC ownership. Measure 4.6-2 addresses compensatory actions to be taken within the construction footprint.

conditions with respect to compensation ratios, other conservation measures and management requirements to mitigate project impacts to less than significant levels.

The SFPUC will obtain required permits and comply with applicable environmental regulations addressing sensitive habitats and species. Compensatory lands—including those restored or enhanced as well as those acquired or designated as protected as part of program mitigation--will be established in perpetuity with a commitment that such lands will not be used for any purpose that conflicts with the primary purpose of maintaining intact wildlife and plant habitat.

One alternative for implementing such habitat compensation is a Habitat Reserve Program (HRP) currently being developed by the SFPUC. The purpose of the HRP is to provide a comprehensive, coordinated approach to mitigation and related regulatory compliance for WSIP projects and operations. This related SFPUC project is described further in Chapter 3.0, Section 3.11. Under the proposed HRP, the SFPUC would proceed as soon as possible with identifying, securing (through designation, management agreement, conservation easement, or acquisition of fee title) and improving lands to be used for habitat compensation so that mitigation is underway concurrent with habitat loss related to WSIP program activities, further ensuring no net loss of resources. The proposed HRP is scheduled for CEQA environmental review in 2007 and targeted for implementation as soon as possible thereafter. Once the HRP is approved and implemented, the SFPUC will use this as one vehicle or method for implementing the mitigation requirements for individual WSIP projects. Otherwise, where appropriate and necessary, the SFPUC will develop and implement appropriate habitat compensation mitigation for individual WSIP projects and operational effects.

Compensation for Serpentine Seep-Related Special Status Plants

Measure 5.5.6-1c: The SFPUC will develop and implement a plan to protect, create, and restore habitat for plant species adapted to serpentine seeps, particularly fountain thistle, around Upper and Lower Crystal Springs Reservoirs. The plan will also include control of pampas grass and any other invasive plant species within the serpentine seep habitat.

Recreational and Visual Resources

System Measures

None required.

6.4.5 Westside Groundwater Basin Resources

System Measures

Groundwater Monitoring to Determine Basin Safe Yield

Measure 5.6-1: The SFPUC will continue ongoing studies, including the existing groundwater and lake level monitoring programs, to determine the safe yield of the North Westside Groundwater Basin in order to avoid overdraft and associated effects including adverse effects on surface water features and seawater intrusion. Using this data, the SFPUC will develop and implement a plan identifying appropriate pumping patterns to avoid overdraft and the undesirable effects associated with overdraft. The plan will establish both a regular (average annual) and an intermittent (dry year or emergency) yield as well as a strategy for modifying pumping patterns such that the pumping levels can be sustained as an ongoing reliable water supply without depletion of groundwater storage or degradation of water quality.

Implementation of a Lake Level Management Plan

Measure 5.6-2: The SFPUC will develop and implement a lake level management plan identifying strategies for altering pumping patterns or lake augmentation to maintain Lake Merced water levels within the desired long-term range should monitoring conducted under Measure 5.6-1 indicate the potential for adverse effects on lake levels due to groundwater pumping. The SFPUC will coordinate the implementation of this measure with Measure 5.6-1.

Drinking Water Source Assessments for Groundwater Wells

Measure 5.6-5: As required by the California Department of Health Services and incorporated as part of the WSIP, the SFPUC will prepare drinking water source assessments for groundwater wells constructed under the Local and Regional Groundwater Projects (SF-2) and will update these assessments every five years. If the assessment indicates no potential for contamination, then no mitigation is required. However, for wells that are considered vulnerable to contamination on the basis of the drinking water source assessment, the SFPUC will develop and implement a source water protection program specifying actions and a program to be implemented to prevent contamination of the drinking water source.

The source water protection program could include nonregulatory components such as watershed restoration, stormwater monitoring, groundwater monitoring, and public education to protect drinking water quality. Land use planning, permitting, and possibly more restrictive regulatory methods may also be implemented by the local municipality where a threat to drinking water quality is indicated, and management of potential sources of microbiological or direct chemical contamination to eliminate or reduce the risk of contamination of the water supply may be considered. The SFPUC will encourage public participation in the development of the program and will update the program every five years along with the drinking water source assessments.

6.4.6 Cumulative Projects and Impacts Related to WSIP Water Supply and System Operations

System Measures

None required.

6.5 Impacts of Mitigation Measures

CEQA Section 15126.4 states that "if a mitigation measure would cause one or more significant effect in addition to those that would be caused by the project as proposed, the effects of the mitigation measure shall be discussed but in less detail than the significant effects of the project as proposed." This section identifies which mitigation measures described in Sections 6.3 and 6.4 above may result in significant effects independent of the identified WSIP impacts, and describes the general nature of those effects. This discussion includes the following categories of mitigation measures:

- Measures that would involve designated long-term use of lands for mitigation purposes. This includes mitigation measures requiring habitat compensation through creation, restoration, and enhancement of habitat as well as permanent set-aside for farmlands
- Measures that would involve construction or operation in sensitive habitats
- Measures that would affect SFPUC regional system water supply sources, potentially reducing overall supply available for customers. This includes mitigation measures requiring increased streamflow releases from storage reservoirs, reduced diversions to storage reservoirs, or reduced groundwater pumping.
- Measures that would involve water transfers from other agencies, with potential to affect other water sources and associated resources or other water users.

Prior to implementation of these types of measures, project-level CEQA review would be conducted as necessary to identify if and what impacts would be associated with these measures in and of themselves. Even though the objective of these measures is to reduce environmental impacts, additional mitigation actions may be necessary during the construction and/or operation of these measures depending on the specific design and location. However, the mitigation measures described in this section and the associated CEQA review are not integral to the approval and adoption of the overall WSIP as a comprehensive program and policy. In some cases, CEQA review of these measures may be incorporated as part of the subsequent project-level environmental review of individual facility improvement projects, while in other cases, as described above for those measures, the measures are optional approaches to avoiding or reducing significant impacts and the SFPUC may elect to implement the alternative approach such that CEQA review would be superfluous.

6.5.1 Measures that Designate Land for Mitigation Purposes

Depending on the actual design of the measure, the following PEIR mitigation measures could be in this category: Measure 4.6-1b (Compensation for Wetlands and Other Biological Resources); Measure 4.13-2 (Siting Facilities to Avoid Prime Farmland); Measure 4.16-4a (Bioregional Habitat Restoration Measures); Measure 5.3.7-6 (Lower Tuolumne River Riparian Habitat Enhancement); Measure 5.4.6-1 (Compensation for Impacts on Terrestrial Biological Resources); Measure 5.5.6-1b (Compensation for Impacts on Terrestrial Biological Resources); and Measure 5.5.6-1c (Compensation for Serpentine Seep-Related Special Status Plants). In general, the types of potential impacts associated with long-term designation of lands for mitigation purposes include:

- *Land use*: change existing character of the land; result in short-term disruption to nearby land uses during construction; and displace existing land uses (similar to Impacts 4.3-1 and 4.3-2, which could be mitigated through siting measures similar to Measure 4.3-2). In particular, habitat compensation could affect existing agricultural uses (similar to Impact 4.13-2, which could be mitigated through measures similar to Measure 4.13-2, avoidance of Prime Farmland)

- *Biological resources*: convert existing habitat types to other types, although habitat compensation would be expected to result in long-term benefit to biological resources; result in short-term disruption to existing biological resources during construction (similar to Impact 4.6-2, which could be mitigated through habitat protection/restoration measures similar to Measure 4.6-2, including construction timing restrictions to avoid impacts on sensitive species)

- *Geology*: change the topography or physical features of a site (which could be mitigated through standard engineering and design measures to avoid substantial changes to unique geologic or physical features)

- *Water quality and hydrology*: alter drainage patterns due to changes in grading and vegetation; result in erosion and sedimentation during construction (similar to Impacts 4.5-1 and 4.5-6, which could be mitigated through standard construction measures for erosion and sedimentation control as well as through compliance with water quality regulations)

- *Traffic, air quality, noise*: temporary construction impacts related to increased truck traffic on local streets, increased dust, and construction noise (similar to Impacts 4.8-1, 4.8-2, 4.8-3, 4.9-1, 4.9-2, 4.10-1 and 4.10-2, which could be mitigated through standard construction measures, compliance with air quality regulations, and traffic, dust and noise control measures similar to Measures 4.8-1a, 4.9-1a, 4.9-1b, 4.9-1c, 4.9-1c, 4.9-1d, 4.10-1a, 4.10-2a, and 4.10-2b)

- *Agricultural resources*: convert prime farmland to non-agricultural uses (similar to Impact 4.13-2, which could be mitigated through measures similar to Measure 4.13-2, avoidance with Prime Farmland); conflict with existing zoning for agricultural uses

As indicated above, standard mitigation approaches are available, and implementation of those measures as well as any applicable water quality or biological resource permit conditions could reduce these impacts to less than significant.

6.5.2 Measures that Involve Sensitive Habitats or Cultural Resources

Depending on the actual design of the measure, the following PEIR mitigation measures could be in this category: Measure 5.3.6-4b (Fishery Habitat Enhancement Projects); Measure 5.3.7-6 (Lower Tuolumne River Riparian Habitat Enhancement); Measure 5.4.5-3a (Minimum Flows for Resident Trout on Alameda Creek, which would requiring modifying the Alameda Creek Diversion Dam to allow bypass flows); Measure 5.4.5-3b (Alameda Diversion Dam Diversion Restrictions or Fish Screens, but only the fish passage barrier or screening option); and

Measure 5.5.5-1 (Create New Spawning Habitat Above Crystal Springs Reservoir). In general, the types of potential impacts associated with measures that involve construction or operation in sensitive habitats include:

- *Biological resources*: convert existing habitat types to other types, although habitat compensation would be expected to result in long-term benefit to biological resources; result in short-term disruption to existing biological resources during construction (similar to Impacts 4.6-1 and 4.6-2, which could be mitigated through habitat protection/restoration measures similar to Measures 4.6-1a, 4.6-1b, and 4.6-2, including construction timing restrictions to avoid impacts on sensitive species)

- *Cultural resources*: alteration of existing structures with potential historic significance such as the Alameda Creek Diversion Dam (similar to Impact 4.7-4 which could be mitigated through historic protection and documentation measures similar to Measures 4.7-4a, 4.7-4b, 4.7-4c, 4.7-4d, and 4.7-4e) or the accidental discovery of cultural resources (similar to Impacts 4.7-1 and 4.7-2, which could be mitigated through paleontological and archaeological measures similar to Measures 4.7-1, 4.7-2a, and 4.7-2b)

- *Geology*: change the topography or physical features of a site (which could be mitigated through standard engineering and design measures to avoid substantial changes to unique geologic or physical features)

- *Water quality and hydrology*: alter drainage patterns due to changes in grading and vegetation; result in erosion and sedimentation during construction; place structures within a 100-year flood hazard area (similar to Impacts 4.5-1 and 4.5-6, which could be mitigated through standard construction measures for erosion and sedimentation control and implementation of water quality and flood protection measures required under applicable permit conditions)

- *Traffic, air quality, noise*: temporary construction impacts related to increased truck traffic on local streets, increased dust, and construction noise (similar to Impacts 4.8-1, 4.8-2, 4.8-3, 4.9-1, 4.9-2, 4.10-1 and 4.10-2, which could be mitigated through standard construction measures, compliance with air quality regulations, and traffic, dust and noise control measures similar to Measures 4.8-1a, 4.9-1a, 4.9-1b, 4.9-1c, 4.9-1c, 4.9-1d, 4.10-1a, 4.10-2a, and 4.10-2b)

As indicated above, standard mitigation approaches are available, and implementation of those measures as well as any applicable water quality or biological resource permit conditions could reduce these impacts to less than significant.

6.5.3 Measures that Affect SFPUC Supply Sources

The following PEIR mitigation measures would be in this category: Measure 5.4.5-3a (Minimum Flows for Resident Trout on Alameda Creek); Measure 5.4.6-3 (Operational Procedures for Calaveras Dam Releases); Measure 5.5.3-2 (Revised Operations Plan for Pilarcitos Watershed Facilities); Measure 5.6-1 (Groundwater Monitoring to Determine Basin Safe Yield); and Measure 5.6-2 (Implementation of Lake Level Management Plan). These measures could have the effect of reducing available local water supply sources needed to meet customer demands and to achieve WSIP goals, objectives, and levels of service. Measures 5.4.5-3a and 5.4.6-3 could reduce storage in Calaveras Reservoir; Measure 5.5.3-2 would limit use of Pilarcitos watershed supplies to current levels and, in turn, may require additional supply from other regional system sources; and Measure 5.6-1 could result in reduced levels of groundwater pumping from the North Westside Groundwater Basin. Depending on the magnitude of these measures, the SFPUC may need to increase use of other water supply sources in order to serve the 300 mgd average annual customer purchase requests in 2030 and to meet the water supply level of service performance objectives of the WSIP.

One possibility could be increased use of water supplies from Hetch Hetchy Reservoir, resulting in potential impacts on the Tuolumne River similar to those discussed in Chapter 5 and Chapter 8 (under Variant 1, All Tuolumne). Other possible alternative water sources and their potential impacts are discussed in Chapters 8 and 9. These include potable water from desalination, increased levels of conservation and water recycling, or other water sources. However, at this time, the timing as well as the magnitude of the potential effects of these measures are unknown, and the actual impact on other SFPUC supply sources could be less than significant if the change is within the typical inter-annual variation of SFPUC customer water deliveries. Other intervening factors, such as results of groundwater monitoring under Measure 5.6-1 or the planned Habitat Conservation Plan for fish in Alameda Creek, could reduce the estimated severity of the potential impacts and obviate or override the need for these measures.

6.5.4 Measures that Affect Other Water Sources

The following PEIR mitigation measure would be in this category: Measure 5.3.6-4a (Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water). At this time, it is unknown what sources of water or water users could be affected by a water transfer arrangement with TID, MID, or other agency or agencies that involves use only of conserved water. Supplemental water could be made available as a result of:

- Water use efficiency and conservation for agricultural, residential and commercial users
- Land use changes, either agricultural to urban, or more water intensive (e.g., pasture) to less intensive (e.g., orchard)
- Conjunctive use of groundwater
- Recycled water
- Tiered water pricing
- Land fallowing of agricultural lands.

In general, the types of potential environmental impacts associated with water transfers from these types of sources include:

- *Land use*: reduced agricultural activity (similar or related to Impact 4.3-2 which could be mitigated through siting measures similar to Measure 4.3-2)
- *Biological resources*: indirect effects on aquatic and/or terrestrial biological resources due to possible reductions in irrigation/drainage system return flows, reductions in discharges

of treated wastewater, changes in land use from more water intensive uses to less water intensive uses, or lowered groundwater tables (similar to Impacts 4.6-1, 4.6-2, 4.6-3, and 4.6-4 which could be mitigated through habitat protection/restoration measures similar to Measures 4.6-1a, 4.6-1b, 4.6-2, 4.6-3a, 4.6-3b, and 4.6-4)

- *Water quality and hydrology*: reduced groundwater recharge due to agricultural water conservation practices such as lining irrigation canals or conversion to drip irrigation, or land use changes (similar to Impact 4.5-2 which could be mitigated through groundwater protection measures similar to Measure 4.5-2)
- *Agricultural resources*: reduced agricultural activity due to farming; potential conversion of idle agricultural land to other uses (similar to Impact 4.13-2, which could be mitigated through measures similar to Measure 4.13-2, avoidance of Prime Farmland)
- *Noise*: increased noise from use of pumps for conjunctive-use groundwater program (similar to Impact 4.10-4, which could be mitigated through standard construction measures for noise controls)
- *Energy*: increased use of energy for conjunctive-use groundwater or recycled water programs (similar to Impact 4.15-2 for the Groundwater Projects, SF-2) and Recycled Water Projects, SF-3, which could be mitigated through energy efficiency measures similar to Measure 4.15-2)
- *Air Quality*: increased particulate emissions from on-farm efficiency measures like land leveling (which could be mitigated through standard dust control measures similar to those listed in Measure 4.9-1a)

As indicated above, standard mitigation approaches are available, and implementation of those measures as well as any applicable water quality or biological resource permit conditions could reduce these impacts to less than significant.

6.6 Summary Tables of All Impacts and Mitigation Measures

TABLE 6.3
IMPACT AND MITIGATION SUMMARY FOR FACILITY CONSTRUCTION AND OPERATION OF SAN JOAQUIN REGION PROJECTS (SJ-1 through SJ-5)

IMPACT	Advanced Disinfection SJ-1	Lawrence Livermore Supply Improvements SJ-2	San Joaquin Pipeline System SJ-3	Rehabilitation of Existing San Joaquin Pipelines SJ-4	Tesla Portal Disinfection Station SJ-5
4.3 Land Use and Visual Quality					
Impact 4.3-1: Temporary disruption or displacement of existing land uses during construction	LS	LS	PSM	PSM	LS
Regulations					
None applicable.					
SFPUC Construction Measures					
No. 1: Neighborhood Notice	N/A	N/A	X	X	N/A
No. 3: On-Site Air and Water Quality Measures during Construction	N/A	N/A	X	X	N/A
No. 5: Traffic	N/A	N/A	X	X	N/A
No. 6: Noise	N/A	N/A	X	X	N/A
No. 10: Project Site	N/A	N/A	X	X	N/A
PEIR Mitigation Measures					
Traffic, Transportation, and Circulation Measures (4.8-1a and 4.8-1b); Air Quality Measures (4.9-1a thru 4.9-1d, 4.9-2a and 4.9-2b); Noise Measures (4.10-1a, 4.10-1b, 4.10-2a thru 4.10-2c, 4.10-3a thru 4.10-3c); and Recreational Resources Measure (4.12-1)	N/A	N/A	X	X	N/A
Impact 4.3-2: Permanent displacement or long-term disruption of existing land uses	LS	N/A	PSU	N/A	LS
Regulations					
None applicable.					
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
4.3-2: Facility Siting Studies	N/A	N/A	X	N/A	N/A
Impact 4.3-3: Temporary construction impacts on scenic vistas or visual character	LS	LS	LS	LS	LS
Regulations					
None applicable.					
SFPUC Construction Measures					
No. 10: Project Site	X	X	X	X	X
PEIR Mitigation Measures					
None required.					

TABLE 6.3 (continued)
IMPACT AND MITIGATION SUMMARY FOR FACILITY CONSTRUCTION AND OPERATION OF SAN JOAQUIN REGION PROJECTS (SJ-1 through SJ-5)

IMPACT	Advanced Disinfection SJ-1	Lawrence Livermore Supply Improvements SJ-2	San Joaquin Pipeline System SJ-3	Rehabilitation of Existing San Joaquin Pipelines SJ-4	Tesla Portal Disinfection Station SJ-5
Impact 4.3-4: Permanent adverse impacts on scenic vistas or visual character	PSM	LS	LS	N/A	PSM
Regulations					
None applicable.					
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
4.3-4a: Architectural Design	X	N/A	N/A	N/A	X
4.3-4b: Landscaping Plans	X	N/A	N/A	N/A	X
4.3-4c: Landscape Screens	X	N/A	N/A	N/A	X
4.3-4d: Minimize Tree Removal	X	N/A	N/A	N/A	X
Impact 4.3-5: New permanent sources of light glare	PSM	PSM	PSM	PSM	PSM
Regulations					
None applicable.					
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
4.3-5: Reduce Lighting Effects	X	X	X	X	X
4.4 Geology, Soils, and Seismicity					
Impact 4.4-1: Slope instability during construction	LS	PSM	N/A	N/A	LS
Regulations					
None applicable.					
SFPUC Construction Measures					
No. 2: Seismic and Geotechnical Studies	X	X	N/A	N/A	X
PEIR Mitigation Measures					
4.4-1: Quantified Landslide Analysis	N/A	X	N/A	N/A	N/A
Impact 4.4-2: Erosion during construction	LS	LS	LS	LS	LS
Regulations					
NPDES stormwater requirements	X	X	X	X	X
SFPUC Construction Measures					
No. 3: On-Site Air and Water Quality Measures during Construction	X	X	X	X	X

TABLE 6.3 (continued)
IMPACT AND MITIGATION SUMMARY FOR FACILITY CONSTRUCTION AND OPERATION OF SAN JOAQUIN REGION PROJECTS (SJ-1 through SJ-5)

IMPACT	Advanced Disinfection SJ-1	Lawrence Livermore Supply Improvements SJ-2	San Joaquin Pipeline System SJ-3	Rehabilitation of Existing San Joaquin Pipelines SJ-4	Tesla Portal Disinfection Station SJ-5
PEIR Mitigation Measures					
None required.					
Impact 4.4-3: Substantial alteration of topography	LS	LS	LS	LS	LS
Regulations					
None applicable.					
SFPUC Construction Measures					
No. 10: Project Site	X	X	X	X	X
PEIR Mitigation Measures					
None required.					
Impact 4.4-4: Squeezing ground and subsidence during tunneling	N/A	N/A	N/A	N/A	N/A
Regulations					
None applicable.					
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
4.4-4: Subsidence Monitoring Program	N/A	N/A	N/A	N/A	N/A
Impact 4.4-5: Surface fault rupture	LS	LS	LS	LS	LS
Regulations					
SFPUC General Seismic Design Requirements	X	X	X	X	X
SFPUC Construction Measures					
No. 2: Seismic and Geotechnical Studies	X	X	X	X	X
PEIR Mitigation Measures					
None required					
Impact 4.4-6: Seismically induced groundshaking	LS	LS	LS	LS	LS
Regulations					
SFPUC General Seismic Design Requirements	X	X	X	X	X
SFPUC Construction Measures					
No. 2: Seismic and Geotechnical Studies	X	X	X	X	X
PEIR Mitigation Measures					
None required.					

TABLE 6.3 (continued)
IMPACT AND MITIGATION SUMMARY FOR FACILITY CONSTRUCTION AND OPERATION OF SAN JOAQUIN REGION PROJECTS (SJ-1 through SJ-5)

IMPACT	Advanced Disinfection SJ-1	Lawrence Livermore Supply Improvements SJ-2	San Joaquin Pipeline System SJ-3	Rehabilitation of Existing San Joaquin Pipelines SJ-4	Tesla Portal Disinfection Station SJ-5
Impact 4.4-7: Seismically induced ground failure, including liquefaction and settlement	LS	LS	LS	LS	LS
Regulations					
SFPUC General Seismic Design Requirements	X	X	X	X	X
SFPUC Construction Measures					
No. 2: Seismic and Geotechnical Studies	X	X	X	X	X
PEIR Mitigation Measures					
None required.					
Impact 4.4-8: Seismically induced landslides or other slope failures	LS	LS	N/A	N/A	LS
Regulations					
SFPUC General Seismic Design Requirements	X	X	N/A	N/A	X
SFPUC Construction Measures					
No. 2: Seismic and Geotechnical Studies	X	X	N/A	N/A	X
PEIR Mitigation Measures					
None required.					
Impact 4.4-9: Expansive or corrosive soils	PSM	PSM	PSM	PSM	PSM
Regulations					
California Building Code	X	X	X	X	X
SFPUC Construction Measures					
No. 2: Seismic and Geotechnical Studies	X	X	X	X	X
PEIR Mitigation Measures					
4.4-9: Characterize Extent of Expansive and Corrosive Soil	X	X	X	X	X
4.5 Surface Water Hydrology and Water Quality					
Impact 4.5-1: Degradation of water bodies as a result of erosion and sedimentation or a hazardous materials release during construction	LS	LS	LS	LS	LS
Regulations					
NPDES stormwater requirements	X	X	X	X	X
Encroachment permitting requirements	N/A	N/A	X	N/A	N/A
SFPUC Construction Measures					
No. 3: On-Site Air and Water Quality Measures During Construction	X	X	X	X	X

TABLE 6.3 (continued)
IMPACT AND MITIGATION SUMMARY FOR FACILITY CONSTRUCTION AND OPERATION OF SAN JOAQUIN REGION PROJECTS (SJ-1 through SJ-5)

IMPACT	Advanced Disinfection SJ-1	Lawrence Livermore Supply Improvements SJ-2	San Joaquin Pipeline System SJ-3	Rehabilitation of Existing San Joaquin Pipelines SJ-4	Tesla Portal Disinfection Station SJ-5
PEIR Mitigation Measures					
None required.					
Impact 4.5-2: Depletion of groundwater resources	LS	N/A	LS	LS	LS
Regulations					
None applicable.					
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
4.5-2: Site-Specific Groundwater Analysis and Identified Measures	N/A	N/A	N/A	N/A	N/A
Impact 4.5-3a: Degradation of water quality due to construction dewatering discharges	LS	N/A	LS	LS	LS
Regulations					
NPDES discharge requirements	X	N/A	X	X	X
Waste Discharge Requirements	X	N/A	X	X	X
SFPUC Construction Measures					
No. 4: Groundwater	X	N/A	X	X	X
PEIR Mitigation Measures					
None required.					
Impact 4.5-3b: Degradation of water quality due to construction-related discharges of treated water	LS	LS	LS	LS	LS
Regulations					
NPDES discharge requirements	X	X	X	X	X
Waste Discharge Requirements	X	X	X	X	X
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
None required.					
Impact 4.5-4: Flooding and water quality impacts associated with impeding or redirecting flood flows	N/A	N/A	PSM	PSM	N/A
Regulations					
None applicable.					

TABLE 6.3 (continued)
IMPACT AND MITIGATION SUMMARY FOR FACILITY CONSTRUCTION AND OPERATION OF SAN JOAQUIN REGION PROJECTS (SJ-1 through SJ-5)

IMPACT	Advanced Disinfection SJ-1	Lawrence Livermore Supply Improvements SJ-2	San Joaquin Pipeline System SJ-3	Rehabilitation of Existing San Joaquin Pipelines SJ-4	Tesla Portal Disinfection Station SJ-5
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
4.5-4a: Flood Flow Protection Measures	N/A	N/A	X	X	N/A
4.5-4b: Site-Specific Flooding Analysis and Identified Measures	N/A	N/A	N/A	N/A	N/A
Impact 4.5-5: Degradation of water quality and increased flows due to discharges to surface water during operation	N/A	N/A	LS	N/A	N/A
Regulations					
NDPES discharge requirements	N/A	N/A	X	N/A	N/A
Waste Discharge Requirements	N/A	N/A	X	N/A	N/A
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
4.5-5: Stormwater Treatment and Groundwater Monitoring	N/A	N/A	N/A	N/A	N/A
Impact 4.5-6: Degradation of water quality as a result of alteration of drainage patterns or an increase in impervious surfaces	LS	PSM	LS	LS	LS
Regulations					
NPDES stormwater requirements	X	X	X	X	X
SFPUC Construction Measures					
No. 10: Project Site	X	X	X	X	X
PEIR Mitigation Measures					
4.5-6: Appropriate Source Controls and Site Design Measures	N/A	X	N/A	N/A	N/A
4.6 Biological Resources					
Impact 4.6-1: Impacts on wetlands and aquatic resources	PSM	PSM	PSM	PSM	PSM
Regulations					
Clean Water Act - Section 404	X	X	X	X	X
SFPUC Construction Measures					
No. 8: Biological Resources	X	X	X	X	X
PEIR Mitigation Measures					
4.6-1a: Wetlands Assessment	X	X	X	X	X
4.6-1b: Compensation for Wetlands and Other Biological Resources	X	X	X	X	X

TABLE 6.3 (continued)
IMPACT AND MITIGATION SUMMARY FOR FACILITY CONSTRUCTION AND OPERATION OF SAN JOAQUIN REGION PROJECTS (SJ-1 through SJ-5)

IMPACT	Advanced Disinfection SJ-1	Lawrence Livermore Supply Improvements SJ-2	San Joaquin Pipeline System SJ-3	Rehabilitation of Existing San Joaquin Pipelines SJ-4	Tesla Portal Disinfection Station SJ-5
Impact 4.6-2: Impact to sensitive habitats, common habitats, and heritage trees	PSM	PSM	PSM	PSM	PSM
Regulations					
None applicable.					
SFPUC Construction Measures					
No. 8: Biological Resources	X	X	X	X	X
PEIR Mitigation Measures					
4.6-2: Habitat Restoration/Tree Replacement	X	X	X	X	X
Biological Resources Measure 4.6-1b	X	X	X	X	X
Impact 4.6-3: Impact on key special-status species – direct mortality and/or habitat effects	PSM	PSM	PSM	PSM	PSM
Regulations					
Federal Endangered Species Act	X	X	X	X	X
California Endangered Species Act	X	X	X	X	X
California Native Plant Protection Act	X	X	X	X	X
SFPUC Construction Measures					
No. 8: Biological Resources	X	X	X	X	X
PEIR Mitigation Measures					
4.6-3a: Protection Measures During Construction for Key Special-Status Species and Other Species of Concern	X	X	X	X	X
4.6-3b: Standard Mitigation Measures for Key Special Status Plants and Animals	X	X	X	X	X
Biological Resources Measure 4.6-1b	X	X	X	X	X
Impact 4.6-4: Water discharge effects on riparian and/or aquatic resources	LS	LS	PSM	PSM	LS
Regulations					
Waste Discharge Requirements	X	X	X	X	X
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
4.6-4 Pipeline and Water Treatment Plant Treated Water Discharge Restrictions	N/A	N/A	X	X	N/A

TABLE 6.3 (continued)
IMPACT AND MITIGATION SUMMARY FOR FACILITY CONSTRUCTION AND OPERATION OF SAN JOAQUIN REGION PROJECTS (SJ-1 through SJ-5)

IMPACT	Advanced Disinfection SJ-1	Lawrence Livermore Supply Improvements SJ-2	San Joaquin Pipeline System SJ-3	Rehabilitation of Existing San Joaquin Pipelines SJ-4	Tesla Portal Disinfection Station SJ-5
Impact 4.6-5: Conflict with adopted conservation plans or other approved biological resources plans	N/A	N/A	PSM	PSM	N/A
Regulations					
None applicable.					
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
Biological Resources Measures 4.6-1a, 4.6-1b, 4.6-2, 4.6-3a, and 4.6-3b	N/A	N/A	X	X	N/A
4.7 Cultural Resources					
Impact 4.7-1: Impacts on paleontological resources	PSM	LS	PSM	PSM	PSM
Regulations					
Paleontological Resources Preservation Act	X	X	X	X	X
SFPUC Construction Measures					
No. 9: Cultural Resources	X	X	X	X	X
PEIR Mitigation Measures					
4.7-1: Suspend Construction Work if Paleontological Resource is Identified	X	N/A	X	X	X
Impact 4.7-2: Impacts on archaeological resources	PSM	PSM	PSM	PSM	PSM
Regulations					
California Health and Safety Code	X	X	X	X	X
SFPUC Construction Measures					
No. 9: Cultural Resources	X	X	X	X	X
PEIR Mitigation Measures					
4.7-2a: Archaeological Testing, Monitoring, and Treatment of Human Remains	X	X	X	X	X
4.7-2b: Accidental Discovery Measures	X	X	X	X	X
Impact 4.7-3: Impacts on historical significance of a historic district or a contributor to a historic district	PSM	N/A	PSM	PSM	N/A
Regulations					
National Historic Preservation Act	X	N/A	X	X	N/A
SFPUC Construction Measures					
None applicable.					

TABLE 6.3 (continued)
IMPACT AND MITIGATION SUMMARY FOR FACILITY CONSTRUCTION AND OPERATION OF SAN JOAQUIN REGION PROJECTS (SJ-1 through SJ-5)

IMPACT	Advanced Disinfection SJ-1	Lawrence Livermore Supply Improvements SJ-2	San Joaquin Pipeline System SJ-3	Rehabilitation of Existing San Joaquin Pipelines SJ-4	Tesla Portal Disinfection Station SJ-5
PEIR Mitigation Measures					
4.7-3: Protection of Historic Districts	X	N/A	X	X	N/A
Cultural Resources Measures 4.7-4a thru 4.7-4f	X	N/A	X	X	N/A
Impact 4.7-4: Impacts on the historical significance of individual facilities resulting from demolition or alteration	PSM	N/A	PSM	PSM	N/A
Regulations					
National Historic Preservation Act	X	N/A	X	X	N/A
SFPUC Construction Measures					
No. 9: Cultural Resources	X	N/A	X	X	N/A
PEIR Mitigation Measures					
4.7-4a: Alternatives Identification and Resource Relocation	X	N/A	X	X	N/A
4.7-4b: Historical Resources Documentation	X	N/A	X	X	N/A
4.7-4c: Secretary of the Interior's Standards for Treatment of Historic Properties	X	N/A	X	X	N/A
4.7-4d: Historic Resources Survey and Redesign	X	N/A	X	X	N/A
4.7-4e: Historic Resources Protection Plan	X	N/A	X	X	N/A
4.7-4f: Pre-construction Surveys and Vibration Monitoring	X	N/A	X	X	N/A
Impact 4.7-5: Impacts on adjacent historic architectural resources	LS	LS	PSM	PSM	PSM
Regulations					
National Historic Preservation Act	X	X	X	X	X
SFPUC Construction Measures					
No. 9: Cultural Resources	X	X	X	X	X
PEIR Mitigation Measures					
Cultural Resources Measures 4.7-4a thru 4.7-4f	N/A	N/A	X	X	X
4.8 Traffic, Transportation, and Circulation					
Impact 4.8-1: Temporary reduction in roadway capacity and increased traffic delays	LS	LS	PSM	PSM	LS
Regulations					
City and county encroachment permits.	X	X	X	X	X
SFPUC Construction Measures					
No. 5: Traffic	X	X	X	X	X
PEIR Mitigation Measures					

TABLE 6.3 (continued)
IMPACT AND MITIGATION SUMMARY FOR FACILITY CONSTRUCTION AND OPERATION OF SAN JOAQUIN REGION PROJECTS (SJ-1 through SJ-5)

IMPACT	Advanced Disinfection SJ-1	Lawrence Livermore Supply Improvements SJ-2	San Joaquin Pipeline System SJ-3	Rehabilitation of Existing San Joaquin Pipelines SJ-4	Tesla Portal Disinfection Station SJ-5
4.8-1a: Traffic Control Plan Measures	N/A	N/A	X	X	N/A
4.8-1b: Coordination of Individual Traffic Control Plans	N/A	N/A	N/A	N/A	N/A
Impact 4.8-2: Short-term traffic increases on roadways	PSM	PSM	PSM	PSM	PSM
Regulations					
City and county encroachment permits.	X	X	X	X	X
SFPUC Construction Measures					
No. 5: Traffic	X	X	X	X	X
PEIR Mitigation Measures					
Traffic, Trasportation, and Circulation Measure 4.8-1a	X	X	X	X	X
Traffic, Transportation, and Circulation Measure 4.8-1b	N/A	N/A	X	X	N/A
Impact 4.8-3: Impaired access to adjacent roadways and land uses	LS	LS	PSM	PSM	LS
Regulations					
City and county encroachment permits.	X	X	X	X	X
SFPUC Construction Measures					
No. 5: Traffic	X	X	X	X	X
PEIR Mitigation Measures					
Traffic, Transportation, and Circulation Measure 4.8-1a	N/A	N/A	X	X	N/A
Impact 4.8-4: Temporary displacement of on-street parking	LS	LS	LS	PSM	LS
Regulations					
City and county encroachment permits.	X	X	X	X	X
SFPUC Construction Measures					
No. 5: Traffic	X	X	X	X	X
PEIR Mitigation Measures					
4.8-4: Accommodation of Displaced Public Parking Supply for Recreational Visitors	N/A	N/A	N/A	N/A	N/A
Traffic, Trasportation, and Circulation Measure 4.8-1a	N/A	N/A	N/A	X	N/A
Impact 4.8-5: Increased traffic safety hazards during construction	PSM	PSM	PSM	PSM	PSM
Regulations					
City and county encroachment permits.	X	X	X	X	X
SFPUC Construction Measures					
No. 5: Traffic	X	X	X	X	X

TABLE 6.3 (continued)
IMPACT AND MITIGATION SUMMARY FOR FACILITY CONSTRUCTION AND OPERATION OF SAN JOAQUIN REGION PROJECTS (SJ-1 through SJ-5)

IMPACT	Advanced Disinfection SJ-1	Lawrence Livermore Supply Improvements SJ-2	San Joaquin Pipeline System SJ-3	Rehabilitation of Existing San Joaquin Pipelines SJ-4	Tesla Portal Disinfection Station SJ-5
PEIR Mitigation Measures					
Traffic, Trasportation, and Circulation Measure 4.8-1a	X	X	X	X	X
Impact 4.8-6: Long-term traffic increases during facility operation	LS	LS	LS	LS	LS
Regulations					
None applicable.					
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
None required.					
4.9 Air Quality					
Impact 4.9-1: Construction emissions of criteria pollutants	PSM	PSM	PSM	PSM	PSM
Regulations					
None applicable.					
SFPUC Construction Measures					
No. 3: On-Site Air and Water Quality Measures during Construction	X	X	X	X	X
PEIR Mitigation Measures					
4.9-1a: SJVAPCD Dust Control Measures	X	X	X	X	X
4.9-1b: SJVAPCD Exhaust Control Measures	X	X	X	X	X
4.9-1c: BAAQMD Dust Control Measures	N/A	N/A	N/A	N/A	N/A
4.9-1d: BAAQMD Exhaust Control Measures	N/A	N/A	N/A	N/A	N/A
Impact 4.9-2: Exposure to diesel particulate matter during construction	LS	N/A	LS	LS	LS
Regulations					
California Health and Safety Code, Section 2485 – reduces emissions of toxic and criteria pollutants by limiting the idling of new heavy-duty diesel vehicles	X	N/A	X	X	X
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
4.9-2a: Health Risk Screening or Use of Soot Filters	N/A	N/A	N/A	N/A	N/A
4.9-2b: Vacate SFPUC Land Managers' Residences in Sunol Valley	N/A	N/A	N/A	N/A	N/A
Impact 4.9-3: Exposure to emissions (possibly including asbestos) from tunneling	N/A	N/A	PSM	PSM	N/A
Regulations					

TABLE 6.3 (continued)
IMPACT AND MITIGATION SUMMARY FOR FACILITY CONSTRUCTION AND OPERATION OF SAN JOAQUIN REGION PROJECTS (SJ-1 through SJ-5)

IMPACT	Advanced Disinfection SJ-1	Lawrence Livermore Supply Improvements SJ-2	San Joaquin Pipeline System SJ-3	Rehabilitation of Existing San Joaquin Pipelines SJ-4	Tesla Portal Disinfection Station SJ-5
OSHA standards for worker safety during tunneling	N/A	N/A	X	X	N/A
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
4.9-3: Tunnel gas odor control	N/A	N/A	X	X	N/A
Impact 4.9-4: Air pollutant emissions during project operation	LS	LS	LS	LS	LS
Regulations					
None applicable.					
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
None required.					
Impact 4.9-5: Odors generated during project operation	LS	LS	N/A	N/A	LS
Regulations					
None applicable.					
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
None required.					
Impact 4.9-6: Secondary emissions at power plants	LS	LS	LS	LS	LS
Regulations					
None applicable.					
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
None required.					
Impact 4.9-7: Conflict with implementation of applicable regional air quality plans addressing criteria air pollutants and state goals for reducing GHG emissions.	N/A	N/A	N/A	N/A	N/A
Regulations					
None applicable.					

TABLE 6.3 (continued)
IMPACT AND MITIGATION SUMMARY FOR FACILITY CONSTRUCTION AND OPERATION OF SAN JOAQUIN REGION PROJECTS (SJ-1 through SJ-5)

IMPACT	Advanced Disinfection SJ-1	Lawrence Livermore Supply Improvements SJ-2	San Joaquin Pipeline System SJ-3	Rehabilitation of Existing San Joaquin Pipelines SJ-4	Tesla Portal Disinfection Station SJ-5
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
None required.					
4.10 Noise and Vibration					
Impact 4.10-1: Disturbance from temporary construction-related noise increases	PSU	PSU	PSU	PSU	PSU
Regulations					
None applicable.					
SFPUC Construction Measures					
No. 6: Noise	X	N/A	X	X	X
PEIR Mitigation Measures					
4.10-1a: Noise Controls	X	N/A	X	X	X
4.10-1b: Vacate SFPUC Caretaker's Residence at Tesla Portal	X	N/A	N/A	N/A	X
Impact 4.10-2: Temporary noise disturbance along construction haul routes	PSU	N/A	PSU	PSU	PSU
Regulations					
None applicable.					
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
4.10-2a: Limit Hourly Truck Volumes	X	N/A	X	X	X
4.10-2b: Restrict Truck Operations	X	N/A	X	X	X
4.10-2c: Vacate SFPUC Land Manager's Residence	N/A	N/A	N/A	N/A	N/A
Impact 4.10-3: Disturbance due to construction-related vibration	LS	LS	PSU	PSU	LS
Regulations					
None applicable.					
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
4.10-3a: Vibration Controls to Prevent Cosmetic or Structural Damage	N/A	N/A	X	X	N/A

TABLE 6.3 (continued)
IMPACT AND MITIGATION SUMMARY FOR FACILITY CONSTRUCTION AND OPERATION OF SAN JOAQUIN REGION PROJECTS (SJ-1 through SJ-5)

IMPACT	Advanced Disinfection SJ-1	Lawrence Livermore Supply Improvements SJ-2	San Joaquin Pipeline System SJ-3	Rehabilitation of Existing San Joaquin Pipelines SJ-4	Tesla Portal Disinfection Station SJ-5
4.10-3b: Limit Vibration Levels at or Below Vibration Perception Threshold	N/A	N/A	X	X	N/A
4.10-3c: Limit Tunnel-Related Detonation to Daylight Hours	N/A	N/A	N/A	N/A	N/A
Impact 4.10-4: Disturbance due to long-term noise increases	LS	LS	LS	N/A	LS
Regulations					
None applicable.					
SFPUC Construction Measures					
No. 6: Noise	X	N/A	X	N/A	X
PEIR Mitigation Measures					
None required.					
4.11 Public Services and Utilities					
Impact 4.11-1: Potential temporary damage to or disruption of existing regional or local public utilities	LS	LS	PSM	LS	LS
Regulations					
OSHA Construction Safety Orders	X	X	X	X	X
DHS separation standards	X	X	X	X	X
SFPUC Construction Measures					
No. 1: Neighborhood Notice	X	X	X	X	X
PEIR Mitigation Measures					
4.11-1a: Notify Neighbors of Potential Utility Service Disruption	N/A	N/A	X	N/A	N/A
4.11-1b: Locate Utility Lines Prior to Excavation	N/A	N/A	X	N/A	N/A
4.11-1c: Confirmation of Utility Line Information	N/A	N/A	X	N/A	N/A
4.11-1d: Safeguard Employees from Potential Accidents Related to Underground Utilities	N/A	N/A	X	N/A	N/A
4.11-1e: Notify Local Fire Departments	N/A	N/A	X	N/A	N/A
4.11-1f: Emergency Response Plan	N/A	N/A	X	N/A	N/A
4.11-1g: Prompt Reconnection of Utilities	N/A	N/A	X	N/A	N/A
4.11-1h: Coordinate Final Construction Plans with Affected Utilities	N/A	N/A	X	N/A	N/A
Impact 4.11-2: Temporary adverse effects on solid waste landfill capacity	PSM	PSM	PSM	PSM	PSM
Regulations					
California Integrated Waste Management Act of 1989	X	X	X	X	X
SFPUC Construction Measures					
None applicable.					

TABLE 6.3 (continued)
IMPACT AND MITIGATION SUMMARY FOR FACILITY CONSTRUCTION AND OPERATION OF SAN JOAQUIN REGION PROJECTS (SJ-1 through SJ-5)

IMPACT	Advanced Disinfection SJ-1	Lawrence Livermore Supply Improvements SJ-2	San Joaquin Pipeline System SJ-3	Rehabilitation of Existing San Joaquin Pipelines SJ-4	Tesla Portal Disinfection Station SJ-5
PEIR Mitigation Measures					
4.11-2: Waste Reduction Measures	X	X	X	X	X
Impact 4.11-3: Impacts related to compliance with statutes and regulations related to solid waste	PSM	PSM	PSM	PSM	PSM
Regulations					
California Integrated Waste Management Act of 1989	X	X	X	X	X
SFPUC Construction Measures					
None applicable.	X	X	X	X	X
PEIR Mitigation Measures					
Public Services and Utilities Measure 4.11-2	X	X	X	X	X
Impact 4.11-4: Impacts related to the relocation of utilities	PSM	PSM	PSM	PSM	PSM
Regulations					
None applicable.					
SFPUC Construction Measures					
No. 1: Neighborhood Notice	X	X	X	X	X
PEIR Mitigation Measures					
Public Services and Utilities Measures 4.11-1a thru 4.11-1h	X	X	X	X	X
4.12 Recreational Resources					
Impact 4.12-1: Temporary conflicts with established recreational uses during construction	N/A	N/A	PSM	PSM	N/A
Regulations					
None applicable.					
SFPUC Construction Measures					
No. 1: Neighborhood Notice	N/A	N/A	X	X	N/A
No. 3: On-Site Air and Water Quality Measures during Construction	N/A	N/A	X	X	N/A
No. 5: Traffic	N/A	N/A	X	X	N/A
No. 6: Noise	N/A	N/A	X	X	N/A
No. 10: Project Site	N/A	N/A	X	X	N/A
PEIR Mitigation Measures					
4.12-1: Coordination with Golf Course/Recreational Facility Managers	N/A	N/A	X	X	N/A
Traffic, Transportation, and Circulation Measures (4.8-1a and 4.8-1b); Air Quality Measures (4.9-1a, 4.9-1b, 4.9-2a, 4.9-2b); and Noise Measures (4.10-1a, 4.10-1b, 4.10-2a thru 4.10-2c, and 4.10-3a thru 4.10-3b)	N/A	N/A	X	X	N/A

TABLE 6.3 (continued)
IMPACT AND MITIGATION SUMMARY FOR FACILITY CONSTRUCTION AND OPERATION OF SAN JOAQUIN REGION PROJECTS (SJ-1 through SJ-5)

IMPACT	Advanced Disinfection SJ-1	Lawrence Livermore Supply Improvements SJ-2	San Joaquin Pipeline System SJ-3	Rehabilitation of Existing San Joaquin Pipelines SJ-4	Tesla Portal Disinfection Station SJ-5
Impact 4.12-2: Conflicts with established recreational uses due to facility siting and project operation	N/A	N/A	N/A	N/A	N/A
Regulations					
None applicable.					
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
4.12-2: Appropriate Siting of Proposed Facilities	N/A	N/A	N/A	N/A	N/A
4.13 Agricultural Resources					
Impact 4.13-1: Temporary conflicts with established agricultural resources	N/A	N/A	PSM	PSM	N/A
Regulations					
None applicable.					
SFPUC Construction Measures					
No. 1: Neighborhood Notice	N/A	N/A	X	X	N/A
No. 3: On-Site Air and Water Quality Measures during Construction	N/A	N/A	X	X	N/A
No. 5: Traffic	N/A	N/A	X	X	N/A
No. 6: Noise	N/A	N/A	X	X	N/A
PEIR Mitigation Measures					
4.13-1a: Supplemental Noticing and Soil Stockpiling	N/A	N/A	X	X	N/A
4.13-1b: Avoidance or Soil Stockpiling	N/A	N/A	N/A	N/A	N/A
Traffic, Transportation, and Circulation Measures (4.8-1a and 4.8-1b); Air Quality Measures (4.9-1a thru 4.9-1d, and 4.9-2a and 4.9-2b); and Noise Measures (4.10-1a, 4.10-b, 4.10-2a thru 4.10-2c, and 4.10-3a thru 4.10-3c)	N/A	N/A	X	X	N/A
Impact 4.13-2: Conversion of farmlands to non-agricultural uses	N/A	N/A	PSM	N/A	N/A
Regulations					
California Land Conservation Act of 1965 (Williamson Act)	N/A	N/A	X	N/A	N/A
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
4.13-2: Siting Facilities to Avoid Prime Farmland	N/A	N/A	X	N/A	N/A

TABLE 6.3 (continued)
IMPACT AND MITIGATION SUMMARY FOR FACILITY CONSTRUCTION AND OPERATION OF SAN JOAQUIN REGION PROJECTS (SJ-1 through SJ-5)

IMPACT	Advanced Disinfection SJ-1	Lawrence Livermore Supply Improvements SJ-2	San Joaquin Pipeline System SJ-3	Rehabilitation of Existing San Joaquin Pipelines SJ-4	Tesla Portal Disinfection Station SJ-5
4.14 Hazards					
Impact 4.14-1: Potential to encounter hazardous materials in soil and groundwater	LS	LS	LS	PSM	LS
Regulations					
None applicable.					
SFPUC Construction Measures					
No. 4: Groundwater	X	N/A	X	X	X
No. 7: Hazardous Materials	X	X	X	X	X
PEIR Mitigation Measures					
4.14-1a: Site Health and Safety Plan	N/A	N/A	N/A	X	N/A
4.14-1b: Materials Disposal Plan	N/A	N/A	N/A	X	N/A
4.14-1c: Coordination with Property Owners and Regulatory Agencies	N/A	N/A	N/A	X	N/A
Impact 4.14-2: Exposure to naturally occurring asbestos	N/A	N/A	N/A	N/A	N/A
Regulations					
Asbestos Airborne Toxic Control Measure					
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
4.14-2: Health Risk Screening and Airborne Asbestos Monitoring Plan	N/A	N/A	N/A	N/A	N/A
Impact 4.14-3: Risk of fires during construction	LS	LS	LS	LS	LS
Regulations					
Public Resources Code fire safety regulations	X	X	X	X	X
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
None required.					
Impact 4.14-4: Gassy conditions in tunnels	N/A	N/A	LS	LS	N/A
Regulations					
Tunnel Safety Orders	N/A	N/A	X	X	N/A

TABLE 6.3 (continued)
IMPACT AND MITIGATION SUMMARY FOR FACILITY CONSTRUCTION AND OPERATION OF SAN JOAQUIN REGION PROJECTS (SJ-1 through SJ-5)

IMPACT	Advanced Disinfection SJ-1	Lawrence Livermore Supply Improvements SJ-2	San Joaquin Pipeline System SJ-3	Rehabilitation of Existing San Joaquin Pipelines SJ-4	Tesla Portal Disinfection Station SJ-5
SFPUC Construction Measures					
None applicable.					
PEIR Mitigation Measures					
None required.

TABLE 6.10
IMPACT AND MITIGATION SUMMARY FOR THE TUOLUMNE RIVER SYSTEM AND DOWNSTREAM WATER BODIES RELATED TO WATER SUPPLY AND SYSTEM OPERATIONS

IMPACT	Significance Determination	Mitigation Measure Required
5.3.1 Stream Flow and Reservoir Water Levels		
Impact 5.3.1-1: Effects on flow along the Tuolumne River below O'Shaughnessy Dam	LS	
PEIR Mitigation Measures		
None required.		
Impact 5.3.1-2: Effects on flow along Cherry Creek below Cherry Dam	LS	
PEIR Mitigation Measures		
None required.		
Impact 5.3.1-3: Effects on flow along Eleanor Creek below Eleanor Dam	LS	
PEIR Mitigation Measures		
None required.		
Impact 5.3.1-4: Effects on flow along the Tuolumne River below La Grange Dam	LS	
PEIR Mitigation Measures		
None required.		
Impact 5.3.1-5: Effects on flow along the San Joaquin River and the Sacramento-San Joaquin Delta	LS	
PEIR Mitigation Measures		
None required.		
5.3.2 Geomorphology		
Impact 5.3.2-1: Effects on sediment transport and channel characteristics between O'Shaughnessy Dam and Don Pedro Reservoir	LS	
PEIR Mitigation Measures		
None required.		
Impact 5.3.2-2: Effects on sediment transport and channel characteristics below La Grange Dam	LS	
PEIR Mitigation Measures		
None required.		
5.3.3 Surface Water Quality		
Impact 5.3.3-1: Effects on water quality in Hetch Hetchy Reservoir and along the Tuolumne River below O'Shaughnessy Dam	LS	
PEIR Mitigation Measures		
None required.		

TABLE 6.10 (continued)
IMPACT AND MITIGATION SUMMARY FOR THE TUOLUMNE RIVER SYSTEM AND DOWNSTREAM WATER BODIES RELATED TO WATER SUPPLY AND SYSTEM OPERATIONS

IMPACT	Significance Determination	Mitigation Measure Required
Impact 5.3.3-2: Effects on water quality in Don Pedro Reservoir and along the Tuolumne River below La Grange Dam	LS	
PEIR Mitigation Measures		
None required.		
Impact 5.3.3-3: Effects on water quality along the San Joaquin River and the Sacramento-San Joaquin Delta	LS	
PEIR Mitigation Measures		
None required.		
5.3.4 Surface Water Supplies		
Impact 5.3.4-1: Effects on Tuolumne River, San Joaquin River, and Stanislaus River water users	LS	
PEIR Mitigation Measures		
None required.		
Impact 5.3.4-2: Effects on Delta water users	LS	
PEIR Mitigation Measures		
None required.		
5.3.5 Groundwater		
Impact 5.3.5-1: Alteration of stream flows along the Tuolumne River, which could affect local groundwater recharge and groundwater levels	LS	
PEIR Mitigation Measures		
None required.		
Impact 5.3.5-2: Alteration of stream flows along the Tuolumne River, which could affect local groundwater quality	LS	
PEIR Mitigation Measures		
None required.		
5.3.6 Fisheries		
Impact 5.3.6-1: Effects on fishery resources in Hetch Hetchy Reservoir	LS	
PEIR Mitigation Measures		
None required.		
Impact 5.3.6-2: Effects on fishery resources along the Tuolumne River between Hetch Hetchy Reservoir and Don Pedro Reservoir	LS	
PEIR Mitigation Measures		
None required.		

TABLE 6.10 (continued)
IMPACT AND MITIGATION SUMMARY FOR THE TUOLUMNE RIVER SYSTEM AND DOWNSTREAM WATER BODIES RELATED TO WATER SUPPLY AND SYSTEM OPERATIONS

IMPACT	Significance Determination	Mitigation Measure Required
Impact 5.3.6-3: Effects on fishery resources in Don Pedro Reservoir	LS	
PEIR Mitigation Measures		
None required.		
Impact 5.3.6-4: Effects on fishery resources along the Tuolumne River below La Grange Dam	PSM	5.3.6-4a or 5.3.6-4b
PEIR Mitigation Measures		
5.3.6-4a: Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water		X
5.3.6-4b: Fishery Habitat Enhancement		X
Impact 5.3.6-5: Effects on fishery resources along the San Joaquin River	LS	
PEIR Mitigation Measures		
None required.		
5.3.7 Terrestrial Biological Resources		
Impact 5.3.7-1: Impacts on riparian habitat and related biological resources in Hetch Hetchy Reservoir and along the bedrock channel portions of the Tuolumne River from O'Shaughnessy Dam to Don Pedro Reservoir		
Sensitive Habitats	LS	
Key Special-status Species	LS	
Other Species of Concern	LS	
Common Habitats and Species	LS	
PEIR Mitigation Measures		
None required.		
Impact 5.3.7-2: Impacts on alluvial features that support meadow and riparian habitat along the Tuolumne River from O'Shaughnessy Dam to Don Pedro Reservoir		
Sensitive Habitats	PSM	5.3.7-2
Key Special-status Species	PSM	5.3.7-2
Other Species of Concern	PSM	5.3.7-2
Common Habitats and Species	PSM	5.3.7-2
PEIR Mitigation Measures		
5.3.7-2: Controlled Releases to Recharge Groundwater in Streamside Meadows and Other Alluvial Deposits		X
Impact 5.3.7-3: Impacts on biological resources in Lake Eleanor and along Eleanor Creek		
Sensitive Habitats	LS	
Key Special-status Species	LS	
Other Species of Concern	LS

7 Growth-Inducement Potential and Indirect Effects of Growth

CHAPTER 7

Growth-Inducement Potential and Indirect Effects of Growth

7.1 Overview and Summary

7.1.1 Approach to Analysis and Chapter Organization

This chapter analyzes the growth inducement potential and associated secondary effects of growth impacts of the San Francisco Public Utilities Commission's (SFPUC's) Water System Improvement Program (WSIP), as required by the California Environmental Quality Act (CEQA). CEQA requirements, other laws and regulations pertinent to land use and water supply planning, and how the project's growth inducing impacts were assessed, are discussed below.

CEQA Requirements

CEQA requires that an environmental impact report (EIR) evaluate the growth-inducing impacts of a proposed project[1]. A growth-inducing impact is defined as follows:

> [T]he ways in which the proposed project could foster economic or population growth, or the construction of additional housing, either directly or indirectly, in the surrounding environment. Included in this are projects which would remove obstacles to population growth…. It must not be assumed that growth in any area is necessarily beneficial, detrimental, or of little significance to the environment.

Regulatory Context for Water Supply and Land Use Planning

The SFPUC does not have authority to make land use decisions in its service area. It cannot approve or deny development proposals; that is the responsibility of the cities and counties to which the SFPUC provides water. However, the SFPUC and its wholesale customers are required, through laws and agreements, to provide water service. Numerous laws are intended to ensure that water supply planning like the WSIP and land use planning (such as the approval of, or establishment of constraints to, development) proceed in an orderly fashion. The laws and agencies described below provide the regulatory and planning context for coordination among water agencies and cities and counties, and yield key documents (e.g., general plans and regional projections) used in this analysis.

- *General Plan Requirements*. Pursuant to state law[2], each city and county is required to adopt a comprehensive, long-term general plan for the physical development of the jurisdiction. The general plan is a statement of development policies and is required to include land use, circulation, housing, conservation, open space, noise, and safety elements. The land use element designates the proposed general distribution, location, and extent of land uses and includes a statement of the standards of population density and building intensity recommended for lands covered by the plan. The city or county is required to prepare the water section of the conservation element in coordination with any countywide water agency and with all districts and/or city agencies that develop, serve, control, or conserve water for that jurisdiction. The water section must include discussion and evaluation of water supply and demand information contained in any applicable urban water management plan that has been submitted to the city or county by a water agency.

- *Urban Water Management Planning Act*. Every urban water supplier is required to prepare an urban water management plan (UWMP) for the purpose of "actively pursu[ing] the efficient use of available supply."[3] In preparing the UWMP, the water supplier is required to coordinate with other appropriate agencies, including other water suppliers that share a common source, water management agencies, and relevant public agencies. When a city or county proposes to adopt or substantially amend a general plan, the water agency is required to provide the planning agency with the current version of the adopted UWMP, the current version of the water agency's capital improvement program or plan, and other information about the system's sources of water supply. The Urban Water Management Planning Act requires urban water suppliers, as part of their long-range planning activities,

1 CEQA Guidelines Section 15126.2(d).
2 California Government Code, Section 65300 *et seq*.
3 California Water Code, Section 10610.2 *et seq.*

to make every effort to ensure the appropriate level of reliability in their water service sufficient to meet the needs of their various categories of customers during normal, dry, and multiple dry water years.

- *Senate Bills 610 and 221*. In 2001, the California legislature adopted two bills pertaining to coordination between land use and water supply planning and decision making:

  - *Senate Bill (SB) 610*. Pursuant to SB 610[4], CEQA review for most large projects[5] is required to include a water supply assessment. The water supply assessments must address whether existing water supplies will suffice to serve the proposed project and other planned development over a 20-year period in average, dry, and multiple-dry year conditions, and must set forth a plan for finding additional supplies necessary to serve the proposed project. Cities and counties can approve projects notwithstanding identified water supply shortfalls provided that they address such shortfalls in their findings.

  - *SB 221*. Pursuant to SB 221[6], land use agencies must require, at the time the subdivision map is considered for approval, that an applicant for a large subdivision[7] demonstrate that sufficient water supply is available to support the development. Proof of available supply must be based on written verification from the applicable public water system and must be supported by substantial evidence (which may include the public water system's UWMP). Water supply verification should require a showing of "real" water as a condition of final subdivision map approval.

The Association of Bay Area Governments

A key regional agency involved in forecasting growth in the SFPUC service area is the Association of Bay Area Governments (ABAG). An advisory organization, ABAG is the official regional planning agency of the San Francisco Bay Region; its mission is to strengthen cooperation and coordination among local governments. Since its inception (1961), ABAG has examined regional issues such as housing, transportation, economic development, and the environment. ABAG members include the nine Bay-Area counties and 99 of 101 cities within the Bay Area, and represent nearly all of the Bay Area's population. ABAG's biennial *Projections* series provides long-term population and economic forecasts through a series of computer models. ABAG's model results are relied on by transportation and air quality agencies, water agencies, local governments, and others. ABAG forecasts are cited by many jurisdictions in their general plans, and were selected by many SFPUC water customers to forecast future water demand.

---

4 Codified at California Water Code Sections 10631, 10656, 10910, 10911, 10912, and 10915.

5 Large projects include residential developments with more than 500 units; retail uses with more than 500,000 square feet of floor space; office buildings with more than 250,000 square feet of floor space; hotels or motels with more than 500 rooms; industrial uses occupying more than 40 acres or having more than 650,000 square feet of floor area; and mixed-use projects that include any use or combination as large as the above uses.

6 Codified at California Business and Professional Code Section 65867.5 and Government Code Sections 66455.3 and 66473.7.

7 A large subdivision is defined as more than 500 dwelling units.

Approach to Analysis and Chapter Organization

On the basis of the CEQA definition of growth stated above, assessing the growth-inducement potential of the WSIP involves answering the question: *Would construction and/or operation of planned improvements proposed as part of the WSIP directly or indirectly support economic or population growth or residential construction?*

By removing the lack of a reliable water supply and supply system as one potential obstacle to growth within the SFPUC service area, the WSIP would have an indirect growth-inducing effect according to the CEQA definition above.[8] Implementation of the WSIP would improve supply reliability for existing water system customers and meet customer purchase requests through the year 2030, as discussed in Chapter 3. Meeting additional purchase requests would provide water to serve additional residential and business customers in the existing SFPUC service area. A variety of factors influence new development or population growth in the area served by SFPUC water, including economic conditions of the region, adopted growth management policies in the affected communities, and the availability of adequate infrastructure (e.g., water service, sewer service, public schools, and roadways, etc.), with economic factors generally the lead driver. While water service is only one of many factors affecting the growth potential of a community, it is one of the chief public services needed to support urban development, and lack of a reliable water supply as well as a service capacity deficiency could constrain future development.

Pursuant to CEQA, growth *per se* is not assumed to be necessarily beneficial, detrimental, or of little significance to the environment; it is the secondary, or indirect, effects of growth that can cause adverse changes to the physical environment. The indirect effects of population and/or economic growth and accompanying development can include increased demand on community services and public service infrastructure; increased traffic and noise; degradation of air and water quality; and conversion of agricultural land and open space to urban uses. Local land use plans (e.g., general plans and specific plans) of the jurisdictions served by the SFPUC establish land use development patterns and growth policies that are intended to allow for the orderly expansion of urban development supported by adequate public services, including water supply, roadway infrastructure, sewer service, and solid waste service. Local jurisdictions conduct CEQA environmental review on their general and specific plans to assess the secondary effects of their planned growth. A project that would induce growth that is inconsistent with local land use plans and policies could indirectly cause adverse environmental impacts, as well as impacts on public services, that the local land use jurisdictions have not previously addressed in the CEQA review of their land use plans and development proposals.

[8] The WSIP would not *directly* induce growth as it does not involve the development of new housing to attract additional population, nor would it indirectly induce growth by establishing substantial permanent or even short-term construction employment opportunities that could stimulate population growth. Construction of the WSIP projects is not expected to involve employment opportunities substantially beyond what would normally be available to construction workers in the area, and workers are expected to be drawn from the local labor pool.

To assess the growth inducement potential of the WSIP and characterize the secondary effects of growth, this chapter also investigates the following questions:

- *What assumptions did the SFPUC and its wholesale customers make regarding growth (population and employment) in projecting future (2030) total water demand and customer purchases from the SFPUC?*
- *Are these assumptions consistent with forecasts prepared and used by local and regional planning agencies (e.g., ABAG, counties and cities) within the service area? What are the growth trends in the Bay Area region?*
- *Are there any notable inconsistencies between the population and employment forecasts used by the SFPUC and the wholesale customers and those of the local and regional planning agencies that suggest that the water supply planning efforts are inconsistent with land use planning efforts?*
- *Is the level of growth projected for 2030 consistent with that identified and planned for in existing adopted general plans?*
- *What are the potential environmental impacts (secondary effects) associated with growth projected to occur in the service area? Have these impacts been evaluated in previous CEQA review documents on existing general and specific plans?*
- *What mitigation measures and findings have the local jurisdictions adopted as part of approving their future growth plans?*

The issues raised in these questions are addressed through the following analyses (the section where the analyses can found is indicated in parentheses); a summary of the chapter's conclusions follows in Section 7.1.2.

- *SFPUC Projections (Section 7.2)*. Accurate demand projections are important in ensuring that future water supplies will be adequate while not surpassing the needs of planned growth. SFPUC and its customers used computer models to forecast future water demand. Section 7.2 presents an overview of the SFPUC water service area, and describes key factors (assumptions, inputs, and methodologies) used in estimating future demand that relate to growth and inform comparisons between water demand and land use planning projections. These factors include baseline population, methodology used to determine existing water usage by land use/account type, the current water supply agreement between the SFPUC and its wholesale customers, and assumptions regarding future land use patterns, water conservation and recycling, and water from other (non-SFPUC) sources through 2030. The demand estimates, in conjunction with estimates of savings from conservation and use of other water sources, provide the basis for the 2030 purchase estimates.
- *Growth Inducement Potential (Section 7.3)*. This section analyzes the WSIP's growth inducement potential: whether the demand to be met by the WSIP would be consistent with local plans and policies or could contribute to growth in the service area beyond that called for in the existing general plan. To gauge the consistency of the WSIP with growth planned in the jurisdictions served by the SFPUC, the analysis compares the growth assumed in the SFPUC projections with growth forecasts (a) developed by ABAG and (b) reflected in adopted land use plans in the service area. With respect to ABAG, this section also

describes ABAG's changing expectations about growth as reflected in its updated projections issued in 2002, 2003 and 2005.

- *Indirect Effects of Growth (Section 7.4)*. Growth (whether planned or unplanned) can cause environmental impacts. Section 7.4 describes the potential impacts of growth that could be supported, in part, by implementation of the WSIP. This section also identifies measures adopted to reduce, eliminate or otherwise mitigate the impacts of planned growth.

7.1.2 Summary of Conclusions

The following bullet items highlight the key findings of this chapter.

Service Area Characteristics, Growth Trends, and Policies

A review of historical growth trends of a selection of jurisdictions in the service area, based primarily on information in general plans and Bay Area Water Supply and Conservation Association (BAWSCA) profiles, shows that:

- Cities in the service area are largely urbanized, most having experienced their most rapid growth in the postwar decades through the 1970s.
- Milpitas and East Palo Alto have experienced high rates of growth more recently.
- San Francisco's population fluctuated somewhat but on average has been essentially stable over the past 50 years.
- Many jurisdictions cannot grow laterally and their general plans include policies to manage growth; many general plans identify strategies consistent with "smart growth" principles, such as encouraging infill development and the redevelopment of previously developed areas, as means to accommodate future growth.
- The SFPUC's wholesale customers vary widely, in a variety of ways: by size, overall demand projected for 2030, the change that the 2030 demand represents in absolute terms and as a percentage of 2001 demand, and the degree to which the customers depend on the SFPUC for their water supply. As such, the WSIP would remove growth obstacles to varying degrees within the service area.

Growth Assumptions Used to Develop 2030 Water Demand and Purchase Requests Compared with ABAG Growth Projections

As discussed in Sections 7.2.2 through 7.3.2, each SFPUC wholesale customer selected a published source for growth projections to use in developing its service area's projections for total water demand in 2030 and subsequently identified its estimated level of water purchase in 2030 from the SFPUC. The majority of customers (about two-thirds) selected the most current ABAG projections available at the time (*Projections 2002*); while the others (about one third) selected other published sources (such as Urban Water Management Plans) for their population growth projections. *Projections 2002* was used by for almost all of the employment growth projections. These customer-selected growth projections were compared to ABAG's most recent projections series, *Projections 2005*.

- The growth assumptions used to derive the 2030 water demand estimates and subsequently the water customer purchase requests from the SFPUC are generally consistent with the most recent ABAG projections for jurisdictions in the service area. For the most part, the analysis demonstrates that, compared to the forecasts in ABAG's *Projections 2005*, the customer-selected projections used to derive water demand in the wholesale and retail service areas indicate:
  - somewhat less growth in employment and population (fewer added jobs and residents) through 2030, due largely to the expectation of more existing jobs in the area in 2005 than ABAG's *Projections 2005* estimates
  - more total employment in 2030 than ABAG's *Projections 2005* projects by about 5 percent overall
  - less total population in 2025 and 2030 by about 5 percent overall
- The growth that would be supported by the WSIP is generally consistent with current ABAG 2005 projections for jurisdictions in the service area. Because of differences in geographic area covered by most of the water customers and the jurisdictions they serve, they do not match exactly, and a few cannot be reasonably compared.

Growth Assumptions Used to Develop 2030 Water Demand and Purchase Requests Compared with General Plan Growth Assumptions

As discussed in Section 7.3.3, the existing, adopted general plans for cities within the SFPUC wholesale customer service area and for San Francisco were reviewed to compare the level of growth projected in these land use plans with that reflected in the growth assumptions used in the WSIP planning studies. The key findings of this review are:

- The horizon years for projections in the general plans considered in the analysis vary from 2005 to 2025; none of the plans extend out to 2030, which is the WSIP planning horizon. Due to the WSIP's longer planning horizon, in some areas the WSIP could support a degree of growth that has not been addressed in adopted land use plans.
- Comparison of the growth assumed in the development of the WSIP demand projections with growth forecasted in locally adopted land use plans indicates that much of the WSIP-related growth has been addressed in the adopted plans. A comparison of general plan projections with those selected by the water customers shows that:
  - The population growth assumed in the demand projections for most (15 of 19) of the water customers for which comparable general plan projections are available is similar to the growth anticipated in the general plans of the cities served by them.
  - The employment growth assumed in the demand projections for most (11 of 16) of the water customers for which comparable general plan projections are available are

generally consistent with (within 20 percent of) the employment growth anticipated in the general plans of the cities served by them. This general consistency was found despite the extraordinary job growth that occurred as a result of the economic boom in the 1990s, which was substantially reflected in employment projections used for the water demand projections (*Projections 2002)* but was not reflected to the same degree in earlier projections series used for many of the general plan employment estimates.

– The employment growth assumed for four wholesale customers is substantially greater (between 20 and 70 percent greater) than the growth anticipated in the respective general plans, due to the economic boom that occurred in the 1990s in the Bay Area, which affected various jurisdictions differently. This difference in growth assumptions suggests that a degree of commercial and industrial growth assumed in the demand projections is not fully addressed in the respective general plans.

- The general plans of jurisdictions in the SFPUC service area vary substantially in age, whereas the ABAG projections are updated every two years.

Indirect Effects of Growth

The indirect effects of growth expected in the general plans of jurisdictions in the service area have been identified in the EIRs prepared for those plans. A table of impacts commonly identified as significant and unavoidable and those commonly identified as significant but mitigable is presented in Section 7.4.

- The most commonly identified significant and unavoidable impacts of growth are:
  - Increased traffic congestion
  - Deterioration of air quality
  - Cumulative effects of increased air pollutant emissions and noise
- Mitigation measures have been adopted by local jurisdictions as part of their general plan approval processes to address the secondary effects of planned growth. These measures are summarized in Appendix E.
- Two cities identified increased demand for potable water supply as a significant and unavoidable effect of growth; the WSIP would address this issue in those two cities.
- Overriding considerations commonly adopted by the decision-making bodies in adopting their general plans include the following:
  - Accommodation of growth in an orderly, fiscally sound manner
  - Economic diversification and job generation
  - Creation of housing, furtherance of regional housing share objectives, and provision of affordable housing

  - Improvements of the local jobs/housing balance
  - Increased sales revenue and positive fiscal impact
  - Promotion of alternative modes of travel to reduce reliance on private vehicles
  - Establishment of policies to preserve natural areas and open space lands

- For many cities that receive water from the SFPUC regional system, the supply to be provided under the WSIP supports and is consistent with the planned growth reflected in their existing adopted general plans. For other communities, it appears that the WSIP supply (in combination with other supply sources available to those communities), could serve a level of growth beyond that identified in the existing general plans. In those cases, secondary effects of such growth could include impacts related to increased density and impacts related to development of new land areas.

  - Density related impacts could include, e.g., increased traffic congestion, air pollution, traffic noise, construction noise, and demand on public services.
  - Land area related impacts could include, e.g., loss of open space and agricultural land, loss of wildlife habitat, potential impacts on cultural resources, and interference with groundwater recharge and degradation of water quality due to increases in impervious surface area.

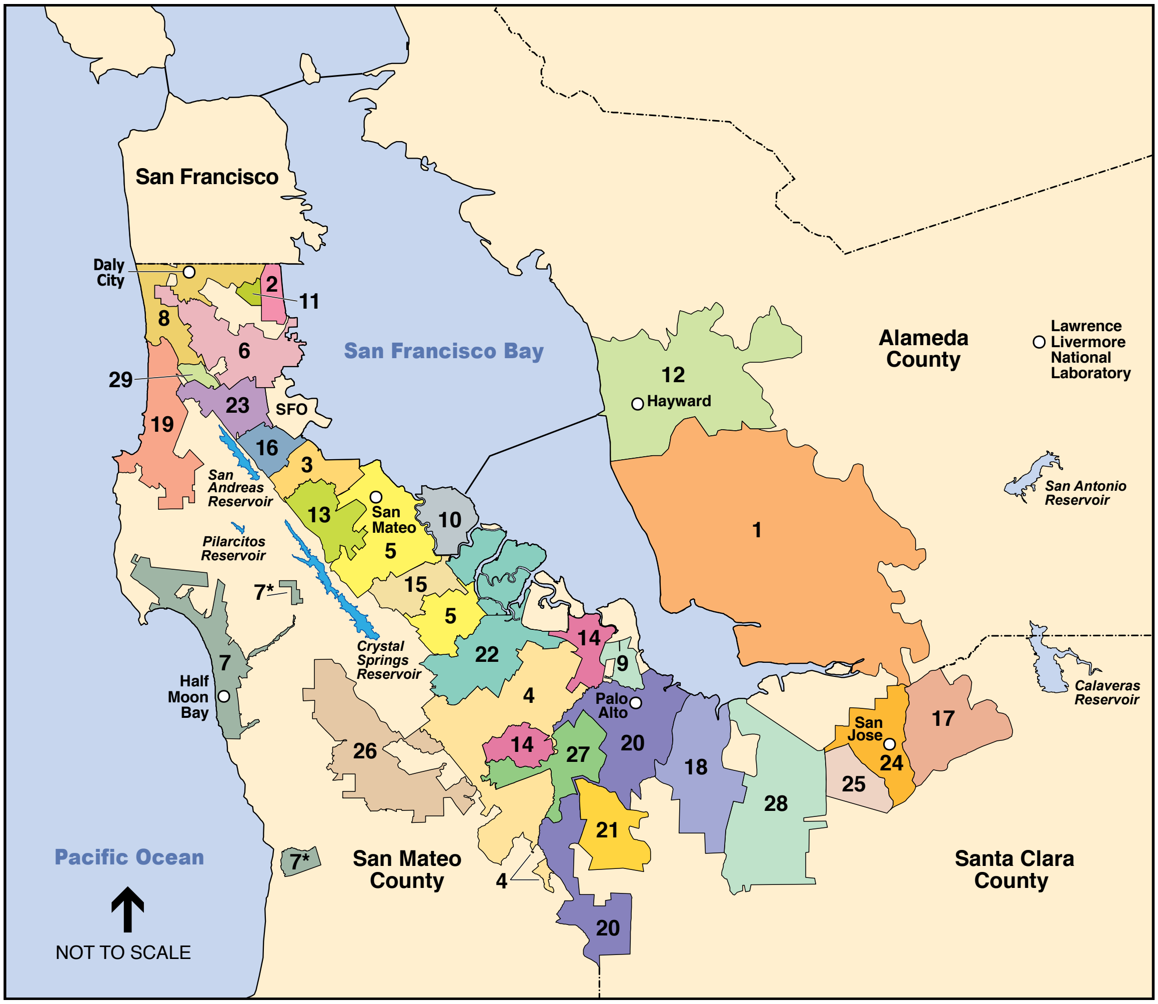
7.2 SFPUC Regional Water System: Customers and Water Demand Projections

7.2.1 SFPUC Service Area

The SFPUC serves retail customers in San Francisco and in Tuolumne County, and primarily wholesale customers in San Mateo, Santa Clara, and Alameda Counties (see Chapter 3, Program Description). **Figure 7.1** shows the SFPUC regional water service area, including the wholesale customers. **Figure 7.2** shows the city and county boundaries of the jurisdictions served by the wholesale customers. **Table 7.1** shows the jurisdictions served by the SFPUC's 27 wholesale customers.[9] Some of the water districts encompass more than one jurisdiction; Table 7.1 shows the percentage of the water district that is located within applicable jurisdictional boundaries. For about half the wholesale customers, the SFPUC is one of several sources of supply.[10]

9 There are 27 wholesale customers, but California Water Service Company (CWS), which is counted as one customer, serves three distinct subgroups—Bear Gulch District, Mid-Peninsula District, and South San Francisco District—which are tracked separately in the SFPUC reports. One former wholesale customer, Los Trancos County Water District, which was purchased by CWS and is now part of the Bear Gulch District, is also tracked separately in most of the SFPUC reports. Therefore, Table 7.1 lists 30 rather than 27 wholesale customer entities.

10 In 2001, the base year used for the demand projections, 14 of the 27 wholesale customers relied on other supply sources for at least some of their water (URS, 2004a).



Legend
(Wholesale customers and members of Bay Area Water Supply and Conservation Agency)

1 Alameda County Water District
2 City of Brisbane
3 City of Burlingame
4 CWS – Bear Gulch
5 CWS – Mid-Peninsula
6 CWS – South San Francisco
7 Coastside County Water District
8 City of Daly City
9 City of East Palo Alto
10 Estero Municipal Improvement District
11 Guadalupe Valley Municipal Improvement District
12 City of Hayward
13 Town of Hillsborough
14 City of Menlo Park
15 Mid-Peninsula Water District
16 City of Millbrae
17 City of Milpitas
18 City of Mountain View
19 North Coast County Water District
20 City of Palo Alto
21 Purissima Hills Water District
22 City of Redwood City
23 City of San Bruno
24 City of San Jose (North)
25 City of Santa Clara
26 Skyline County Water District
27 Stanford University
28 City of Sunnyvale
29 Westborough Water District

* Portions of Coastside County Water District not served by the SFPUC regional water system.

NOTE: For the purposes of this PEIR, the California Water Service (CWS) Company is a single wholesale customer with three different water service districts.

City/County Jurisdictions Served by SFPUC and Its Wholesale Customers

TABLE 7.1
JURISDICTIONS SERVED BY SFPUC WHOLESALE CUSTOMERS

Wholesale Customer	Jurisdictions Served (Percentage of Wholesale Customer Service Area in Jurisdictional Boundary [each totals 100%[a]])
Alameda County Water District	Fremont (65%) Newark (14%) Union City (21%)
City of Brisbane	Brisbane (100%)
City of Burlingame	Burlingame (98%) Other Unincorporated San Mateo County (2%)
CWS–Bear Gulch District[b]	Atherton (11%) Menlo Park (28%) Portola Valley (6.7%) Woodside (6.6%) Other Unincorporated San Mateo County (47.7%)
CWS–Mid-Peninsula District[b]	San Mateo (77%) San Carlos (23%)
CWS–South San Francisco District[b]	South San Francisco (91%) Colma (2%) Daly City (0.1%) Other Unincorporated San Mateo County (7%)
Coastside County Water District	Half Moon Bay (65%) Half Moon Bay Unincorporated (35%)
City of Daly City	Daly City (100%)
City of East Palo Alto	East Palo Alto (100%)
Estero MID[c]	Foster City (90%) San Mateo (10%)
Guadalupe Valley MID[c]	Brisbane[d] (100%)
City of Hayward	Hayward (100%)
Town of Hillsborough	Hillsborough (100%)
Los Trancos County Water District[e]	Portola Valley (10%) Other Unincorporated Mateo County (90%)
City of Menlo Park	Menlo Park (100%)
Mid-Peninsula Water District	Belmont (95%) Other Unincorporated San Mateo County (4%) San Carlos (1%)
City of Millbrae	Millbrae (100%)
City of Milpitas	Milpitas (100%)
City of Mountain View	Mountain View (100%)
North Coast County Water District	Pacifica (98%) Other Unincorporated San Mateo County (2%)
City of Palo Alto	Palo Alto (100%)
Purissima Hills Water District	Los Altos Hills (96.8%) Other Unincorporated Santa Clara County (3.2%)
City of Redwood City	Redwood City (91%) San Carlos (0.1%) Woodside (5.9%) Other Unincorporated San Mateo County (3.3%)
City of San Bruno	San Bruno (98%) Other Unincorporated San Mateo County (2%)
City of San Jose (North)	San Jose (100%)
City of Santa Clara	Santa Clara (100%)
Skyline County Water District	Woodside (63.6%) Other Unincorporated San Mateo County (36.4%)
Stanford University	Not applicable[f]
City of Sunnyvale	Sunnyvale (100%)
Westborough Water District	South San Francisco (100%)

a Due to rounding, totals may not be exactly 100%.
b CWS = California Water Service Company.
c MID = Municipal Improvement District.
d Guadalupe Valley MID is within the city of Brisbane.
e Los Trancos County Water District was purchased by CWS and is now part of the CWS–Bear Gulch District. Jurisdictions served are shown here for informational purposes.
f The Stanford University water system serves the Stanford campus only, primarily the central campus, rather than any distinct jurisdictions. The central campus is located in unincorporated Santa Clara County adjacent to the city of Palo Alto.

SOURCE: URS, 2004a.

Because water demand is projected to remain constant from 2000 to 2030 for the generally small and discrete retail customers located outside San Francisco (e.g., Lawrence Livermore National Laboratory, the community of Sunol, and the Groveland Community Services District), this analysis assumes that the potential for the WSIP to induce growth in these areas is negligible; therefore, the analysis focuses on the program's growth-inducement potential in the Bay Area in the areas served by the SFPUC's wholesale customers and in San Francisco.

SFPUC Wholesale Customers' Master Sales Agreement

As described in Chapter 2, Existing Regional Water System, the SFPUC holds contractual agreements with its wholesale customers. Wholesale water rates are set in accordance with the 1984 Settlement Agreement and Master Sales Water Contract (Master Sales Agreement) between the City and County of San Francisco and each of the wholesale customers (City and County of San Francisco, et al., 1984). The current master contract expires in 2009. Under the Master Sales Agreement, the City and County of San Francisco is required to supply up to 184 mgd (the "Supply Assurance") on an annual average basis to the wholesale customers collectively, subject to reductions in the event of a drought, water shortage, earthquake, or other natural disaster, and for rehabilitation and maintenance of the system. The agreement requires that wholesale customers employ best efforts to use all sources of water owned or controlled by them, including groundwater. The SFPUC and each of the wholesale customers, except for San Jose and Santa Clara, have negotiated individual supply assurance contracts (individual supply assurances) that cumulatively total 184 mgd. San Jose and Santa Clara do not have supply assurance contracts with the SFPUC.

In general, the individual supply assurances specify the amount of water a customer is entitled to purchase from the SFPUC according to a multi-step formula and multi-step vesting process. The contracts with Hayward and the Estero Municipal Improvement District (Estero MID) are exceptions to this type of contract, as they do not specify a quantified limit on purchases from the SFPUC. A specified amount of the total 184 mgd is set aside for growth in consumption by Hayward and Estero MID.[11] If the combined usage by Hayward and Estero MID exceeds this amount, the Master Sales Agreement provides a method for proportional reduction in the other water customers' supply guarantee (Bay Area Water Users Association [BAWUA], 1993; BAWSCA, 2006b).

The individual supply assurances for the wholesale customers under the current Master Sales Agreement are shown in Appendix E, Section E.1. Of the 23 wholesale customers that have individual supply assurance contracts with a specified quantity, 12 submitted 2030 purchase estimates (discussed in Section 7.2.2, below) that exceed their current individual supply assurance, while 11 submitted purchase estimates that are less than or equal to their current individual supply assurance. Consistent with CEQA requirements, the existing base year (2001) demand, not the supply assurances, is considered the baseline for the analysis presented in this

[11] A 1993 memorandum from BAWSCA (then BAWUA) to its member agencies regarding allocation of the supply assurance indicated that the combined usage for Hayward and Estero MID at the time was 21.782 mgd, and that an additional 6.2 mgd was set aside to allow for growth in Hayward and Estero MID consumption (BAWUA, 1993) for a total of 28 mgd. The current BAWSCA annual survey (BAWSCA, 2006b) shows combined usage in FY 2004/2005 of 24.10 mgd for Hayward and Estero MID and a reserve amount of 3.9 mgd (equaling the same combined amount allocated for Hayward and Estero MID (28 mgd) as in the 1993 memorandum).

chapter. The information on current supply assurances is presented for informational purposes. BAWSCA estimates that, excluding Santa Clara and San Jose (which, as noted, do not have supply assurance contracts), wholesale customer purchases from the SFPUC will approach the current 184 mgd wholesale customer supply assurance by about 2020, and that, including San Jose and Santa Clara, purchases from the SFPUC will approach 184 mgd by about 2008 (BAWSCA, 2006b).

7.2.2 Demand Projections

Future water demand projections for both retail and wholesale customers were developed using end-use demand models that break down total water use, by water service account, to specific end uses such as toilets, faucets, and irrigation. Projections for the wholesale service area were developed in close consultation with the wholesale customers, who provided critical inputs to the demand model – including selection of the source of population and employment projections to be used – and subsequently submitted statements concurring with the demand projections. Most (about two-thirds) of the customers selected ABAG's *Projections 2002* as the source of population projections used in their demand model;[12] other customers selected the BAWSCA annual survey, urban water management plans, or city planning sources for growth projections. Projections for San Francisco were developed based on information provided by the San Francisco Planning Department.

To develop yearly projections to 2030, the population and employment increase for each five- or ten-year increment was divided evenly and applied yearly throughout the five- or ten-year period to form a linear yearly projection between increments. The selected projections were then input into the demand model, which applied the growth rate from the selected projection to growth in the applicable water customer accounts. In general, population projections were used as the source of growth rates for residential, institutional, and other miscellaneous water accounts and employment projections were applied to commercial and industrial accounts.

Table 7.2 shows the 2030 water demand projections for the SFPUC wholesale and retail service area. The 2030 demand projections take into account expected growth in population and employment, the influence of plumbing codes (which include water efficiency requirements), and assumptions about rates of water fixture replacement. Thus, the 2030 demand projections factor in some "passive" water savings due to plumbing code changes, as well as the effects of conservation savings accrued prior to the base year. As part of WSIP planning, the SFPUC also undertook studies to determine the potential for continuation of existing conservation programs as well as additional conservation programs and recycled water projects that could be implemented to offset demand for potable water supplies. These studies, and the wholesale and retail service area demand studies, are described in detail in Appendix E, Section E.2.

[12] Because *Projections 2002* provides forecasts only to 2025, population and employment projections for 2025-2030 were estimated using the 2020-2025 population/employment growth rate, which was applied to the 2025 estimate and carried forward linearly at that rate to 2030.

TABLE 7.2
SUMMARY OF 2030 DEMAND PROJECTIONS, WATER SUPPLY ASSUMPTIONS, AND SFPUC PURCHASE ESTIMATES

	A	B	C	D	E	F	G	H	I	J
Customer	**2030 Projected Demand (with Plumbing Code Savings) (mgd[a])**	**2030 Projected Conservation Savings (mgd[a])**	**2030 Demand Adjusted for Conservation (mgd[a])**	**2030 Projected Use of Recycled Water (mgd[a])**	**2030 Projected Use of Ground-water Sources (mgd[a])**	**2030 Projected Use of Other Surface Water Sources (mgd[a])**	**2030 Projected Demand Adjusted for Use of Other Sources and Conservation (mgd[a])**	**2030 Purchase Estimates (mgd[a])**	**Percent of Total 2030 Demand (with Plumbing Code Savings) met by SFPUC Purchases**	**Percent of 2030 Demand Adjusted for Conservation met by SFPUC Purchases**

NOTE: Numbers may not sum due to rounding.
a mgd = million gallons per day.
b CWS = California Water Service Company.
c CWS–Bear Gulch District includes the former Los Trancos County Water District.
d The upper range purchase estimate assumes loss of all local water sources (surface water and groundwater) and the lower range estimate assumes continuation of local sources; both estimates assume Level B water conservation.
e The purchase estimate range reflects a range of potential groundwater usage established under a pilot project, from the sustainable yield (3.76 mgd) to the lowest annual production yield (1.34 mgd), according to Daly City's best estimate of 2030 water purchases (SFPUC, 2004).
f MID = Municipal Improvement District.
g 2030 conservation savings is based on URS 2004c and the City's UWMP as confirmed by the City (Popp, 2007).
h 2030 demand and conservation savings are based on information provided by the City of Palo Alto to the SFPUC (City of Palo Alto, 2005a).
i In November 2005, Redwood City informed the SFPUC that it would be purchasing its low-range estimate of 11.6 mgd due to anticipated implementation of 1 mgd of recycled water in 2030 (City of Redwood City, 2005a). The high-range purchase estimate total of 300 mgd published in URS 2004b remains the SFPUC 2030 purchase estimate total for planning purposes, to be consistent with the previous and ongoing WSIP studies. The purchase estimate range originally submitted apparently reflects the average of the City's estimated conservation savings range plus the originally estimated range of recycled water use.
j Portion of north San Jose only.
k Demand and purchase estimates are based on Westborough Water District's 2005 UWMP, as requested by the District in a letter to the SFPUC (Westborough Water District, 2007). The UWMP discusses ongoing and planned future demand management programs but does not quantify conservation savings in relation to the demand and purchase estimate. The District's original estimate of water purchases indicated conservation savings of 0.020 mgd (SFPUC 2004).
l The low range of the SFPUC retail customer purchase estimate reflects the identified groundwater, recycled water, and conservation programs totaling 10 mgd in San Francisco that are included as part of the WSIP proposed water supply option.

2030 Purchase Estimates

Each wholesale customer is responsible for its own water management planning decisions and for determining the percentage of its future water demand that it desires to meet with SFPUC supplies. Following completion of 2030 demand modeling and the conservation potential and recycled water potential studies, the wholesale customers considered conservation potential and other water supply sources and submitted purchase estimates for SFPUC water for 2030 (URS, 2004b). The purchase estimates include the effects of continuing current conservation programs and additional conservation programs that the SFPUC and/or its wholesale customers plan to implement, as well as the use of recycled water and other supply sources (see Table 7.2). Conservation and demand management programs are an integral component of water suppliers' supply portfolio, as shown in Table 7.2. Table 7.2 shows the percentage of total 2030 demand met by purchases from the SFPUC for each customer and also shows the percentage of all "physical" water supply sources (including recycled water) met by SFPUC purchases (i.e., the percentage of demand after conservation savings are taken into account). As shown, purchases from the SFPUC in 2030 of 300 mgd represent approximately 72 percent of the total SFPUC service area demand (with plumbing code savings) and about 74 percent of demand adjusted for additional conservation.[13] **Figure 7.3** depicts historical water deliveries for the wholesale and retail service areas as well as the projected demand on the SFPUC system (i.e., estimated purchases) to 2030.

Change in Water Demand and Purchases from Base Year

Table 7.3 shows the base-year demand estimates for each wholesale customer and the retail service area (2001 and 2000, respectively), the 2000/2001 purchases from the SFPUC, and the change in demand and purchases forecasted for 2030. The base-year demand estimate is based on actual consumption data (adjusted for unaccounted-for water[14]) and therefore reflects the effects of conservation programs implemented to date. As Table 7.3 shows, overall customer demand (wholesale and retail customers) in the service area is expected to increase by about 51 mgd in 2030 and purchases from the SFPUC regional water system are expected to increase by about 24-39 mgd from the base year 2000/2001. As shown in the table, essentially no change is projected in total demand for the SFPUC retail service area, which is predominantly the City and County of San Francisco. For purposes of planning future 2030 water delivery requirements for the regional system, the SFPUC selected the high range purchase estimates of 300 mgd as the target goal for the average annual water delivery by 2030. This is an increase of approximately 39 mgd from the 2001 deliveries and 35 mgd from the current normal-year average annual demand estimates.

---

[13] The demand studies also calculated the effects of plumbing codes (which include efficiency requirements) on water savings, and found that a total savings of 35.7 mgd is expected to be achieved in 2030 as a result of plumbing code requirements. Table E.2.4 in Appendix E.2 shows 2030 plumbing code savings for the retail service area and each wholesale customer.

[14] Unaccounted-for water refers to the difference between total water produced in a system and total water billed to customers (i.e., water consumed). Unaccounted-for water includes water delivery system leaks, water not billed or tracked in the system, such as water used for fire fighting and system flushing, and any unauthorized use.

a mgd = million gallons per day.
b Demand estimates shown here include unaccounted-for water, which is the difference between total water produced and total water billed to customers (water consumed). Unaccounted-for water includes fire fighting use, maintenance requirements, system flushing, leaks, and any unauthorized use.
c Based on URS 2004b.
d CWS = California Water Service Company.
e MID = Municipal Improvement District.
f The former Los Trancos County Water District is now part of CWS–Bear Gulch District; information presented here reflects information in background reports (URS, 2004a, 2004b).
g 2030 demand is based on information provided by the City of Palo Alto to the SFPUC (City of Palo Alto, 2005a).
h In November 2005, Redwood City informed the SFPUC that it would be purchasing its low range estimate of 11.6 mgd due to anticipated implementation of 1 mgd of recycled water in 2030 (City of Redwood City, 2005a). The high-range purchase estimate total published in URS 2004b of 300 mgd remains the SFPUC 2030 purchase estimate for planning purposes to be consistent with the previous and ongoing WSIP studies.
i Portion of north San Jose only.
j Demand and purchase estimates are based on Westborough Water District's 2005 UWMP, as requested by the district in a letter to the SFPUC (Westborough Water District, 2007). Base year demand shown here is based on 2001 total water production presented in the UWMP (which is equal to 2001-02 purchases from the SFPUC).

7.3 Growth Inducement Analysis

As discussed in the approach to analysis, above, evaluation of the WSIP's growth-inducing impacts involves considering whether the growth that would be supported by implementation of the WSIP is planned growth, anticipated by the land use planning agencies in the areas served by SFPUC water and reflected in their adopted general plans. This section compares the population and employment projections used in the water demand models (referred to herein as customer-selected projections) with the population and employment projections of the regional planning agency, ABAG, and the projections in the general plans (or related land use planning documents) of cities in the service area. The water customers' UWMPs (which have been prepared since the demand studies for the wholesale and retail service areas [URS, 2004a, Hannaford and Hydroconsult, 2004] were completed) are also compared with the population projections used in the demand model. These comparisons establish whether the employment and population growth that the SFPUC and its water customers used as a basis to derive their water demand projections is also forecasted by ABAG and anticipated by local jurisdictions in their general plans. The major conclusions of these comparisons are summarized in Section 7.1, above.

7.3.1 Analysis Assumptions

Use of Demand Model Population and Employment Assumptions

While the 2030 water demand projections are based on projected growth in residential and non-residential water accounts and cannot be directly correlated to demographic projections (because they include various customer-specific model inputs and adjustments), the customer-selected population and employment projections provide a basis of comparison with other growth forecasts for the area. The projections of employment and population selected by the wholesale customers and the SFPUC as the basis for growth in water accounts and future water demand are shown in **Table 7.4** and summarized by county in **Table 7.5**. Wholesale customers are sorted by county to facilitate the analysis of consistency of these projections with ABAG's projections.

Geographic Areas

ABAG projections are published for cities and their planning areas and for unincorporated county areas. The boundaries of most of the water customer service areas are not congruent with city boundaries (as shown in Table 7.1). Therefore, in order to evaluate the consistency of the customer-selected projections with ABAG projections, the ABAG city and county jurisdiction information had to be made to "fit" the wholesale customer service area boundaries. For purposes of comparing population and employment projections this analysis uses the following assumptions about the correspondence between wholesale customers' service areas and "ABAG jurisdictions."[15] Because there is no "perfect fit" between the wholesale customer service area

[15] For this analysis, ABAG's projections for subregional study areas, rather than projections for the cities as defined by their corporate limits, were used. The subregional study areas include the named incorporated city and any adjacent unincorporated area within the city's planning area.

TABLE 7.5
EMPLOYMENT AND POPULATION PROJECTIONS USED FOR WATER DEMAND ESTIMATES: SUMMARY BY COUNTY[a]

	Employment			Population		
	2001	2030	% change	2001	2030	% change
Wholesale Customers						
Alameda County	238,565	335,701	41%	456,962	542,688	19%
Santa Clara County	501,186	635,809	27%	466,452	580,391	24%
San Mateo County[b]	394,346	517,056	31%	703,185	814,904	16%
Total Wholesale Customers	1,134,097	1,488,566	31%	1,626,599	1,937,983	19%
Retail Customers						
San Francisco (City and County)[c]	638,840	795,400	25%	760,075	849,942	12%
Total	1,772,937	2,283,966	29%	2,386,674	2,787,925	17%

a Figures shown by county are the projections used in demand modeling for the water customers in that county, not the county as a whole. (The SFPUC serves a limited portion of Alameda County and Santa Clara County, which are predominately served by East Bay Municipal Utilities District and Santa Clara Valley Water District, respectively.)
b Population estimates for San Mateo County include updated figures for Westborough Water District from its Urban Water Management Plan.
c Estimates for 2001 for San Francisco interpolated linearly for the PEIR analysis from estimates for 2000 and 2005 presented in the SFPUC technical memorandum (Hannaford and Hydroconsult, 2004).

SOURCES: Hannaford and Hydroconsult, 2004; URS, 2004a; Westborough Water District, 2005; Mundie & Associates, 2006.

boundaries and the ABAG city and county jurisdiction boundaries, the population and employment projections will differ somewhat simply as a result of this imperfect geographic fit.

- Wholesale customers that serve most or all of one or more cities are assumed to correspond to those cities.
- Wholesale customers that serve most or all of a city plus smaller portions (i.e., less than half) of other cities and any unincorporated county areas are assumed to correspond only to the cities they serve most or all of.
- ABAG does not provide separate or segregable projections for most unincorporated county areas. Therefore, unincorporated areas served by wholesale customers are not captured in the correspondence established for this analysis. (The exception to this is unincorporated Half Moon Bay, for which ABAG provides separate projections and which is assumed, along with the incorporated city, to correspond to the Coastside County Water District service area).[16]

Refer to Appendix E, Section E.3 (Table E.3.A.2 of Attachment E.3.A) for the list of ABAG jurisdictions assumed in this analysis to correspond to respective water customer service areas and vice versa. The same correspondence between service areas and cities is also assumed for the comparison of water customer-selected projections with growth projections in the general plans of jurisdictions in the SFPUC service area.

16 Because this analysis uses ABAG's subregional study area projections, the projections may include population and employment forecasts for some portion of the unincorporated areas within a wholesale customer's service area. However, it is not known whether, or the degree to which, the unincorporated areas served by a wholesale customer encompass the same geography as the unincorporated areas within the corresponding ABAG subregional study area. With the exception of unincorporated Half Moon Bay, unincorporated areas are identified as "nonsegregable unincorporated areas" in Table E.3.A.1 of Appendix E (Section E.3, Attachment E.3.A) and are assumed not to be captured in the correspondence established for this analysis.

Time Periods

The base year for the wholesale water customers' projections is 2001 and the base year for the retail customer's (i.e., San Francisco's) projections is 2000. Projections for both the wholesale customers and San Francisco extend through 2030. ABAG projections are provided in five-year intervals (for the first year of each decade as well as mid-decade); *Projections 2003* and *Projections 2005* provide forecasts through 2030, but *Projections 2002* extends only through 2025.

To establish a consistent time period for comparison in this PEIR analysis, the customer-selected projections from the respective base years (2000 and 2001) through 2030 presented in the SFPUC's published demand studies were interpolated to establish estimates for 2005 and 2025. An estimate for 2001 was interpolated for the retail service area, from the 2000 base year population and employment estimates, to establish a consistent base year. The years 2005, 2025, and 2030 were then used to evaluate consistency between the customer projections and the ABAG projections. The base year estimates for 2001 and projections for 2005, 2025, and 2030 are shown in Appendix E, Section E.3 (Table E.3.4).

7.3.2 ABAG Projections

Every two years ABAG publishes regional projections of employment and population growth for the nine-county San Francisco Bay Area. These projections are the most comprehensive set of employment and population projections that cover the area served by the SFPUC. *Projections 2002* and *Projections 2003* (ABAG, 2001; ABAG, 2002) were reviewed in preparation of this analysis. ABAG's most recent projections set, *Projections 2005* (ABAG, 2004) is the basis for the comparison presented here. The sidebar reviews the findings of a comparison between ABAG *Projections 2002*, *2003*, and *2005*.

ABAG projections are used for various planning purposes by many of the cities in the nine-county area covered by ABAG. Many of the SFPUC wholesale customers selected the ABAG's *Projections 2002* (the projections set that was current at the time) for use in the water demand model. Since that set was published, ABAG has issued two subsequent sets of projections—*Projections 2003* and *Projections 2005.* These two subsequent projections incorporate a fundamental shift in ABAG's projections methodology. Rather than taking existing local land use policy as a given (as had previously been the case), in the projections following *Projections 2002* ABAG assumes that local policy will be amended in the future to adopt "smart growth" principles. Specifically, the projections assume that higher density growth will be focused in urban core areas, and that more housing will be produced in those areas, compared to that previously assumed. The result of these assumptions is to increase the expected population in already developed areas. Most of the SFPUC service area is located in such already developed areas. Another difference reflected in *Projections 2003* and *Projections 2005* is more current and accurate reflection of effects of the dot com recession, especially the estimates of employment in 2005.

To assess whether ABAG's changing assumptions about future growth principals in the region combined with the updated information on current population and employment levels would result in substantially revised estimates of population or employment levels in the areas served by SFPUC water by 2030, an analysis was undertaken to compare the three sets of projections. First *Projections 2002* was compared to *Projections 2003* and then *Projections 2003* was compared to *Projections 2005*.

Based on the improved understanding of the extent of job and population losses that had been sustained in the first part of the decade, employment and population estimates for 2005 in *Projections 2003* are lower than had been projected in *Projections 2002*, and lower still in *Projections 2005*. At the same time, as might be expected from the assumption of more growth occurring in the urban core areas with the adoption and implementation of smart growth principles that ABAG assumes will occur, *Projections 2003* and *Projections 2005* have somewhat steeper growth curves between the present and 2030. Nevertheless, the general trends for the three are similar. The net result of the two principal changes in the later projection sets (that is, lower current population and employment estimates combined with more growth between now and 2030) is that the estimates for the WSIP horizon year of 2030 are similar among all three sets of ABAG projections. (Although *Projections 2002* only extends to 2025, projections for WSIP planning were extrapolated to 2030.) Section 7.3 text includes the key points from the comparison of the projections used in the demand study with ABAG *Projections 2005* projections. More detailed information on the comparison of the three ABAG projection sets is presented in Appendix E, Section E.3. Figures E.3.1 and E.3.2 in Appendix Section E.3 illustrate the differences in forecasted growth rates for the nine Bay Area counties and the four counties of the SFPUC service area reflected in the three projections sets.

Employment Projections

Table 7.6 compares the water customer-selected employment projections to the ABAG *Projections 2005* forecasts for the corresponding geographic areas for the years 2005, 2025, and 2030. The projections selected by the individual water customers (and interpolations for 2005 and 2025 prepared for this analysis) are shown in Table E.3.4 in Appendix E.3; Table 7.6 groups the projections by county. As shown, for the service area as a whole, the customer-selected employment projections forecast about 5 percent more jobs in 2030 than does *Projections 2005*. Thus, on the whole, the projections used in the water demand analysis remain generally consistent with current regional employment growth projections. The table supports the following observations:

- On a countywide basis, customer-selected projections of total employment in 2005 are consistently higher than *Projections 2005* estimates for 2005. The customer-selected projections were prepared a number of years prior to 2005, and therefore these 2005 employment estimates are truly forecasts. The *Projections 2005* estimates for 2005, in contrast, are based on observed data that reflect a more recent understanding of the impact of the "dot com bust" on the Bay Area economy. That is, the higher estimates of the customer-selected projections for 2005 reflect the experience of economic growth experienced by many Bay Area jurisdictions in the 1990s, without the benefit of information about the extent to which a slow down in employment growth occurred in the late 1990s and early 2000s. In contrast, *Projections 2005*, which was prepared a short time before 2005, reflects observed data on the continuing effects of the economic slow down, and shows lower 2005 employment estimates. Nevertheless, because *Projections 2005* also forecasts more growth in employment (i.e., more added jobs) between 2005 and 2030 than do the customer-selected projections, overall employment predicted by *Projections 2005* in 2030 (relying on more accurate 2005 estimates), is within a few percentage points of the overall employment predicted in 2030 by the customer-selected projections (relying on projected 2005 numbers).

- Water customer-selected employment projections for 2030 for Alameda and San Mateo County jurisdictions and San Francisco are generally consistent with (within 10 percent of) *Projections 2005*. Customer-selected projections for Santa Clara County jurisdictions are higher than *Projections 2005*. Customer-selected projections for 2025 are also generally consistent with *Projections 2005* for Alameda County jurisdictions and San Francisco.

- In each county, the numbers of new jobs expected in the customer-selected projections between 2005 and 2030 are smaller than the numbers forecasted in *Projections 2005*. The additional new job growth in *Projections 2005* reflects an increased understanding of the job loss that occurred between 2000 and 2005 combined with the expectation that, over the long term, the losses will be recovered and new jobs will be attracted to the area (but not enough new jobs to attain the totals that were predicted in *Projections 2002*).

- In each county, the customer-selected projection sources show employment growing at a slower rate during the 2005-2030 period as compared to the average rate of change

TABLE 7.6
COMPARISON OF EMPLOYMENT PROJECTIONS:
SFPUC CUSTOMERS AND ABAG *PROJECTIONS 2005* (SUMMARY BY COUNTY)[a,b]

	2005	2025	2030	Change 2005–2030
SFPUC Customer-selected Projections				
Alameda County	251,963	318,953	335,701	83,738
Santa Clara County	519,755	612,598	635,809	116,054
San Mateo County	411,273	495,898	517,056	105,783
Total Wholesale Customers	1,182,991	1,427,449	1,488,566	305,575
San Francisco (City and County)	656,480	770,500	795,400	138,920
Total	1,839,471	2,197,949	2,283,966	444,495
ABAG *Projections 2005*				
Alameda County	212,560	308,120	329,800	117,240
Santa Clara County	393,700	512,830	544,610	150,910
San Mateo County	309,470	435,600	469,900	160,430
Total Wholesale Customers	915,730	1,256,550	1,344,310	438,580
San Francisco (City and County)	575,800	776,100	829,090	253,290
Total	1,491,530	2,032,650	2,173,400	681,870
Customer-selected Projections as a Percentage of ABAG *Projections 2005*				
Alameda County	119%	104%	102%	71%
Santa Clara County	132%	119%	117%	77%
San Mateo County	133%	114%	110%	66%
Total Wholesale Customers	129%	114%	111%	70%
San Francisco (City and County)	114%	99%	96%	55%
Total	123%	108%	105%	65%

a Includes only those portions of each county served by SFPUC wholesale water customers or served directly by the SFPUC (i.e., San Francisco); see Appendix E, Section E.3 (Table E.3.A.2 of Attachment E.3.A) for correspondence assumed between ABAG jurisdictions and water customer service areas. (The SFPUC serves a limited portion of Alameda County and Santa Clara County, which are predominately served by East Bay Municipal Utilities District and Santa Clara Valley Water District, respectively.)

b Wholesale customer-selected projections for 2005 and 2025 interpolated linearly for the PEIR from estimates for 2001 and 2030 presented in the Wholesale Customer Demand Projections Technical Report (URS, 2004a).

SOURCES: Hannaford and Hydroconsult, 2004; URS, 2004a; ABAG, 2004; Mundie & Associates, 2006

predicted in *Projections 2005* for the same period.[17] The growth rate in the customer-selected projection sources (e.g., *Projections 2002*) is what was used in the model to help forecast future water demand. (Note that the estimates of employment in 2005 provided in *Projections 2005* are noticeably lower than the customers' estimates of employment for that same year. This accounts for the fact that even though the average rate of change is faster in *Projections 2005,* as compared to the customer-selected projection sources, the number of jobs in 2030 in the customer-selected projections is higher than those in *Projections 2005*. (See Tables E.3.37 and E.3.38 in Appendix E, Section E.3, for employment and population growth rates in *Projection 2005* and the water customer projections, respectively.)

17 This comparison refers to the average rate of change over the 25-year period (2005-2030) reflected in Table 7.6. To predict non residential water use, the change in base year and projected employment through 2030 was used to develop annual growth rates for each customer. The demand model applied this annual growth rate to base year non-residential water use to estimate future water use.

- For Santa Clara County the customer-selected projections predicted 17 percent more jobs in 2030 than are currently forecasted by ABAG in *Projections 2005*. Similar to the other counties, customer-selected projections expect fewer *new* jobs through 2030 than are forecasted in *Projections 2005*; however, because the number of jobs estimated for 2005 was more than 30 percent higher than the number estimated in *Projections 2005*, the expectations of future total employment remain higher than the ABAG forecast. Similarly, for San Mateo County, the customer-selected projections predicted 14 percent more jobs in 2025 than are forecasted by ABAG in *Projections 2005*. As in the other counties, the customer-selected projections expect fewer new jobs through 2025 than are forecasted in *Projections 2005*. However, because the number of jobs estimated for 2005 was more than 30 percent higher than the number estimated in *Projections 2005*, the expectations of future total employment remain higher than estimated in *Projections 2005*. By 2030, because of the faster rate of job growth reflected in *Projections 2005* (compared with the customer-selected projections), the difference in expected jobs is narrowed to 10 percent.

- Overall, the job projections selected by the wholesale customers are about 11 percent higher in 2030 than those of *Projections 2005*, and projections selected by San Francisco are about 4 percent lower than those of *Projections 2005*. With less than 10 percent variation for the service area as a whole, the employment projections used in the water demand studies remain consistent with ABAG's current long-term projections for job growth within the regional service area.

Population

Table 7.7 compares the population projections used by the SFPUC and its wholesale customers to develop future water demand projections to the ABAG *Projections 2005* forecasts for the corresponding geographic areas, for 2005, 2025, and 2030. The projections selected by the individual water customers (and the interpolations for 2005 and 2025 done for this analysis) are shown in Table E.3 4 in Appendix E, Section E.3; Table 7.7 groups the projections by county. As shown, for the service area as a whole, the customer-selected projections forecast about 5 percent less population in 2030 than does *Projections 2005*. Thus, on the whole, the projections used in the water demand analysis remain consistent with current regional population projections. Table 7.7 supports the following conclusions:

- On a countywide basis, water customer projections of total population in 2005 are about the same as (within 5 percent of) *Projections 2005* estimates for 2005.

- *Projections 2005* population estimates for 2025 and 2030 are also similar to, although consistently higher (by 4 percent and 5 percent, respectively) than, the customer-selected projections in those years. The difference is likely attributable in large part to the extent of ABAG's smart growth assumptions, which would locate approximately 150,000 additional households (compared to *Projections 2002*) in the more urban communities of the Bay Area between 2010 and 2030.

- The numbers of new residents expected in the customer-selected projections between 2005 and 2030 are smaller in all counties than the numbers expected by *Projections 2005*.

TABLE 7.7
COMPARISON OF POPULATION PROJECTIONS:
SFPUC CUSTOMERS AND ABAG *PROJECTIONS 2005* (SUMMARY BY COUNTY)[a,b]

	2005	2025	2030	Change 2005–2030

Total	99%	96%	95%	73%

a Includes only those portions of each county served by SFPUC wholesale water customers or served directly by the SFPUC (i.e., San Francisco); see Appendix E, Section E.3 (Table E.3.A.2 of Attachment E.3.A) for the correspondence assumed between ABAG jurisdictions and water customer service areas.
b Wholesale customer-selected projections for 2005 and 2025 interpolated linearly for the PEIR analysis from estimates for 2001 and 2030 presented in the Wholesale Customer Demand Projections Technical Report (URS, 2004a).
c Estimates for San Mateo County include updated figures for the Westborough Water District from its Urban Water Management Plan.

SOURCES: Hannaford and Hydroconsult, 2004; URS, 2004a; ABAG, 2004; Westborough Water District, 2005; Mundie & Associates, 2006.

- On a countywide basis, the customer-selected projection sources show population growing at a slower rate during the 2005-2030 period as compared to the average rate of change predicted in *Projections 2005* for the same period.[18] The growth rate in the customer-selected projection sources (e.g., *Projections 2002*) is what was used in the model to help forecast future water demand. (See Tables E.3.37 and E.3.38 in Appendix E, Section E.3, for employment and population growth rates in *Projection 2005* and the water customer projections, respectively.)

18 This comparison refers to the average rate of change over the 25-year period (2005-2030) reflected in Table 7.7. To predict residential water use, the change in base year and projected population through 2030 was used to develop annual growth rates for each customer. The demand model applied this annual growth rate to base year residential water use (and other non-industrial and non-commercial water use) to estimate future water use.

7.3.3 General Plan Projections

Comparison of General Plan and Demand Study Projections

A comparison for consistency between the growth projections used as the basis for water demand and purchase requests estimates in the WSIP planning studies and the growth projections presented in the general plans of jurisdictions in the SFPUC service area helps determine whether the growth that would be supported by implementation of the WSIP would be planned growth reflected in adopted general plans, or is somehow more than or different from what is called for in current general plans (in terms of amount and/or location). The general plans of 21 cities that are served in whole or part by SFPUC and its wholesale customers have population projections that are generally comparable to the water customer-selected population projections.[19,20]

Table 7.8 presents a comparison of the population projections selected by the water customers for use in the WSIP demand models with the population projected in the general plan for the respective cities. The table shows the difference (in number and percentage) in projected population from these two sources. Because the general plans vary considerably in age and have a range of projection years, none of which extends to 2030, ABAG's *Projections 2005* forecasts for 2030 are also included in the table for reference. The population projections assumed in the water customers' UWMPs, which were prepared more recently than the demand forecasts, also are included for reference. The comparison indicates the following:

- The population projections used for two of the wholesale customers (East Palo Alto and Sunnyvale) in the water demand studies are less than (from 2 to 6 percent less) the projections assumed in the general plans of the jurisdictions served by them.

- The population projections assumed for 13 of the water customers (ACWD, CWS-South San Francisco in combination with Westborough Water District, Daly City, Hayward, Hillsborough, Mid-Peninsula Water District, Millbrae, Mountain View, Palo Alto, San Bruno, San Francisco, and Santa Clara) are higher but within 1 to 10 percent of the projections presented in the respective general plans.

- Based on the two summary points above, the population growth assumed in the demand models for most of the water customers (17 of 20), for which comparable general plan projections are available, is similar to the growth anticipated in the general plans of the cities served by them. That is, the growth assumed in the demand models would be planned growth that is reflected in currently adopted general plans.

---

19 General plans with projection years earlier than 2005 were not considered comparable to the 2030 population and employment projections used in the water demand studies. In addition, a few general plans did not include population or employment estimates in a form that could be compared to the customer-selected projections (e.g., where population growth is considered in terms of needed new housing units without information on assumed household size from which population estimates could be derived). Several wholesale customers' service areas do not correspond to jurisdictional boundaries closely enough to allow meaningful comparisons; refer to the discussion of correspondence between water customers and jurisdictions in Appendix E.3 and the correspondence assumptions shown in Table E.3.A.2 of Attachment E.3.A, Appendix E.3. The 21 cities, served by 19 water customers, represent approximately two-thirds of 32 cities served by the SFPUC regional system.

20 The 21 cities are served by 18 wholesale customers and the SFPUC (for the retail service area), referred to collectively here as 19 water customers.

TABLE 7.8
COMPARISON OF WATER DEMAND POPULATION ESTIMATES AND GENERAL PLAN POPULATION ESTIMATES

Customer	UWMP Population in 2030	*Projections 2005* Population in 2030	Water Customer-Selected Population Projection for 2030	General Plan Population Projection for General Plan Projection Year[a]	General Plan Projection Year[a]	Difference: Water Customer Population and General Plan Population	% Difference (Water Customer Population and General Plan Population)
Customer-selected projection less than or equal to general plan projection							
City of East Palo Alto	32,712	43,600	32,712	34,600	2020	-1,888	-5.5%
City of Sunnyvale[b]	159,100	159,100	151,610	154,600	2020	-2,990	-1.9%
Customer-selected projection 1–10% greater than general plan projection							
Alameda County Water District	405,900	404,700	379,931	359,113		20,818	5.8%
Fremont	*257,100*	*257,200*		*229,213*	2020		
Newark	*53,500*	*53,400*		*49,800*	2020		
Union City	*95,300*	*94,100*		*80,100*	2020		
CWS–South San Francisco District and Westborough Water District[c, d]	83,450	73,660	73,884	68,685	2020	5,199	7.6%
City of Daly City	115,651	127,200	115,651	113,000	2020	2,651	2.3%
City of Hayward	162,800	171,500	162,757	160,300	2025	2,457	1.5%
Town of Hillsborough		11,800	12,708	11,800	2025	908	7.7%
Mid-Peninsula Water District[e]	28,930	28,800	27,997	27,800	2010	197	0.7%

City of Mountain View	81,700	89,600	81,670	75,200	2010	6,470	8.6%
City of Palo Alto	69,199	92,200	69,199	62,880	2010	6,319	10.0%
City of San Bruno	See note f	50,700	48,229	46,400	2020	1829	3.9%
City and County of San Francisco[g]	849,942	903,300	849,942	811,100	2020	38,842	4.8%
City of Santa Clara	140,698	142,100	140,698	129,900	2010	10,798	8.3%
Customer-selected projection more than 10% greater than general plan projection							
City of Burlingame[g,h]	31,900	31,900	34,967	31,500	2010	3,467	11.0%
City of Milpitas[i]	91,400	91,400	88,841	94,400	2020	5,559	-5.9%
Coastside County Water District[j]	24,973	27,100	24,973	21,065	2020	3,908	18.6%
Estero Municipal Improvement District (MID)[j,k]	40,866	32,500	40,096	30,803	2010	9,293	30.2%

NOTE: Most wholesale customer service areas are not contiguous with city limits (or with the city and its planning area), and therefore the population projections from the jurisdictions' general plans and ABAG should be considered as general comparisons only. The following are not included, because the water service area and jurisdictional boundaries are not comparable or the general plan of the corresponding jurisdiction does not provide a comparable population projection: Brisbane, CWS–Bear Gulch, CWS–Mid-Peninsula, Menlo Park, North Coast County Water District, Purissima Hills Water District, Redwood City, San Jose North, Skyline County Water District, and Stanford University.

a The general plan population projection and projection year are the most distant population projection and the year of the most distant population projection available in the general plan or general plan element.
b The service area of Sunnyvale's water district is contiguous with the city limits; however, another water utility (CWS) serves several small areas within the city.
c CWS = California Water Service Company.
d CWS–South San Francisco serves South San Francisco, Colma, a small portion of Daly City, and the unincorporated area of Broadmoor. The water customer estimate for the Westborough Water District is from the district's Urban Water Management Plan. The general plan figure is the combined total projected population in the South San Francisco and Colma general plans (67,400 and 1,285 respectively); the general plan projection year shown (2020) is for South San Francisco, the projection year for Colma is 2005. The *Projections 2005* figure is for South San Francisco and Colma (71,800 and 1,860, respectively).
e The Mid-Peninsula Water District serves Belmont, portions of San Carlos, and unincorporated areas of San Mateo County. The general plan figure is for the city of Belmont, from the 2002 housing element.
f The San Bruno UWMP (City of San Bruno,2007) shows two population projections for 2030: 50,700, based on ABAG's *Projections 2005*, and 48,229, based on the City's Adjusted Draft General Plan.
g UWMP and *Projections 2005* figures are for household population, since the customer-selected figure is for household population.
h Burlingame's water system also serves portions of unincorporated Burlingame and a few properties in the city of San Mateo and town of Hillsborough.
i The general plan population is based on the 2002 Milpitas General Plan.
j The general plan figure is for the city of Half Moon Bay only, from the 1993 Half Moon Bay Local Coastal Program Land Use Plan (Table 9.3, Chapter 9, page 189). In addition to incorporated Half Moon Bay, the Coastside County Water District serves unincorporated areas of Half Moon Bay and the unincorporated communities of El Granada, Miramar, and Princeton by the Sea.
k Estero MID serves Foster City and a portion of the city of San Mateo. The general plan figure is for Foster City.

SOURCES: ABAG, 2004; ACWD, 2005; CWS-South San Francisco, 2006; City and County of San Francisco, 2004; City of Belmont, 2002a; City of Burlingame, 2002a; City of Burlingame, 2005; City of Daly City, 2004a; City of Daly City, 2005; City of East Palo Alto, 1999a; City of East Palo Alto, 2006; City of Foster City, 2001a; City of Fremont, 2003a; City of Half Moon Bay, 1993; City of Hayward, 2002a; City of Hayward, 2005; City of Millbrae, 1998a; City of Millbrae, 2005; City of Milpitas, 2002a; City of Milpitas, 2005; City of Mountain View, 2002a; City of Mountain View, 2005; City of Newark, 2002a; City of Palo Alto, 1998a; City of Palo Alto, 2005b; City of San Bruno, 2003a; City of San Bruno, 2007; City of Santa Clara, 2002a; City of Santa Clara, 2005; City of South San Francisco, 2002a; City of Sunnyvale, 2002a; City of Sunnyvale, 2005; City of Union City, 2002a; Coastside County Water District, 2005; Estero MID, 2005; Hannaford and Hydroconsult, 2004; Mid-Peninsula Water District, 2006; SFPUC, 2005; Town of Colma, 1999a; Town of Hillsborough, 2002a; URS, 2004a, Westborough Water District, 2005.

- The population projections assumed by four of the water customers (Burlingame, Coastside County Water District, Estero Municipal Improvement District, and Milpitas) appear to be more than 10 percent greater than the projections assumed in the respective general plans. The difference in these projections results from the longer 2030 planning horizon used for water planning and differences in the geographic area covered by the two sets of projections. Based on the difference in projections, however, the growth assumed in the demand models of these wholesale customers does not appear to be fully addressed in the general plans of the cities served by these customers.

- Two of the four customers assuming greater population growth than is reflected in the respective general plan also show somewhat greater growth than is forecasted in *Projections 2005*. Both of these customers (Burlingame and Estero MID) serve unincorporated areas outside the city's jurisdictional boundaries and ABAG subregional areas. In addition, Estero MID serves a non-segrable part of the city of San Mateo that is not included with the *Projections 2005* forecast for Foster City used in this comparison. The other customer (Coastside County Water District) assumes less growth than is forecasted in *Projections 2005* for 2030.

Compared to the population forecasts, fewer general plans (or general plan elements) prepared by jurisdictions served by the wholesale customers include comparable employment forecasts. The general plans of 18 cities that are served in whole or part by 16 SFPUC water customers have employment projections that are generally comparable to the water customer-selected employment projections.[21] **Table 7.9** presents a comparison of the employment projections selected by the water customers for use in the WSIP demand models with the employment projected in the general plan for the respective cities. The table shows the difference (in number and percentage) in employment estimates in these two sources. Because the general plans vary considerably in age and have a range of projection years, ABAG's *Projections 2005* forecasts for 2030 are included in the table for reference. The comparison indicates the following:

- The employment projections assumed for four wholesale customers are lower than the projections in their respective general plans. The projection for Millbrae is substantially less (33 percent); the combined projection for CWS-South San Francisco and Westborough Water District is about 10 percent less, and the projection for Daly City is slightly less (1 percent).

- The employment growth assumed for eight water customers is greater than but within 20 percent of the growth assumed in the respective general plans. The water customer-selected employment projections of two wholesale customers (Hayward, and Hillsborough) and of San Francisco are within 10 percent of the projections assumed in their respective general plans, and the customer-selected projections of five wholesale customers (Milpitas, Mountain View, Palo Alto, Santa Clara, and Sunnyvale) are 10 to 20 percent greater than the projections assumed in the respective general plan.

[21] General plans with projection years earlier than 2005 were not considered comparable to the employment projections used in the demand studies. A few general plans did not include population or employment estimates in a form that could dependably be compared to the customer-selected projections (e.g., where employment growth [additional jobs] is discussed without the baseline employment levels being provided). Several wholesale customers have service areas that do not correspond to jurisdictional boundaries closely enough to allow meaningful comparisons with the general plan projections. Table E.3.A.2 of Attachment E.3.A, Appendix E.3, shows the jurisdictions that are assumed to correspond to wholesale customers for purpose of comparing population and employment projections

TABLE 7.9
COMPARISON OF WATER DEMAND EMPLOYMENT ESTIMATES AND GENERAL PLAN EMPLOYMENT ESTIMATES

Customer	*Projections 2005* Employment in 2030	Water Customer Selected Employment Projection for 2030	General Plan Employment Projection for General Plan Projection Year[a]	General Plan Projection Year[a]	Difference: Water Customer Employment and General Plan Employment	% Difference (Water Customer Employment and General Plan Employment)
Customer-selected projection less than or equal to general plan projection						
City of Daly City	29,830	33,981	34,260	2020	-279	-1%
City of Millbrae	9,960	8,009	12,006	2015	-3,997	-33%
CWS–South San Francisco District and Westborough Water District[b,c]	56,080	63,975	71,400	2020	-7,425	-10%
Customer-selected projection 1–20% greater than general plan projection						
City of Hayward	100,430	113,843	108,830	2025	5,013	5%
Town of Hillsborough	2,030	1,380	1,360	2025	20	1%
City of Milpitas	68,940	76,129	65,200	2010	10,929	17%
City of Mountain View	81,110	95,669	84,810	2010	10,859	13%
City of Palo Alto	117,090	114,224	98,500	see note d	15,724	16%

Newark	*24,960*		*26,560*	2020		
Union City	*44,000*		*20,710*	2020		
Subtotal: Fremont, Newark, Union City	*229,370*		*177,800*			
City of East Palo Alto	6,110	8,673	5,940	2010	2,733	46%
Estero Municipal Improvement District (MID)[f]	21,110	31,840	18,760	2010	13,080	70%
City of San Bruno	28,400	25,770	19,180	2020	6,590	34%

NOTE: Most wholesale customer service areas are not contiguous with city limits (or with the city and its planning area), and therefore the employment projections from the jurisdictions' general plans and ABAG should be considered as general comparisons only. The following are not included, because the water service area and jurisdictional boundaries are not comparable or the general plan of the corresponding jurisdiction does not provide a comparable employment projection: Brisbane, Burlingame, CWS–Bear Gulch, CWS–Mid-Peninsula, Coastside County Water District, Daly City, East Palo Alto, Guadalupe Valley MID, Menlo Park, Mid-Peninsula Water District, North Coast County Water District, Purissima Hills Water District, Redwood City, San Jose North, Skyline County Water District, and Stanford University.

a The general plan projection and projection year are the most distant employment projection and the year of the most distant employment projection available in the general plan or general plan element.
b CWS = California Water Service Company.
c CWS–South San Francisco serves South San Francisco, Colma, a small portion of Daly City, and the unincorporated area of Broadmoor.
d Employment estimate for Palo Alto is based on the Housing Element 1999-2006 (City of Palo Alto 2002) estimate that the city will "eventually contain 98,000 to 99,000 jobs within the next several years if the economy recovers in the near term."
e The service area of Sunnyvale's water district is contiguous with the city limits; however, another water utility (CWS) serves several small areas within the city.
f Estero MID serves Foster City and a portion of the city of San Mateo. The general plan figure is for Foster City.

SOURCES: City and County of San Francisco, 2004;City of Daly City, 2004a; City of East Palo Alto, 2001a; City of Foster City, 2001a; City of Fremont, 2003a; City of Hayward, 2002a; City of Millbrae, 1998a; City of Milpitas, 2002b; City of Mountain View, 2002a; City of Newark, 2002a; City of Palo Alto, 2002; City of San Bruno, 2003a; City of Santa Clara, 2002a; City of South San Francisco, 2002a; City of Sunnyvale, 2002a; City of Union City, 2002a; Hannaford and Hydroconsult, 2004; Town of Hillsborough, 2002a; URS, 2004a.

- The employment growth assumed for the remaining four water customers (ACWD, East Palo Alto, Estero Municipal Improvement District, and San Bruno) are between 25 and 70 percent greater than the projections assumed in the respective general plans. The difference in these projections results primarily from the longer 2030 planning horizon used for water planning and, for Estero MID, differences in the geographic area covered by the two sets of projections. Based on the difference in projections, however, the employment growth assumed in the demand models of these wholesale customers does not appear to be fully addressed in the general plans of the cities served by these customers.

These observations, in turn, suggest the following:

- The employment growth assumed in the demand models of most (12 of 16) of the water customers for which comparable general plan projections are available is greater than the growth anticipated in the general plans of the cities served by them. For all but four, however, the difference in projection is less than 20 percent. The reasons for differences between general plan and demand study employment projections included the following:

  – *Differences in horizon years*. For the employment projections surveyed, none of the general plan's horizon years extend to 2030; five of the general plan horizon years are 2010.

  – *Differences in base years*. In almost all cases the demand study projections were prepared after the general plans projections. As a result, the demand study projections reflect to a greater extent the economic boom of the 1990s than do the projections in the general plans. That is, the projections vary as a result of when they were prepared, especially with respect to the economic growth that occurred in the 1990s. For the most part, general plans were prepared before the extent of the economic boom in the 1990s was fully appreciated, and have not been updated to reflect the economic growth that occurred during that period. In two cases (Palo Alto and Estero MID), the demand study's 2001 estimate is greater than the general plan's estimate for 2010. The region subsequently experienced substantial job losses from the "dot com bust" in the first part of this decade; therefore, demand study projections prepared before the "bust" was fully understood somewhat over projected 2005 job levels, compared with ABAG's *Projections 2005*. *Projections 200*5 forecasts substantial recovery over time, however, and by 2030 the employment projections selected for use in the demand study are fairly consistent with those of *Projections 2005* for most jurisdictions.

  – *Differences in the extent to which certain jurisdictions were impacted by the economic boom and subsequent recession.* The three series of ABAG projections reviewed for this analysis reflect evolving information about the extent of job gains and losses in bay area jurisdictions in the late 1990s and early 2000s. Some jurisdictions have sustained successive and substantial job losses whereas others experienced fewer losses or losses have been offset by a degree of economic recovery. The net effect of the two cycles has been that over the WSIP planning horizon, employment expectations, as reflected in projections selected by the water customers, are for the most part generally consistent with the projections presented in jurisdictions' general plans. The projections selected by four wholesale customers, however, are 25 to 70 percent greater than the projections of the respective general plans. Although the relationship between water use and non-residential development depends upon the type of commercial or industrial development that occurs, given the difference in employment assumptions, it is likely that the impacts of employment growth assumed in the WSIP demand forecasts in the jurisdictions served by these wholesale customers has not been fully analyzed in the respective general plan impact analyses.

7.3.4 Growth in Water Demand Compared with Growth in Population and Employment

The relationship between the growth in water demand and growth in population and employment within a water service area is not linear. Because of differences in water use rates for a water agency's different retail customers, depending on such factors as types and sizes of residences, types of businesses, and a range of other variables that can affect consumption rates, a direct per capita or per job relationship is not expected between water demand and the population and employment within a service area.[22] As such, growth in water demand by 2030 would not be expected to track directly with population and employment growth. In addition, differences would be expected between the different wholesale water customers as a result of additional variables including climate and housing density. In general, water demand within the SFPUC service area as a whole would be expected to grow somewhat more slowly than population and employment due to the increasing efficiency of water fixtures expected from plumbing code requirements.

A comparison of the percent change in the SFPUC wholesale customers' water demand projected for 2030 (from Table 7.3) and percent change in population and employment (from Table 7.4) is shown in **Table 7.10** for each wholesale customer and the retail service area. The data presented reflect considerable variability between the water customers; for most the increase in projected water demand is smaller than the increase in projected population or job growth. The exceptions to this are noted and discussed in the customer summaries in Section 7.3.6.

7.3.5 Growth Trends in the Service Area

As part of the review of general plans for the comparisons presented above, a selection of general plans from cities in each of the counties in the SFPUC service area were reviewed in greater depth to ascertain a better understanding of historical growth trends in the service area. The general plans of the following cities were reviewed: East Palo Alto, Fremont, Hayward, Milpitas, Newark, Redwood City, San Francisco, San Mateo, Santa Clara, South San Francisco, Sunnyvale, Union City. These jurisdictions represent a range of sizes and include some of the larger cities and some of the cities projecting relatively substantial increases in water demand by 2030. Information provided in BAWSCA profiles of its member agencies supplemented the review, which is described in more detail in Appendix E, Section E.4 of this PEIR.

The results of this review indicate the following population growth trends in the region:

- Cities in the service area are largely urbanized, most having experienced their most rapid growth in the postwar decades through the 1970s.
- Milpitas and East Palo Alto have experienced high rates of growth more recently.
- San Francisco's population has fluctuated somewhat but on average has been essentially stable over the past 50 years

[22] As described in Section 7.2.2 and in more detail in Appendix E, Section E.2, the SFPUC expressly did not take a per capita approach to projecting 2030 demand, but rather undertook a detailed demand study utilizing actual account data in end-use demand models, which broke down total water use, by water service account, to specific end uses in each wholesale customer service area and San Francisco.

TABLE 7.10
PERCENT CHANGE IN POPULATION, EMPLOYMENT, AND WATER DEMAND 2001 – 2030

Customer	Customer's Demand as Percentage of Total 2030 Demand (%)	Percent Change in		
		Employment (%)	Population (%)	Water Demand (%)

NA = Not applicable; the former Los Trancos County Water District had only residential accounts and Stanford University used other parameters, such as increase in building square footage, to forecast growth in non-residential accounts.

[a] CWS = California Water Service Company
[b] MID = Municipal Improvement District
[c] The former Los Trancos County Water District is now part of CWS–Bear Gulch District; information presented here reflects information in background reports.

SOURCES: URS, 2004a; Hannaford and Hydroconsult, 2004; City of Palo Alto, 2005a; Westborough Water District, 2005.

General plans include policies to manage growth, and many identify strategies consistent with "smart growth" principles, such as encouraging infill development and the redevelopment of previously developed areas, as means to accommodate future growth.

7.3.6 Customer-Specific Summaries

This section summarizes for each wholesale customer and San Francisco the following key information regarding both (1) their water demand and the growth projections used in forecasting that demand, and (2) the consistency between the growth called for in the adopted general plans and that which could be supported by the WSIP.

Summary of Customer-Specific Review

The combined total 2030 water demand for San Francisco and the wholesale customers, taking into account projected plumbing code savings, is 417 mgd. To meet the customer purchase requests, the SFPUC regional water system would provide 284 – 300 mgd,[23] or about 68 – 72 percent of this total 417 mgd service area demand and about 71 – 74 percent of remaining demand after planned conservation programs have been implemented. SFPUC water would supplement other supply sources used by some of its water customers of groundwater, other surface water supplies, and recycled water, as well as conservation savings (refer to Table 7.2).

Overall, the estimated water demand from the SFPUC regional water system through 2030 is about 14 percent higher than 2001 levels. As the summaries by water customer presented below indicate, the increased water that would be available as a result of the WSIP would enable growth to varying degrees in the SFPUC service area. As the summaries and information presented in this chapter indicate, the water customers vary in size, their overall projected demand for 2030, the change the 2030 demand represents in absolute terms (i.e., in mgd) and as a percentage of 2001 demand, and the degree to which they depend on the SFPUC for their water supply. Not surprisingly, considering the different jurisdictions within the service area, expectations about future growth and growth-related constraints and opportunities also vary somewhat. However, the jurisdictions have much in common with respect to growth and growth management. The SFPUC service area is largely urbanized; many of the jurisdictions served cannot grow laterally (because they are bordered by other cities, the bay, and/or protected areas) and have identified infill development, redevelopment, and increasing densities as approaches to accommodating future growth. Such growth is consistent with ABAG principles of smart growth and is, in general, the kind of growth that the WSIP would have the potential to induce or support.

As discussed below, the growth that would be supported by the SFPUC regional water system under the WSIP is generally consistent with ABAG projections for jurisdictions in the service area. Because of differences in the geographic area covered by most of the water customers and the jurisdictions they serve, the population projections of ABAG, general plans, and the SFPUC wholesale and retail demand studies are not expected to match exactly. However, the comparisons presented below do show reasonably consistent expectations in most areas.

[23] As previously noted and discussed in more detail in Chapter 3 of this PEIR, for planning purposes the high range purchase estimate of 300 mgd was selected as the target goal for the average annual water delivery by 2030.

The age of the jurisdictions' general plans vary considerably, as previously noted. Due to the WSIP's longer planning horizon (especially considering the age of some of the local general plans), the WSIP would support a degree of growth that has not been addressed in adopted general plans. The effects of planned growth and growth that is not addressed in adopted land use plans of jurisdictions in the SFPUC service area are discussed in Section 7.4, below.

Customer Summaries

Each customer summary provides the following:

- Total 2030 demand
- Change in demand from 2001 (mgd and percent)
- Percent of projected demand that would be met by the SFPUC
- Customer's 2030 purchase estimate
- Change in purchases from the SFPUC from 2001 (mgd and percent)
- Customer's current supply assurance
- How projected growth in population and employment compares with growth in water demand
- Consistency of population and employment (for general plans that present employment projection data) assumed in developing water demand with projected growth contained in general plans.

The discussion of individual customers presented in this section indicates that different ABAG series result in markedly different projections for some jurisdictions. For an illustration of the differences in growth rates forecasted for the nine Bay Area counties and the four counties of the SFPUC service reflected in ABAG's last three projections sets, see Figures E.3.1 and E.3.2 in Appendix E, Section E.3.2.

Unless otherwise specified, the ABAG projections referenced in this section are from *Projections 2005* (ABAG, 2004). The demand study referenced is the *SFPUC Wholesale Customer Water Demand Projections Technical Report* (URS, 2004a), except for the discussion of the SFPUC retail service area. The source of retail service area demand information is the report entitled *City and County of San Francisco Retail Water Demands and Conservation Potential* (Hannaford and Hydroconsult, 2004).

ACWD

The ACWD's total 2030 water demand, based on the demand study and taking into account plumbing code savings, is 59.3 mgd. This represents a 16 percent increase in total service area demand over the 2001 base-year demand estimate. ACWD uses multiple supply sources to meet its water demand. In 2030, ACWD projects it will purchase about 23 percent of its water demand and about 25 percent of remaining demand from the SFPUC after conservation has been implemented. The SFPUC portion of ACWD's supply would supplement ACWD's projected conservation savings and use of groundwater, other surface water supplies, and recycled water (refer to Table 7.2) to meet future demand increases. ACWD's 2030 estimated purchase of 13.76 mgd from the SFPUC represents a 1.77 mgd, or 15 percent, increase over its 2001 purchases. ACWD's current water supply assurance is 13.76 mgd.

Population projections used in the demand study are generally consistent with the growth cited in the general plans of the three cities served by ACWD (Fremont, Newark, and Union City) and the growth projected for the three cities by ABAG. The population projections used in the demand study for 2030 are approximately 6 percent higher than those presented in the cities' general plans (combined), which is likely attributable to the longer planning horizon of the WSIP (2030 compared to 2020 for the general plans). The population estimate in the demand study is approximately 6 percent less than is projected in ABAG's *Projections 2005* for the three cities in 2030.

The employment projection used in the demand study is about 25 percent higher than the (combined) employment projections cited in the cities' general plans, but is generally consistent with (about 3 percent less than) the combined ABAG *Projections 2005* employment projection for the three cities. This may be partially attributable to the longer planning horizon of the WSIP (and ABAG). The projections in Table 7.9 indicate that the ABAG projections for Fremont are 23 percent higher than the general plan projection; the ABAG projection for Newark is about 6 percent less than the general plan projection; and the ABAG projection for Union City is more than double that of the general plan. Business and industrial demand accounts for approximately 20 percent of ACWD's projected 2030 demand (SFPUC, 2006).

City of Brisbane

Brisbane's total 2030 water demand, taking into account plumbing code savings, is 0.93 mgd. This represents a 111 percent increase in total service area demand over the 2001 base-year demand estimate. The SFPUC is Brisbane's only source of potable water supply. In 2030, Brisbane projects it will purchase 96 percent of its total water demand from the SFPUC and 100 percent of demand after conservation has been implemented, based on Brisbane's purchase estimate (refer to Table 7.2). Brisbane's 2030 estimated purchase of 0.89 mgd from the SFPUC represents a 0.50 mgd, or 128 percent, increase over its 2001 purchases. Brisbane's current water supply assurance is 0.46 mgd.

The projected 111 percent increase in service area demand for Brisbane is apparently primarily due to the city's expectation of substantial job growth in the 2001- 2030 planning period. The demographic projections used in the demand model, which were provided by the City of Brisbane, assume a 45 percent increase in population and a 417 percent increase in employment by 2030.

Both the City of Brisbane water district and Guadalupe Valley MID provide water to the city of Brisbane; therefore, this discussion combines the 2030 projections used in the demand study for both customers to allow a comparison with projections developed for the city. The 2030 population assumed for Brisbane in the demand study is 4,606. The combined population projection used in the demand study for 2030 for the two districts is 6,164, which is 18 percent higher than the population projected by ABAG for Brisbane of 5,240 (ABAG, 2004). The Brisbane General Plan, adopted in 1994, does not have a comparable population projection. The 1999–2006 housing element cites an ABAG estimate of 4,010 for 2005, but does not project beyond that year.

The combined employment projection for the two water customers is about 24 percent higher than ABAG's *Projections 2005* forecast for Brisbane in 2030. The combined projections for the two water districts represent a 139 percent increase in jobs from 2005[24] to 2030. This projected increase, while substantial, is slightly lower than the 149 percent increase predicted for Brisbane by *Projections 2005* for the same period.

Both water districts are operated by the City of Brisbane and both used city population and employment projections as the source of projections in the water demand study. If a water customer selected a projection source other than ABAG for the demand study, they were asked to provide the source and the reason the source was more appropriate for them than ABAG.[25] Brisbane noted that ABAG projections do not divide the city's population into the two separate water districts. The selected population projections were based on the number of available units in each district under the zoning ordinance and population density assumptions (persons per unit) using information from the Brisbane Building and Planning Department and the housing element, and an additional population estimate based on the 2000 U.S. Census data. The city identified 1,366 additional units for the two districts (660 in the Brisbane service area and 706 in the Guadalupe Valley service area) with an assumed density factor of 2.2 persons per unit, for a projected additional population of 3,005 above the initial population of 3,159. Thus, the projection used appears to be consistent with existing planning and zoning within the City.

City of Burlingame

Burlingame's total 2030 water demand, taking into account plumbing code savings, is 4.9 mgd. This represents a 3 percent increase in total service area demand over the 2001 base-year demand estimate. The SFPUC is Burlingame's only source of potable water supply. In 2030, Burlingame estimates it will purchase 96 percent of its total water demand from the SFPUC and 100 percent of demand after conservation has been implemented, based on Burlingame's purchase estimate (refer to Table 7.2). Burlingame's 2030 estimated purchase of 4.70 mgd from the SFPUC represents a 0.06 mgd, or 1 percent, increase over its 2001 purchases. Burlingame's current water supply assurance is 5.23 mgd.

Burlingame's water demand projections assumes 16 percent growth in population and 16 percent growth in employment by 2030. The population projection used for Burlingame in the demand study is about 11 percent higher than the growth cited in the 2002 general plan housing element for 2010, and 10 percent higher than the 2030 population estimated in ABAG's *Projections 2005* for the city and its sphere of influence. Because the housing element projection only extends to

24 The 2005 estimates were interpolated from the employment figures in the SFPUC demand study for this analysis, as shown in Table E.3.4 of Appendix E, Section E.3.

25 The request for projection source information was part of the SFPUC Capital Improvement Project Wholesale Customer Demand Projections/DSS Modeling Wholesale Customer Population Projection Selection Form submitted by each wholesale customer.

2010, it would be expected to be less than the population for 2030 used to derive water demand projections. The difference between the customer-selected projections used in the demand study and ABAG projections apparently stems from ABAG's lowered expectations about population growth in Burlingame. The demand study cites as its source ABAG *Projections 2002*, which expected more growth in the city than does *Projections 2005*. For example, *Projections 2002* forecasted a 2025 population of 33,600, and *Projections 2005* forecasts a 2025 population of 31,700, and the population now expected in *Projections 2005* in 2030 was expected in 2015 in *Projections 2002*. (*Projections 2002* does not provide 2030 estimates for a direct comparison of projections for 2030.) Burlingame's UWMP, published in 2005, cites *Projections 2005* as the projection source and uses the lower 2030 population estimate of 31,900. In addition, 2 percent of Burlingame's water service area is unincorporated San Mateo County, for which segregable ABAG and San Mateo County General Plan projections are not available.

Given the moderate expectations for growth assumed in the demand model (16 percent over 29 years), the revisions to ABAG's expectations of growth for the region, and the much shorter planning horizon contained in the city's housing element, the growth assumed in the demand model is generally consistent with the local and regional planning agencies.

CWS–Bear Gulch District

The total 2030 water demand estimated for the CWS–Bear Gulch District, taking into account plumbing code savings, is 14.06 mgd. This estimate includes the projected 2030 demand of 0.14 mgd of the former Los Trancos County Water District, which is now part of CWS–Bear Gulch, and represents a 4 percent increase in total service area demand over the 2001 base-year demand estimate. CWS–Bear Gulch District uses multiple services to meet its water demand. In 2030, CWS–Bear Gulch estimates it will purchase about 84 percent of the district's total water demand from the SFPUC and about 90 percent of remaining demand after conservation has been implemented, based on CWS–Bear Gulch District's purchase estimate (refer to Table 7.2). CWS–Bear Gulch District's 2030 estimated purchase of 11.76 mgd (including the former Los Trancos district) from the SFPUC represents a 0.53 mgd, or 5 percent, increase over the combined CWS–Bear Gulch and Los Trancos County Water District 2001 purchases. The current water supply assurance for the three CWS districts combined (i.e., including CWS-Mid Peninsula and CWS–South San Francisco) is 35.5 mgd.

Because the CWS–Bear Gulch District serves many communities, including Atherton, Menlo Park, Portola Valley, part of Woodside, and areas of unincorporated San Mateo County (i.e., the communities of West Menlo Park, Ladera, North Fair Oaks, and Menlo Oaks), its population projections are not comparable to those of ABAG or the respective jurisdictions' general plans.

The CWS–Bear Gulch District's UWMP, published in December 2005, shows a much lower 2030 population estimate (59,220) than the customer-selected estimate shown in the demand study (73,719). The UWMP's estimate of the district's 2004 population, 54,350, is also substantially lower than the 2001 base-year population of 66,197 used in the demand study. The differences appear to result from the different methods used to estimate the population of the service area, which, as noted, serves parts of a number of incorporated cites and unincorporated parts of the county. The UWMP states that the population estimates are different because “initial conditions for the DSS model hav[e] changed since the DSS model was first created and when [the UWMP] was written.” The UWMP notes that, although the “initial conditions” for the two estimates changed, the rates of growth of both projections are similar. A comparison of expected growth from 2004 to 2030 in the UWMP, based on the estimates cited above, shows the population is expected to grow by about 9 percent, and the expected growth from 2001 to 2030 in the wholesale demand study is about 11 percent. Based on a comparison of the SFPUC’s share of the UWMP’s planned 2030 water supply and the 2030 purchase estimate, no change is expected in water demand. The UWMP estimates 14,708 acre-feet per year, or about 11.76 mgd, from the SFPUC. This is equivalent to the combined 2030 purchase estimates of CWS–Bear Gulch (11.6 mgd) and the former Los Trancos County Water District.

CWS–Mid-Peninsula District

The total 2030 water demand estimated for the CWS–Mid-Peninsula District, taking into account plumbing code savings, is 18.1 mgd. This represents a 5 percent increase in total service area demand over the 2001 base-year demand estimate. The SFPUC is CWS-Mid Peninsula’s only source of potable water supply. In 2030, CWS–Mid-Peninsula District estimates it will purchase about 95 percent of its total water demand from the SFPUC and 100 percent of demand remaining after conservation has been implemented, based on CWS-Mid-Peninsula District’s purchase estimate (refer to Table 7.2). CWS–Mid-Peninsula District’s 2030 estimated purchase of 17.24 mgd from the SFPUC represents a 0.49 mgd, or 3 percent, increase over its 2001 purchases. The current combined water supply assurance for the three CWS districts is 35.5 mgd.

Because the CWS–Mid-Peninsula District serves portions of San Carlos and San Mateo and adjacent unincorporated areas of San Mateo County, including the Highlands and Palomar Park, its population and employment projections are not comparable to those of ABAG or the respective jurisdiction’s general plans since they cover different geographic areas.

CWS–South San Francisco District

The CWS–South San Francisco District’s 2030 water demand, taking into account plumbing code savings, is 9.9 mgd. This represents an 11 percent increase in total service area demand over the 2001 base-year demand estimate. CWS–South San Francisco District’s uses multiple supply sources to meet its water demand. In 2030, CWS–South San Francisco estimates it will purchase about 81 percent of its total demand from the SFPUC and about 85 percent of the district’s remaining demand after conservation has been implemented, based on CWS–South San Francisco’s purchase estimate (refer to Table 7.2). CWS–South San Francisco District’s 2030 estimated purchase of 7.97 mgd from the SFPUC represents a 0.41 mgd, or 5 percent, increase over its 2001 purchases. The current combined water supply assurance for the three CWS districts is 35.5 mgd.

Both CWS–South San Francisco and Westborough County Water District provide water to South San Francisco; therefore, this discussion combines the 2030 population projections for the two water customers to allow a comparison with the city’s general plan and ABAG projections for the city. (The 2030 customer-selected projection for CWS-South San Francisco [59,584] is based on the 2004 demand study. The 2030 projection for Westborough [14,300] is from Westborough's 2005 UWMP, based on a letter from the water district to the SFPUC [Westborough Water District, 2007] indicating that the population estimates in the UWMP more accurately reflect the district's service area than did the population estimates used in the demand study.) The combined estimated 2030 population to be served by the two wholesale customers (73,884) is about 8 percent higher than that projected in the general plan and about the same as (0.3 percent higher than) ABAG's 2030 projections for the city.

The combined employment projection for the two water customers in the demand study is about 10 percent lower than the employment projection cited in the city's general plan, and about 14 percent higher than ABAG's *Projections 2005* 2030 projections.

Coastside County Water District

The Coastside County Water District's (Coastside CWD) total 2030 water demand, taking into account plumbing code savings, is 3.2 mgd. This represents a 25 percent increase in total service area demand over the 2001 base-year demand estimate. Coastside CWD uses multiple sources to meet its water demand. In 2030, Coastside CWD estimates it will purchase 70 to 94 percent of its total water demand from the SFPUC and 74 to 100 percent of remaining demand after conservation has been implemented, based on Coastside CWD's purchase estimate (refer to Table 7.2). Coastside CWD's 2030 estimated purchase of 2.24 – 3.02 mgd from the SFPUC represents a 0.44 – 1.22 mgd, or 24 – 68 percent, increase over its 2001 purchases. The high-end of its purchase estimate range assumes loss of all local water sources (i.e., groundwater and other surface water). Coastside CWD's current water supply assurance is 2.18 mgd.

The customer-selected population projection used for Coastside CWD in the demand study is 19 percent higher than the population of 21,065 for 2020 cited in Half Moon Bay's 1993 Local Coastal Program Land Use Plan (which serves as the general plan), and about 8 percent lower than the 2030 ABAG projections for Half Moon Bay and unincorporated Half Moon Bay. In addition to the city itself, Coastside CWD serves unincorporated areas of Half Moon Bay and the unincorporated communities of El Granada, Miramar, and Princeton by the Sea. The difference in geographic area covered by the land use plan and the water district may account for the differences in the population projections. In addition, some of the district's increase in SFPUC water purchase is needed to replace existing local supplies that, because of water quality concerns, are no longer suitable for use.

The 2030 employment projection used for Coastside CWD in the demand study is about 20 percent less than the combined *Projections 2005* employment forecasts for Half Moon Bay and unincorporated Half Moon Bay for 2030 (8,490). The 1993 Local Coastal Program Land Use Plan does not have a comparable employment projection.

Half Moon Bay currently is in the process of updating its general plan. According to information about the public review draft available on the city's website, the updated general plan will incorporate provisions of Measure D, a growth control measure adopted by voters in 1999.

Measure D limits residential growth in the city to 1 percent per year, with an optional 50 percent additional growth (i.e., 1.5 percent) allowed in the downtown area (City of Half Moon Bay, 2005a). A 1991 growth control measure, Measure A, was incorporated into the adopted 1993 Land Use Plan; however, Measure D further restricts residential growth (City of Half Moon Bay, 2005b). The Draft Local Coastal Program Amendment posted on the city's website states that ABAG's *Projections 2005* expects 820 new households for Half Moon Bay by 2025, reflecting a 1.1 percent annual growth rate, and another 200 units in the unincorporated coastside area. The draft plan states that ABAG's projection for Half Moon Bay and unincorporated Half Moon Bay shows a combined population of about 26,500 in 2025 (City of Half Moon Bay, 2005c).

City of Daly City

Daly City's total 2030 water demand, taking into account plumbing code savings, is 9.1 mgd. This represents a 5 percent increase in total service area demand over the 2001 base-year demand estimate. Daly City uses multiple supply sources to meet its water demand. In 2030, Daly City estimates it will purchase 54 to 80 percent of its total water demand from the SFPUC and 57 to 85 percent of remaining demand after conservation has been implemented, based on Daly City's purchase estimate (refer to Table 7.2). Daly City's 2030 estimated purchase of 4.90 – 7.32 mgd from the SFPUC represents a -0.18 – 2.24 mgd, or -4 – 44 percent, change from its 2001 purchases. The purchase estimate range reflects a range of potential groundwater usage established under a pilot project, from the sustainable yield (3.76 mgd) to the lowest annual production yield (1.34 mgd). Daly City's current water supply assurance is 4.29 mgd.

The customer-selected population projection used for Daly City in the demand study is about the same as (2 percent higher than) the buildout population cited in the city's general plan, and 9 percent lower than the 2030 population projected by ABAG.

The employment projection for Daly City in the demand study is about the same as (1 percent less than) the employment projection cited in the city's general plan, and about 14 percent higher than the ABAG *Projections 2005* employment projection.

City of East Palo Alto

East Palo Alto's total 2030 water demand, taking into account plumbing code savings, is 4.8 mgd. This represents a 92 percent increase in total service area demand over the 2001 base-year demand estimate. The SFPUC is East Palo Alto's only source of potable water supply. In 2030, East Palo Alto estimates it will purchase 97 percent of its total water demand from the SFPUC and 100 percent of remaining demand after conservation has been implemented, based on East Palo Alto's purchase estimate (refer to Table 7.2). East Palo Alto's 2030 estimated purchase of 4.64 mgd from the SFPUC represents a 2.60 mgd, or 127 percent, increase over its 2001 purchases. East Palo Alto's current water supply assurance is 1.96 mgd.

East Palo Alto's customer-selected projections used to derive water demand assume 34 percent growth in population and 164 percent growth in employment by 2030. Besides the projected population and employment growth assumed in the demand model, the projected 92 percent increase in demand reflects expected new commercial and residential development having higher per-account water use rates than existing accounts. To accommodate this new development, two new account categories were created for the demand model, as follows:

- a new commercial account category was created to represent additional water demand of 1.2 mgd from new commercial uses, which are assumed to have a use rate of 5,000 gallons per account per day, in the Ravenswood Business District
- a new residential account category was created to represent additional water demand of 0.3 mgd from new single-family residences in the Ravenswood Business District

In more general terms the East Palo Alto's Urban Water Management Plan attributes the near doubling of demand by 2030 to a shift in development density in the city. The UWMP states that the city is shifting from traditional single family dwelling units to higher density multiple-family units that is expected to substantially increase water demand without a commensurate increase in the number of water connections.

The population projection used for East Palo Alto in the demand study is about 6 percent less than the growth expected by 2020 in the city's general plan and 25 percent less than that projected by ABAG's *Projections 2005* for East Palo Alto in 2030. This substantial difference is likely due to adjustments made to the demand study projections to account for the portion of residential customers in East Palo Alto that are served by two other water districts (which are not BAWSCA members and do not receive SFPUC water): the Palo Alto Mutual Water Company and the O'Connor Tract Mutual Cooperative Water Company. According to the demand study, the single- and multi-family residential accounts served by these two water companies were subtracted from the total population served by East Palo Alto (URS, 2004a).

The customer-selected employment projection for East Palo Alto used in the demand study is substantially higher (about 46 percent) than the employment projection cited in the city's general plan (and about 42 percent higher than the ABAG *Projections 2005* employment projection). A combination of the following factors likely accounts for the difference:

- The Ravenswood Business District, a proposal to amend the general plan and zoning ordinance to redevelop 146 acres in the northeast section of East Palo Alto, is not reflected in the general plan projections but is reflected in the WSIP projections. The city began preparing an environmental impact report on the Ravenswood Business District in 2002; as then envisioned, the development would have resulted in an estimated 1,800 jobs above general plan employment projections.[26] Economic changes have likely slowed the pace at which revitalization can occur in East Palo Alto, and the Ravenswood Business District is currently being redefined.
- The difference is partially attributable to the longer planning horizon of the WSIP (2030 versus 2010) and changing expectations about employment growth as reflected in different

[26] The Ravenswood Business District area identified in the administrative draft EIR for the project consists of about 146 acres of land, exclusive of streets. Existing land uses within the area include a variety of industrial, commercial, residential, and agricultural uses; approximately 45 acres are vacant and undeveloped.

ABAG projections series. The customer-selected projection is consistent with (about 6 percent less than) *Projections 2002* employment forecasts for 2030.

- The base year employment projection identified in the general plan is 2,760 for year 2000; the base year employment estimate in the demand study is 3,289 for year 2001. The latter estimate may more accurately reflect the substantial increases in job growth that occurred in the late 1990s.

Commercial and industrial demand accounts for approximately 41 percent of East Palo Alto's projected 2030 demand (SFPUC, 2006).

Estero MID

The Estero MID service area includes Foster City and a part of the City of San Mateo. Estero's total 2030 water demand, taking into account plumbing code savings, is 6.8 mgd. This represents a 17 percent increase in total service area demand over the 2001 base-year demand estimate. The SFPUC is Estero MID's only source of potable water supply. In 2030, Estero MID estimates it will purchase 91 – 100 percent of its total water demand from the SFPUC and 100 percent of remaining demand after conservation has been implemented, based on Estero MID's purchase estimate (refer to Table 7.2). Estero MID's 2030 estimated purchase of 6.20 – 6.80 mgd from the SFPUC represents a 0.58 – 1.18 mgd, or 10 – 21 percent, increase over its 2001 purchases. Estero MID's water supply assurance contract does not specify a limit on purchase.

The customer-selected 2030 population projection used for Estero MID in the demand study is 30 percent higher than the population projection in the Foster City General Plan housing element (adopted in 2001),[27] and about 23 percent higher than the 2030 Foster City population estimated by ABAG in *Projections 2005*. The difference between the demand study and general plan projections is probably due both to the general plan's horizon year of 2010 and the fact that Estero MID serves more than Foster City. (According to the wholesale customer demand study, about 10 percent of the water district is within the city of San Mateo and 90 percent is within Foster City. However, a comparison of the population estimates used for the demand study with the 2000 census for Foster City and ABAG's near term and 2030 projections indicates a population difference of about 20 percent between the water district and Foster City, as discussed below.)

A comparison of Estero's 2001 base-year population (34,568) with the 2000 census population for Foster City (28,756) (U.S. Census Bureau, 2000) shows that the population of the Estero MID service area was roughly 20 percent higher than Foster City's for the base year. A comparison of the population estimates used for Estero in the demand study with *Projections 2005* estimates for Foster City shows that the district's 2001 base-year population is about 20 percent higher than the 2000 population,[28] 16 percent higher than the projection for 2005, and, as noted, about 23 percent higher than ABAG's projection for 2030. This fairly consistent relationship between Foster City

[27] The General Plan land use element (amended in 1999) also includes population and employment projections. The land use element projects a 2005 population of 31,471, slightly higher than the later housing element projection for 2010, and 27 percent less than the 2030 population forecast used in the demand study.

[28] *Projections 2005* shows the 2000 census figure for Foster City.

and Estero population estimates suggests that the difference between the demand study and ABAG projections for 2030 is due to the difference in geographic area covered by the two sets of projections. Similarly, this difference in geographic area partially accounts for the difference between the water customer’s projected 2030 population and the Foster City General Plan population at buildout. As noted, another important difference is in the shorter-term planning horizon (2010) used in the General Plan projection. Residential demand accounts for a little more than half (52 percent) of Estero’s 2030 demand (SFPUC, 2006).

The customer-selected employment projection for Estero MID in the demand study is substantially higher (about 70 percent) than the employment projection cited in Foster City’s 2001 housing element[29] and the ABAG *Projections 2005* employment projection (about 51 percent higher). As with the population projections, the difference is due to the difference in the geographic area covered by the sets of projections and, for the general plan, the longer planning horizon of the WSIP (2030 versus 2010). An additional factor contributing to the difference between employment projections is the more dynamic nature of employment in the area (compared to population) in the late 1990s and early 2000s. The Foster City housing element employment projection is based on ABAG’s *Projections 2000* (ABAG, 1999), whereas the demand study used the employment projections in *Projections 2002*. A comparison of these two ABAG projections sets show that *Projections 2002* expected continued strong job growth in Foster City into the future (15 to 18 percent more jobs in 2005, 2010, 2015, and 2020 than were projected for those years in *Projections 2000*). The influence of the economic boom on *Projections 2002* thus contributed to some of the difference between the general plan and water demand study projections.

Projections 2005, by contrast, reflects improving information about the effects of dramatic job losses that were incurred in the area, with job forecasts for Foster City 23 to 33 percent lower than those of *Projections 2002* for the years that can be compared (2005, 2010, 2015, 2020, and 2025). *Projections 2005* employment forecasts for San Mateo also are 15 to 30 percent lower than those in *Projections 2002*, for the years that can be compared. This would account for the greater difference between customer-selected and ABAG employment projections than would be expected due to differences in geographic area covered by the two projections. As discussed in Section 7.3.2, above, *Projections 2005* forecasts a greater increase in jobs over time than was forecasted in *Projections 2002*, so that by 2025 (the last year the two sets can be compared) there is less difference between projections than there is in the near-term.

Commercial/institutional and industrial demand accounts for approximately 12 percent of Estero’s projected 2030 demand (SFPUC, 2006).

29 The General Plan land use element (amended in 1999) also includes employment projections. The land use element projects a 2010 employment projection of 21,460, somewhat higher than the later housing element projection, and about 48 percent less than the 2030 employment forecast used in the demand study.

Guadalupe Valley MID

Guadalupe Valley MID serves part of the City of Brisbane. The district's total 2030 water demand, taking into account plumbing code savings, is 0.81 mgd. This represents a 153 percent increase in total service area demand over the 2001 base-year demand estimate. The SFPUC is Guadalupe Valley MID's only source of potable water supply. In 2030, Guadalupe Valley MID estimates it will purchase 88 percent of its total water demand from the SFPUC and 100 percent of remaining demand after conservation has been implemented, based on Guadalupe Valley's purchase estimate (refer to Table 7.2). Guadalupe Valley MID's 2030 estimated purchase of 0.71 mgd from the SFPUC represents a 0.41 mgd, or 138 percent, increase over its 2001 purchases. Guadalupe Valley MID's current water supply assurance is 0.52 mgd.

The projected 153 percent increase in service area demand for Guadalupe Valley MID is apparently due to the City of Brisbane's expectation of substantial population growth in the 2001-2030 in the area served by this water district. The demographic projections used in the demand model, which were provided by Brisbane, assume a 249 percent increase in population and a 28 percent increase in employment by 2030.

The customer-selected projections used for Guadalupe Valley MID in the demand study assume a population of 1,558 in 2030 and 5,668 jobs. Since Guadalupe Valley MID serves only part of Brisbane, the population and employment projections used in the demand study are not comparable to the city as a whole. Refer to the discussion under Brisbane for a comparison of combined water district projections with general plan and ABAG projections.

City of Hayward

Hayward's total 2030 water demand, based on the demand study and taking into account plumbing code savings, is 28.7 mgd. This represents a 49 percent increase in total service area demand over the 2001 base-year demand estimate. The SFPUC is Hayward's only source of potable water supply. In 2030, Hayward estimates it will purchase 97 percent of its total water demand from the SFPUC and 100 percent of remaining demand after conservation has been implemented, based on Hayward's purchase estimate (refer to Table 7.2). Hayward's 2030 estimated purchase of 27.95 mgd from the SFPUC represents a 10.34 mgd, or 59 percent, increase over its 2001 purchases. Hayward's water supply assurance contract does not specify a limit on purchases.

The percentage increase in water demand for Hayward projected for 2030 (49 percent) is considerably greater than the projected growth in both population and employment assumed in the demand model (16 percent and 30 percent, respectively). Given both the substantial increase in total demand projected for Hayward (9.4 mgd) and the substantial difference in the expected demand and population and employment growth rates, this discrepancy warrants additional discussion.

Hayward residents have among the lowest rates of per capita water use compared with residents in other communities served by the SFPUC. This is a consequence of past development patterns that have included high density development with little or no landscaping. The general plan states that during development surges that occurred from the 1950's to mid 1980's, because few development standards existed, "some apartment buildings were poorly designed with as many units as possible loaded on the site… and there was little or no play space for children…" (City of Hayward, 2002a). In addition, single family homes typically were located on smaller lots compared with other parts of the Bay Area and many had minimal, if any, landscaping. The city currently expects that new housing developed in the city will have higher water use rates due to comparatively larger lots with more landscaping. The city is also encouraging renovation efforts that include landscaping common areas within neighborhoods and assisting homeowners with rehabilitating their private properties. As a result, per capita water use rates are expected to increase somewhat (City of Hayward, 2005). According to the general plan, city planners also are encouraging development consistent with smart growth principles, including infill development and higher densities in urban core areas. Because of the city's experience with poorly planned, designed, and constructed high density development in the past, the city has met with some resistance regarding higher densities. However, successful transit oriented developments have demonstrated that well planned development can accommodate higher densities without diminishing quality of life for resident.

The demand model incorporated adjustments in recognition of these factors. The higher water demand projected for 2030 results from adjustments made to account for expected changes in water usage for new and existing residential accounts, as well as changes expected in some industrial accounts. To accommodate the anticipated changes, in response to input from the city, the demand model was adjusted to include several new account categories, as follows:

- A new category of residential account was created to accommodate the addition of more than 2,000 new homes the city expects to be developed. These new residences are expected to be on larger lots than existing housing, include more landscaping, and have a higher per capita water use rate.
- A new account category was created for newly renovated single family homes, which have more landscaping than previously and use more water.
- Based on the city's general plan, which indicates that the city expects to attract high technology manufacturing industries, a new account category was added for higher-demand commercial and industrial uses. The higher water demand expected from this new industrialization was incorporated into the model.

Hayward's demand model also was adjusted to increase the expected percentage of unaccounted-for water in its system. The five-year average for the Hayward water system was 7.2 percent. A 9 percent unaccounted-for water was used in the demand study because Hayward's unaccounted-for water includes water used for hydrant flushing and other maintenance purposes. Although many agencies categorize these uses as "other," Hayward does not. Because these types of uses are difficult to anticipate, Hayward adjusted its unaccounted-for water to 9 percent, consistent with its 2001 UWMP (URS, 2004a). The SFPUC reviewed each of the requests for adjustments against current billing records and other documentation, including the city's Water Master Plan and general plan, before making a determination that the requested adjustments were reasonable.

The customer-selected population projection used for Hayward in the demand study is generally consistent with the growth cited in the city's general plan and the growth expected by ABAG. The 2030 Hayward population used in the demand study is approximately 2 percent higher than the population identified in the city's general plan and about 5 percent lower than projected by ABAG.

The employment projection for Hayward in the demand study is generally consistent with (about 5 percent higher than) the employment projection cited in the city's general plan and about 13 percent higher than ABAG's *Projections 2005* 2030 projections.

Town of Hillsborough

Hillsborough's total 2030 water demand, taking into account plumbing code savings, is 3.9 mgd. This represents a 5 percent increase in total service area demand over the 2001 base-year demand estimate. The SFPUC is Hillsborough's only source of potable water supply. In 2030, Hillsborough estimates it will purchase 95 percent of its total water demand from the SFPUC and 100 percent of remaining demand after conservation has been implemented, based on Hillsborough's purchase estimate (refer to Table 7.2). Hillsborough's 2030 estimated purchase of 3.70 mgd from the SFPUC represents a 0.14 mgd, or 4 percent, increase over its 2001 purchases. Hillsborough's current water supply assurance is 4.09 mgd.

The customer-selected population projection used for Hillsborough in the demand study is generally consistent with the growth identified in the city's general plan and the growth expected by ABAG. The 2030 Hillsborough population used in the demand study is approximately 8 percent higher than both the population identified in the city's general plan (for 2025) and that projected for 2030 by ABAG. The difference between the demand study and ABAG 2030 projections is probably due to the fact that the Hillsborough's water service area includes a portion of unincorporated San Mateo County, in addition to the town itself. A comparison of Hillsborough's 2001 base-year population for the water demand projections with ABAG projections for 2000 and 2005 show that the difference in ABAG and Hillsborough projections is about the same in the base year as in 2030: Hillsborough's 2001 population is about 7 percent higher than ABAG's 2000 population and 6 percent higher than ABAG's 2005 population. This suggests that the difference between the projections may be due to differences in the geographic area covered.

The employment projection for Hillsborough used in the demand study is about the same as (1 percent more than) the projection for 2025 in the town's general plan. The projection is considerably less (32 percent) than ABAG's projection for 2030.

City of Menlo Park

The City of Menlo Park, represented by the Menlo Park Municipal Water District estimates a total 2030 water demand, taking into account plumbing code savings, of 4.7 mgd. This represents a 15 percent increase in total service area demand over the 2001 base-year demand estimate. The SFPUC is Menlo Park's only source of potable water supply. In 2030, Menlo Park estimates it will purchase 97 percent of the water district's total water demand from the SFPUC and

100 percent of remaining demand after conservation has been implemented, based on Menlo Park's purchase estimate (refer to Table 7.2). Menlo Park's 2030 estimated purchase of 4.54 mgd from the SFPUC represents a 0.97 mgd, or 27 percent, increase over its 2001 purchases. Menlo Park's current water supply assurance is 4.46 mgd.

Because the water district serves less than half of the city, the population projection used for Menlo Park in the demand study is not directly comparable to general plan or ABAG projections for the city. Nevertheless, the 2030 water demand population projection is consistent with growth identified in the city's general plan, assuming the district would serve the same percentage of the city's population. In 2001, the water district served 12,153—or 39 percent—of the city's more than 30,785[30] residences. The customer-selected population used in the demand study for 2030 (13,655) is 39 percent of the general plan buildout population (35,285, projected for 2010). ABAG projects a population for Menlo Park of 41,100 in 2030, 16 percent more than the population projected at general plan buildout. (The CWS–Bear Gulch District, discussed above, and O'Connor Water District, which is not an SFPUC customer, serve the remaining portions of Menlo Park.)

Mid-Peninsula Water District

The Mid-Peninsula Water District primarily serves the City of Belmont, although it also serves a small part of unincorporated San Mateo County and the City of San Carlos. Mid-Peninsula's total 2030 water demand, taking into account plumbing code savings, is 3.8 mgd. This represents a 4 percent increase in total service area demand over the 2001 base-year demand estimate. The SFPUC is the Mid-Peninsula Water District's only source of potable water supply. In 2030, the District estimates it will purchase 97 percent of its total water demand from the SFPUC and 100 percent of remaining demand after conservation has been implemented, based on Mid-Peninsula's purchase estimate (refer to Table 7.2). Mid-Peninsula Water District's 2030 estimated purchase of 3.70 mgd from the SFPUC represents a 0.24 mgd, or 7 percent, increase over its 2001 purchases. Mid-Peninsula Water District's current water supply assurance is 3.89 mgd.

The customer-selected population projection used for the Mid-Peninsula Water District in the demand study is about the same as (approximately 1 percent higher than) the projection cited in the 2002 Belmont housing element for 2010, and 3 percent lower than the 2030 population projected by ABAG for Belmont.

The employment projection for Mid-Peninsula Water District in the demand study is substantially higher (about 58 percent) than ABAG's *Projections 2005* projections for Belmont in 2030. The difference is due to the lower number of jobs estimated for Belmont in the near term in *Projections 2005*, compared with the customer-selected projections used in the demand study, as a consequence of the substantial job losses sustained in the area in the first part of this decade. The projections used in the demand study expected almost twice as many jobs in 2005 as are estimated in *Projections 2005* (15,742 compared to 8,190).[31] Because *Projections 2005* forecasts

30 This was the city's population in 2000 according to the U.S. Census.
31 The demand study estimate for 2005 was interpolated for this PEIR analysis from the employment figures in the SFPUC demand study; refer to Table E.3.4 of Appendix E, Section E.3.

a higher rate of subsequent job growth (a 72 percent increase in jobs compared to a 41 percent increase assumed in the demand study projections), by 2030 the difference in total jobs forecasted by the two projections is less than in the near term.

City of Millbrae

Millbrae's total 2030 water demand, taking into account plumbing code savings, is 3.3 mgd. This represents a 5 percent increase in total service area demand over the 2001 base-year demand estimate. The SFPUC is Millbrae's only source of potable water supply. In 2030, Millbrae estimates it will purchase 97 percent of its total water demand from the SFPUC and 99 – 100 percent of remaining demand after conservation has been implemented, based on Millbrae's purchase estimate (refer to Table 7.2). Millbrae's 2030 estimated purchase of 3.19 mgd from the SFPUC represents a 0.72 mgd, or 29 percent, increase over its 2001 purchases. Millbrae's current water supply assurance is 3.15 mgd.

The population projection used for Millbrae in the demand study is generally consistent with the growth identified in the city's general plan and the 2030 population projected by ABAG. The 2030 Millbrae population used in the demand study is approximately 1.3 percent higher than the population cited in the city's general plan, and 3 percent higher than the 2030 Millbrae population projected by ABAG.

The employment projection for Millbrae in the demand study is about 33 percent lower than the employment projection cited in the city's general plan and about 20 percent lower than ABAG's *Projections 2005* employment projection.

City of Milpitas

Milpitas' total 2030 water demand, taking into account plumbing code savings, is 17.7 mgd. This represents a 48 percent increase in total service area demand over the 2001 base-year demand estimate. Milpitas uses multiple supply sources to meet its water demand. In 2030, Milpitas estimates it will purchase about 46 percent of its total 2030 water demand from the SFPUC and about 48 percent of remaining demand after conservation has been implemented, based on Milpitas' purchase estimate. The SFPUC portion of Milpitas' supply would supplement the city's use of recycled water and other surface water supplies in addition to the conservation savings (refer to Table 7.2). Milpitas' 2030 estimated purchase of 8.20 mgd from the SFPUC represents a 1.37 mgd, or 20 percent, increase over its 2001 purchases. Milpitas' current water supply assurance is 9.23 mgd.

The projected percentage increase in water demand for Milpitas in 2030 (48 percent) is somewhat greater than the projected growth in both population and employment assumed in the demand models (42 percent growth projected for each category). Given the relatively substantial increase in total service area demand for Milpitas (5.74 mgd) this discrepancy in demand and demographic growth rates warrants additional discussion. Several new billing account categories were created in the demand model for Milpitas to reflect observed changes in land use and water consumption rates. All new single family residential accounts (above those existing in 2001) were placed into a new single family residential category that assumes larger homes with higher outdoor water usage. It was assumed that these accounts use approximately 50 percent more water than existing accounts; all of the additional water usage was allocated to outdoor use. In addition, based on information in the city's Water Master Plan and conversations with the wholesale customer, the model also included a new commercial category, which was assumed to have higher water usage than existing accounts. All new commercial accounts (above those existing in 2001) were placed in this category. Therefore, the differences in rates of increase (in demand compared with population and employment) do not indicate inconsistencies between the city's water supply and land use planning efforts. The city's estimated 2030 purchase from the SFPUC (which, as noted in the preceding paragraph, is 20 percent above 2001 purchases) does not reflect the growth in total demand.

The customer-selected population projection used for Milpitas in the demand study is approximately 15 percent greater than the growth identified in the city's general plan and is generally consistent with (about 3 percent less than) the growth projected by ABAG. The City of Milpitas is currently preparing a Transit Area Specific Plan that is expected, upon adoption, to result in a buildout population of 95,014, somewhat greater than the population projection used in the demand study (Williams, 2007).

The employment projection for Milpitas in the demand study is about 17 percent higher than the employment projection cited in the city's general plan, and about 10 percent higher than the ABAG *Projections 2005* employment projection.

City of Mountain View

Mountain View's total 2030 water demand, taking into account plumbing code savings, is 14.8 mgd. This represents a 12 percent increase in total service area demand over the 2001 base-year demand estimate. Mountain View uses multiple supply sources to meet its water demand. In 2030, Mountain View estimates it will purchase 89 percent of its total water demand from the SFPUC and 91 – 97 percent of remaining demand after conservation has been implemented, based on Mountain View's purchase estimate (refer to Table 7.2). Mountain View's 2030 estimated purchase of 13.20 mgd from the SFPUC represents a 2.23 mgd, or 20 percent, increase over its 2001 purchases. Mountain View's current water supply assurance is 13.46 mgd.

The customer-selected population projection used for Mountain View in the demand study is 9 percent higher than the buildout population identified in the city's general plan, and 9 percent lower than the 2030 population projected by ABAG. The difference between the demand study and general plan projections may be attributable to the general plan's horizon year of 2010.

The employment projection for Mountain View in the demand study is about 13 percent higher than the employment projection cited in the city's general plan, and about 18 percent higher than the ABAG employment projection.

North Coast County Water District

The North Coast County Water District primarily serves the city of Pacifica; a small part of its service area encompasses a portion of unincorporated San Mateo County. North Coast County's total 2030 water demand, taking into account plumbing code savings, is 3.8 mgd. This represents a5 percent increase in total service area demand over the 2001 base-year demand estimate. The SFPUC is North Coast's only source of potable water supply. In 2030, the District estimates it will purchase 95-100 percent of its total water demand from the SFPUC and remaining 100 percent of demand after conservation has been implemented, based on North Coast's purchase estimate (refer to Table 7.2). North Coast County's 2030 estimated purchase of 3.61 – 3.80 mgd from the SFPUC represents a 0.16 – 0.35 mgd, or 5 – 10 percent, increase over its 2001 purchases. North Coast County's current water supply assurance is 3.84 mgd.

The customer-selected population projection used for North Coast County Water District in the demand study (47,829) is 13 percent higher than the 2030 Pacifica population projected by ABAG (42,200). The difference in the projections is apparently due to ABAG's lowered expectations of population growth in Pacifica. The demand study cites as its source ABAG *Projections 2002*, which expected more growth in Pacifica than does *Projections 2005*. (For example, *Projections 2002* estimated a population of 44,300 in 2025, whereas *Projections 2005* estimates a 2025 population of 41,700. North Coast County's UWMP, published in December 2005, uses a 2030 population estimate of 42,100, which is similar to ABAG's. The UWMP also forecasts somewhat lower water demand in 2030 than did the wholesale customer demand study (3.46 compared to 3.80 mgd). According to the UWMP, the "source of the discrepancy appears to be differing data for the District's base year, and differences in ABAG *Projections 2002* and *Projections 2005*" (North Coast County Water District, 2005). The Pacifica General Plan (which appears to date from 1980, except for a 1992 housing element) does not provide a comparable population projection.

The employment projection for North Coast in the demand study is 12 percent less than the ABAG *Projections 2005* employment projection for Pacifica.

City of Palo Alto

Palo Alto's total 2030 water demand, taking into account plumbing code savings, is 14.36 mgd based on the City's 2005 UWMP, as requested by the City in a letter to the SFPUC (City of Palo Alto, 2005). This represents a 1 percent increase in total service area demand over the 2001 base-year demand estimate. The SFPUC is Palo Alto's only source of potable water supply. In 2030, Palo Alto estimates it will purchase 91 percent of its total water demand from the SFPUC, and 94 percent of remaining demand after conservation has been implemented, based on the city's purchase estimate. The SFPUC portion of Palo Alto's supply would supplement the city's projected conservation savings and use of recycled water (refer to Table 7.2). Palo Alto's 2030 estimated purchase of 13.00 mgd from the SFPUC represents a -0.19 mgd, or 1 percent, decrease from its 2001 purchases. Palo Alto's current water supply assurance is 17.07 mgd.

The customer-selected population projection used for Palo Alto in the demand study is 10 percent higher than the buildout population identified in the city's general plan; the projection is not comparable to ABAG's projections for Palo Alto, since the wholesale demand projection does not include Stanford University (a distinct SFPUC wholesale customer), whereas ABAG does include the university. The difference between the demand study and general plan projections may be attributable to the general plan's horizon year of 2010.

The employment projection for Palo Alto in the demand study is about 16 percent higher than the employment projection cited in the city's general plan, but slightly lower than (by about 2 percent) than the ABAG employment projection for 2030.

Purissima Hills Water District

The Purissima Hills Water District serves about two-thirds of the Town of Los Altos Hills and a small part of adjacent unincorporated Santa Clara County. The total 2030 water demand estimated for the water district, taking into account plumbing code savings, is 3.3 mgd. This represents a 51 percent increase in total service area demand over the 2001 base-year demand estimate. The SFPUC is Purissima Hills Water District's only source of potable water supply. In 2030, the District estimates it will purchase 98 percent of its total water demand from the SFPUC and 100 percent of remaining demand after conservation has been implemented, based on Purissima Hills' purchase estimate (see Table 7.2). Purissima Hills' 2030 estimated purchase of 3.22 mgd from the SFPUC represents a 1.02 mgd, or 46 percent, increase over its 2001 purchases. Purissima Hills' current water supply assurance is 1.62 mgd.

Because the Purissima Hills Water District serves only part of the town's residences and some unincorporated county areas, the population projection used for the district in the demand study is not comparable to general plan or ABAG projections for the town. Nevertheless, the 2030 water demand population projection for the water district is consistent with growth identified in the town's 2002 Housing Element (Town of Los Altos Hills, 2002), assuming the district would serve the same percentage of the town's population. In 2001, the Purissima Hills Water District served 6,032—or 64 percent—of the approximately 9,455 residences estimated for the town and its sphere of influence in 2000. The customer-selected population projection used in the demand study (6,763) is 64 percent of the projection shown in the Housing Element (10,500 projected for 2025). Both the demand study and Housing Element projections reflect an annual population growth rate of approximately 0.4 percent. ABAG projects a population for Los Altos Hills of 10,700 in 2030, 2 percent more than the Housing Element population projection for 2025. The Housing Element cites ABAG projections for employed residences (and indicates some reservations about these ABAG projections) but does not provide projections for jobs with which to compare the demand study employment (job) projections.

Although the water district projects a 51 percent increase in water demand, that increase is not reflected in expected population and employment growth. The population and employment estimates used in the demand model indicate a 12 percent increase in population and a 9 percent increase in employment from 2001 to 2030. The demand model for the Purissima Hills Water District includes a "new/renovated single family residential" account category that has a much higher water use rate (1,605 gallons per day per account), than does the "old single family residential" category (716 gallons per day per account), which accounts for the substantial increase in water demand compared to projected population and employment growth.

City of Redwood City

The City of Redwood City provides water to Redwood City as well as to part of San Carlos, part of Woodside, and part of unincorporated San Mateo County. Redwood City's total 2030 water demand, taking into account plumbing code savings, is 13.4 mgd. This represents a 13 percent increase in total service area demand over the 2001 base-year demand estimate. The SFPUC is Redwood City's only source of potable water supply.

In 2030, Redwood City estimates it will purchase 87 percent of its total water demand from the SFPUC, and 92 percent of remaining demand after conservation has been implemented, based on Redwood City's purchase estimate and subsequent communication with the SFPUC. Redwood City's 2030 estimated purchase of 11.60 mgd from the SFPUC represents essentially no change (-0.04 mgd) from its 2001 purchases. In the purchase estimate originally submitted to the SFPUC in 2004, Redwood City estimated it would purchase 11.60 – 12.60 mgd, which corresponds to 87 – 94 percent of its total 2030 demand and 94 – 98 percent of remaining demand after conservation has been implemented. The estimated purchases of 11.60 – 12.60 mgd from the SFPUC represent a -0.04 – 0.96 mgd change from the City's 2001 purchases (refer to Table 7.2). Subsequently, in 2005, Redwood City informed the SFPUC that it would be purchasing its low range estimate (11.6 mgd) due to the estimated use of 1 mgd of recycled water in 2030. Redwood City's current water supply assurance is 10.93 mgd.

The customer-selected population projection used for Redwood City in the demand study is 24 percent lower than ABAG's 2030 population projection of 122,300 for the city and its sphere of influence. The 2030 Redwood City population used in the demand study is approximately 7 percent more than the 2020 projection shown in the city's Downtown Precise Plan, which cites ABAG's *Projections 2005* forecast for 2020 for the city within its jurisdictional boundary. The city's water service area includes only a portion of the city's sphere of influence (Bonte, 2006), which probably accounts for the difference between the ABAG projection for the city and its sphere of influence and that assumed in the demand study. ABAG's 2030 projection of 94,300 for Redwood City within the city limits only is within 1 percent of the demand study projection. Because the population projection included in the city's 1990 general plan is for 2000 (earlier than 2005), it is not considered comparable to the 2030 WSIP population projection for this analysis. According to the city, the 2003 UWMP was selected for use in the demand study because the UWMP contained the most current population and employment projections at the time.

The employment projection for Redwood City in the demand study is about 9 percent higher than the *Projections 2005* employment projection for 2030. The City's general plan does not have a comparable employment projection.

City of San Bruno

San Bruno's total 2030 water demand, taking into account plumbing code savings, is 4.5 mgd. This represents a 2 percent increase in total service area demand over the 2001 base-year demand estimate. In 2030, the SFPUC will be San Bruno's only source of potable supply, although in the past the City has used other sources of water supply. In 2030, San Bruno estimates it will purchase 96 percent of its total water demand from the SFPUC and 100 percent of remaining demand after conservation has been implemented, based on San Bruno's purchase estimate (refer to Table 7.2). San Bruno's 2030 estimated purchase of 4.30 mgd from the SFPUC represents a 1.60 mgd, or 59 percent, increase over its 2001 purchases. San Bruno's current water supply assurance is 3.25 mgd.

The customer-selected population projection used for San Bruno in the demand study is about 4 percent higher than the projection for 2020 cited in the city's 2003 general plan housing element and 5 percent lower than the 2030 population projected by ABAG. The general plan, adopted in 1984, does not include comparable projections; the City of San Bruno is currently working on a general plan update.

The employment projection used for San Bruno in the demand study is about 34 percent higher than the projection for 2020 cited in the city's 2003 general plan housing element, but about 9 percent lower than the 2030 ABAG employment projection. The demand study employment projection is based on the city's 2001 draft general plan. The draft general plan had not been adopted at the time of Draft PEIR publication, so the housing element provides the city's published employment projections. Base year employment estimates in the 2003 housing element and 2001 draft general plan are similar (16,500 and 16,600, respectively). The sources of the job estimates for the housing element and draft general plan are ABAG *Projections 2000* and *Projections 2002*, respectively. The housing element indicates an expected annual growth rate for the period 2000-2020 of 0.8 percent, whereas the draft general plan indicates an expected annual growth rate for the period 2000-2020 of 1.7 percent. (This average annual growth rate for the 2000–2020 period was applied to the 2020 to 2030 period for the WSIP forecasts). Consequently, the differences in the forecasts are a direct reflection of the shifting expectations in the two ABAG Projections series, with *Projections 2002* forecasts reflecting more of the economic boom that occurred in the late 1990s and early part of the 2000s in the Bay Area, as well as the 10-year difference in the horizon year. Commercial demand accounts for approximately 20 percent of San Bruno's projected 2030 demand (SFPUC 2006b).

City of San Jose (North)

The San Jose Municipal Water District–North (San Jose North) serves part of the northern San Jose/Alviso area of the city. The district's total 2030 water demand, taking into account plumbing code savings, is 6.5 mgd. This represents a 25 percent increase in total service area demand over the 2001 base-year demand estimate. In 2030, the SFPUC will be San Jose's only source of potable supply, although in the past the City has used other sources of water supply. In 2030, the District estimates it will purchase 98 percent of its total water demand from the SFUPC and 100 percent of remaining demand after conservation has been implemented, based on

San Jose North's purchase estimate (refer to Table 7.2). San Jose's 2030 estimated purchase of 6.34 mgd from the SFPUC represents a 1.92 mgd, or 43 percent, increase over its 2001 purchases. San Jose does not have a water supply assurance contract with the SFPUC.

The customer-selected projections used in the demand study for San Jose assume 23 percent growth in population and 34 percent growth in employment by 2030. Because this water district only serves part of the northern section of San Jose, the population projection used for San Jose North in the demand study is not comparable to projections contained in the city's general plan or ABAG projections for San Jose.

City of Santa Clara

Santa Clara's total 2030 water demand, taking into account plumbing code savings, is 33.9 mgd. This represents a 31 percent increase in total service area demand over the 2001 base-year demand estimate. Santa Clara uses multiple supply sources to meet its water demand. In 2030, Santa Clara estimates it will purchase about 14 percent of its total 2030 water demand from the SFPUC and about 15 percent of remaining demand after conservation has been implemented, based on the City's purchase estimate. The SFPUC portion of Santa Clara's supply would supplement the city's conservation savings and use of recycled water, groundwater, and other surface water supplies (refer to Table 7.2). Santa Clara's 2030 estimated purchase of 4.90 mgd from the SFPUC represents a 1.06 mgd, or 28 percent, increase over its 2001 purchases. Santa Clara does not have a water supply assurance contract with the SFPUC.

The customer-selected population projection used for Santa Clara in the demand study is generally consistent with the growth cited in the city's general plan and the growth projected by ABAG. The 2030 population estimated in the demand study is approximately 8 percent higher than that cited in the city's general plan, which may be attributable to the longer planning horizon of the WSIP (2030 compared to 2010 for the general plan). The 2030 Santa Clara population estimated in the demand study is about 1 percent less than the population projected by ABAG.

The employment projection used for Santa Clara in the demand study is 17 percent higher than the projection in the City's general plan (for 2010) and 16 percent higher than the ABAG 2030 employment projection.

Skyline County Water District

Skyline County Water District serves part of the town of Woodside and part of unincorporated San Mateo County along Highway 35 (Skyline Boulevard), from Highway 84 to Highway 92. Skyline County's total 2030 water demand, taking into account plumbing code savings, is 0.31 mgd. This represents an 82 percent increase in total service area demand over the 2001 base-year demand estimate. The SFPUC is Skyline County's only source of potable water supply. In 2030, Skyline estimates it will purchase about 97 percent of the district's total water demand from the SFPUC and 100 percent of remaining demand after conservation has been implemented, based on Skyline's purchase estimate (see Table 7.2). Skyline's 2030 estimated purchase of

0.30 mgd from the SFPUC represents a 0.13 mgd, or 76 percent, increase over its 2001 purchases. Skyline's current water supply assurance is 0.18 mgd.

Because Skyline County Water District serves part of Woodside and a portion of unincorporated San Mateo County, the population projection used for the district in the demand study is not comparable to either general plan or ABAG projections. The water district selected historical data—the BAWSCA annual survey—as its source for population projections. The district stated that, because of the limited development potential in the district—much of which is owned by the Mid-Peninsula Regional Open Space Authority and San Mateo County Parks and Recreation Department—it expected less growth than was projected for the greater San Francisco Bay Area. Nevertheless, the demand model estimates show a district population in 2030 that is more than twice that in 2001 (an increase from 1,210 to 2,683, or 122 percent). This substantial increase (in contrast to the stated low expectations of growth) is apparently due to the possibility that three other water districts—the Kings Mountain Water Company, the Skylonda Mutual Water Company, and the Cuesta La Honda Water Company—may become part of Skyline County Water District. The Skyline County Water District notes that growth in the areas served by these water companies is also constrained by publicly owned open space lands (Skyline County Water District, 2003). No change is projected in the number of jobs in the district.

Stanford University

Stanford University's total 2030 water demand, taking into account plumbing code savings, is 6.8 mgd. This represents a 76 percent increase in total service area demand over the 2001 base-year demand estimate. Stanford uses multiple supply sources to meet its water demand. In 2030, Stanford estimates it will purchase about 62 percent of its total 2030 water demand from the SFPUC and about 69 percent of remaining demand after conservation has been implemented, based on Stanford's purchase estimate. The SFPUC portion of Stanford's supply would supplement the university's use of other surface water supplies in addition to the conservation savings (refer to Table 7.2). Stanford's 2030 estimated purchase of 4.20 mgd from the SFPUC represents a 1.84 mgd, or 78 percent, increase over its 2001 purchases. Stanford's current water supply assurance is 3.03 mgd.

The customer-selected population projection used for Stanford in the demand study assumes 42 percent growth in population; the demand projections for Stanford did not include assumptions about employment growth. Stanford has special water account categories to reflect that it is a university rather than a city or water district. Besides residential categories (i.e., student and faculty housing), account categories include construction projections and medical school, commercial space, and academic occupants. The demand model added a special "lake water" billing category account in order to include lake water that is used for irrigation of the campus in order to more accurately reflect the actual total demand on campus. According to the demand study the effect of this specific change was to increase total demand. The Stanford Community Plan (adopted in 2000) includes an Academic Growth Boundary (AGB) which limits development on the campus. The AGB, which applies the concept of urban growth boundaries promoted in the Santa Clara County General Plan to the campus setting, limits development to the area within the AGB. The AGB is established for 25 years, during which time it may only be modified by a fourth-fifths vote of all members of the county board of supervisors.

City of Sunnyvale

Sunnyvale's total 2030 water demand, taking into account plumbing code savings, is 26.8 mgd. This represents an 8 percent increase in total service area demand over the 2001 base-year demand estimate. Sunnyvale uses multiple supply sources to meet its water demand. In 2030, Sunnyvale estimates it will purchase about 45 percent of its total 2030 water demand from the SFPUC and about 46 percent of remaining demand after conservation has been implemented, based on Sunnyvale's purchase estimate. The SFPUC portion of Sunnyvale's supply would supplement the city's conservation savings and use of recycled water, groundwater, and other surface water supplies (refer to Table 7.2). Sunnyvale's 2030 estimated purchase of 12.10 mgd from the SFPUC represents a 2.41 mgd, or 25 percent, increase over its 2001 purchases. Sunnyvale's current water supply assurance is 12.58 mgd.

The customer-selected population projection used for Sunnyvale in the demand study is generally consistent with the growth cited in the city's general plan and the growth projected by ABAG. The 2030 Sunnyvale population estimated in the demand study is approximately 2 percent less than that cited in the general plan and about 5 percent less than projected by ABAG.

The employment projection for Sunnyvale in the demand study is about 11 percent higher than the employment projection cited in the city's general plan, and about 37 percent higher than the ABAG *Projections 2005* employment projection.

Westborough Water District

The Westborough Water District's total 2030 water demand and 2030 purchase estimate are based on the district's 2005 UWMP, as requested by the district and described below in this summary (Westborough Water District, 2005; Westborough Water District, 2007). Based on the UWMP, the district's 2030 water demand, taking into account plumbing code savings, is 1.03 mgd. This represents a 1 percent increase (0.01 mgd) in total service area demand over the 2001 base-year demand estimate. The SFPUC is Westborough's only source of potable water supply. In 2030, Westborough estimates it will purchase 100 percent of its total water demand from the SFPUC. Westborough's 2030 purchase estimate of 1.03 mgd is 1 percent higher (0.01 mgd) than its 2001 purchases. Although this purchase estimate does not explicitly include quantified conservation savings, the UWMP describes demand management programs that the district is currently implementing, those it plans to continue, and two new programs it plans to start during the 2006-2010 UWMP planning period. The purchase estimate originally submitted by the district indicated conservation savings of 0.02 mgd. Westborough's current water supply assurance is 1.32 mgd.

The district's total 2030 water demand, taking into account plumbing code savings, was calculated in the demand study to be 0.88 mgd. This represented an 11 percent decrease in total service area demand over the 2001 base-year demand estimate. In 2004, following completion of the demand, conservation, and other related studies, Westborough submitted a purchase estimate of 1.2 mgd, an 18 percent increase over 2001 purchases, and 36 percent greater than the demand study's projected demand. Demand estimates in Westborough's UWMP, which was published in December 2005, differ from these demand study projections. In February 2007 Westborough Water District formally submitted a request to the SFPUC (Westborough Water District, 2007) that the district's calculation of future water demands in 2030 of 1.03 mgd, as cited in the UWMP, be used in SFPUC planning efforts.

The updated UWMP projection of 1.03 mgd demand and purchases in 2030 is 17 percent higher than was projected in the SFPUC demand study and 17 percent lower than the purchase estimate originally submitted by the district. The UWMP attributes the difference between its projected 2030 demand and the demand developed in the DSS model to "differing assumptions about the District's base year, and projected population" (Westborough Water District, 2005). The UWMP base year population estimates for 1990 and 2000 are from U.S. Census data for Census Tracts 6025 and 6026. The 2000 population is 13,033 and the projected 2030 population is 14,300 (a 10 percent increase) compared with the estimated 2001 base year population of 10,017 and 2030 projected population of 10,146 (a 1 percent increase) used in the demand study. (The BAWSCA [then BAWUA] annual survey was the source of population projections selected by Westborough Water District for the modeling exercise [URS, 2004a].)

Based on the information presented in the UWMP and the February 2007 letter from the Westborough Water District to the SFPUC, this PEIR uses the demand, purchase, and population estimates presented in the UWMP. To be consistent with previous and ongoing WSIP studies, the high-range purchase estimate total published in URS 2004b of 300 mgd, based on the previously submitted purchase estimates of Westborough and the other water customers, remains the SFPUC's 2030 purchase estimate for planning purposes.

Since the Westborough Water District serves only part of South San Francisco, the population projection used in the demand study is not comparable to that of the city as a whole. Refer to the discussion under CWS–South San Francisco for a comparison of combined water district projections with those of the city's general plan and ABAG.

SFPUC Retail Service Area

The total 2030 water demand for San Francisco and the rest of the retail service area, taking into account plumbing code savings, is approximately 93.4 mgd. This represents a 0.2 percent decrease in total service area demand from the 2001 base-year estimate. The SFPUC regional water system is currently the only source of potable water supply for San Francisco and for the SFPUC's other major retail customers. In 2030, the SFPUC regional water system would provide about 86– 97 percent of total SFPUC retail service area water demand and 89 – 97 percent after conservation has been implemented. San Francisco's 2030 estimated purchase of 80 – 91 mgd from the regional water system represents a 10 percent decrease to 1 percent increase compared to 2001 SFPUC regional water system purchases. The low range of the purchase estimate would be supplemented by identified groundwater, recycled water and conservation programs totaling

10 mgd in San Francisco that are included as part of the WSIP proposed water supply option (refer to Table 7.2).

San Francisco's water demand projections are based on demographic projections that assume 12 percent growth in population and 25 percent growth in employment by 2030. The population projection used for San Francisco in the retail demand study is generally consistent with the growth cited in the city's general plan, and somewhat less consistent with the growth projected by ABAG. The 2030 population for San Francisco estimated in the demand study is approximately 5 percent more than indicated in the city's general plan and about 8 percent less than projected by ABAG in *Projections 2005* for 2030. At the time ABAG's draft *Projections 2005* was distributed to jurisdictions for review in 2004, the CCSF informed ABAG that San Francisco expects less growth by 2030 than is forecasted in *Projections 2005* and cited the estimates in the CCSF's 2002 Land Use Allocation as more realistic (Macris, 2004). The 2030 household population shown in SFPUC's UWMP, which were linearly extrapolated from City Planning estimates for 2000 and 2025, are the same as the population projection used in the demand study (849,942) (SFPUC, 2005).

The employment projection used for San Francisco in the retail demand study is about 7 percent higher than the employment projection citied in the city's general plan for 2020, and about 4 percent lower than the ABAG *Projections 2005* employment projection.

7.4 Indirect Effects of Growth

The WSIP would support planned growth and growth that is projected to occur in the service area by ABAG. Most of the projected population growth and much of the employment growth that would be supported by the SFPUC regional water system under the WSIP has been addressed in the adopted general plans of jurisdictions within the service area. The impacts of planned growth are identified and evaluated in the EIRs and other CEQA documents prepared by the jurisdictions for their general plans and related land use plans (such as general plan elements and specific plans that general plans are subsequently amended to incorporate). This section presents a summary of the impacts associated with planned growth in the service area and the mitigation measures adopted by the jurisdictions to reduce or eliminate those impacts. It includes a summary of the impacts commonly found to be mitigable and those commonly found not to be mitigable to a less-than-significant level. It also includes a summary of overriding considerations that were commonly identified by city councils in adopting land use plans despite the plans' unavoidable significant impacts. The WSIP would also support a degree of growth that, while consistent with the projections of the regional planning agency (ABAG), is not covered in adopted land use plans because the WSIP projections reflect more recent employment trends (i.e., the substantial job growth that occurred in the Bay Area in the latter part of the 1990s) than do most of the general plans and the WSIP planning horizon is longer than the planning horizon of the general plans. Therefore, this section also qualitatively describes the impacts that could result from growth supported by the WSIP beyond what has already been evaluated in the CEQA review of the adopted land use plans. Finally, as a means of gauging whether the impacts of projects developed in the planning area subsequent to adoption of the current general plans are being mitigated as prescribed in the general plan EIRs, a review of the EIRs for several large projects was undertaken and is summarized in this section.

7.4.1 Impacts

Significance Criteria

The EIRs prepared for the local general plans and related planning documents of the jurisdictions in the SFPUC service area evaluated the environmental effects associated with growth projected in the respective general plans. The impact findings identified in these environmental documents are incorporated by reference into this PEIR pursuant to CEQA Guidelines Section 15150 and are summarized here. Please see Section 1.3.5 in PEIR Chapter 1, Introduction, for a list of locations where documents incorporated by reference are available for public review.

Approach to Analysis

This section provides a summary overview of the potential indirect effects of growth that could result from implementation of approved land use plans of the jurisdictions served by SFPUC water. In addition, this section reviews the role of the SFPUC and the jurisdictions in the wholesale service area in addressing these effects; provides a discussion of the key regional growth issues in the SFPUC service area; and reviews recent examples of environmental analyses conducted at the project level within the SFPUC service area.

Impact 7-1: The WSIP would support planned growth in the SFPUC service area, although it appears that some growth would occur irrespective of the WSIP due to increased water delivery efficiencies (e.g., plumbing code changes), conservation, and other water supply sources. Planned growth would in turn result in indirect effects. In most cases, the effects of planned population and employment growth have been identified and addressed in the EIRs for the general plans and associated area plans and specific plans adopted by the jurisdictions in the service area. Some of the identified indirect effects of growth are significant and unavoidable; others are significant but can be mitigated.

In some areas the WSIP could support a degree of population and/or employment above that planned for in jurisdictions' adopted general plans, as indicated by a comparison of the levels of growth assumed in WSIP demand studies and general plan documents. In some jurisdictions (Foster City, Half Moon Bay, and Burlingame), the WSIP could support more population growth than is forecasted in adopted general plans. In some jurisdictions (East Palo Alto, Foster City, San Bruno, Fremont, Newark and Union City), the WSIP could support more employment growth than is forecasted in adopted general plans of the respective jurisdictions. To the extent that growth supported by the WSIP has not been fully analyzed in EIRs for the general plans and related land use plans of the jurisdictions served by SFPUC water, due to the WSIP's longer planning horizon, the WSIP would have impacts that are similar to, but potentially more severe than, the impacts identified in local general plan CEQA documents. To the extent the WSIP would support employment growth not fully anticipated in the general plans of jurisdictions in the service area because the general plans were prepared before the extent of the economic boom was realized, the WSIP would have impacts associated with economic development and higher numbers of

employees within the service area that are potentially new or more severe than impacts previously identified. These impacts would include traffic, air quality, noise, and demands on public services resulting from an influx of commuters from out of the area to jobs within the service area, and impacts resulting from increased demand for housing and other services within the service area to better accommodate the workforce. In addition, although the general plan EIRs reviewed for this PEIR were prepared prior to the passage of the California Global Warming Solutions Act of 2006 and do not include assessments of impacts from greenhouse gas emissions, it is expected that planned growth in the area could result in a significant and unavoidable contribution to increases in greenhouse gas emissions (e.g., from increased fossil fuel use for transportation and construction, increased industrial and commercial activities, residential energy use, operation of power plants, and oil refining).

Potentially significant unavoidable impacts as a result of planned growth in the SFPUC service area have been identified in the following areas: traffic congestion, air pollution, traffic noise, construction noise, increased demand for public schools and other public services, loss of recreational opportunities and impacts on visual quality resulting from the loss of open space, cumulative effects on overutilized parks, loss of wildlife habitat and wetlands, cumulative impacts on cultural resources, increased flooding potential, increased urban runoff pollutants, seismic hazards, induced population growth, failure to meet housing demand for projected population growth, exposure of new development to contaminated soil or groundwater, insufficient water supply, insufficient wastewater disposal capacity, loss of agricultural resources, land use conflicts, conflicts with existing land use plans or policies, and changes in density, scale, and character of an area.

Impacts from growth in years beyond that evaluated in the EIRs for adopted land use plans would occur due to an increased density of development or the use of additional land area. Impacts from increased density could include additional traffic congestion, air pollution, noise, and demand on public services; land area (or “footprint”) impacts could include the loss of agricultural resources and open space, impacts on wildlife habitat and other biological resources, disturbance of cultural resources, increased soil erosion, and water quality impacts from increased urban runoff. In addition, to the extent that a water supply shortage is identified as a future impact, the WSIP would address the need for additional water supply.

The program would support much of the planned growth in the jurisdictions served by SFPUC water. In general, development planned and approved through the general plan process in the SFPUC service area would have environmental impacts. The environmental consequences of this planned growth have been largely addressed in local plans and the associated CEQA review as well as in other, project-specific documentation. In a number of jurisdictions, negative declarations or mitigated negative declarations were prepared for general plans and related planning documents that were found not to have significant environmental effects. The analysis presented in this section focuses on the significant effects of growth identified in general plan, area plan, and specific plan EIRs. These EIRs substantially address the impacts and mitigation measures identified in the mitigated negative declarations.

The planning documents and associated environmental documents listed below were reviewed for this analysis. The EIRs and City Council and Board of Supervisor findings resolutions are summarized in this PEIR (in this chapter and Appendix E, Section E.5) and are incorporated by reference pursuant to CEQA Guidelines Section 15150. Please see Section 1.3.5 in PEIR Chapter 1, Introduction, for a list of locations where documents incorporated by reference are available for public review. In addition to listed planning documents and EIRs, statements of overriding considerations adopted in conjunction with adoption of the general plans were also reviewed.

- City of Union City General Plan, Housing Element, and EIR (2002a, 2002b, 2002c, 2002d, 2002e, 2002f)
- Town of Woodside General Plan and Negative Declaration (1988a, 1988b), Housing Element (2002, 2003)

Table 7.11 summarizes the environmental effects associated with planned growth in the program area, as identified in the general plan, area plan, and specific plan EIRs for the jurisdictions in the SFPUC wholesale customer and retail service areas. Because the table reflects the determinations of multiple jurisdictions, some impacts are listed as both significant and unavoidable and significant but mitigable, reflecting differences in the jurisdictions in the service area. Appendix E, Section E.5, Table E.5.1 presents a more detailed summary of the relevant growth impacts and mitigation measures identified in the EIRs for these local land use plans. These environmental impacts are the indirect effects of growth supported by the WSIP.[32]

Significant and Unavoidable Impacts

The environmental effects of growth most commonly identified as significant and unavoidable in the service area are increased traffic, cumulative traffic impacts, deterioration of air quality, the cumulative effects of increased air pollutant emissions, and noise impacts, primarily as a result of increased traffic. Traffic and air quality effects are discussed in greater detail below under “Key Regional Effects of Growth.”

The WSIP would address a significant unavoidable impact that was identified by two cities: increased demand for potable water supply. The WSIP provides for increased supply and related water treatment facility and storage upgrades to reliably meet projected demand (i.e., projected retail demand and projected wholesale customer purchase requests) to 2030. The SFPUC’s role in addressing this indirect effect of growth is discussed at the end of this subsection.

[32] To assess whether mitigation measures identified in general plan EIRs to reduce growth-related impacts are in fact being applied at the project level, a review of the EIRs of several current major projects in the service area was undertaken. The review indicated that the mitigation measures identified in general plan EIRs to reduce the adverse impacts of growth are being applied at the project level. Information on the review of the project EIRs is presented in Appendix E.6.

TABLE 7.11
SIGNIFICANT IMPACTS ASSOCIATED WITH PLANNED GROWTH IN THE PROGRAM AREA

Significant and Unavoidable Impacts

- Impacts due to the loss of open space (to development) on visual quality
- Alteration of the visual setting or degradation of existing views, and cumulative visual quality impacts
- Conversion of agricultural land to nonagricultural uses
- Cumulative loss of agricultural land
- Increases in air pollutant emissions and/or ozone precursors or violation of air quality standards
- Cumulative air quality impacts
- Impacts on natural habitat, including individual or cumulative loss of wetlands
- Cumulative impacts on cultural resources
- Exposure to seismic or geologic hazards
- Cumulative impacts on soil resources
- Exposure to soil or groundwater contamination
- Cumulative effects from increased exposure to man-made hazards
- Increases in impervious surfaces and/or alterations to drainage resulting in exposure to flood hazards and/or the need for new drainage facilities
- Water pollution from stormwater runoff
- Land use impacts
- Cumulative impacts from the depletion of nonrenewable resources and the alteration of landforms
- Noise impacts, including increases in traffic noise, exposure to construction noise, and exposure to aircraft noise
- Impacts related to population growth (directly or indirectly induced) and jobs/housing balance
- Increased demand for schools and/or other public facilities
- Loss of recreational open space
- Cumulative impacts on recreational facilities
- Local and regional traffic impacts
- Cumulative traffic impacts
- Impacts on landfill capacity
- Increases in water demand
- Large and wasteful increase in energy consumption and cumulative energy-related impacts

Significant but Mitigable Impacts

- Impacts on scenic resources, including resources within a scenic highway
- Creation of new source(s) of light and glare
- Alteration of visual setting or degradation of existing views
- Conversion of agricultural land to nonagricultural uses
- Conflicts between agricultural uses and adjacent land uses
- Construction-related air quality impacts
- Exposure of new sensitive land uses to toxic air contaminants and/or odor emissions sources
- Increases in air pollutant emissions
- Conflicts with, or obstruction of, the implementation of an applicable air quality attainment plan or related plan
- Impacts on/loss of special-status species
- Impacts on biological resources due to individual or cumulative impacts on wetlands, riparian habitat, or other sensitive habitat
- Conflicts with local policies or ordinances protecting biological resources
- Disruption of wildlife migration or travel corridors
- Cumulative impacts on biological resources
- Individual or cumulative impacts on historical, archaeological, and/or paleontological resources
- Disturbance of human remains

TABLE 7.11 (Continued)
SIGNIFICANT IMPACTS ASSOCIATED WITH PLANNED GROWTH IN THE PROGRAM AREA

Significant but Mitigable Impacts (continued)

- Exposure to seismic, geological, or soils-related hazards
- Exposure to flooding due to levee or dam failure
- Increased risk of wildland fires
- Release of or exposure to hazardous materials
- Increased risk of structural fires and degree of damage from industrial chemical fires
- Impacts related to emergency response
- Degradation of surface water and/or groundwater quality
- Construction impacts on water quality
- Increased surface runoff and flood hazard
- Incompatible and/or inappropriate land uses; conflicts between adjacent land uses
- Loss of agricultural land or premature urbanization of rural areas
- Inefficient land use patterns
- Intensification of land uses
- Exposure to excessive noise levels or groundborne vibration
- Permanent or substantial temporary or periodic increases in ambient noise levels
- Construction noise impacts
- Increased traffic noise
- Increased demand for housing and related impacts on housing affordability
- Increased demand for special housing needs
- Substantial population and/or job growth
- Jobs/housing imbalances, oversupply of jobs
- Increased demand for and/or impacts on public services and facilities, including increased need for new fire and police facilities, schools, parks, and other public facilities
- Increased demand for new or expanded recreational facilities
- Loss or degradation of recreational open space
- Local and regional traffic impacts
- Congestion impacts on transit service and bicyclists
- Construction traffic impacts
- Increased traffic safety concerns
- Impacts on landfill capacity or demand for solid waste services
- Increased demand for new or expanded water and wastewater facilities
- Need for new or expanded stormwater drainage facilities
- Increased demand on water supply
- Increased demand for public utilities
- Increased demand for energy

SOURCES: City of Belmont, 1988a; 1990a; City of Brisbane, 1994b; City of East Palo Alto, 1999a; City of Foster City, 1993b; City of Fremont, 1991b; City of Fremont 1991c; City of Hayward, 2002b; City of Menlo Park, 1994b; City of Millbrae, 1998b; City of Millbrae, 1998d; City of Milpitas, 2002e; City of Mountain View, 1992b; City of Newark, 1992b; City of Palo Alto, 1998b; City of Redwood City, 2007a; City of San Bruno, 1984a; City of San Jose, 1994b; City of San Mateo, 1990b; City of Santa Clara, 1992b; City of Union City, 2002c; County of San Mateo, 1986b; County of Santa Clara, 1994b; County of Santa Clara, 2000b.

Measures to partially mitigate traffic impacts identified in the EIRs include participation in regional transportation planning, implementation of local and regional transit/transportation plans, promotion of alternative modes of transportation, implementation of roadway- and intersection-specific improvements (e.g., adding various combinations of turn lanes and through lanes and expanding intersection capacity), and encouragement of higher density development and supportive uses around transit stations. Measures to partially mitigate air quality impacts identified in the EIRs include participation in regional planning efforts to improve air quality, requiring measures to reduce construction emissions (both equipment emissions and dust), and implementation of many of the same (or similar) measures adopted to improve traffic impacts, such as encouraging alternative forms of transportation, improving roadways to maintain efficient vehicular movement, and encouraging higher density infill development and mixed uses. Measures to partially mitigate noise impacts identified in the EIRs include adoption and enforcement of noise ordinances, requiring the use of construction practices to protect sensitive receptors, and requiring project-specific review of noise impacts and project mitigation measures such as setbacks, buffering, and insulation. (Refer to Appendix E, Section E.5 for a more detailed summary of the mitigation measures.)

Overriding Considerations

Jurisdictions may approve land use plans that would result in significant unavoidable impacts by adopting statements of overriding considerations pursuant to CEQA; these statements provide the rationale for approving a plan despite its significant unavoidable impacts. In the SFPUC service area, some jurisdictions have determined that certain social, economic, and/or other considerations outweigh the adverse environmental effects. These considerations are summarized in **Table 7.12**. Of the key overriding considerations identified in the table, the following considerations were commonly identified by the local jurisdictions in the region:

- Accommodation of growth in an orderly, fiscally sound manner
- Economic diversification and job generation
- Creation of housing, furtherance of regional housing share objectives, and provision of affordable housing
- Improvement of the local jobs/housing balance
- Increased sales revenue and positive fiscal impact
- Promotion of alternative modes of travel to private vehicles; reduction in reliance on private vehicles
- Establishment of policies to preserve natural areas and open space lands

Impacts Commonly Identified as Significant but Mitigable

Impacts commonly identified as significant but mitigable by jurisdictions in the service area include obstruction of views or alteration of the visual setting; construction-related air quality impacts; adverse impacts on habitat and wetlands; impacts on historical, archaeological, or paleontological resources, including potential disturbance of unknown cultural resources; exposure to seismic and geologic hazards; creation of a hazard related to the use or transport of

TABLE 7.12
KEY OVERRIDING CONSIDERATIONS FOR SIGNIFICANT UNAVOIDABLE IMPACTS OF PLANNED GROWTH AND DEVELOPMENT

- Compliance with legal mandates to adopt and maintain a comprehensive long-term plan
- Provision of a database and statement of policies to guide decision-making
- Policies that assure adequate mitigation of land use impacts
- Realization of a comprehensively planned community that provides for a logical extension of services, including law enforcement, fire protection, parks, and public utilities
- Provision of coordinated guidance in addressing the impacts of new development and redevelopment within the urban area while not substantially increasing traffic, noise, and seismic impacts compared to existing trends
- Policies and strategies to alleviate some environmental effects that are not otherwise addressed in routine land use planning or through the existing general plan elements
- Strengthened community and neighborhoods, protection of neighborhoods from commercial encroachment, and encouragement of participation in community and governmental activities
- Facilitation of public participation and the continuation of the city's desire to provide leadership on issues of regional interest
- Protection of community character
- Enhanced public facilities and programs
- Improvement of infrastructure
- Expanded opportunities for economic activities and development; increased economic vitality
- Economic growth that supplies jobs for existing and future residents while protecting environmental resources and prudently managing traffic capacity
- Economic benefits, including increases in new jobs, sales tax revenues, and property tax revenues
- Creation of new sources of employment and income to the city
- Increased diversity of employment opportunities
- Provision of a wide range of new employment opportunities and shopping opportunities
- Improvement of jobs/housing balance and provision of more opportunities for revenue-generating uses
- Balance of residential and commercial interests
- Increased housing opportunities
- Increased diversity of housing types, including affordable housing
- Achievement of affordable housing goals and maintenance of social diversity while protecting environmental resources
- Targeting of state-mandated "fair share" requirements for new housing units as a goal, including creation of affordable housing to help maintain the city's economic base without incurring even greater adverse impacts on the area's air quality due to greater commute distances required for local employees
- Increase in the amount of affordable housing and the ability of the city to contribute its fair share of regional housing opportunities
- Alternatives to residential infill within existing residential neighborhoods that are affected by airport noise would create more adverse impacts than new residential infill
- Encouragement and support of school districts to take specific mitigatory action(s), where appropriate
- Improved transportation and circulation systems
- Reduction of reliance on the automobile
- Enhanced transit-oriented development at transit hubs
- Improved local and regional transit connections through development of intermodal facility and high-density office and residential uses in transit station area
- Long-term preservation and maintenance of sensitive ecosystems, open space, and aquatic resources
- Policies, programs, and land use designations that enhance the preservation of natural resources
- Installation of open space, park, recreation, and resource protection amenities
- Environmental benefits resulting from incorporation of innovative and extensive environmental mitigation
- Designation of new areas and retention of substantial existing areas of land for open space, and provision of neighborhood and community parks for a variety of open space and recreational opportunities for the city and region
- Providing for recreational needs of the existing and future population
- Impacts that cannot feasibly be mitigated to a less-than-significant level would occur whether or not the general plan or any feasible alternative were adopted
- Policies that direct future urban development into the cities
- Policies that minimize the potential loss of rural open space surrounding urban areas within the county
- Providing for planned urban expansion, in contrast to urban sprawl, thereby decreasing demand for government revenues for public infrastructure and services
- Enhanced cultural, recreational, and educational facilities and a modern government center, enabling the city to provide more efficient service in an inviting setting

hazardous materials; exposure of people and property to flooding; water quality impacts; land use incompatibilities; increased noise, including ambient noise levels and short-term construction noise; increased housing demand; increased demand for public services, including fire and police protection, schools, recreational facilities, and other public services; and increased need for new or expanded water or wastewater treatment facilities. Appendix E, Section E.5, Table E.5.1 summarizes these impacts. The WSIP addresses water supply needs reflected in the retail demand studies and wholesale customer purchase estimates (discussed further in the following section).

Impacts of Planned Growth to 2030

As discussed above (and in Chapter 3, Program Description), the WSIP would meet the SFPUC's regional water system purchase requests in the wholesale and retail service areas to the year 2030. The demand projections for the retail service area and each wholesale customer service area were developed using a detailed end-use model that employed ABAG's population and employment projections or the projections of a limited number of other local agencies. Thus, the projections reflect the future growth expectations of the regional planning agency or other agencies with knowledge of the service area.

In most cases, the levels of population growth reflected in the 2030 water customer-selected population projections are generally consistent with the population growth projected in the respected general plans, as indicated by the general plans' projected population (see Table 7.8). That growth, therefore, has been addressed in the adopted general plans, and the growth-related impacts have been analyzed in the general plans' impact analyses. The additional availability of water and improved water supply reliability through the WSIP would support a portion of this growth. In a few cases, the general plans do not project population growth into the future to the degree assumed in the WSIP. In these cases, the WSIP would support a degree of population growth beyond the level that is projected in the adopted general plans.

For the most part, the employment growth reflected in the 2030 water customer-selected population projections also is generally consistent with the employment growth projected in the respected general plans, as indicated by the general plans' projected employment shown in Table 7.9. However, there has been much more recent employment growth, and greater fluctuations in employment levels, in the region compared with populations. As a consequence, not all of the employment growth reflected in water customer-selected projections is reflected in the general plans of respective jurisdictions. Therefore, while much of the employment growth expected in the area has been addressed in the adopted general plans, the WSIP would support a degree of employment growth that has not been addressed in the jurisdictions' general plans nor have the impacts associated with such growth been fully analyzed in the CEQA documents prepared for the planning documents.

Two principal factors account for the discrepancy between WSIP population projections and those of general plans in the service area. One is the WSIP's 2030 planning horizon, which extends farther into the future than the general plan horizons of jurisdictions served by SFPUC water.[33] The other is the age of some jurisdictions' general plans, several of which were adopted more than 10 years ago.

The above two factors, and a third, are the principal factors that account for the discrepancy between WSIP employment projections and those of general plans in the service area. The third factor is the economic boom and recession that occurred in the Bay Area in the 1990s and first half of the current decade. Phenomenal job growth occurred during the "dot com boom" was not captured in projections prepared prior to this boom, while the extent of job losses in early 2000s was not fully capture in projections prepared in the early 2000s. As the comparison of the last three ABAG projections sets suggest, although there are differences between the individual projections, by 2030 a similar level of employment is expected for the area as a whole.

The impact discussion in the previous section describes the indirect effects of planned growth in the service area; these effects were identified and evaluated in the EIRs produced for the general plans and related land use planning documents that guide the nature and extent of development in the service area. As noted above, however, the effects of greenhouse gas emissions were not addressed in these prior EIRs. Given that the WSIP projections extend beyond the projections of many adopted general plans, especially in terms of expected employment growth, this analysis also considers the potential impacts of growth that could occur beyond the projections indicated in local general plans and related land use plans. In contemplating the potential impacts of growth beyond the previously evaluated growth, it is important to consider the following:

- Most of the service area is urbanized; many of the jurisdictions experienced peak growth periods in previous decades, with slowing growth rates in more recent decades. Urban areas provide less opportunity for substantial growth beyond existing city limits or spheres of influence. Thus, these communities are subject to certain physical constraints (such as neighboring jurisdictions) that would preclude major changes from current planning policies and growth trends.

- Various jurisdictions have identified increased densities and infill development as important means to accommodate future development. In addition to constraints on available land and fewer options to grow laterally, more compact development is being adopted by some jurisdictions in recognition of its value in supporting public transit systems. The promotion of public transit, in turn, is increasingly recognized as a way to alleviate traffic problems in the region. Infill development is generally consistent with ABAG assumptions about smart growth. Given such trends in current planning documents and the promotion of smart growth principles by the regional planning agency, it is reasonable to assume that as general plans are updated to guide future growth (i.e., through the 2030 WSIP buildout), city planners will continue to seek solutions to planning issues that minimize the extent of adverse environmental effects.

- Notwithstanding the constraints to lateral expansion that exist for many jurisdictions, some jurisdictions abut less-developed unincorporated county lands; therefore, at least some jurisdictions could conceivably annex portions of adjacent unincorporated areas to accommodate the jurisdiction's anticipated development.

33 As discussed in Section 7.2, water agencies typically have a longer planning horizon than do local land use planning agencies because of the time required to plan, permit, and construct water supply infrastructure.

Based on the above considerations, the growth supported by the WSIP beyond the level evaluated in adopted land use plans would likely have impacts related to increased density or the development of new land areas, potentially resulting in impacts that are more severe than those identified in the EIRs of adopted land use plans and plan elements.

- Impacts from increased density of development include increased traffic congestion, air pollution, traffic noise, construction noise, and increased demand on public services. On the other hand, it should be noted that accommodating growth by increasing the density of development can help offset some of these identified impacts if it provides sufficient density to support development of public transit or neighborhood retail businesses that help reduce dependency on the use of private vehicles.

- Land area impacts include the loss of open space and agricultural land, loss of wildlife habitat and related impacts on biological resources, potential impacts on cultural resources, and increased impervious surface area, resulting in interference with groundwater recharge and the degradation of surface water quality from polluted runoff.

- Because the WSIP impacts would be similar in kind to those identified in jurisdictions' general plan and plan element EIRs, albeit potentially more severe, the mitigation measures identified in the general plan EIRs (summarized in Appendix E, Section E.5) should apply to such impacts and would serve to reduce them.

- Impacts from employment growth beyond that evaluated in jurisdictions' general plans include increased traffic, especially if workers would be commuting from outside the bay area to new jobs forecasted to occur by 2030; air quality and noise impacts as a result of the increased traffic, and impacts on various public services.

Project-Level Impacts of Growth

As part of this PEIR analysis a selection of EIRs of major projects currently being undertaken in the SFPUC service area were reviewed. The purpose of the review was to assess whether, at least for the small selection of EIRs reviewed, the mitigation measures identified in general plan EIRs were being implemented at the project level. The specific impacts of a project necessarily depend on its particular circumstances, such as the location and nature of the project. Nevertheless, the review indicated that in these instances mitigation measures are being identified to reduce the impacts of growth consistent with measures identified in the general plan EIRs. A summary of the project review and table of impacts and mitigation measures associated with each is included in Appendix E, Section E.6, of this PEIR.

WSIP Role in Addressing the Indirect Effects of Growth

Three jurisdictions in the SFPUC service area identified demand on existing water supply as a significant or significant unavoidable impact. This section summarizes the water supply impacts and mitigation measures identified by these jurisdictions in their general plans and associated EIRs. However, the demand projections in these general plan EIRs are somewhat outdated in that their horizon years are 2000 and 2005, and actual demand (according to 2001 records) has proven to be somewhat different from the EIR projections. The WSIP would help to meet the future demand of these jurisdictions to 2030 (as currently projected by the water agencies that serve them).

The Foster City *General Plan Revision* EIR (1993b) identified increased water demand resulting from future development as a significant and unavoidable cumulative impact. Estero MID, which provides water service to Foster City, obtains all of its water from the SFPUC. The EIR projected that cumulative water demands on the SFPUC system would exceed the system's capacity. As mitigation, the EIR identified a measure requiring new projects to pay fair share contributions to infrastructure improvements, and a measure requiring water conservation in existing and new development; however, the EIR concluded that the impact could not be fully mitigated through these measures. The WSIP would help meet increased demand projected by Estero MID, thus alleviating an impact related to insufficient supply. However, the timeline and current demand estimates have been substantially revised since the general plan EIR was published. The 1993 EIR projected water demand requirements to the year 2000 and estimated that average daily demand that year would be about 7.2 mgd. By contrast, the SFPUC's wholesale demand study cites an Estero MID 2001 demand of 5.8 mgd, and projects its 2030 demand at 6.8 mgd—less than was estimated in the General Plan than for 2000.

The *City of San Mateo Proposed General Plan Revisions EIR* (1990b) also identified inadequate water supply as a significant unavoidable impact. San Mateo receives water from the CWS–Mid-Peninsula District and Estero MID; 77 percent of CWS-Mid Peninsula District service area is within San Mateo and 10 percent of the Estero MID service area is within San Mateo. Both water agencies obtain all of their water from the SFPUC. The EIR projected that San Mateo's demand would increase from 10.2 mgd in 1988 to 12.1 mgd in 2005, and that the existing 1990 water supply contract (of 184 mgd for the wholesale service area as a whole) would not be adequate to meet the needs of the wholesale service area in 2005. As mitigation, the EIR specified conservation measures (i.e., requiring new development to install water-saving bathroom fixtures and use drip irrigation) and inquiry into the use of groundwater for irrigation of public parks and facilities.

As it turned out, 2001 purchases for the wholesale service area totaled 171 mgd (URS, 2004b), somewhat less than the 184 mgd contract limit the general plan EIR indicated would be inadequate to meet service area demand in 2005. In addition, according to the latest BAWSCA annual survey (BAWSCA, 2006b), purchases of SFPUC water for the wholesale service area in FY 2004/2005 totaled 167 mgd. The wholesale demand study estimated base year (2001) demand for the CWS–Mid-Peninsula District to be 17.9 mgd and 2005 demand to be 17.5 mgd, and projected that 2030 demand would increase to 18.1 mgd. The 2001 demand for Estero MID was estimated at 5.8 mgd, 2005 demand at 6 mgd, and 2030 demand at 6.8 mgd. Based on these numbers and San Mateo's share of the total (based on the percentage of these two wholesale customers within the San Mateo jurisdictional boundary), 2001 demand for San Mateo was approximately 13.8 mgd and estimated demand for 2005 was 14.1 mgd, somewhat higher than was projected for 2005 in the 1990 EIR. Assuming the current proportion of service from the two districts, San Mateo's projected demand for 2030 would be approximately 14.8 mgd. Obviously, the WSIP was not available to mitigate the impact of insufficient water supply projected in the general plan EIR for 2005; it is, however, designed to address projected future capacity shortfalls in the wholesale service area and to meet 2030 purchase requests of the two districts serving San Mateo.

The *City of Fremont General Plan Final Program EIR* (1991b) identifies effects on water supply due to increases in population and employment as a significant but mitigable impact. However, the focus of the impact and its mitigation is on the share of the city's supply from the State Water Project. As mitigation, the EIR identifies general plan policies intended to conserve water, and also recommends that Fremont work with area cities and water districts to find a means of increasing the state's water supply for the area. The ACWD, the wholesale customer that serves Fremont, Newark, and Union City, projects an increase in purchases from the SFPUC of only 1.8 mgd above the FY 2001/2002 purchase of 11.99 mgd (to 13.76 in 2030), although the total projected increase in demand for ACWD is 8.2 mgd. The WSIP would meet the ACWD's 2030 purchase estimate.

Key Regional Effects of Planned Growth

This section provides a summary discussion of the key regional effects in the SFPUC service area identified in general plan EIRs, which concern traffic, air quality, and water quality.

Traffic and Circulation

Planned growth in the SFPUC service area is expected to significantly affect local and regional transportation systems, including roadways, highways, transit, and pedestrian and bicycle facilities. Transportation impacts as a result of planned growth in the service area include the following (see Appendix E, Section E.5):[34]

- Increased traffic relative to existing traffic and the capacity of the street system (significant and unavoidable)
- Degradation of levels of service on area roads or highways (significant and unavoidable)
- Increased vehicle delays at area intersections and impacts on intersections in adjacent cities (significant and unavoidable)
- Declines of average speeds on individual roadway segments (significant but mitigable)
- Cumulative traffic impacts on roadway segments and/or intersections (significant and unavoidable)
- Traffic safety impacts (significant and unavoidable)
- Impacts on parking capacity (significant but mitigable)
- Traffic congestion interference with transit service and/or bicycle levels of service (significant but mitigable)
- Constraints on providing for bicycle and pedestrian travel as a result of increased competition for use of roads and highways by motor vehicles (significant but mitigable)

[34] The most severe level of impact cited by any jurisdiction is indicated; the same impact may have a less severe (or no) effect in some jurisdictions.

- Loss of homes due to road widening (significant and unavoidable)
- Construction traffic impacts (significant but mitigable)

As mitigation for traffic and circulation impacts, the general plan EIRs of numerous jurisdictions specify coordination and cooperation with other agencies to develop or improve regional transportation facilities. The following is an overview of the agencies responsible for transportation planning in the four counties of the SFPUC service area.

Transportation planning is addressed at the regional level by the Metropolitan Transportation Commission (MTC), the agency responsible for transportation planning, coordination, and financing for the nine-county Bay Area. California state law requires every county that includes an urbanized area to develop, and update biennially, a congestion management program (CMP). The congestion management agency (CMA) of each county is responsible for developing the CMP. In order to receive state and federal funds, transportation projects must be recommended by that county's CMA as part of its CMP. The CMAs for each of the four counties are as follows: the Alameda County Congestion Management Agency, the Santa Clara Valley Transportation Authority, the City/County Association of Governments of San Mateo County, and the San Francisco County Transportation Authority.

The MTC is responsible for updating the regional transportation plan, a comprehensive, long-range document that charts the future development of mass transit, highway, airport, seaport, railroad, bicycle, and pedestrian facilities. The current plan, *Transportation 2030*, promotes smart growth development patterns through programs that link transportation and land use decisions.

Air Quality

The four counties served by the SFPUC are located in the San Francisco Bay Area Air Basin (SFBAAB). The SFBAAB lies to the west of the Coast Range mountains, which, in the Bay Area, split into western and eastern ranges. San Francisco Bay lies between the two ranges. Air flows into the SFBAAB from the west at the Golden Gate, and then flows out of the SFBAAB to the east at the Carquinez Strait (where it enters the neighboring San Joaquin Valley Air Basin). The SFPUC service area is located in 3 of 11 climatological regions of the SFBAAB: West Alameda, Santa Clara Valley, and Peninsula. Of these, air pollution potential is highest in the Santa Clara Valley, where high summer temperatures, stable air, and the surrounding mountains combine to promote ozone formation. There are also many emissions sources within and upwind of these areas. West Alameda has a relatively high pollution potential during the summer and fall. Planned growth in the SFPUC service area is expected to significantly affect air quality within the air basin. Impacts on air quality as a result of planned growth in the service area include the following (see Appendix E, Section E.5):[35]

- Increases in air emissions and/or ozone precursors (significant and unavoidable)

[35] The most severe level of impact cited by any jurisdiction is indicated; the same impact may have a less severe (or no) effect in some jurisdictions.

- Periodic construction- and/or demolition-related air quality impacts (significant but mitigable)
- Violation of stationary source air quality standard or contribution to an existing or projected air quality violation (significant and unavoidable)
- Increases in exhaust emissions from traffic (significant and unavoidable)
- Cumulative impacts on regional air quality in the Bay Area (significant and unavoidable)
- Exposure of new sensitive land uses to toxic air contaminant or local odor emissions sources (significant and unavoidable)
- Conflicts with, or obstruction of, the implementation of an applicable air quality attainment plan or congestion management plan (significant but mitigable)

With respect to federal air quality standards, the SFBAAB is designated as nonattainment for ozone, unclassified for fine particulate matter, and attainment for other applicable criteria pollutants. With respect to state air quality standards, the SFBAAB is designated as nonattainment for ozone and particulate matter, unclassified for hydrogen sulfide, and attainment for other criteria pollutants.

The Bay Area Air Quality Management District (BAAQMD) is the regional agency responsible for air quality regulation within the SFBAAB. The BAAQMD's *Clean Air Plan* (CAP), last adopted in 2000, applies control measures to stationary and mobile sources and outlines transportation control measures. Although the 2000 CAP is an ozone plan, it includes attainment planning for particulate matter as an informational item. The 1997 CAP and 2000 CAP included 19 transportation control measures, many of which were partially implemented between 1998 and 2000. The 2000 CAP continues to implement and expand key mobile-source programs included in the 1997 CAP.

In response to the federal designation as nonattainment for ozone, the BAAQMD, ABAG, and MTC prepared and adopted an ozone attainment plan to meet the federal standard. The current plan, adopted in 2001, updates and supplements the previous (1999) ozone attainment plan and contains control strategies for stationary and mobile sources. To achieve compliance with the state and federal ozone standards, in September 2005 the BAAQMD, MTC, and ABAG prepared the draft *Bay Area 2005 Ozone Strategy*. This document shows how the San Francisco Bay Area will achieve compliance with the state and federal ozone standards, reduce transport of ozone to neighboring air basins, and fulfill California Clean Air Act planning requirements for the state ozone standard. The draft ozone strategy includes stationary-source control measures, mobile-source control measures, and transportation control measures. (Refer to Section 4.9, Air Quality, for more information.)

The BAAQMD reviews proposed development projects and has permit authority over most types of stationary emission sources. The BAAQMD can impose emission limits, set fuel or material specifications, or establish operational limits to reduce air emissions. The BAAQMD also regulates new or expanding stationary sources of toxic air contaminants. Measures identified in the general plan EIRs to mitigate air quality impacts include working with the BAAQMD to include specific measures in the CAP, but more commonly involve transportation issues and the promotion of alternative modes of transportation.

As discussed under Impact 7.1, above, it is expected that planned growth in the existing SFPUC service area also could contribute to significant increases in greenhouse gas (GHG) emissions. Since the California Global Warming Solutions Act of 2006 (AB 32) was recently codified (in September 2006), the general plan EIRs reviewed for this PEIR do not address the impact of planned growth on GHG emissions and climate change. Because AB 32 limits statewide GHG emissions to 1990 levels, increases in GHG emissions associated with planned growth could impede achievement of mandated future reductions in GHG emissions, which would be a potentially significant and unavoidable impact. AB 32 requires the California Air Resources Board (CARB) to establish a GHG emissions cap for 2020 as well as to adopt Early Action Measures and a plan to ensure that emissions reductions (as mandated by AB 32) will be achieved. All future growth will be required to comply with the CARB's adopted measures by January 1, 2011 (enforced by January 1, 2012). Adherence to these measures will presumably achieve reductions that would help minimize overall GHG emissions increases. However, there is insufficient information available at this programmatic level of analysis to determine the extent of GHG emissions that may result from planned growth in the SFPUC service area and the relationship between CARB's Early Action Measures and growth-related sources of GHG emissions.

Hydrology and Water Quality

Planned growth in the SFPUC service area is expected to significantly affect hydrology and water quality. These impacts include the following (see Appendix E, Section E.5):[36]

- Degradation of surface water and/or groundwater quality (significant but mitigable)
- Increases in impervious surfaces and/or alteration of area drainage resulting in flood hazards and/or the need for new drainage facilities (significant and unavoidable)
- Exposure to people and property to flooding (significant but mitigable)
- Flood hazards, including hazards related to potential dam failure (significant but mitigable)
- Water pollution from stormwater runoff (significant and unavoidable)
- Erosion and sedimentation impacts from increased runoff from inadequately designed drainage systems (significant but mitigable)
- Increased demand on groundwater resources (significant but mitigable)
- Increased frequency and severity of downstream flooding due to increase in impervious surfaces from cumulative development (significant but mitigable)

[36] The most severe level of impact cited by any jurisdiction is indicated; the same impact may have a less severe (or no) effect in some jurisdictions.

The California State Water Resources Control Board and the nine Regional Water Quality Control Boards (RWQCBs) implement and enforce the National Pollutant Discharge Elimination System (NPDES) program, which was established to protect water quality under the federal Clean Water Act. Water quality is regulated at the state level under the Porter-Cologne Water Quality Control Act through standards and objectives set forth in water quality control plans, known as basin plans. The San Francisco Bay RWQCB regulates water quality in the SFPUC service area through its basin plan, which was adopted in 1995. Stormwater in Alameda, Santa Clara, and San Mateo Counties is managed in accordance with an NPDES permit from the San Francisco Bay RWQCB. The NPDES permit includes a comprehensive plan to reduce the discharge of pollutants and requires participating communities to implement an approved stormwater management plan. The stormwater programs incorporate construction controls, stormwater ordinances and other regulatory approaches, public education and industrial outreach, inspections, wet-weather monitoring, and special studies. In 2003, the San Francisco Bay RWQCB updated provisions in its municipal stormwater permits to require that new development and redevelopment projects incorporate treatment measures and other source control and site design features to reduce the level of pollutants in stormwater discharges and to manage runoff flows. Mitigation measures typically identified in general plan EIRs in the SFPUC service area include requiring development projects to incorporate best management practices consistent with the NPDES permit, identify and remediate drainage system deficiencies, and implement erosion and sediment control plans for construction projects.

Conclusion: Indirect Effects of Growth Supported by the WSIP

As indicated above, the WSIP would indirectly contribute to environmental impacts caused by growth; some of these impacts would be unavoidable.

The WSIP would support some of the growth that is reflected in the adopted land use plans of jurisdictions in the SFPUC service area. The EIRs prepared for general plans and related land use plans in the service area identified impacts of planned growth and mitigation measures to reduce the identified impacts. Some of the impacts of planned growth cannot be reduced to a less-than-significant level. In these cases, the respective decision-making body (e.g., city council) identified overriding considerations that justified adoption of the general plan despite its adverse impacts. Due to the longer planning horizon of the WSIP and relative age of some of the adopted general plans, and differing expectations about the level of job growth that will occur in the coming decades, not all of the growth that the WSIP would in part support has been addressed in adopted land use plans or evaluated in the plans’ CEQA documents. Therefore, the WSIP could result in impacts that are somewhat more severe than those identified in the general plan EIRs, although it is likely that the impacts would be similar in kind to those previously identified. Potential impacts beyond those previously identified would generally be related either to increased density of development or to the conversion of less developed areas to urban uses. The measures specified in adopted general plans to mitigate the impacts of growth should also serve to reduce impacts of the WSIP.

The key regional effects of planned growth relate to air quality, traffic congestion, and water quality. Regional agencies, including the MTC, BAAQMD, and RWQCB, and the jurisdictions in the service area, are working both regionally and locally to address these impacts.

By providing water to support planned growth, the WSIP would help to mitigate the environmental impact identified in general plan EIRs for some jurisdictions in the service area of insufficient water supply.

8 WSIP Variants and Impact Analysis

CHAPTER 8
WSIP Variants and Impact Analysis

8.1 Overview

The San Francisco Public Utilities Commission (SFPUC) has requested that this Program Environmental Impact Report (PEIR) include environmental analysis of three variants to the Water System Improvement Program (WSIP or proposed program). The WSIP variants are variations of the proposed program which are designed to meet or exceed all WSIP goals and objectives but differ with respect to water supply source or drought-year level of service. The variants are not necessarily intended to be alternatives to the proposed program that would lessen or avoid environmental impacts as required by the California Environmental Quality Act (CEQA); the CEQA alternatives are described and analyzed in Chapter 9.

Subsequent to the publication of the Draft PEIR, the SFPUC requested that the PEIR address a fourth variant. Please refer to Chapter 13 (Vol. 7) of the PEIR, Section 13.4 for a description and analysis of the fourth variant, the *Phased WSIP Variant*. This chapter describes and analyzes the potential environmental effects of three WSIP variants: *WSIP Variant 1 – All Tuolumne*; *WSIP Variant 2 – Regional Desalination for Drought*; and *WSIP Variant 3 – 10% Rationing*. The variants include the same fundamental facility components and operation/maintenance plan as the proposed WSIP. The major difference between the variants and the proposed program is either in the proposed source(s) of water supply or in the drought-year rationing level of service. To implement these differences, the variants would involve some variation in the extent of facility improvement projects needed. The descriptions and assumptions of the WSIP variants presented in this chapter are based on the report entitled *Water Supply Options* (SFPUC, 2007) and related supporting documentation. **Table 8.1** summarizes and compares the key components of the proposed program and the three variants.

The WSIP variants are designed to meet or exceed all of the goals, objectives, and levels of service of the proposed program as described in Chapter 3, Program Description, Tables 3.2 and 3.5. Thus, all variants are designed to serve the 2030 customer purchase request (regional water system demand) of 300 million gallons per day (mgd) on an average annual basis. **Table 8.2** compares the level of service performance among existing conditions, the proposed program, and the three variants. As shown on this table, while the proposed program and all the variants would meet the WSIP minimum levels of service, some would provide slightly better performance than others with respect to water supply service during drought sequences (discussed in more detail below).

The environmental impact analysis for the WSIP variants presented in this chapter is adapted from Chapter 4, WSIP Facility Projects – Settings and Impacts, Chapter 5, WSIP Water Supply and System Operations – Settings and Impacts, and Chapter 7, Growth-Inducement Potential and Indirect Effects of Growth, of this PEIR. The analysis is based on the same setting information included in those chapters and, for Variant 2, supplemented with information relevant to the regional desalination facility, and uses the same approach to the analysis. Impacts associated with facilities-related construction and operations are discussed separately from impacts associated with water supply and system operations, and the impact analysis and significance determinations are relative to the existing condition (2005) baseline. For the common elements, the variant analysis refers to the same impacts and mitigation measures described in Chapters 4, 5, and 6, supplemented where appropriate with additional impacts and mitigation measures. As described in more detail below, the variants would result in the same impacts as the proposed program for most impact areas. Therefore, to avoid redundancy, this chapter refers extensively to the analyses in Chapters 4 and 5 and focuses on the impacts that differ from those identified for the proposed program, summarizing which impacts would or would not occur under the three variants and augmenting the analysis where appropriate.

Variants 1 and 3 would include all the same or fewer facility improvement projects as the WSIP. Therefore, the basis for the facility impacts of Variants 1 and 3 rely on the detailed analysis presented in Chapter 4 for the proposed program. The basis for the discussion of impacts under Variant 2 also relies on the analysis presented in Chapter 4, however, this variant would require an additional major facility improvement project—the regional desalination project—which is still in the preliminary planning and development phase and lacks site-specific design and siting information. Therefore, the facility impact analysis for the regional desalination project under Variant 2 is also preliminary and at a much more general level of detail than the analysis in Chapter 4. For all three variants, though, the evaluation of potential impacts on water resources due to the water supply and system operations variations relies on the detailed analysis for the proposed program in Chapter 5 and compares the relative impacts of the variants to the impacts identified for the proposed program.

TABLE 8.1
SUMMARY DESCRIPTION OF THE WSIP VARIANTS

Program Element	Existing Condition	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Planning Year	2005	2030	2030	2030	2030
Customer Purchase Request (annual average)	265 mgd	300 mgd	300 mgd	300 mgd	300 mgd
Water Supply Sources[a] (during nondrought and drought periods)	▪ Local watersheds (with Calaveras and Lower Crystal Springs Reservoirs operating at reduced levels based on Department of Safety of Dams restrictions) ▪ Tuolumne River	▪ Local watersheds (with Calaveras and Lower Crystal Springs Reservoirs restored) ▪ Tuolumne River, with 27 mgd increased average annual diversion ▪ Recycled water/groundwater/ additional conservation in San Francisco, 10 mgd	▪ Local watersheds (with Calaveras and Lower Crystal Springs Reservoirs restored) ▪ Tuolumne River, with 32 mgd increased average annual diversion	▪ Local watersheds (with Calaveras and Lower Crystals Springs Reservoirs restored) ▪ Tuolumne River, with 20 mgd increased average annual diversion ▪ Recycled water/groundwater/ additional conservation in San Francisco, 10 mgd	Same as proposed program[b]
Supplemental Dry-Year Water Supply Sources (for implementation during drought periods)	None	▪ Additional Tuolumne River diversions from Turlock and Modesto Irrigation District (TID and MID) transfers of 23 mgd (average over design drought) ▪ Westside Basin conjunctive use, 6 mgd (average over design drought)	Same as proposed program	▪ Potable water from regional desalination plant, 23 mgd (average over design drought) ▪ Westside Basin conjunctive use, 6 mgd (average over design drought)	▪ Additional Tuolumne River diversions from TID and MID transfers of 35 mgd (average over design drought) ▪ Westside Basin conjunctive use, 6 mgd (average over design drought)
Maximum Drought Rationing Policy	No defined limit but assumed incidental rationing of up to 25%	20%	Same as proposed program	Same as proposed program	10%
System Firm Yield	219 mgd	256 mgd	Same as proposed program	Same as proposed program	268 mgd
WSIP Facility Improvement Projects	None	All projects listed in Chapter 3, Table 3.10	Same as proposed program except two projects would not be implemented: Local Groundwater Projects (part of SF-2) and Recycled Water Projects (SF-3)	Same as proposed program	Same as proposed program
Other Facility Improvements	None	None	None	Bay Area Regional Desalination Plant(s) and associated pumping plant(s) and pipelines needed for intertie facilities	None

TABLE 8.1 (Continued)
SUMMARY DESCRIPTION OF THE WSIP VARIANTS

Program Element	Existing Conditions	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Delivery, Operations, and Maintenance	(see Chapter 2, Section 2.3)	(see Chapter 3, Section 3.8)	Same as proposed program	Same as proposed program except, during drought periods, the SFPUC would receive water from the Bay Area regional desalination plant through transfer with other Bay Area water agencies	Same as proposed program except, during drought periods, the maximum rationing would be 10%
Permits and Approvals	(see Chapter 2, Sections 2.4 and 2.5)	(see Chapter 3, Section 3.12)	Same as proposed program	Same as proposed program except: ▪ Agreements with partners in Bay Area regional desalination project ▪ See Table 8.4 for list of potential permits for the Bay Area regional desalination plant ▪ Transfer agreements with TID and MID not needed	Same as proposed program except: ▪ Transfer agreements with TID and MID would be for 35 mgd instead of 23 mgd during droughts

[a] The amount of water from the various sources listed represent the average annual amount as modeled over the 82-year period of hydrologic record using the Hetch Hetchy/Local Simulation Model. In order to maximize use of available water sources under each scenario, the model uses slight variations in levels of service performance during drought years for the different scenarios, affecting the average annual amount of water diverted from the Tuolumne River. Therefore, the average annual diversions from the Tuolumne River under each scenario cannot be directly compared to each other. Thus, when comparing the average annual Tuolumne River diversions under Variant 1 with that of the proposed program, there would be an additional 5 mgd (average annual increase) diverted from the Tuolumne River coupled with a slightly reduced level of service (i.e., slightly more frequent drought rationing) instead of 10 mgd of recycled water/groundwater/conservation; however, both scenarios would still meet the WSIP level of service objectives. Refer to Table 8.2 for description of the level of service performance for the different scenarios.

[b] Under Variant 3, the water supply sources would be the same as the proposed program, but there would be slightly increased diversions from Tuolumne River during drought periods, but this slight increase is not apparent in the average annual diversion values.

SOURCE: SFPUC, 2006.

TABLE 8.2
WSIP VARIANTS – TUOLUMNE RIVER DIVERSIONS AND LEVEL OF SERVICE PERFORMANCE

System Operating Parameter	Existing Conditions	Proposed Program	WSIP Variant 1 – All Tuolumne	WSIP Variant 2 – Regional Desalination for Drought	WSIP Variant 3 – 10% Rationing
Estimated Tuolumne River Diversions over 82-Year Period of Hydrologic Record					
Average Annual Increase by the SFPUC	N/A	27 mgd	32 mgd	20 mgd	27 mgd[a]
Average Annual Diversions by the SFPUC	218 mgd	245 mgd	250 mgd	238 mgd	245 mgd[a]
Drought-Year Shortages based on 82-Year Period of Hydrologic Record					
Years of Shortages (10% Shortage)	6 out of 82 years (1 in 14 years)	6 out of 82 years (1 in 14 years)	8 out of 82 years (1 in 10 years)	Same as proposed program	8 out of 82 years (1 in 10 years)
Years of Shortages (20% Shortage)	8 out of 82 years (1 in 10 years)	2 out of 82 years (1 in 41 years)	6 out of 82 years (1 in 14 years)	Same as proposed program	None
Number of Years Drought-Year Supplies Triggered[b]	N/A	24	26	23	25
Drought-Year Shortages during 8.5-Year Design Drought					
Years of Shortages (10% Shortage)	1 year	3 years	2 years	Same as proposed program	6.5 years
Years of Shortages (20% Shortage)	5 years	3.5 years	5.5 years	Same as proposed program	None
Years of Shortages (25% Shortage)	1.5 years	None	Same as proposed program	Same as proposed program	Same as proposed program
Water Quality					
Complies with current and foreseeable future federal and state water quality requirements?	Yes for current requirements, no for foreseeable future requirements.	Yes, all supplies would meet water quality requirements.	Same as proposed program	Same as proposed program	Same as proposed program
Provides clean, unfiltered water from Hetch Hetchy Reservoir; filtered water from other watersheds?	Yes	Yes, filtration avoidance for Hetch Hetchy supply would be maintained.	Same as proposed program	Same as proposed program	Same as proposed program
Continued implementation of watershed protection measures?	Yes, ongoing implementation of Peninsula and Alameda Watershed Management Plans, and Hetch Hetchy watershed protection agreement with the U.S. National Park Service.	Yes, existing activities augmented by implementation of the Watershed and Environmental Improvement Program and PEIR mitigation measures.	Same as proposed program	Same as proposed program	Same as proposed program
Seismic Reliability					
Complies with current seismic standards?	System complies with seismic standards applicable at the time facilities were constructed, but some system components no longer comply with current seismic standards.	Yes, all WSIP projects would be designed to meet current seismic standards.	Same as proposed program	Same as proposed program	Same as proposed program
Capable of delivering basic service to all regions in the service area 24 hours following a major earthquake?[c]	No	Yes, seismic upgrades implemented as part of WSIP would allow system to accommodate 229 mgd demand within 24 hours.	Same as proposed program	Same as proposed program	Same as proposed program
Facilities restored to meet average-day demand within 30 days of a major earthquake?	No	Yes, seismic upgrades implemented as part of WSIP would allow system to accommodate 300 mgd demand within 30 days.	Same as proposed program	Same as proposed program	Same as proposed program
Delivery Reliability					
Provides operational flexibility to allow for planned maintenance without service interruptions?	Limited to parts of the system	Yes, program would include complete planned maintenance program.	Same as proposed program	Same as proposed program	Same as proposed program
Provides operational flexibility and system capacity to replenish local reservoirs, as needed?	Limited ability	Yes, program would provide operational flexibility and system capacity to replenish local reservoirs.	Same as proposed program	Same as proposed program	Same as proposed program
Capable of minimizing risk of service interruption due to unplanned facility upsets or outages?	Limited ability	Yes, maintenance program would incorporate provisions for unplanned facility upsets or outages.	Same as proposed program	Same as proposed program	Same as proposed program
Capable of serving average 2030 demand of 300 mgd with one planned shutdown of a major facility and one unplanned facility outage?	No	Yes	Same as proposed program	Same as proposed program	Same as proposed program

TABLE 8.2 (Continued)
WSIP VARIANTS – TUOLUMNE RIVER DIVERSIONS AND LEVEL OF SERVICE PERFORMANCE

	Existing Conditions	Proposed Program	WSIP Variant 1 – All Tuolumne	WSIP Variant 2 – Regional Desalination for Drought	WSIP Variant 3 – 10% Rationing
Water Supply					
Capable of reliably serving average 2030 demand of 300 mgd during nondrought years?	No, although the system could occasionally serve 300 mgd during nondrought years, it could not reliably deliver this amount.	Yes, system would be capable of reliably serving average annual purchase requests of 300 mgd during nondrought years.	Same as proposed program	Same as proposed program	Same as proposed program
Meets drought-year delivery needs through 2030 while limiting rationing to 20% during 8.5-year design drought?	No	Yes, rationing would not exceed 20% during an 8.5-year design drought.	Same as proposed program	Same as proposed program	Yes, rationing would not exceed 10% during the 8.5-year design drought.
Meets system firm yield of 256 mgd?	No	Yes, system firm yield objective would be achieved.	Same as proposed program	Same as proposed program	Yes, system firm yield objective would be 268 mgd, surpassing WSIP objective
Diversifies water supply options during nondrought and drought periods and improves use of new water sources, including groundwater, recycled water, additional conservation, and water transfers?	No	Yes, the proposed program includes 10 mgd of recycling, groundwater, and additional conservation in all years and relies on groundwater from conjunctive-use program and water transfers during drought years.	Not during normal (nondrought) years except for the use of surface supplies to offset groundwater use to support the conjunctive-use program. Yes during drought years, since groundwater from conjunctive-use program and water transfers would be utilized.	Yes, includes 10 mgd of recycling, groundwater and additional conservation in all years and relies on desalination, and conjunctive use during drought years.	Same as proposed program

[a] Because of the reduced level of rationing, Variant 3 – 10% Rationing would result in slightly increased average annual Tuolumne River diversions over the 82-year hydrologic record compared to the proposed program, but due to rounding, the levels of diversion appear to be the same.
[b] The number of times over the 82-year hydrologic record that drought-year supplies would be used to augment supplies. See Table 8.1 for the source of drought-year supplies under existing conditions, the proposed program, and the variants.
[c] Basic service is defined as average winter-month usage with a regional performance objective of 229 mgd. The performance objective is to provide delivery to at least 70 percent of the turnouts in each region (104 mgd for East/South Bay; 44 mgd for Peninsula; and 81 mgd for San Francisco).

This chapter is organized as follows. Each of the three variants and its associated facilities-related impacts are described in detail in Sections 8.2, 8.3, and 8.4, respectively; these sections provide the facilities impact analysis for the variants, similar to Chapter 4. Section 8.5 evaluates the impacts resulting from water supply and system operations for all variants, similar to Chapter 5. As with the proposed program, the Hetch Hetchy/Local Simulation Model (HH/LSM) water supply planning model (described in Chapter 3, Section 3.4 and detailed in Appendix H) was used to evaluate the performance of the three variants relative to the goals and objectives of the WSIP, based on historical hydrologic data for the 82-year period from 1920 to 2002, as well as to predict the impacts of water supply and system operations on the affected water resources. The last section, Section 8.6, presents a comparison of the major impacts of the proposed program and the three variants.

8.2 WSIP Variant 1 – All Tuolumne

8.2.1 Description

Water Supply

The water supply for *WSIP Variant 1 – All Tuolumne* would be identical to that proposed for the WSIP, except that to accommodate the estimated 35-mgd average annual increase in purchase request (from 265 to 300 mgd) by the year 2030, customers would be served entirely with additional water from the Tuolumne River watershed. The water supply would not include the 10 mgd from implementation of the Recycled Water Projects (SF-3), Local Groundwater Projects[1] (a component of SF-2, Groundwater Projects), and additional conservation programs in San Francisco in the WSIP proposed water supply option. In all other respects, *WSIP Variant 1 – All Tuolumne* would include the same water supply sources as the proposed program. During all hydrologic year types, this variant would continue to maximize use of local water supplies from the Alameda and Peninsula watersheds and would accommodate the remaining purchase requests from Tuolumne River diversions. During extended dry-year sequences, supplemental water would be obtained from Tuolumne River diversions through transfers from the Turlock Irrigation District (TID) and Modesto Irrigation District (MID) as well as through implementation of a conjunctive-use program in the Westside Groundwater Basin, identical to the WSIP. Using the HH/LSM, the SFPUC determined that the average annual Tuolumne River diversion could increase by 32 mgd under this variant compared to existing (2005) conditions and by 5 mgd[2] compared to the proposed program.

1 The Local Groundwater Projects involve the development of 4 mgd of new potable water groundwater sources in San Francisco. About 2 mgd of local groundwater would be developed from four new groundwater wells; 2 mgd would be obtained by converting groundwater currently used for irrigation to a potable supply and meeting the irrigation demands previously met by groundwater with recycled water.

2 When comparing the Tuolumne River diversions under Variant 1 with the proposed program, there would be an additional 5 mgd (average annual) diverted from the Tuolumne River coupled with a slightly reduced level of service (i.e., slightly more frequent drought rationing) instead of 10 mgd of recycled water/groundwater/additional conservation. Refer to Table 8.2 for description of the level of service performance for the different scenarios.

Regional Water System Operations

Under *WSIP Variant 1 – All Tuolumne*, the operation, maintenance, and delivery strategy of the SFPUC regional water system would be essentially identical to that proposed under the WSIP (see Chapter 3, Section 3.8, Proposed System Operations Strategy). Specific operating procedures, however, would vary slightly due to the absence of local recycled and groundwater supplies in San Francisco and the increased use of Tuolumne River water supplies to accommodate the 2030 customer demands. The differences in operating procedures between this variant and the proposed program and the effects of this variant on water resources are discussed in more detail in Section 8.5, below.

Level of Service Performance

WSIP Variant 1 – All Tuolumne would achieve all of the proposed WSIP level of service performance goals through 2030, as shown in Table 8.2. However, as shown in the table, even though it would achieve the performance goals, this variant would have different implications in terms of its performance during the design drought when compared to the WSIP. These differences are due to minor variations in the assumptions used to model the operating strategy required to provide customer water deliveries during the design drought, and actual operations during a drought sequence would likely be similar for Variant 1 and the proposed program.

As shown in Table 8.2, modeling results indicate that the proposed program would perform slightly better than Variant 1 with respect to drought response. While both the proposed program and Variant 1 would limit rationing to 20 percent during drought sequences, *WSIP Variant 1 – All Tuolumne* would result in an estimated slight increase in the number of drought-year shortages compared to the WSIP. When modeled over the 82-year period of hydrologic record (1920–2002), Variant 1 would trigger the drought response program 26 times in the 82-year period, with rationing required in 14 of those years; this compares to 24 times that the drought response program would be triggered under the proposed program, with rationing in 8 of the years. Another way of indicating the difference in level of service performance is to consider that, when modeled over the 8.5-year design drought, Variant 1 would require 2 years of rationing at 10 percent and 5.5 years at 20 percent (7.5 out of 8.5 years subject to rationing), while the proposed program would require 3 years of rationing at 10 percent and 3.5 years at 20 percent (6.5 out of 8.5 years subject to rationing). The slight increase in severity of rationing is due to absence of the 10 mgd from implementation of the Recycled Water Projects (SF-3), Local Groundwater Projects (a component of SF-2, Groundwater Projects), and additional conservation programs in San Francisco. Instead of serving a net 290 mgd demand with system resources (300 mgd purchase request less 10 mgd of recycling, groundwater and additional conservation projects in San Francisco), the regional system would serve a 300 mgd demand, requiring a greater level of rationing to deliver the same amount of water.

Facility Requirements

WSIP Variant 1 – All Tuolumne would require the construction of nearly all of the same facility improvement projects as the proposed program. Under this variant, the Recycled Water Projects (SF-3) and Local Groundwater Projects in San Francisco (a component of SF-2, Groundwater Projects) would not be constructed. All other WSIP projects would be constructed and implemented as described in Chapter 3, Section 3.9, Proposed Facility Improvement Projects.

Institutional Requirements

WSIP Variant 1 – All Tuolumne would involve the same institutional requirements as the proposed program, as described in Chapter 3, Section 3.12, Required Actions and Approvals, except that the SFPUC would not need permits for the recycled water or groundwater projects in San Francisco.

8.2.2 Setting

The regional setting for facility improvement projects for *WSIP Variant 1 – All Tuolumne* is the same as the regional setting for the WSIP study area described in Chapter 4, extending from Oakdale Portal in Tuolumne County west along the regional water system to its terminus in San Francisco. Similarly, the regional setting for potentially affected watersheds and drainages, including the Tuolumne River, Alameda Creek, and Peninsula watersheds, is the same as that described for the proposed program in Chapter 5.

8.2.3 Impact Analysis – Facilities Construction and Operation

Under *WSIP Variant 1 – All Tuolumne*, potential impacts related to the construction and operation of WSIP facilities would be the same in all respects as those described for the proposed program in Chapter 4, except for impacts associated with the Recycled Water Projects (SF-3) and Local Groundwater Projects in San Francisco (a component of SF-2, Groundwater Projects). The Recycled Water Projects includes two recycled water projects scheduled to occur from 2010 to 2012: a series of recycled water treatment/storage/transmission facilities along the westside of San Francisco and the Harding Park/Lake Merced project. Since these projects would not be constructed under *WSIP Variant 1 – All Tuolumne*, no impacts associated with the Recycled Water Projects would occur, and the associated mitigation measures would not be required.

The Groundwater Projects (SF-2) includes three groundwater projects scheduled for construction from 2009 to 2014: the Lake Merced, other Local Groundwater, and Westside Groundwater Basin conjunctive-use projects. Under the variant, only the Lake Merced and Westside Groundwater Basin conjunctive-use components would be constructed; therefore, impacts associated with the other Local Groundwater component would not occur.

This variant would have slightly fewer environmental impacts than those associated with WSIP facilities construction and operation, particularly in the west side of San Francisco; as a result, there would be fewer impacts contributing to cumulative facilities impacts in the San Francisco Region of the regional water system. However, in all other respects, this variant would result in the same facilities-related cumulative impacts as those identified and described in Chapter 4 for the proposed program. **Table 8.3** identifies the impacts that would occur under *WSIP Variant 1 – All Tuolumne* related to facilities construction and operation.

Impacts associated with water supply and systemwide operations for all of the variants are discussed below in Section 8.5. The growth-inducement potential of Variant 1 as well as the indirect environmental effects associated with growth would be identical to those described for the proposed program in Chapter 7.

8.2.4 Mitigation Measures – Variant 1

Nearly all mitigation measures for facilities-related impacts identified for the proposed program and described in Chapter 6 would apply to Variant 1. Table 8.3 summarizes the facilities-related impacts of Variant 1; where applicable, the corresponding mitigation measures are presented in Chapter 6. Variant 1 would require slightly fewer mitigation measures compared to the proposed program, since the Recycled Water Projects (SF-3) and other Local Groundwater Projects in San Francisco (a component of SF-2, Groundwater Projects) would not be constructed. Mitigation measures related to water resources impacts applicable to Variant 1 would be identical to those for the proposed program, as described in Chapters 5 and 6 and discussed below in Section 8.5.

8.3 WSIP Variant 2 – Regional Desalination for Drought

8.3.1 Description

Water Supply

The water supply for *WSIP Variant 2 – Regional Desalination for Drought* would be identical to that proposed for the WSIP, except that during drought years the SFPUC would receive water from a proposed regional desalination plant instead of water transfers from TID and MID. Under this variant, the SFPUC, through its participation in the Bay Area Regional Desalination Project (BARDP) (a description of the BARDP is provided below under Facility Requirements), would receive additional water supply of up to 26 mgd during drought periods (an average annual yield of 23 mgd over the 8.5-year design drought), either directly or indirectly, from one or two regional desalination plants to meet the WSIP water supply and firm yield objectives. As described below under Facility Requirements, the BARDP would include facilities and institutional arrangements for a regional desalination plant(s) as well as those required for water transfers and conveyance to the participating agencies. The SFPUC would not need to develop water transfers agreements with TID and MID for supplemental water during drought periods under this variant, thereby reducing the overall increase in average annual diversion from the Tuolumne River by the SFPUC.

TABLE 8.3
SUMMARY OF FACILITY CONSTRUCTION AND OPERATION IMPACTS FOR WSIP VARIANTS

Impact	Variants 1, 2, and 3																				Variant 1 only	Variants 2 and 3 only		Variant 2 only[a]
	Advanced Disinfection	Lawrence Livermore Supply Improvements	San Joaquin Pipeline System	Rehabilitation of Existing San Joaquin Pipelines	Tesla Portal Disinfection Station	Alameda Creek Fishery Enhancement	Calaveras Dam Replacement	Additional 40-mgd Treated Water Supply	New Irvington Tunnel	SVWTP – Treated Water Reservoirs	San Antonio Backup Pipeline	Bay Division Pipeline Reliability Upgrade	BDPL Nos. 3 and 4 Crossovers	Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault	Baden and San Pedro Valve Lots Improvements	Crystal Springs/San Andreas Transmission Upgrade	HTWTP Long-Term Improvements	Lower Crystal Springs Dam Improvements	Pulgas Balancing Reservoir Rehabilitation	San Andreas Pipeline No. 3 Installation	Groundwater Projects – Lake Merced and Regional Components Only	Groundwater Projects	Recycled Water Projects	Regional Desalination for Drought

</table>

NOTE: Shaded boxes indicate where potential impacts and/or significance levels for the variant differ from those of the proposed program.

[a] The regional desalination plant and associated facilities under Variant 2 could result in additional impacts that are not shown in the table but would be determined during project-level environmental review when more detailed siting, design, construction and operation information is available. As discussed further in the text, additional potentially significant impacts could include: water quality and aquatic resources impacts due to disposal of brine concentrate; water quality and aquatic resources impacts due construction and operation of intake and outfall structures; potential for impacts associated with seiche, tsunami or mudflow; and potential cumulative impacts associated with increased salinity in the Delta due to increased diversion of freshwater inflow from the Tuolumne River coupled with discharge of brine concentrate.

THIS PAGE INTENTIONALLY LEFT BLANK

During nondrought years, similar to the proposed program, the SFPUC would accommodate the projected increase of 35 mgd in purchase requests through 2030 by implementing additional conservation programs, Recycled Water Projects (SF-3), and Local Groundwater Projects in San Francisco (a component of SF-2, Groundwater Projects) and by diverting additional surface water from the Tuolumne River. On an average annual basis over the 82-year period of hydrologic record, Variant 2 would result in a 20-mgd increase in diversions from the Tuolumne River over the existing condition, 7 mgd less than the proposed program. During drought years, the increase in system firm yield through 2030 would be met through potable water produced by the BARDP combined with the Westside Groundwater Basin conjunctive-use project (a component of SF-2, Groundwater Projects) along with the yield associated with the restoration of storage capacity in Calaveras and Crystal Springs Reservoirs as part of the WSIP facility improvement projects. During the 8.5-year design drought, the average annual yield from the BARDP would be 23 mgd; average annual yield from the Westside Groundwater Basin conjunctive-use project would be 6 mgd, which is the same as under the proposed program.

Regional Water System Operations

Under *WSIP Variant 2 – Regional Desalination for Drought*, the operation, maintenance, and delivery strategy of the SFPUC regional water system would be essentially the same as that proposed under the WSIP during nondrought periods (see Chapter 3, Section 3.8, Proposed System Operations Strategy). However, during drought periods under this variant, the BARDP would supplement the water supply sources in addition to the Westside Basin conjunctive-use project. During drought periods, the SFPUC would receive water from a regional desalination plant or plants through water transfers from other Bay Area water supply agencies; water transfer facilities and operations would be developed as needed as part of the BARDP. The differences in regional system operating procedures between this variant and the proposed program are discussed in more detail in Section 8.5, below.

Level of Service Performance

As indicated in Table 8.2, *WSIP Variant 2 – Regional Desalination for Drought* would achieve all of the proposed level of service performance goals through 2030. However, as shown in the table, even though it would achieve the performance goals, this variant would have slightly different implications in terms of its performance during drought years when compared to the proposed program. These differences are due to minor variations in the assumptions used to model the operating strategy required to provide customer water deliveries during the design drought, and actual operations during a drought sequence would likely be similar for Variant 2 and the proposed program.

Modeling results indicate that Variant 2 would perform slightly better than the proposed program with respect to drought response. When modeled over the 82-year period of hydrologic record (1920–2002), under Variant 2 the drought response program would be triggered 23 times in the 82-year period, with rationing required in 8 of those years; this compares to 24 times under the WSIP that the drought response program would be needed, also with rationing in 8 of the years. Both Variant 2 and the proposed program would perform similarly during the design drought sequence. As stated above, these minor differences are due to the modeling assumptions, and there would likely be no noticeable differences between Variant 2 and the proposed program during actual operations.

This level of service analysis for Variant 2 assumes full implementation of the BARDP and does not incorporate any evaluation of feasibility or reliability associated with the BARDP. Feasibility and reliability studies associated with the BARDP are being conducted as part of that planning effort (see below under “Development of BARDP”) and are not available at this time.

Facility Requirements

Under *WSIP Variant 2 – Regional Desalination for Drought*, all of the same facility improvement projects would be implemented as those proposed under the WSIP, as described in Chapter 3, Section 3.9, Proposed Facility Improvement Projects. In addition, Variant 2 would require construction of one or two Bay Area regional desalination plants and associated conveyance and delivery facilities, as described below.

Bay Area Regional Desalination Project

The BARDP involves a partnership among regional water agencies, including the SFPUC, Contra Costa Water District (CCWD), East Bay Municipal Utility District (EBMUD), and Santa Clara Valley Water District (SCVWD), for the purpose of developing desalination as a regional water supply to improve supply reliability for over 5 million people served by the four agencies. The proposed BARDP would develop and implement one or two desalination plants and associated facilities capable of producing about 65 to 71 mgd of potable water from ocean water, seawater, or brackish water. The BARDP would benefit participating agencies by allowing them to either directly receive desalination product water into their water systems or to receive transfers from other agencies that directly receive desalination product water. However, the institutional commitments and arrangements to implement a full-scale desalination plant as well as the necessary technical and feasibility studies have not been completed.

Development of the BARDP

A pre-feasibility study has been completed for the BARDP facility (URS, 2003). In 2005, the agencies received a grant from the California Department of Water Resources to complete a feasibility study to evaluate the institutional feasibility for the BARDP, and in 2006 the participating agencies received a second grant from the California Department of Water Resources to construct a desalination pilot plant (EBMUD, 2006). The pre-feasibility study included a review of the participating agencies and their water needs, a summary of recent desalination projects, preliminary identification of permitting requirements, an overview of the desalination process and product water quality issues, and a preliminary siting study identifying three possible locations for a regional desalination plant. The pilot plant would test technologies and methods for intake of source water, pretreatment, brine disposal, and other processes required for a full-scale plant. The pilot plant and related studies are scheduled to be implemented from 2007 to 2009.

The participating agencies are currently preparing a feasibility study for the project. Elements of the feasibility study include an analysis of the institutional issues for implementation of the full-scale BARDP, assessment of site and infrastructure options for the three short-listed sites, preparation of preliminary site layouts for a single large facility and a smaller facility, preparation of a detailed scope of environmental analysis for the development of a full-scale BARDP, public outreach, and preparation of the feasibility study report. If the feasibility study and pilot testing demonstrate the viability of the project, it is expected that environmental review would occur in 2009, design in 2010, and construction of the full-scale BARDP in 2012. The pilot plant has not been designed, and the CEQA and permitting processes have not begun.

For the purposes of the programmatic review of WSIP Variant 2 in this PEIR, the conclusions developed in the *Bay Area Regional Desalination Project Pre-Feasibility Final Report* (URS, 2003) and *Bay Area Regional Desalination Project, Grant Proposal for Proposition 50 Chapter 6(a) Funding* (EBMUD, 2006) are summarized below and used to make broad assumptions regarding the facility requirements of the desalination plant needed in Variant 2. However, extensive technical studies are still necessary to identify the appropriate site(s) and to develop the conceptual engineering for a desalination project in the Bay Area. The preliminary assumptions are subject to change pending further investigations, design and siting of the plant, pilot plant test results, as well as clarification of institutional uncertainties. If the BARDP is to be implemented, site-specific environmental review will be required prior to project approval.

Preliminary Description of BARDP

The studies cited above and completed to date have identified three possible locations for a regional desalination plant: the Oceanside site in San Francisco, Bay Bridge site in Oakland, and East Contra Costa site near Pittsburg in eastern Contra Costa County. The preferred project would consist of a 65 to 71 mgd desalination plant(s) located at one or two of these three sites, as shown in **Figure 8.1**. Currently, the pilot plant and top-ranked site for the regional plant is the East Contra Costa site, which is generally located along the industrial shoreline area of eastern Contra Costa County, as shown in **Figure 8.2**.

The desalination plant would use brackish or saline water as source water and produce potable drinking water that meets all drinking water standards; the potable water or "product water" produced from the plant would be of similar quality to the water that is currently being provided to customers by the participating municipal utilities that would receive the product water in their distribution systems. The conceptual processes for the desalination plant include filtration to remove suspended solids, a dual-stage reverse-osmosis[3] system to remove salts, and post-treatment to stabilize and disinfect the water to make it suitable for mixing in drinking water systems. Depending on the site(s) selected for the development of the full-scale BARDP, the desalination project may require multiple components, including raw water supply/intake facilities, process and treatment facilities, and concentrate disposal facilities/outfall structures. To

3 Reverse osmosis is a process to remove salt from water whereby pressure is applied to water with higher salt concentration in order to force it to flow across a membrane towards water with lower salt concentration. The majority of total dissolved solids remain on the side of the membrane with the higher salt concentration.

Figure 8.1
Potential Sites for Regional Desalination Plant

convey the product water from the desalination plant to the water supply agencies, transmission pipelines and pump station(s) would also be required. It is assumed that the BARDP would use or modify existing distribution and transmission facilities to the extent possible.

For the East Contra Costa site, it is estimated that a booster pump station and about two miles of pipeline would be needed to connect to the existing transmission facilities of the CCWD, EBMUD, or both. Energy consumption for a desalination plant at the East Contra Costa site is estimated at 7,500 kilowatt-hours per million gallons of product water, depending on the site and the size of the plant. Energy consumption at the Bay Bridge site in Oakland is estimated at 19,000 kilowatt-hours per million gallons of product water, and at the Oceanside site in San Francisco is estimated at 22,000 kilowatt-hours per million gallons of product water. At both the Oakland and San Francisco sites, further studies are needed to determine the extent and nature of additional water conveyance, transfer, or delivery facilities. Depending on the final site selected, it might be possible to modify some facilities that are already present at the site (such as intake structures, outfall structures, or energy facilities), in which case new facilities would not be needed as part of either the desalination plant or the associated conveyance or delivery facilities.

SFPUC Water System Improvement Program . 203287

Figure 8.2
Location of Regional Desalination Project Pilot Plant

Proposed operation of the regional desalination plant(s) would be developed as part of the technical studies and would depend on numerous factors, including the site(s) selected, final design of the plant, and institutional agreements among participating agencies.

Under this variant, the SFPUC would receive transfer water from other Bay Area water agencies in all cases, except if the facility were located in San Francisco. As a possible operating scenario, during drought years the SFPUC could receive an equivalent share of its BARDP water in the form of a surface water transfer from EBMUD. Potable water received from EBMUD could be conveyed to the SFPUC/EBMUD intertie located in the city of Hayward. The water received through the intertie, up to 26 mgd, would then be conveyed into the SFPUC regional system through the Bay Division Pipelines.[4] Alternatively, in the event that a facility is located in San Francisco, the SFPUC could receive water directly from the desalination plant.

4 Use of the SFPUC/EBMUD intertie for drought supply would require further environmental review, since the intertie project description only included use for emergencies and critical maintenance.

Institutional Requirements

Implementation of the *WSIP Variant 2 – Regional Desalination Project* would have all of the same institutional requirements as the proposed program, except that it would not require the transfer agreements with TID and MID for the supplemental dry-year supply, and it would require additional institutional agreements for the BARDP. In addition to the institutional agreement among the participating agencies, the BARDP would require various agreements, permits, and approvals for construction and operation. The BARDP would require interagency cooperation to cover environmental/construction costs and transfer agreements among participating agencies involved in water transfers. A preliminary list of operating permits and approvals from federal, state, and local regulatory agencies that may apply to the BARDP is presented in **Table 8.4**, below. A subset of these permits and regulatory approvals may be applicable, depending on the site(s) selected for the development of the BARDP. Although not shown in the table, the BARDP would also be subject to requirements of CEQA, and possibly the National Environmental Policy Act (NEPA) if federal agencies become involved; however, the lead agency or agencies for the CEQA and NEPA processes would not be identified until institutional agreements among the participating agencies are developed.

8.3.2 Setting

The regional setting for *WSIP Variant 2 – Regional Desalination for Drought* is the same as the regional setting for the WSIP study area described in Chapters 4 and 5, except for the BARDP component described below. The BARDP setting includes the facilities setting extending from Oakdale Portal in Tuolumne County west along the regional system to its terminus in San Francisco, as well as the water resources setting encompassing the Tuolumne River, Alameda Creek, and Peninsula watersheds.

The regional setting for the BARDP desalination plant and associated facilities described below is based on the East Contra Costa site since it is the site selected for pilot testing. However, the final site for the regional desalination plant has not been selected and is pending the completion of ongoing studies, including the feasibility study and pilot plant project. For the purposes of providing a general review in this PEIR for review of WSIP Variant 2, it is assumed that the BARDP site would be located in eastern Contra Costa County.

The East Contra Costa site is located in an unincorporated area of Contra Costa County between Pittsburg and Antioch. The Suisun Bay and New York Slough are located to the north and northeast of the county’s shoreline. The potential sites for the desalination plant are located in generally industrial areas that include such facilities as the PG&E Pittsburg Substation, the Delta Diablo Sanitation District facilities, and Mirant Pittsburg Power Plant. One possible site would be co-located with an existing power plant, sharing its intake and outfall structures.

Potentially affected waters in the vicinity of the proposed BARDP include Suisun Bay and New York Slough, both tributaries to San Pablo Bay. Suisun Bay receives flow from the Sacramento and San Joaquin Rivers. Due to freshwater inflow from rivers, the salinity of water in Suisun Bay is generally lower than in downstream waters such as San Pablo Bay (Contra Costa

TABLE 8.4
PRELIMINARY PERMITS AND APPROVALS FOR THE BAY AREA REGIONAL DESALINATION PROJECT

Agency/Requirement(s)	Activities Subject to Requirement	Relevance to the BARDP
FEDERAL		
U.S. Army Corps of Engineers: Clean Water Act, Section 404 Permit, Rivers and Harbors Act of 1899, Section 10	Filling of wetlands or surface waters	Intake and outfall structures, pipelines (creek crossings)
U.S. Fish and Wildlife Service: Federal Endangered Species Act, Section 7 Consultation	Effects on federally listed species and habitat	Desalination plant and associated facilities, concentrated salt discharge from reverse-osmosis process
National Marine Fisheries Service: Federal Endangered Species Act, Section 7	Effects on federally listed fish species	Desalination plant and associated facilities, concentrated salt discharge from reverse-osmosis process
STATE		
California Coastal Commission: California Coastal Act, Coastal Development Permit	Development in coastal zone, including tidelands, submerged lands, and public trust lands	Desalination plant and associated facilities, pipelines
California Department of Fish and Game: Streambed Alteration Agreement	Changes in natural condition of streams, lakes, and rivers	Pipelines (creek crossings)
California Endangered Species Act, Section 2081 Agreement	Effects on state-listed species and habitats	Facility construction and operations
California Department of Health Services: Drinking Water Permit Source Water Assessment and Protection Plan	Drinking water permit	Desalination plant and facilities for new water supply source
California State Lands Commission	Offshore components on any ungranted tidelands	Intake and outfall structures
California State Water Resources Control Board	Water-rights permit	Desalination plant for new water supply source
California Regional Water Quality Control Board, San Francisco Bay Region: Clean Water Act, Section 401 Water Quality Certification	Activities affecting surface water quality	Pipelines (creek crossings) All proposed facilities
National Pollutant Discharge Elimination System Permit or Waste Discharge Requirements for discharge of brine	Operation of plant for discharge of brine	
National Pollutant Discharge and Elimination System Permit for Stormwater	Construction and operation activities	
State Historic Preservation Office	Any activities affecting potentially historic resources	Use of existing, potentially historic structures or facilities
REGIONAL		
San Francisco Bay Conservation and Development Commission	Activities affecting the San Francisco Bay shoreline	Intake and outfall structures

NOTE: Federal and state environmental review requirements under NEPA and CEQA not shown on this table since federal involvement and NEPA requirements are currently unknown and state lead agency under CEQA is also unknown.

County and City of Pittsburg, 2001). Extensive marsh and wetland areas along Suisun Bay provide habitat for a variety of plant and wildlife species.

8.3.3 Impact Analysis – Facilities Construction and Operation

Under *WSIP Variant 2 – Regional Desalination for Drought*, facilities construction and operation impacts would consist of WSIP facilities impacts, BARDP impacts, and the cumulative and growth impacts of both.

WSIP Facilities Impacts

Potential impacts related to the construction and operation of WSIP facilities would be the same in all respects for Variant 2 as those described for the proposed program in Chapter 4. These impacts are summarized in Table 8.3.

Bay Area Regional Desalination Project Impacts

The impact analysis for the BARDP in the context of Variant 2 is based on the general project description provided above, including descriptions from the pre-feasibility study (URS, 2003) and the pilot plant grant application (EBMUD, 2006). However, since the BARDP is still in the conceptual planning phase, detailed project information has not yet been developed for its design, construction, or operation, and CEQA environmental documentation has not been completed (or even started). Therefore, for the purpose of this PEIR, a conceptual-level, generalized impact analysis of the BARDP is presented based on the BARDP assumptions described above. The formal CEQA environmental review of the BARDP will be conducted at a time deemed appropriate by the participating agencies and under the purview of the designated CEQA lead agency. The impact discussion presented below is intended solely to provide a basis for comparing potential environmental impacts at a programmatic level among the proposed program and three variants; the impacts and their significance determinations are based on limited, preliminary information and the actual project-specific impact assessment will be conducted during formal CEQA environmental review of the BARDP.

Chapter 4 includes programmatic impact analyses and mitigation measures for the construction and operation of generic facility types, including pipelines, pump stations, and treatment facilities. Much of this information is applicable to the regional desalination plant and associated facilities, and the reader is referred to Chapter 4 for those discussions. In general, due to the preliminary nature of the project design, uncertainty regarding site locations, and lack of site- and project-specific information, most of the potential impacts associated with construction and operation of a desalination plant and related facilities are considered potentially significant at this conceptual level of analysis. However, in most cases, it is presumed that potential impacts could be avoided or reduced to a less-than-significant level through careful site selection and site layout, appropriate project design, and environmentally-sensitive construction and operation techniques or through implementation of mitigation measures, as described below.

Plans and Policies

The pre-feasibility study identified three options for BARDP institutional arrangements: (1) contracting among the participating agencies, with one being the lead agency, (2) creating a joint powers authority among the participating agencies, or (3) each participating agency contracting with a third party such as the California Department of Water Resources or the U.S. Bureau of Reclamation. The specific plans and policies applicable to the BARDP would depend on the institutional arrangements for its construction and operation as well as on the final project location.

Based on the identification of a preliminary site along the eastern Contra Costa County shoreline, the Bay Conservation and Development Commission's (BCDC) *San Francisco Bay Plan* was reviewed for relevant goals and policies applicable to the construction and operation of a desalination plant (BCDC, 2005).

The *San Francisco Bay Plan* guides conservation of San Francisco Bay waters and development of its shoreline. The Bay Plan includes specific policies applicable to geographic segments of the bay shoreline, although none are identified in the vicinity of the East Contra Costa site. The Bay Plan includes the following policies relevant to desalination:

> Policy 10: Desalination projects should be located, designed, and operated in a manner that: (a) avoids or minimizes to the greatest practicable extent adverse impacts on fish, other aquatic organisms, and wildlife and their habitats; (b) ensures that the discharge of brine into the bay is properly diluted and rapidly disperses into the bay waters to minimize impacts; and (c) is consistent with the discharge requirements of the Regional Water Quality Control Board.
>
> Policy 11: Because desalination plants do not need to be located in the bay or directly on the shoreline: (a) no bay fill should be approved for desalination plants except for a minor amount of fill needed for pipelines, fish screening devices, and other directly related facilities that provide bay water to a plant and discharge diluted brine from the plant back into the bay; and (b) maximum feasible public access consistent with the project should be included as part of any desalination project that uses bay waters.

It is presumed that the final design of the BARDP would be consistent with the *San Francisco Bay Plan*. Similarly, it is assumed that project planning, site selection, and design of the BARDP would be consistent with other applicable land use plan policies, if any, although in the absence of site-specific information there remains the potential for conflicts with adopted plans.

Land Use and Visual Quality

In the process of selecting the preliminary site along the eastern Contra Costa County shoreline, potential sites considered for the desalination plant were generally limited to those with compatible land uses (e.g., sites with existing industrial or utility uses such as refineries, wastewater treatment plants, power plants, or airports). Some open space/marsh sites adjacent to existing industrial uses were also considered. However, pending final site selection for the plant and associated facilities, potential land use and visual impacts are considered to be similar to those described in Chapter 4, Section 4.3 (Impacts 4.3-1 to 4.3-5). These impacts include the potential for temporary conflicts with established uses during construction, permanent displacement of existing land uses, temporary or permanent degradation of visual resources/scenic views, and new sources of light and glare. In the absence of a specific site location and project design, these impacts are considered potentially significant. It is presumed that implementation of appropriate site selection, design measures, construction techniques, and mitigation measures could avoid land use and visual impacts or reduce them to a less-than-significant level.

Geology, Soils, and Seismicity

At any of the identified BARDP sites, there would be a potential for seismic and/or geologic hazards. The final site selection for the desalination plant and associated facilities would include geotechnical investigations. These studies would be performed to determine the engineering suitability and feasibility of the site as well as appropriate design measures to minimize geologic hazards. Thus, as standard practice, the design and construction of the desalination plant and associated facilities would incorporate and implement recommendations from the geotechnical investigations. In addition, the facilities would be designed and constructed consistent with current building and seismic codes as well as applicable regulations (see Chapter 4, Section 4.4).

However, until the final sites are selected for the plant and associated facilities and preliminary engineering design completed, potential geology, soils, and seismicity impacts (Impacts 4.4-1 to 4.4-9) would be considered potentially significant. Similar to potential geologic and seismic impacts described in Chapter 4, impacts of the BARDP could be avoided or reduced to a less-than-significant level by implementing recommendations from the geotechnical investigations, complying with applicable building codes and regulations, and implementing appropriate site selection, design measures, and construction techniques.

Water Quality and Hydrology

Construction impacts associated with the desalination facilities would be similar to those described in Chapter 4, Section 4.5 (Impacts 4.5-1, 4.5-2, and 4.5-3); these impacts are related to the potential for water quality degradation from erosion and sedimentation, short-term depletion of groundwater resources from construction dewatering, and construction discharges to surface waters and would be considered potentially significant. Depending on the site selected for the BARDP, there could be impacts associated with flooding similar to those for WSIP facilities (Impact 4.5-4), but either site selection or incorporation of flood protection measures could reduce these impacts to less than significant. Similarly, implementation of the associated mitigations requiring preparation of erosion control plans and compliance with National Pollutant Discharge Elimination System (NPDES) construction permits could reduce these impacts to a less-than-significant level. Construction activities associated with the installation of intake structures, outfalls, or other facilities in the ocean or bay could result in potentially significant water quality impacts not discussed in Chapter 4; these include temporary disturbance of bottom sediments and potential degradation of water quality from chemicals in sediments or construction materials. It is presumed that implementation of appropriate site selection, design measures, construction techniques, and site-specific mitigation measures as well as compliance with applicable water quality regulations could avoid these impacts or reduce them to a less-than-significant level.

The operational impact associated with increased impervious surfaces would be similar to that described in Chapter 4, Section 4.5 (Impact 4.5-6); this impact and would be considered potentially significant but could be mitigated with site-specific management practices and control measures similar to those described in Chapter 6. In the absence of siting and design information, the BARDP is considered to have potentially significant long-term impacts associated with flooding, seiche, tsunami, and mudflow hazards (unlike the WSIP projects), although it is presumed that implementation of appropriate site selection, design measures, construction techniques, and mitigation measures could avoid these impacts or reduce them to a less-than-significant level. Impact 4.5-5 regarding discharges of treated water for some of the WSIP facilities would not apply to the BARDP.

One water quality impact that is unique to the operation of a desalination plant and not discussed in Chapter 4 involves the disposal of brine concentrate, a waste product from the desalination process that contains the chemicals and minerals removed from seawater or brackish water to produce potable water. The brine concentrate or "reject water" from the desalination process is likely to have a salt content approximately twice that of bay or ocean waters and therefore would be denser and less buoyant than the receiving waters. The concentrate could also have higher concentrations of metals and other potentially toxic constituents than are present in the bay or ocean. Disposal of the brine concentrate through either an existing outfall or a new outfall built for the plant could result in significant localized water quality impacts (as well as associated biological resource impacts, as discussed separately below). Detailed studies will be required to determine if disposal of the brine concentrate would be consistent with applicable water quality objectives and criteria, including criteria for toxic pollutants.

The design and operation of the outfall structure would require regulatory permitting through the NPDES program and approval by the California Regional Water Quality Control Board; furthermore, siting a desalination plant on the eastern Contra Costa County shoreline would require disposal to the Delta, which has more stringent discharge standards than those for the bay or ocean. To avoid significant water quality impacts, site-specific studies to determine the hydraulics and dilution of brine concentrate would be needed to ensure appropriate mixing in the outfall structure during a range of diurnal, tidal, and seasonal conditions and to protect aquatic resources that could be affected by the discharge. In order for the BARDP to be feasible, it would have to incorporate design and operation measures that ensure regulatory compliance with discharge requirements for long-term protection of water quality. Although it is possible that appropriate design and operation of the BARDP along with compliance with water quality regulations and implementation of mitigation measures could reduce potentially significant water quality impacts, due to the limited information available and unknown status of project details, water quality impacts are considered potentially significant and unavoidable in order to be conservative in this preliminary evaluation. The CEQA environmental review of the BARDP will provide a detailed impact analysis based on project-specific information and determine if there are feasible mitigation measures to reduce impacts to a less-than-significant level. The diversion of brackish water from this zone and discharge of higher-salinity concentrate could result in a cumulative effect on the Delta and upstream users. The daily tidal exchange of water through this area is so great that the discharge of concentrate from the BARDP alone would not present a regional salinity issue, but its contribution to salinity changes in the context of past, present, and proposed water diversion projects in the Delta and upstream rivers tributary to the Delta needs further evaluation. This potential cumulative effect is considered to be potentially significant but mitigable through design and operation measures or other compensatory actions to offset potential salinity effects.

Biological Resources

Construction and operation of the desalination plant and associated facilities could result in potentially significant impacts on biological resources, depending on the final sites selected, the design of the proposed facilities, and other project characteristics to be determined. Although the preliminary site location for the desalination plant along the eastern Contra Costa County shoreline includes previously disturbed areas in predominantly industrial use, some of the area may include marshes, wetlands, or other sensitive habitat. Potential impacts of the desalination facilities on wetlands, sensitive habitats, special-status species, and other aquatic resources would be similar to those described in Chapter 4, Section 4.6 (Impacts 4.6-1 to 4.6-4), although the types of habitat and affected species would be different. Similarly, depending on the final site selection and the ultimate project design, the BARDP could result in conflicts with adopted conservation plans or other approved biological resources plans (Impact 4.6-5). In the absence of more detailed project information, these impacts would all be considered potentially significant. However, in most cases, it is presumed that implementation of appropriate site selection, design measures, construction techniques, and mitigation measures involving compliance with permit requirements of the appropriate resource agencies could avoid these impacts or reduce them to a less-than-significant level.

In addition to the biological resources impacts discussed in Chapter 4, the BARDP would result in significant impacts on marine or other aquatic resources associated with construction and operation of both the intake and outfall structures. Construction of these facilities would result in disturbance and displacement of these resources. Operation of the intake facility could result in the incidental entrapment or entrainment of fish and other aquatic organisms, potentially including special-status species. Discharge of brine concentrate through the outfall would affect bottom-dwelling aquatic organisms sensitive to extreme salinity or temperature changes and could also affect many filter-feeding animals.[5] As discussed above under Hydrology and Water Quality, in order to be feasible the BARDP would have to incorporate design and operation measures that ensure regulatory compliance with intake and discharge requirements. In addition to ensuring protection of water quality for aquatic habitats, the BARDP will be required to comply with any other permit conditions for potentially affected special-status species or sensitive habitats. Although potential aquatic resources (including special-status species) and associated water quality impacts for the BARDP could possibly be mitigated through design/operation and mitigation measures and regulatory compliance, this impact is considered

5 Filter feeders are animals that feed by straining suspended matter and food particles from water.

potentially significant and unavoidable in order to be conservative in this preliminary evaluation. The CEQA environmental review of the BARDP will provide a detailed impact analysis based on project-specific information and determine if there are feasible mitigation measures to reduce impacts to a less-than-significant level.

Cultural Resources

Unlike other facilities proposed under the WSIP, the desalination plant would not be a component of the SFPUC regional water system and therefore would not be associated with its historic properties. However, due to uncertainty regarding the location of the BARDP as well as whether or not the plant would utilize existing structures or facilities, it is premature to conclude that the project would not affect historic, archaeological, or paleontological resources. In the absence of more detailed project information, impacts on cultural resources (similar to Impacts 4.7-1, 4.7-2, 4.7-4 and 4.7-6 described in Chapter 4) would be considered potentially significant. However, it is presumed that implementation of appropriate site selection, design measures, construction techniques, and mitigation measures involving the appropriate resource agencies could avoid impacts or reduce them to a less-than-significant level.

Traffic, Transportation, and Circulation

Chapter 4, Section 4.8 presents a general description of the types of construction and operation impacts on traffic, transportation, and circulation for treatment plants, pipelines, and pump stations. These include construction-related effects on roadway capacity, traffic delays, impaired access to adjacent land uses, displacement of parking, and increased traffic safety hazards as well as long-term traffic increases during facility operation. Similar types of impacts (Impacts 4.8-1 to 4.8-6) would be expected during construction and operation of the BARDP and associated facilities. In the absence of more detailed project information, impacts on traffic, transportation, and circulation would be considered potentially significant. However, implementation of appropriate site selection, design measures, construction techniques, and mitigation measures could avoid impacts or reduce them to a less-than-significant level.

Air Quality

The preliminary site for the BARDP is located in the San Francisco Bay Area Air Basin, as described in Chapter 4, Section 4.9, and would be subject to the same air quality conditions and regulations. Air quality impacts similar to those described in Chapter 4 for pipelines, treatment facilities, and pump stations (Impacts 4.9-1 to 4.9-7) related to construction and operational air quality emissions and odors could also occur with the BARDP. In addition, increased energy demand for long-term operation of a desalination plant could indirectly result in increased use of fossil fuels and emissions of greenhouse gases. In the absence of more detailed project information, air quality impacts would be considered potentially significant. However, it is presumed that implementation of appropriate site selection, design measures, construction techniques, and mitigation measures as well as compliance with applicable air quality regulations could avoid these impacts or reduce them to a less-than-significant level.

Noise and Vibration

Construction and operation of the BARDP could result in similar types of noise and vibration impacts as those described in Chapter 4, Section 4.10 (Impacts 4.10-1 to 4.10-4), although operation of the desalination plant could have different noise characteristics than those associated with a water treatment plant. Based on preliminary siting of the facility within or near existing industrial and utility uses, it is likely that the desalination plant site would not be located in proximity to sensitive receptors. However, in the absence of more detailed project information, impacts related to temporary and/or long-term increases in noise and vibration would be considered potentially significant. It is presumed that implementation of appropriate site selection, design measures, construction techniques, and mitigation measures (including measures to assure compliance with local noise ordinances) could avoid these impacts or reduce them to a less-than-significant level.

Public Services and Utilities

Implementation of the BARDP would not increase the demand for municipal water supply, wastewater capacity, or governmental services such as schools or parks. The BARDP design would include onsite storm drainage facilities, which would be required to comply with the local storm drainage district as well as any applicable NPDES permit requirements; however, depending on the site, it is not expected that expansion of existing storm drainage facilities would be required. The long-term solid waste disposal needs would depend on the final design and operational characteristics of the BARDP facilities and would include the ongoing disposal of pretreatment sludge generated by the desalination process. The design of BARDP facilities would likely include fire protection and security features, so the demand for fire protection or police protection services is not expected to increase. However, in the absence of more detailed project information, impacts on public services and utilities would be considered potentially significant. It is presumed that implementation of design measures, construction techniques, and mitigation measures (including compliance with regulations related to solid waste) could avoid these impacts or reduce them to a less-than-significant level.

Recreational Resources

Implementation of the BARDP would not increase demand for recreational facilities, include new recreational facilities, or require expansion of existing recreational facilities. Based on the assumption that the BARDP facilities would be sited on or near compatible land uses, such as sites with existing industrial or utility uses, this project is not likely to be located in the immediate vicinity of existing recreational resources. However, there are established recreational uses along the eastern Contra Costa County shoreline, including marinas and boat ramps, as well as water-based recreational uses in the Delta that could be affected by the BARDP and any associated intake and/or outfall structures. Recreational resources would be identified following specific site selection. In the absence of more detailed project information, impacts on recreational resources would be considered potentially significant. It is presumed that implementation of design measures, construction techniques, and mitigation measures could avoid these impacts or reduce them to a less-than-significant level.

Agricultural Resources

Based on a preliminary site on the eastern Contra Costa County shoreline near Pittsburg, the BARDP would not affect any farmlands, as no agricultural activity occurs in the vicinity. However, the California Department of Conservation maps indicate important farmland is present in some parts of eastern Contra Costa County (California Department of Conservation, 2004). Therefore, until the BARDP site is identified, agricultural resources impacts would be considered potentially significant but mitigable with appropriate site selection.

Hazards

The BARDP would be subject to the same hazardous materials regulatory framework as that described in Chapter 4, Section 4.14. Similar to the WSIP facilities, construction and operation of the BARDP could result in hazardous materials impacts. Due to the industrial nature of the site vicinity in eastern Contra Costa County, there is a potential to encounter hazardous materials in soil and groundwater during construction. If the BARDP were co-located with an existing facility or required the demolition of existing structures, hazardous building materials could be encountered. Operation of the desalination plant would likely require the handling and storage of hazardous materials, which could expose the public or the environment to hazardous materials. Therefore, construction and operation of the BARDP could result in similar types of hazardous materials impacts as those described in Impacts 4.14-1 to 4.14-3 and 4.14-5 to 4.14-8 (Impacts 4.14-3 and 4.14-4 do not apply, since the site is not located within a wildland fire area and no tunnel construction is proposed). In the absence of more detailed project information, these hazardous materials impacts would be considered potentially significant; however, it is presumed that implementation of appropriate site selection, design measures, construction techniques, and mitigation measures as well as compliance with all applicable federal, state, and local hazardous materials regulations could avoid these potential impacts or reduce them to a less-than-significant level.

Energy Resources

Implementation of the BARDP would result in the substantial use of nonrenewable energy resources during both construction and operation. In the pre-feasibility study, energy consumption for operation of the desalination plant was estimated to range from 7,500 to 22,000 kilowatt-hours per million gallons of product water, depending on the site selected for the BARDP. Even though these estimates are subject to change pending more detailed project design, the desalination plant would require extensive power consumption for long-term operations. Energy-intensive processes include pumping raw water to the filtration system, filtration, reverse-osmosis, and product water pumping. The project would result in the long-term use of large amounts of energy, and more detailed studies would be needed as part of project feasibility and design to determine the extent of available power, energy conservation measures to be incorporated into project design, and the impact of plant operation in the context of regional energy availability. The use of conventional energy sources has a limited range of available mitigation options. However, the development of the BARDP includes the exploration and investigation of energy-saving technologies and the use of alternative energy sources for BARDP operation. If conventional energy sources were used, the energy impacts would likely be potentially significant and unavoidable, although some of the impacts could potentially be mitigated through project design. Due to the unknown effectiveness of energy-saving technologies as applied to the BARDP, and in the absence of more detailed information, energy impacts would be considered potentially significant and unavoidable in order to be conservative in this preliminary evaluation. The CEQA environmental review of the BARDP will provide a detailed impact analysis based on project-specific information and determine if there are feasible mitigation measures to reduce impacts to a less-than-significant level.

Cumulative and Growth Impacts

This variant would generally result in the same facilities-related cumulative impacts as those identified and described in Chapter 4, Section 4.17, for the WSIP facilities, independent of the BARDP. When the BARDP is included as part of the WSIP under Variant 2, the combined impacts of the BARDP described above together with the WSIP facilities impacts described in Chapter 4 would constitute the collective impact. The BARDP would not contribute to any overlapping impacts due to the distance between the SFPUC facilities from the East Contra Costa site, but it would contribute to multi-regional impacts, exacerbating the collective impacts described in Chapter 4, Section 16. When considered in terms of cumulative impacts, Variant 2 would result in the same cumulative impacts as those identified for the proposed program augmented by the additional cumulative impacts of the BARDP due to its contribution to other past, present and reasonably foreseeable future projects in the vicinity of the East Contra Costa site. Implementation of the BARDP in combination with the WSIP would contribute additional cumulative facilities-related impacts in the eastern Contra Costa County region (or wherever the final site(s) is located); the extent of that contribution would be determined based on more specific project design, siting, and scheduling information in the project EIR for the BARDP. In addition, Variant 2 would contribute to cumulative long-term energy impacts in Northern California when considered in combination with the increased energy demands associated with the BARDP plus the WSIP facilities, as described in Section 4.15. The extent of the additional contribution to cumulative energy impacts of Variant 2 compared to the proposed program would be due to the BARDP’s contribution to long-term energy demands, and the associated implications with respect to regional energy resources (including the potential to increase emissions of greenhouse gases); this additional contribution would be evaluated based on more detailed project design and siting in the project-specific EIR for the BARDP.

Impacts associated with the SFPUC water supply and systemwide operations for all of the variants are discussed below in Section 8.5. Although the BARDP in itself could have implications with respect to growth inducement, within the context of WSIP Variant 2, the BARDP would serve only as a supplemental dry-year and emergency water supply. Therefore, the growth-inducement potential of Variant 2 as well as the indirect environmental effects associated with growth would be identical to those described for the proposed program in Chapter 7. The growth-inducement potential of the BARDP as a whole and the project’s indirect environmental effects would be evaluated as part of the formal CEQA review of the BARDP.

8.3.4 Mitigation Measures – Variant 2

All mitigation measures for WSIP facilities-related impacts identified for the proposed program and described in Chapter 6 would apply to Variant 2, in addition to the mitigation measures associated with the BARDP to be developed when the project-specific CEQA review is conducted. Table 8.3 identifies the facilities-related impacts of Variant 2; where applicable, the corresponding mitigation measures are presented in Chapter 6. In some instances, the same programmatic mitigation measures for the WSIP facilities could apply to the BARDP, although more comprehensive mitigation requirements would be developed as part of the project-level CEQA review of the BARDP, which will identify site-specific measures to reduce the identified impacts.

Mitigation measures related to water resources impacts on the Tuolumne River, Alameda, and Peninsula watersheds and the Westside Groundwater Basin applicable to Variant 2 would be identical to those for the proposed program, as described in Chapters 5 and 6 and discussed below in Section 8.5.

8.4 WSIP Variant 3 – 10% Rationing

8.4.1 Description

Water Supply

The water supply for *WSIP Variant 3 – 10% Rationing* would be identical to that under the proposed program, except that additional supplies from TID and MID transfers would be needed during drought years. This variant would reduce the maximum rationing during drought years from 20 to 10 percent, effectively modifying the WSIP system performance objective for dry-year delivery and increasing the system firm yield to 268 mgd (compared to 256 mgd for the proposed program). During nondrought and drought years, this variant would accommodate the projected increase in purchase requests through 2030 (35 mgd) in the same manner as the proposed program: surface water from the Tuolumne River, Alameda, and Peninsula watersheds; and implementation of additional conservation programs, Recycled Water Projects (SF-3), and Local Groundwater Projects in San Francisco (part of SF-2, Groundwater Projects). Under Variant 3, drought-year demand would additionally be served through the Westside Groundwater Basin conjunctive-use project (a component of SF-2, Groundwater Projects) and through TID and MID transfers, similar to the proposed program (except with an increase in TID and MID transfers). *WSIP Variant 3 – 10% Rationing* would require additional annual average TID and MID transfers of up to 12 mgd during the 8.5-year design drought (35 mgd compared to 23 mgd under the proposed program). Using the HH/LSM, the SFPUC determined that the average annual Tuolumne River diversion would be slightly greater under Variant 3 when compared to the proposed program due to the additional transfers during drought sequences; however, when presented in terms of the number of million gallons per day, both Variant 3 and the proposed program would result in an average annual diversion from the Tuolumne River of about 27 mgd over the 82-year period of hydrologic record.

Regional Water System Operations

Under *WSIP Variant 3 – 10% Rationing*, the operation, maintenance, and delivery strategy of the SFPUC regional water system would be identical to that proposed under the WSIP at all times, except during drought years. During an extended dry period, the SFPUC would implement the same drought response program as that described for the WSIP in Chapter 3, Section 3.8.1, except that the maximum rationing would be 10 percent. During extended drought sequences following implementation of the supplemental dry-year supplies (TID and MID transfers and Westside Basin conjunctive-use program), the SFPUC would limit rationing to 10 percent on a systemwide basis. In order to implement this variant, the SFPUC would need to establish a transfer agreement with TID and MID for 35 mgd (compared to 23 mgd for the proposed program).

Level of Service Performance

WSIP Variant 3 – 10% Rationing would achieve all of the proposed level of service performance goals through 2030, as indicated in Table 8.2, and would exceed the WSIP level of service for drought-year rationing. However, as shown in the table, even though it would achieve the performance goals, this variant would have different implications in terms of its performance during the design drought when compared to the WSIP.

Modeling results indicate that under Variant 3, rationing would occur slightly more frequently than under the proposed program. However, Variant 3 would reduce the degree of rationing during the design drought. When modeled over the 82-year period of hydrologic record (1920–2002), Variant 3 would trigger the drought response 25 times in the 82-year period, with rationing required in 8 of those years; this compares to 24 times that the drought response program would be triggered under the proposed program, with rationing in 8 of the years. The minor difference is due to the modeling assumptions, and there would likely be no noticeable difference between Variant 3 and the proposed program during actual operations in terms of the frequency of drought response actions. When modeled over the 8.5-year design drought, Variant 3 would require 6.5 years of rationing at 10 percent (6.5 out of 8.5 years subject to rationing), while the proposed program would require 3 years of rationing at 10 percent and 3.5 years at 20 percent (6.5 out of 8.5 years subject to rationing).

Facility Requirements

The facility requirements under *WSIP Variant 3 – 10% Rationing* would be identical to those of the proposed program, as described in Section 3.9, Proposed Facility Improvement Projects. All facilities proposed under the WSIP would be required, and no additional facilities would be needed.

Institutional Requirements

WSIP Variant 3 – 10% Rationing would require the same type of agreements with TID and MID to secure water transfers as those needed under the proposed program. The only difference is in the quantity of water subject to the transfer agreement for Variant 3, which would be an annual average of 35 mgd over the design drought compared to 23 mgd for the proposed program. No other institutional requirements are expected.

8.4.2 Setting

The regional setting for facility improvement projects for *WSIP Variant 3 – 10% Rationing* is the same as the regional setting for the WSIP study area described in Chapter 4, extending from Oakdale Portal in Tuolumne County west along the regional water system to its terminus in San Francisco. Similarly, the regional setting for potentially affected watersheds and drainages, including the Tuolumne River, Alameda Creek, and Peninsula watersheds, is the same as that described for the proposed program in Chapter 5.

8.4.3 Impact Analysis – Facility Construction and Operations

Table 8.3 identifies the impacts that would occur under *WSIP Variant 3 – 10% Rationing* related to facilities construction and operations. All facilities-related impacts would be the same in all respects as those identified for the proposed program and described in Chapter 4, including the cumulative impacts. All of the same mitigation measures presented in Chapter 6 would be required. No additional impacts would result.

Impacts associated with water supply and systemwide operations for Variant 3 are discussed below in Section 8.5. The growth-inducement potential of Variant 3 as well as the indirect environmental effects associated with growth would be similar to those described for the proposed program in Chapter 7. The overall availability and reliability of water supply is the most relevant factor influencing future growth and development, as discussed in Chapter 7, with the difference in rationing policy during drought sequences between the proposed project and Variant 3 not likely a significant factor affecting growth.

8.4.4 Mitigation Measures – Variant 3

All mitigation measures for facilities-related impacts identified for the proposed program and described in Chapter 6 would apply to Variant 3. Table 8.3 summarizes the facilities-related impacts of Variant 3; where applicable, the corresponding mitigation measures are presented in Chapter 6. No additional facilities-related mitigation measures would be required. Mitigation measures related to water resources impacts applicable to Variant 3 would be identical to those for the proposed program, as described in Chapters 5 and 6 and discussed below in Section 8.5.

8.5 All Variants – Impacts of Water Supply and System Operations

This section presents the impacts resulting from water supply and system operations for all variants, similar to the analysis presented in Chapter 5 for the proposed program. The WSIP variants would meet the need for additional water in 2030 through different combinations of water from the Tuolumne River, additional conservation, recycling, groundwater and desalination. Under all variants, the SFPUC would continue to use water supplies from the Bay Area watersheds to the maximum extent practical, but the contribution from the Bay Area watersheds would be almost the same for the WSIP and the three variants. As described previously in Sections 8.2, 8.3, and 8.4, the regional water system would be operated somewhat differently under each of the three variants to accommodate the various mixes of water sources and different shortage criteria.

The variants would alter the way the regional water system would be operated, which would, in turn, affect water levels in reservoirs on the Tuolumne River and its tributaries and in the Alameda and Peninsula watersheds. Altered operation of the regional water system would also affect flow in streams in the Tuolumne River, Alameda, and Peninsula watersheds. As described in Chapter 5 for the WSIP, the other environmental impacts of the variants would result from variant-induced changes in water levels in reservoirs and flow in streams. The variants would have minor differences in effects on the Westside Groundwater Basin compared to the WSIP.

As discussed in Sections 8.2, 8.3, and 8.4 and presented in Table 8.2, all three variants would achieve the WSIP levels of service, but they would vary slightly from each other and from the proposed program with respect to their predicted performance during drought periods. Water rationing would occur about the same frequency but would be slightly more severe with Variant 1 than with the WSIP. Rationing would occur with about the same frequency and severity under Variant 2, and with about the same frequency but with less severity under Variant 3. Consequently, it should be noted that the environmental impacts of the variants are not associated with a common and equal level of water supply service.

Similar to the analysis for the proposed program in Chapter 5, the SFPUC applied the HH/LSM to the variants, and model results were used to predict potential impacts of the variants on water resources in the Tuolumne River, Alameda, and Peninsula watersheds. The model output was used to provide quantitative estimates of changes that would occur with implementation of the variants compared to the existing condition. The model was employed to estimate flow in streams and rivers and water levels in reservoirs with each of the three variants in place. Technical specialists then assessed the effects of variant-induced changes in stream flows and reservoir levels on geomorphology, water quality, groundwater, fisheries, terrestrial wildlife and vegetation, and recreation in the three affected watersheds. Impacts on the Westside Groundwater Basin due to the variants were evaluated based on a qualitative comparison with impacts identified for the proposed program.

The environmental impacts of water supply and system operations under the variants on resources in the Tuolumne River, Alameda, and Peninsula watersheds compared to the existing condition are summarized in **Tables 8.5**, **8.6**, and **8.7**, respectively. For comparative purposes, the tables also present the water resources impacts of the WSIP compared to the existing condition (summarizing the analysis in Chapter 5 of this PEIR). Significance determinations were made for the impacts of the variants and are shown in the tables following the narrative descriptions. Impacts on reservoir water levels and stream flow in each watershed, which were used as the basis for analysis of all other environmental impacts of water system operations under the variants, are discussed in detail below for each variant. The impacts are assessed before mitigation measures have been applied.

Similarly, the environmental impacts of water supply and system operations under the variants on the Westside Groundwater Basin compared to the existing condition are summarized in **Table 8.8**, and the cumulative impacts under the variants are summarized in **Table 8.9**.

Tables 8-5, 8-6, 8-7, 8-8, and 8-9 use several standard phrases to indicate how the impacts of a variant compare to the impacts of the proposed program. In these tables, the phrase “same as the proposed program” is used when an impact of a variant is identical or almost identical to that of the proposed program. The phrase “similar to the proposed program” is used when an impact of a variant is similar in character to that of the proposed program and the magnitude of the impact is close to but not identical to the impact of the proposed program. The phrases “similar to but greater than the proposed program” and “similar to but less than the proposed program” are used when an impact of a variant is similar in character to that of the proposed program but the magnitude of the impact is discernibly greater than or less than the impact of the proposed program, although as explained below, the degree of variance is generally small.

In general, the impacts of the variants compared to the existing condition are quite similar to those of the WSIP compared to the existing condition. Although some of the impacts of the variants differ somewhat from those of the WSIP (sometimes greater and sometimes less severe), the magnitude of the differences is generally small. With the exception of impacts on the North Westside Groundwater Basin under Variant 1 (Impacts 5.6-1, 5.6-2, and 5.6-3), the significance determinations made for the variants are the same as those for the WSIP. Under Variant 1, Local Groundwater Projects would not be implemented, and there would be no wells developed in the North Westside Groundwater Basin. Therefore, the PSM impacts on the North Westside Groundwater Basin under the proposed program would be not applicable under Variant 1. In all other cases, impacts determined to be less than significant for the WSIP are also less than significant for the variants and impacts determined to be potentially significant for the WSIP are also potentially significant for the variants. Similarly, with the exception of measures associated with the North Westside Groundwater Basin, all mitigation measures identified for the proposed program in Chapter 5 and described in Chapter 6 would be similar for all variants.

TABLE 8.5
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITION – TUOLUMNE WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.3.1, Stream Flow and Reservoir Water Levels				
Impact 5.3.1-1: Effects on flow along the Tuolumne River below O'Shaughnessy Dam	Would reduce average monthly storage in Hetch Hetchy Reservoir year-round and would lower monthly average water levels by up to 10 feet with the greatest reduction just prior to snowmelt runoff. Would have little or no effect on average monthly flow in this reach of the Tuolumne River in most summer, fall and winter months of all hydrologic year types. Would reduce average monthly flow in some spring months with the greatest reductions (up to 30%) occurring in dry years. Would reduce average spring monthly flow by up to 90% very infrequently. Flow reductions would manifest themselves as delays in spring releases from Hetch Hetchy Reservoir above minimum required for up to 8 days. Could affect peak flows. (LS)	Would reduce average monthly storage in Hetch Hetchy Reservoir year-round and would lower monthly average water levels by up to 12 feet with the greatest reduction just prior to snowmelt runoff. Would have little or no effect on average monthly flow of this reach of the Tuolumne River in most summer, fall and winter months of all hydrologic year types. Would reduce average monthly flow in some spring months with the greatest reductions (up to 33%) occurring in dry years. Would reduce average monthly flow by up to 90% very infrequently. Flow reductions would manifest themselves as delays in spring releases from Hetch Hetchy Reservoir above minimum required by up to 9 days. Could affect peak flows. (LS)	Would reduce average monthly storage in Hetch Hetchy Reservoir year-round and would lower monthly average water levels by up to 7 feet with the greatest reduction just prior to snowmelt runoff. Would have little or no effect on average monthly flow of this reach of the Tuolumne River in most summer, fall and winter months of all hydrologic year types. Would reduce average monthly flow up to in some spring months with the greatest reductions (up to 30%) occurring in dry years. Would reduce average monthly flow by up to 90% very infrequently. Flow reductions would manifest themselves as delays in spring releases from Hetch Hetchy Reservoir above minimum required by up to 7 days. Could affect peak flows. (LS)	Would reduce average monthly storage in Hetch Hetchy Reservoir year-round and would lower monthly average water levels by up to 10 feet with the greatest reduction just prior to snowmelt runoff. Would have little or no effect on average monthly flow of this reach of the Tuolumne River in most summer, fall and winter months of all hydrologic year types. Would reduce average monthly flow up to 30% in some spring months. Would reduce average monthly flow by up to 90% very infrequently. Flow reductions would manifest themselves as delays in spring releases from Hetch Hetchy Reservoir above minimum required by up to 10 days. Could affect peak flows. (LS)
Impact 5.3.1-2: Effects on flow along Cherry Creek below Cherry Dam	Water levels in Lake Lloyd would not be altered such that they would be substantially outside the range experienced under the existing condition. Would reduce year-round average monthly storage in Lake Lloyd by about 1,000 AF and average monthly water levels by about 1 foot. Would have little or no effect on magnitude and timing of releases to Cherry Creek. (LS)	Would reduce average monthly storage in Lake Lloyd by about 1,000 AF and average monthly water levels by about 1 foot. Would not alter releases to Cherry Creek. (LS)	Would alter average water levels by about 1 foot. Would not alter releases to Cherry Creek. (LS)	Would not alter water levels or alter releases to Cherry Creek. (LS)

TABLE 8.5 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITION — TUOLUMNE WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.3.1, Stream Flow and Reservoir Water Levels (cont.)				
Impact 5.3.1-3: Effects on flow along Eleanor Creek below Eleanor Dam	Would have little effect on water levels in Lake Eleanor. Change in storage would be limited to infrequent transfers to Lake Lloyd and periods of severe drought. Would have little or no effect on magnitude and timing of releases to Eleanor Creek. (LS)	Would not alter water levels or releases. (LS)	Would not alter water levels or releases. (LS)	Would not alter water levels or release. (LS)
Impact 5.3.1-4: Effects on flow along the Tuolumne River below La Grange Dam	Would reduce average monthly storage in Don Pedro Reservoir in most months and would lower average monthly water levels by up to 10 feet and by as much as 27 feet in severe droughts. Would have little or no effect on average monthly flow in most summer months of all hydrologic year types. Would reduce average monthly flow below La Grange Dam in some months between November and June by up to 25%. Maximum percentage reduction in average monthly flow would be 92%, occurring very infrequently (one month in the 82-year hydrologic simulation). Flow reductions would manifest themselves as delays in spring releases from Don Pedro Reservoir above minimum required. In years when several spring pulse releases above the minimum required are made, the WSIP may eliminate one or more of the pulse releases and would delay others by several days or weeks. Could affect peak flows. (LS)	Would reduce average monthly storage in Don Pedro Reservoir almost year-round and would lower average monthly water levels by up to 12 feet. Would lower water levels by as much as 37 feet in severe droughts. Would have little or no effect on average monthly flow in most summer months of all hydrologic year types. Would reduce average monthly flow below La Grange Dam in some months between November and June by up to 32%. Would reduce average monthly flow by up to 95% very infrequently. Flow reductions would manifest themselves as delays in spring releases from Don Pedro Reservoir above minimum required. Would delay spring releases above minimum required by up to several weeks. Delays would be similar to but slightly greater than with WSIP. (LS)	Would reduce average monthly storage in Don Pedro Reservoir almost year-round and would lower average monthly water levels by up to 6 feet. Would lower water levels by as much as 16 feet in severe droughts. Would have little or no effect on average monthly flow in most summer months of all hydrologic year types. Would reduce average monthly flow below La Grange Dam up to 21% in some months between November and June. Would reduce monthly flow by up to 80% very infrequently. Flow reductions would manifest themselves as delays in spring releases from Don Pedro Reservoir above minimum required. Would delay spring releases above minimum required by up to several days. Delays would be less than with WSIP. (LS)	Would reduce average monthly storage in Don Pedro Reservoir year-round and would lower average monthly water levels by up to 11 feet. Would lower water levels by as much as 38 feet in severe droughts. Would have little or no effect on average monthly flow in most summer months of all hydrologic year types. Would reduce average monthly flow below La Grange Dam in some months between November and June by up to 25%. Would reduce average monthly flow by up to 95% very infrequently. Flow reductions would manifest themselves as delays in spring releases from Don Pedro Reservoir above minimum required. Would delay spring releases above minimum required by up to several weeks. Delays would be similar to WSIP. (LS)

TABLE 8.5 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITION — TUOLUMNE WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.3.1, Stream Flow and Reservoir Water Levels (cont.)				
Impact 5.3.1-5: Effects on flow along the San Joaquin River and the Sacramento-San Joaquin Delta.	Most WSIP-induced flows in the Tuolumne River between La Grange Dam and its confluence with the San Joaquin River would occur from January through June in wet or above-normal years. The greatest reductions would occur in years following extended droughts when storage in Don Pedro Reservoir is being replenished and could result in a average monthly flow reduction of up to 25 to 50% along the San Joaquin River between the Tuolumne and Stanislaus River confluences. Flow reductions of these magnitudes would be rare events occurring four to five times in the 82-year period of hydrologic record. Overall, the WSIP would not cause an alteration of flows along the San Joaquin River or in the Sacramento-San Joaquin Delta such that it would be substantially outside the range experienced under existing condition. (LS)	Similar to but slightly greater than proposed program (LS)	Similar to proposed but less than proposed program (LS)	Similar to proposed program (LS)
Section 5.3.2, Geomorphology				
Impact 5.3.2-1: Effects on sediment transport and channel characteristics between O'Shaughnessy Dam and Don Pedro Reservoir	Would have little effect on the very large and infrequent floods between O'Shaughnessy Dam and Don Pedro Reservoir that are capable of moving boulders and altering the characteristics of bedrock channels. Infrequent reductions in duration and magnitude of peak flows could affect sediment deposition and erosion in side channels and meadows and groundwater levels in riparian zones. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.3.2-2: Effects on sediment transport and channel characteristics below La Grange Dam	Would have little effect on very large and infrequent floods below La Grange Dam, but would result in infrequent reduction in duration and magnitude of peak flows could affect sediment deposition and erosion in main channel and groundwater levels in riparian zones. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)

TABLE 8.5 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITION — TUOLUMNE WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.3.3, Surface Water Quality				
Impact 5.3.3-1: Effects on water quality in Hetch Hetchy Reservoir and along the Tuolumne River below O'Shaughnessy Dam	Changes in reservoir levels would have little effect on temperature in Hetch Hetchy Reservoir in all year types. Would have little effect on temperature or dissolved oxygen along the Tuolumne River below O'Shaughnessy Dam in most year types. During extreme droughts (once in 82-year hydrologic record), warmer water released to the river would result in prolonged violations of the water quality objectives for temperature. However, water temperatures would still remain within an acceptable range for coldwater fish and would not substantially affect the river's ability to support COLD beneficial use designation. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.3.3-2: Effects on water quality in Don Pedro Reservoir and along the Tuolumne River below La Grange Dam	Changes in reservoir levels would have little effect on temperature in Don Pedro Reservoir in all year types. Releases from the reservoir would still be from the cool water pool below the thermocline. Thus, no increase in water released to the Tuolumne River below La Grange Dam would occur. Would have little effect on temperature in the river below the reservoir most of the time, but on infrequent occasions would cause mean daily temperature increases of 1 or 2 °C and, on very rare occasions, increases of 10 °C at confluence with San Joaquin River. Although these very rare occasions would result in violations of water quality objectives for water temperatures, they would not impair the river's ability to support the designated beneficial uses, including coldwater fisheries. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.3.3-3: Effects on water quality along the San Joaquin River and the Sacramento-San Joaquin Delta	Very infrequently following protracted droughts, flow reductions could cause salinity, expressed in terms of electroconductivity, to rise above established water quality objectives for the San Joaquin River at Vernalis. Under these circumstances the USBR, the agency responsible for compliance with these objectives, would increase releases from New Melones Reservoir to compensate for the reduction in flow and related impacts on water quality.	Similar to proposed program (LS)	Similar to proposed program (LS)	Similar to proposed program (LS)

TABLE 8.5 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITION — TUOLUMNE WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.3.3, Surface Water Quality (cont.)				
Impact 5.3.3-3 (cont.)	WSIP-related changes in Delta inflow would occur when flow through the Delta is at its seasonal maximum and would be too small to adversely affect water quality. (LS)			
Section 5.3.4, Surface Water Supplies				
Impact 5.3.4-1: Effects on Tuolumne River, San Joaquin River, and Stanislaus River water users	Under the WSIP, SFPUC's water supply facilities would continue to be operated in compliance with the provisions of the Raker Act, which requires that the SFPUC operate its water facilities so as to not infringe on the established water rights of TID and MID. Thus, the WSIP would have no adverse effect on the availability of Tuolumne River water to TID and MID or on the quality of water available to them. During most year types the WSIP would have no effect on the availability of Stanislaus River water to the USBR and other water supply agencies that receive water from New Melones Reservoir. On rare occasions following protracted droughts, WSIP-induced flow reductions along the San Joaquin River could cause flows to fall below established flow and water quality objectives at Vernalis, and the USBR would be required to increase releases from New Melones Reservoir or other San Joaquin Valley CVP facilities to compensate for these reduction in flows. Availability and quality of water at water agencies' and irrigators' diversion points along the San Joaquin, and Stanislaus Rivers would not be changed appreciably. (LS)	Similar to proposed program. (LS)	Similar to but less than proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.3.4-2: Effects on Delta water users	Under rare circumstances, small reductions in Delta inflow between June and September of wet and above normal years would reduce water availability at the SWP and CVP diversion points. (LS)	Similar to proposed program. (LS)	Similar to but less than proposed program. (LS)	Similar to proposed program. (LS)

TABLE 8.5 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITION — TUOLUMNE WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.3.5, Groundwater				
Impact 5.3.5-1: Alteration of stream flows along the Tuolumne River, which could affect local groundwater recharge and groundwater levels	Would result in slight increases in groundwater discharge to the Tuolumne River along some reaches below La Grange Dam and reductions in stream flow to the groundwater basin along other reaches. Overall, the WSIP would have little or no effect on groundwater levels and groundwater recharge. The production rate of existing wells would not be affected. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
Impact 5.3.5-2: Alteration of stream flows along the Tuolumne River, which could affect local groundwater quality	Effects on groundwater quality would be slight and limited to a shallow, unconfined aquifer located along the Tuolumne River in the vicinity of Modesto that is only used for sub-potable uses. No adverse effects on identified beneficial uses of groundwater basin would result. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
Section 5.3.6, Fisheries				
Impact 5.3.6-1: Effects on fishery resources in Hetch Hetchy Reservoir	WSIP-related reductions in seasonal storage within Hetch Hetchy Reservoir would fall within the existing range of natural variation in seasonal storage volumes. No adverse impacts on resident fish habitat within the reservoir would occur. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.3.6-2: Effects on fishery resources along the Tuolumne River between Hetch Hetchy Reservoir and Don Pedro Reservoir	Little or no change on fisheries in most summer, fall and winter months. In spring months, average monthly flows would be reduced by 4 to 30 percent and the start of large spring releases from Hetch Hetchy Reservoir could be delayed by several days. These reductions and delays in spring flows would be within the natural interannual variation that has occurred in the past and would not adversely affect fishery resources along this stretch of the Tuolumne River. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.3.6-3: Effects on fishery resources in Don Pedro Reservoir	WSIP-related reductions in seasonal storage within Don Pedro Reservoir would fall within the existing range of natural variation in seasonal storage volumes. No adverse impacts on resident fish habitat within the reservoir would occur. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)

**TABLE 8.5 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE
WSIP VARIANTS COMPARED TO EXISTING CONDITION — TUOLUMNE WATERSHED**

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.3.6, Fisheries (cont.)				
Impact 5.3.6-4: Effects on fishery resources along the Tuolumne River below La Grange Dam	In wet or above-normal years when Don Pedro Reservoir is being filled, changes in the timing and duration of releases from the reservoir would decrease average monthly flows along the lower Tuolumne River beneath La Grange Dam. The greatest average flow reductions would occur during June and could potentially result in elevated water temperatures. Changes to stream flow and water temperature would result in a reduction in the linear extent of suitable habitat for rearing Chinook salmon and oversummering steelhead/rainbow trout, potentially adversely affecting these fish populations in the lower Tuolumne River. (PSM)	Similar to than proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to proposed program. (PSM)
Impact 5.3.6-5: Effects on fishery resources along the San Joaquin River	During certain drought conditions, WSIP operations would reduce inflow to Don Pedro Reservoir and, as a result, increase the seasonal (summer) temperatures of water released from the reservoir, which would also affect water temperature along the lower San Joaquin River. However, the greatest flow reductions would occur after most out-migrating juvenile Chinook salmon have left the San Joaquin River. Other fish species inhabiting the river are tolerant of elevated water temperatures and would not likely be affected. (LS)	Similar to proposed program. (LS)	Similar to but less than proposed program. (LS)	Similar to proposed program. (LS)
Section 5.3.7, Terrestrial Biological Resources				
Impact 5.3.7-1: Impacts on riparian habitat and related biological resources in Hetch Hetchy Reservoir and along the bedrock channel portions of the Tuolumne River below O'Shaughnessy Dam to Don Pedro Reservoir				
• Sensitive Habitats	Riparian and meadow habitat in Hetch Hetchy Reservoir is already limited and would not be significantly affected by predicted annual fluctuations in reservoir storage. Along the upper Tuolumne River, the dynamic hydrology regime, steep banks, and rocky substrate limits riparian tree structure and minimizes the encroachment of riparian vegetation into the channel. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)

TABLE 8.5 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITION — TUOLUMNE WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.3.7, Terrestrial Biological Resources (cont.)				
Impact 5.3.7-1 (cont.)				
• Key Special Status Species	Changes to habitat in the reservoir and along the upper Tuolumne River would be minimal and would not significantly alter the composition, extent, and structure of special-status species. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
• Other Species of Concern	Changes to habitat in the reservoir and along the upper Tuolumne River would be minimal and would not significantly alter the composition, extent, and structure of other species of concern. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
• Common Habitats and Species	Effects on common habitats and species in the reservoir and along the upper Tuolumne River would be minimal. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.3.7-2: Impacts on alluvial features that support meadow and riparian habitat along the Tuolumne River from O'Shaughnessy Dam to Don Pedro Reservoir				
• Sensitive Habitats	Delayed snowmelt releases, reductions in flow, and the resulting reduction in groundwater recharge would result in a reduction in the extent and diversity of wetland and riparian habitats, including sensitive wetland and riparian habitats in the Poopenaut Valley. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)
• Key Special Status Species	A reduction in wetland and riparian habitat would reduce suitable breeding habitat for key-special status species potentially occurring along this reach (e.g. foothill yellow-legged frog, California red-legged frog, and the willow flycatcher), the populations of which are already critically reduced in the Sierra Nevada. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)
• Other Species of Concern	A reduction in the extent and diversity of wetland and riparian habitats would reduce habitat quality and extent for animal and plant species of concern. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)

TABLE 8.5 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITION — TUOLUMNE WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.3.7, Terrestrial Biological Resources (cont.)				
Impact 5.3.7-2 (cont.)				
• Common Habitats and Species	All habitats affected by the WSIP are considered sensitive. A large number of common animal species depend on sensitive meadows and larger riparian areas potentially affected by the WSIP for food and cover. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)
Impact 5.3.7-3: Impacts on biological resources in Lake Eleanor and along Eleanor Creek				
• Sensitive Habitats	Increased transfers to Lake Lloyd during extended droughts could slightly reduce the extent and quality of wetland habitat in Lake Eleanor. Quantity and timing of releases to Eleanor Creek would be similar to existing conditions and would not affect sensitive riparian habitats. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
• Key Special Status Species	Effects on habitat in Lake Eleanor and along Eleanor Creek would be minimal and would not significantly affect key special status species, including foothill yellow-legged frog. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
• Other Species of Concern	Minimal effects on riparian habitats in Lake Eleanor and along Eleanor Creek resulting from the WSIP would not adversely affect other species of concern. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
• Common Habitats and Species	Effects on common habitats and species in Lake Eleanor and along Eleanor Creek would be incremental and small. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
Impact 5.3.7-4: Impacts to biological resources in Lake Lloyd and along Cherry Creek				
• Sensitive Habitats	Change in monthly water levels would be minimal and would not significantly affect surrounding vegetation and wetland habitats. During dry years, small increases in releases to Cherry Creek would benefit riparian habitats. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)

TABLE 8.5 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITION — TUOLUMNE WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.3.7, Terrestrial Biological Resources (cont.)				
Impact 5.3.7-4 (cont.)				
• Key Special Status Species	Effects on habitat in Lake Lloyd and Cherry Creek would be minimal and would not significantly affect key special status species, including foothill yellow-legged frog. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
• Other Species of Concern	Changes riparian habitats associated with Lake Lloyd and Cherry Creek would be minimal. No adverse effects on other species of concern occur. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
• Common Habitats and Species	Effects on common habitats and species would be minimal. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
Impact 5.3.7-5: Impacts on biological resources in Don Pedro Reservoir				
• Sensitive Habitats	Large fluctuations in reservoir storage levels under existing conditions have precluded the development of riparian and wetland habitats in Don Pedro Reservoir. Thus, WSIP-induced changes in reservoir levels would have a minimal effect on sensitive habitats. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
• Key Special Status Species	Due to very limited potential habitat for California red-legged frog in Don Pedro Reservoir, impacts on this key special-status species would be minimal. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
• Other Species of Concern	Would result in an incremental reduction in the quality and extent of habitat for other species of concern, including western pond turtle, several bat and bird species, and bald eagle. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
• Common Habitats and Species	Increased drawdown of Don Pedro Reservoir would not affect common habitats. Thus, impacts to common species would be minimal. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)

TABLE 8.5 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITION — TUOLUMNE WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.3.7, Terrestrial Biological Resources (cont.)				
Impact 5.3.7-6: Impacts on biological resources along the Tuolumne River below La Grange Dam				
• Sensitive Habitats	Delayed spring releases and reductions in average and total flow (particularly during and following an extended drought) below La Grange Dam would reduce or eliminate suitable conditions for recruitment of some riparian species along the river. (PSM)	Similar to proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to proposed program. (PSM)
• Key Special Status Species	Because of the known presence of key special-status species and the very limited amount of remaining suitable habitat along this reach of the Tuolumne River, this incremental impact would be potentially significant. (PSM)	Similar to proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to proposed program. (PSM)
• Other Species of Concern	Species of concern that would be adversely affected by changes in the extent and quality of suitable riparian habitat include western pond turtle, several bat species, and a wide variety of riparian- and marsh-associated bird species. (PSM)	Similar to proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to proposed program. (PSM)
• Common Habitats and Species	The populations of common species that depend on riparian habitat could be adversely affected by the alteration of habitat. (PSM)	Similar to proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to proposed program. (PSM)
Impact 5.3.7-7: Conflicts with the provisions of adopted conservation plans or other approved biological resources plans for the Tuolumne Wild and Scenic River	The Tuolumne River Wild and Scenic Plan does not apply to the exercise of CCSF's water rights under the Raker Act. Implementation of the WSIP would not conflict with any adopted conservation plan or biological resources plan. (LS).	Same as proposed program (LS)	Same as proposed program (LS)	Same as proposed program (LS)

TABLE 8.5 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITION — TUOLUMNE WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.3.8, Recreation and Visual Resources				
Impact 5.3.8-1: Effects on reservoir recreation due to changes in water system operations	During the primary recreation season (between Memorial Day and Labor Day), average monthly water levels in Hetch Hetchy Reservoir would be lowered by less than 5 feet compared to the existing condition except in critically dry years, when up to a 10-foot drop in reservoir levels would be expected. This drop in reservoir levels would not likely be perceptible to most hikers. Only during the off-season when visitation to the reservoir is low (between January and March) would the increased drawdown be noticeable. There would be no WSIP-induced changes in water levels in Lake Eleanor and minimal changes in water levels in Lake Lloyd. There would be no effect on recreation. During prolonged drought periods, drawdown of water levels at Don Pedro Reservoir would exceed the 450-foot threshold level for recreational uses, potentially impairing the use of boat ramp facilities. When compared to the existing condition, the frequency of these incidences would increase from 13 to 24 summer months over the 82-year hydrologic record. These infrequent events would not significantly affect boating facilities. Non-native fish populations in Don Pedro Reservoir can tolerate the changes in reservoir levels and, thus, no effects on fishing activities would result. Visual impacts associated with reservoir drawdown would not be noticeable to most recreational users. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.3.8-2: Effects on river recreation due to changes in water system operations	With the WSIP, the onset of large releases from Hetch Hetchy Reservoir in the early spring would be delayed by up to 8 days and the total volume of releases reduced. However, during the rest of the year, the WSIP would have very little effect on the number of days flow in the river is suitable for whitewater rafting and would have very little effect on the need for scheduled releases from Holm Powerhouse.	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)

TABLE 8.5 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITION — TUOLUMNE WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.3.8, Recreation and Visual Resources (cont.)				
Impact 5.3.8-2 (cont.)	Relatively minor changes in upper Tuolumne River flow associated in May and June would be imperceptible to visitors. No change in flow releases during the peak recreational period (July through August) would occur. With the WSIP, the onset of releases from La Grange Dam above the minimum flow requirements would be delayed, and the total volume of releases would be reduced. Releases during the rest of the year would be similar to those under the existing condition. Minimum flow conditions would be maintained under all circumstances during summer. (LS)			
Impact 5.3.8-3: Effects on aesthetic values of the Tuolumne Wild and Scenic River	During below-normal and dry years, WSIP-induced reductions in flow would result in a reduction of flows of up to 30 percent in May. However, because flow in the upper river would remain within the range experienced under the existing condition, WSIP-related flow reductions would likely be imperceptible to or unobserved by visitors. (LS)	Same as proposed program (LS)	Same as proposed program (LS)	Same as proposed program (LS)
Section 5.3.9, Energy Resources				
Impact 5.3.9-1: Effects on hydropower generation at facilities along the Tuolumne River	Increased diversions from Hetch Hetchy Reservoir would increase the SFPUC's average annual hydropower generation by about 1.4 percent (23,000 MWh). The resultant reduction in inflow to Don Pedro Reservoir would decrease MID/TID's average annual hydropower generation by approximately 2.4 percent (14,000 MWh). Overall, hydropower generation on the Tuolumne River would be increased by about 0.4 percent (9,000 MWh). (B)	Similar to proposed program. (B)	Similar to proposed program. (B)	Similar to proposed program. (B)

LS = Less than Significant, no mitigation required.
SM or PSM = Significant or Potentially Significant, can be Mitigated to less than significant.
SU or PSU = Significant Unavoidable or Potentially Significant Unavoidable, cannot be mitigated to less than significant.
B = Beneficial

TABLE 8.6
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITIONS – ALAMEDA WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desal for Drought	Variant 3 – 10% Rationing
Section 5.4.1, Stream Flow and Reservoir Water Levels				
Impact 5.4.1-1: Effects along Calaveras Creek below Calaveras Reservoir	Under the WSIP, the restored capacity of Calaveras Reservoir would change the nature of releases from the reservoir to Calaveras Creek. Changes in reservoir operation would result in substantial flow reductions along Calaveras Creek below Calaveras Dam in winter and early spring of wet and above-normal precipitation years. Reduced winter flows would remain in the range of existing flows. Instream fishery releases to Calaveras Creek in summer months would be beneficial. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.4.1-2: Effects on flow along Alameda Creek below the diversion dam	In all year types, system operations under the WSIP would increase diversions from Alameda Creek to Calaveras Reservoir between the months of December and May, nearly eliminating low and moderate (1 to 650 cfs) flows in Alameda Creek downstream of the diversion dam and substantially reducing many higher (greater than 650 cfs) flows that have occurred since 2002. The resultant reduction in stream flows and alteration of the stream hydrograph is considered an adverse effect. (SU)	Same as proposed program (SU)	Same as proposed program (SU)	Same as proposed program (SU)
Impact 5.4.1-3: Effects in San Antonio Reservoir and along San Antonio Creek	Typically, San Antonio Reservoir would remain slightly higher than under existing conditions. Every fifth year, during planned maintenance for the Mountain Tunnel, the reservoir would be drawn to replace flows not provided by the Hetch Hetchy system, resulting in lower water levels and increased reservoir storage for one to two years after the maintenance period. With the exception of occasional operational changes due to maintenance, the proposed program would result in minor increases and decreases in winter and spring flows along San Antonio Creek in some wet and above-normal years but flows would remain within range of existing conditions. (LS)	Similar to proposed program (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.4.1-4: Effects on flow along Alameda Creek below the confluence of San Antonio Creek	Would result in a substantial reduction (8 to 52 percent) in flow volumes during January, February, and March of normal or wetter years and a moderate increase (about 14 percent) in flow volumes in April of normal years. These changes in flow would be dampened by inflows from other tributaries in the Sunol Valley and would not result in adverse hydrologic effects. (LS)	Similar to proposed program (LS)	Similar to proposed program (LS)	Similar to proposed program (LS)

TABLE 8.6 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITIONS – ALAMEDA WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desal for Drought	Variant 3 – 10% Rationing
Section 5.4.2, Geomorphology				
Impact 5.4.2-1: Effects on channel formation and sediment transport along Calaveras Creek	Would increase erosion, sediment transport, and deposition along Calaveras Creek during heavy rainfall (compared to existing condition). However, this sediment transport would be similar to the long-term conditions that formed the current channel. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
Impact 5.4.2-2: Effects on channel formation and sediment transport along Alameda Creek downstream of the diversion dam	Would reduce peak flows in Alameda Creek downstream of the diversion dam through increased use of the diversion tunnel. High flows (up to 650 cfs) and annual sluicing would still transport substantial quantities of sediment downstream. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.4.2-3: Effects on channel formation and sediment transport along San Antonio Creek downstream of San Antonio Reservoir	Flows and associated geomorphic changes would be within the range of historical flows and changes. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
Section 5.4.3, Surface Water Quality				
Impact 5.4.3-1: Effects on water quality in Calaveras Reservoir	Increased reservoir storage would result in minimal changes in temperature. The existing oxygenation system, sized to be operated in a larger reservoir, would maintain or improve DO concentrations, nutrient levels, and algal biomass when compared to existing conditions. Turbidity would be lowered due to the larger storage capacity. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.4.3-2: Effects on water quality in San Antonio Reservoir	Proposed program would maintain higher overall storage, leading to similar or larger cold/cool water volumes and minimal changes in temperature. Overall DO conditions, nutrient, and algae levels are expected to be similar to existing conditions. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.4.3-3: Effects on water quality along Calaveras, San Antonio, and Alameda Creeks	Under future operations, water temperatures and DO conditions along Calaveras Creek would be similar to existing conditions. The trapping of nutrients in the reservoir would reduce nutrients in downstream waters and the oxidation of ammonia would reduce the potential for excess ammonia releases from the reservoir.	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)

TABLE 8.6 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITIONS – ALAMEDA WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desal for Drought	Variant 3 – 10% Rationing
Section 5.4.3, Surface Water Quality (cont.)				
Impact 5.4.3-3 (cont.)	Release mechanisms from San Antonio Reservoir would remain unchanged. Thus, the temperature, DO conditions, and levels of nutrients of associated constituents in downstream waters would be similar to existing conditions. Would lower water temperatures in Alameda Creek from the vicinity of the diversion tunnel to several miles downstream of the confluence with Calaveras Creek. DO conditions and nutrient levels would be similar to the existing condition. (LS)			
Section 5.4.4, Groundwater				
Impact 5.4.4-1: Changes in groundwater levels, flows, quality, and supplies	Changes in stream flows would result in minimal changes in the groundwater levels of Sunol Valley groundwater resources. Groundwater quality would not be affected. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
Section 5.4.5, Fisheries				
Impact 5.4.5-1: Effects on fishery resources in Calaveras Reservoir	The increase in reservoir storage would result in increased coldwater pool volume, which would increase the volume of habitat available for coldwater and warmwater resident fish species. Elevated reservoir water levels could improve connectivity and migration of fish between the reservoir and upstream tributaries. (B)	Similar to proposed program. (B)	Similar to proposed program. (B)	Similar to proposed program. (B)
Impact 5.4.5-2: Effects on fishery resources along Calaveras Creek below Calaveras Dam and along Alameda Creek below confluence with Calaveras Creek	Year-round fishery releases from Calaveras Reservoir to Calaveras Creek, including summer base flows that do not occur under the existing condition, would improve habitat quality and availability for resident rainbow trout and other fish inhabiting Calaveras and Alameda creeks. (B)	Similar to proposed program. (B)	Similar to proposed program. (B)	Similar to proposed program. (B)
Impact 5.4.5-3: Effects on fishery resources along Alameda Creek downstream of the Alameda Creek Diversion Dam	Following implementation of the Calaveras Dam Replacement Project (SV-2), operation of Calaveras Reservoir and the Alameda Creek Diversion Dam would be restored to pre-2002 conditions. A substantial increase in diversions from Alameda Creek to Calaveras Reservoir would reduce flows in this stretch	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)

TABLE 8.6 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITIONS – ALAMEDA WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desal for Drought	Variant 3 – 10% Rationing
Section 5.4.5, Fisheries (cont.)				
Impact 5.4.5-3 (cont.)	of the creek. Diversion of most or all flows during late winter and spring months would reduce the ability of resident rainbow trout to spawn and for eggs to incubate. In addition, the increased diversion of flows to the reservoir would divert fish from Alameda Creek to the reservoir, prevent fish passage to downstream reaches of Alameda Creek, and increase the potential for fish entrainment since there are currently no screens on the diversion. (PSM)			
Impact 5.4.5-4: Effects on fishery resources in San Antonio Reservoir	Slight increases in storage and water levels in San Antonio Reservoir would increase the coldwater pool volume in the reservoir and increase coldwater and warmwater habitat in the reservoir, provide greater opportunities for connectivity and migration of fish between the reservoir and upstream habitat, and benefit coldwater fish species downstream. (B)	Similar to proposed program. (B)	Similar to proposed program. (B)	Similar to proposed program. (B)
Impact 5.4.5-5: Effects on fishery resources along San Antonio Creek below San Antonio Reservoir	Releases to San Antonio Creek from San Antonio Reservoir would be similar to existing conditions but with slightly greater total releases in winter and spring. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.4.5-6: Effects on fishery resources along Alameda Creek below confluence with San Antonio Creek	Minor changes in flows along San Antonio Creek would result in minimal effects on the contribution of San Antonio Creek flows to downstream fishery habitat along Alameda Creek. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Section 5.4.6, Terrestrial Biological Resources				
Impact 5.4.6-1: Effects on riparian habitat and related biological resources in Calaveras Reservoir				
• Sensitive Habitats	Increased reservoir storage elevations would result in the inundation and permanent loss of seasonal wetlands, seeps, perennial freshwater marsh, and riparian habitat that have established since 2002. (PSM)	Same as proposed program. (PSM)	Same as proposed program. (PSM)	Same as proposed program. (PSM)

TABLE 8.6 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITIONS – ALAMEDA WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desal for Drought	Variant 3 – 10% Rationing
Section 5.4.6, Terrestrial Biological Resources (cont.)				
Impact 5.4.6-1 (cont.)				
• Key Special Status Species	Since 2002, yellow-legged frogs have occupied approximately 10,000 linear feet of stream channel along Arroyo Hondo between the maximum reservoir elevation mandated by the DSOD and the spillway elevation. Higher maintained reservoir levels would reduce the length of this high-quality habitat along the creek and adversely affect existing populations of foothill yellow-legged frog, (PSM)	Same as proposed program. (PSM)	Same as proposed program. (PSM)	Same as proposed program. (PSM)
• Other Species of Concern	No plant species would be inundated under future conditions. Potential changes to grassland, riparian, and marsh habitats associated with wildlife species of concern in and near Calaveras Reservoir would be minor. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
• Common Habitats and Species	Raised reservoir elevations would inundate low-diversity, weedy, upland vegetation within the “bathtub ring” that provides little habitat value. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
Impact 5.4.6-2: Effects on riparian habitat and related biological resources along Alameda Creek, from below the diversion dam to the confluence with Calaveras Creek				
• Sensitive Habitats	Composition and structure of sensitive riparian habitats along this reach of Alameda Creek is the result of prevailing conditions prior to 2002. A return to the pre-2002 diversions from Alameda Creek would return flow conditions to those under which these habitats formed. No significant alteration of structure, composition, or diversity of riparian habitats would occur. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
• Key Special Status Species	A reduction in the frequency, duration, and magnitude of flows below the diversion dam would reduce the total available aquatic breeding habitat and food sources for California red-legged frog and foothill yellow-legged frog populations that currently occupy this reach of Alameda Creek. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)

TABLE 8.6 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITIONS – ALAMEDA WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desal for Drought	Variant 3 – 10% Rationing
Section 5.4.6, Terrestrial Biological Resources (cont.)				
Impact 5.4.6-2 (cont.)				
• Other Species of Concern	Because the prevailing riparian habitats along this reach are the result of pre-2002 flows, adverse impacts to raptor, songbird, and mammal species of concern would be minimal. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
• Common Habitats and Species	Implementation of the WSIP would not affect common upland habitats and species in this area. (N/A)	Similar to proposed program. (N/A)	Similar to proposed program. (N/A)	Similar to proposed program. (N/A)
Impact 5.4.6-3: Effects on riparian habitat and related biological resources along Calaveras Creek, from Calaveras Reservoir to the confluence with Alameda Creek				
• Sensitive Habitats	Following completion of the Calaveras Dam Replacement Project (SV-2), there would be no cone valve releases into Calaveras Creek below the dam during the two- to five-year period when the reservoir is being refilled. However, minimum instream flow releases below Calaveras Dam would ensure that existing riparian vegetation along this reach is sustained even during protracted dry periods. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
• Key Special Status Species	Future outlet works at Calaveras Dam would have the capacity to make higher volume releases than under existing conditions. Depending on the timing and volume of operational releases, they could adversely affect the reproductive success of special status amphibian species along this reach (e.g. California red-legged frog and foothill yellow-legged frog). (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)
• Other Species of Concern	Potential changes in the structure and species composition of breeding habitat for riparian-nesting birds such as raptors, egrets, and songbird species of concern in the vicinity of Calaveras Creek below the reservoir would be minimal. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
• Common Habitats and Species	Little change in extent and condition of common habitats and species. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)

TABLE 8.6 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITIONS – ALAMEDA WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desal for Drought	Variant 3 – 10% Rationing
Section 5.4.6, Terrestrial Biological Resources (cont.)				
Impact 5.4.6-4: Effects on riparian habitat and related biological resources along Alameda Creek, from Calaveras Creek to San Antonio Creek				
• Sensitive Habitats	Changes in winter and summer flows along Alameda Creek would affect existing riparian communities along this reach, but the extent of this potential impact would be small. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
• Key Special Status Species	Depending on annual rainfall and localized site conditions along this creek segment, changes in winter and summer flows along this reach could result in both beneficial and adverse impacts on habitat for California red-legged frogs and foothill yellow-legged frog populations. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)
• Other Species of Concern	Minor changes in the structure and diversity of riparian habitat in this section of the creek would not substantially alter the extent or quality of breeding habitat for songbirds, raptors, and mammals. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
• Common Habitats and Species	Common upland habitats would be unaffected. The overall extent of riparian habitat would be similar to the existing condition. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.4.6-5: Effects on riparian habitat and related biological resources in San Antonio Reservoir				
• Sensitive Habitats	The average range of reservoir elevations under the WSIP would be slightly less than existing and any loss of existing perennial freshwater marsh or riparian scrub would be balanced by development of similar habitat at higher elevations. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
• Key Special Status Species	Negligible changes in the extent of riparian scrub and freshwater marsh habitat resulting from future reservoir operations would not significantly affect habitat conditions for California red-legged frog and California tiger salamander at San Antonio Reservoir. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)

TABLE 8.6 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITIONS – ALAMEDA WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desal for Drought	Variant 3 – 10% Rationing
Section 5.4.6, Terrestrial Biological Resources (cont.)				
Impact 5.4.6-5 (cont.)				
• Other Species of Concern	Apart from maintenance drawdown every five years, only minimal changes in reservoir levels would result. During drawdown periods, waterfowl and other littoral species could be temporarily displaced from preferred habitat. This would be a negligible effect. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
• Common Habitats and Species	Minor changes in reservoir levels would result in negligible impacts on common habitats and species. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.4.6-6: Effects on riparian habitat and related biological resources along San Antonio Creek between Turner Dam and the confluence with Alameda Creek				
• Sensitive Habitats	Releases to San Antonio Creek would be rare and similar to existing conditions. No notable change in conditions for riparian and wetland habitats are anticipated. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
• Key Special Status Species	Impacts on California red-legged frog habitat would be minimal. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
• Other Species of Concern	Future conditions along this section of San Antonio Creek would be similar to existing conditions and would have no effect on habitat of other species of concern. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
• Common Habitats and Species	Common habitats and species would be unaffected. (N/A)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
Impact 5.4.6-7: Effects on riparian habitat and related biological resources along Alameda Creek below the confluence with San Antonio Creek				
• Sensitive Habitats	WSIP-induced reductions in flow along Alameda Creek below the confluence with San Antonio Creek would be buffered by other stream inputs downstream. Minimal impacts on habitat would result. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)

TABLE 8.6 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITIONS – ALAMEDA WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desal for Drought	Variant 3 – 10% Rationing
Section 5.4.6, Terrestrial Biological Resources (cont.)				
Impact 5.4.6-7 (cont.)				
• Key Special Status Species	Little habitat for key special-status species exists along this reach of Alameda Creek. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
• Other Species of Concern	Minimal impacts on other species of concern. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
• Common Habitats and Species	Would result in minimal flow changes during normal to wet years and limited impacts on terrestrial ecological resources. (N/A)	Same as proposed program. (N/A)	Same as proposed program. (N/A)	Same as proposed program. (N/A)
Impact 5.4.6-8: Conflicts with the provisions of adopted conservation plans or other approved biological resources plans	Proposed program as a whole was found to be consistent with the provisions of the Alameda WMP. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
Section 5.4.7 Recreation and Visual Resources				
Impact 5.4.7-1: Effects on recreation facilities and/or activities	Under both existing and future conditions, water recreation is prohibited in SFPUC reservoirs. Thus, changes in reservoir water levels would not adversely affect recreation. Operations under the WSIP would substantially reduced flows along Alameda Creek in the Sunol Regional Wilderness during winter and early spring months and adversely affect the recreational experience of hikers; however, with the changes in project description for the Calaveras Dam Replacement (SV-2) project, bypass flows would be reduced from the diversion dam when flows are present. (LS)	Same as proposed program (LS)	Same as proposed program (LS)	Same as proposed program (LS)
Impact 5.4.7-2: Visual effects on scenic resources or visual character of water bodies	Apart from raised water levels in Calaveras Reservoir and substantial reductions in flows along Alameda Creek in the Sunol Regional Wilderness area during winter and spring months, changes in stream flow and reservoir elevations in the Alameda watershed would not be apparent to most recreational users. WSIP-induced reductions in stream flows along Alameda Creek would substantially change quality of visual resources in the Sunol Regional Wilderness area; however, with the changes in project description for the Calaveras Dam Replacement (SV-2) project, bypass flows would be reduced from the diversion dam when flows are present. (LS)	Same as proposed program (LS)	Same as proposed program (LS)	Same as proposed program (LS)

LS = Less than Significant, no mitigation required.
SM or PSM = Significant or Potentially Significant, can be Mitigated to less than significant.
SU or PSU = Significant Unavoidable or Potentially Significant Unavoidable, cannot be mitigated to less than significant.
B = Beneficial

TABLE 8.7
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITION – PENINSULA WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.5.1, Stream Flow and Reservoir Water Levels				
Impact 5.5.1-1: Effects on flow along San Mateo Creek	In most years, WSIP improvements to Lower Crystal Springs Dam would raise average monthly water levels in Crystal Springs Reservoir by 2 to 8 feet. Every fifth year, planned system maintenance would reduce importation of water from the Tuolumne River and would require that water be withdrawn from Crystal Springs Reservoir to meet water deliveries. Maintenance activities would decrease water levels by as much as 16 feet during the months of October, November and December. Little change in average monthly storage and water levels in San Andreas Reservoir compared to existing condition. Maintenance activities would decrease water levels by as much as 14 feet during the months of October, November and December. Under the WSIP, Crystal Springs Reservoir would be operated as it is currently operated and releases to San Mateo Creek would occur infrequently, as they do under the existing condition, and would be of a similar magnitude. San Mateo Creek is currently an intermittent stream and would remain so under the proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program (LS)
Impact 5.5.1-2: Effects on flow along Pilarcitos Creek	Increased water demand in the Coastside CWD service area would result in increased releases from Pilarcitos Reservoir. The reservoir would be drawn down more rapidly than under the existing condition. In some late spring and summer months of most hydrologic year types, the WSIP would result in increased flow in Pilarcitos Creek immediately below Pilarcitos Reservoir. In summer months of dry years, there would be almost no releases to the creek as occurs under the existing condition. The period without flow or with very low flow would be extended. Similar to existing conditions, flow in Pilarcitos Creek immediately below Stone Dam would be intermittent. Under the WSIP, total spills from Stone Dam to the creek would be reduced, but the magnitude of the flows in lower reaches of the creek would be similar to existing conditions. (LS)	Similar to but greater than with proposed program because lowered water levels in Crystal Springs Reservoir would enable greater diversions from Pilarcitos Creek and less spills at Stone Dam. (LS)	Similar to proposed program.(LS)	Similar to proposed program. (LS)
Section 5.5.2, Geomorphology				
Impact 5.5.2-1: Changes in sediment transport and channel morphology in the Peninsula watershed	Changes in flow along Pilarcitos Creeks and reservoir levels in Pilarcitos, San Andreas, and Crystal Springs Reservoirs would result in small incremental changes in sediment transport and channel-forming processes. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program (LS)

TABLE 8.7 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITION – PENINSULA WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.5.3, Surface Water Quality				
Impact 5.5.3-1: Effects on water quality in Crystal Springs Reservoir, San Andreas Reservoir, and San Mateo Creek	Under future conditions, increased water storage and water levels in Crystal Springs Reservoir would increase phosphorous and nitrogen concentrations, which could increase the growth of algae in reservoir water. However, any changes in water quality would be minor and would not affect beneficial uses. Water storage and water levels in San Andreas Reservoir would be similar to the existing condition. Changes in water quality would be negligible. Releases of high-quality Crystal Springs Reservoir water would occur at about the same frequency and magnitude as under current conditions and would not affect water quality in San Mateo Creek. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.5.3-2: Effects on water quality in Pilarcitos Reservoir and along Pilarcitos Creek	Proposed operations would generally be within the same range as existing conditions although replacement Measure 5.5.3-2a would cause Pilarcitos Reservoir to be drawn down earlier in the summer compared to existing conditions. Water temperature could increase and dissolved oxygen content could be reduced. During dry years summertime releases from Pilarcitos Reservoir to Pilarcitos Creek would be eliminated or reduced to a low level for a longer period of time with the WSIP, which would increase the temperature of instream flows between Pilarcitos Creek and Stone Dam and reduce the creek's ability to support designated cold freshwater habitat along this reach. Slight reductions in spill over Stone Dam would be minor and would not adversely affect water quality along Pilarcitos Creek. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)
Section 5.5.4, Groundwater				
Impact 5.5.4-1: Alteration of stream flows along Pilarcitos Creek, which could affect groundwater levels and water quality	Reduction in flows along Pilarcitos Creek below Stone Dam would be too small to have appreciable effect on groundwater recharge in lower Pilarcitos Creek watershed and would not affect groundwater quality. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)

TABLE 8.7 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITION – PENINSULA WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.5.5, Fisheries				
Impact 5.5.5-1: Effects on fishery resources in Crystal Springs Reservoir (Upper and Lower)	Increased storage in Crystal Springs Reservoir would increase the volume of coldwater and warmwater habitat for resident fish species and provide greater opportunities for connectivity and migration of fish between the reservoir and upstream tributary habitat. However, elevated water levels in Crystal Springs Reservoir would inundate approximately 1,500 linear feet of trout spawning habitat upstream of the reservoir along Laguna and San Mateo Creeks.(PSU)	Same as proposed program. (PSU)	Same as proposed program. (PSU)	Same as proposed program. (PSU)
Impact 5.5.5-2: Effects on fishery resources in San Andreas Reservoir	Average monthly storage and water levels would be similar to existing conditions. Minor changes in water quality would not adversely affect fishery resources. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
Impact 5.5.5-3: Effects on fisheries resources along San Mateo Creek	Stream flow in San Mateo Creek would be similar to existing conditions. Overall, fishery habitat conditions along San Mateo Creek would be comparable to existing conditions. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.5.5-4: Effects on fisheries resources in Pilarcitos Reservoir	Proposed operations would be within the same range as existing conditions although replacement Measure 5.5.3-2a would cause Pilarcitos Reservoir to be drawn down earlier in the summer compared to existing conditions. This would reduce the volume and quality of coldwater habitat available for resident fish species. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)
Impact 5.5.5-5: Effects on fishery resources along Pilarcitos Creek below Pilarcitos Reservoir	Under the WSIP, the extended period of no or very little flow in Pilarcitos Creek below Pilarcitos Reservoir during summer months of dry years would result in significant impacts on resident trout, other resident fish species and aquatic resources, and habitat quality and availability for anadromous steelhead. Increased drawdown of Pilarcitos Reservoir would increase the temperature of releases in summer and fall and reduce the quality and availability of habitat for coldwater fish species. A reduction in the frequency and magnitude of spills over Stone Dam would reduce flows along the lower reach. Reduced instream flows during winter months would adversely affect migratory fish habitat. (PSM)	Similar to proposed program but fishery effects would be greater because spills over Stone Dam would be less. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)

TABLE 8.7 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITION – PENINSULA WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.5.6, Terrestrial Biological Resources				
Impact 5.5.6-1: Impacts on biological resources in Upper and Lower Crystal Springs Reservoirs				
• Sensitive Habitats	Implementation of the Lower Crystal Springs Dam Improvements project (PN-4) would raise average monthly water levels in Crystal Springs Reservoir and result in a short-term reduction in the overall extent of freshwater marsh as the reservoir fills. Proposed changes in operations would maintain maximum reservoir levels during summer for longer periods than under existing conditions, which could affect the composition and structure of riparian habitats. In addition, sensitive upland habitats that are unable to tolerate these longer periods of inundation would be lost. (PSM)	Same as proposed program (PSM)	Same as proposed program (PSM)	Same as proposed program (PSM)
• Key Special Status Species	Elevated reservoir levels would inundate existing populations of special status plant species, including serpentine-associated fountain thistle and Marin western flax, and their habitat could be permanently lost. The extent of available habitat for San Francisco garter snake and California red-legged frog would be temporarily reduced during reservoir refill, but wetland habitat that would establish at higher elevations could potentially be more extensive. Raised reservoir levels would provide greater opportunities for largemouth bass and other predators to access frogs and snakes. Periodic drawdown during planned maintenance could adversely affect San Francisco garter snake foraging habitat. (PSM)	Same as proposed program (PSM)	Same as proposed program (PSM)	Same as proposed program (PSM)
• Other Species of Concern	Changes in wetland habitat due to reservoir refill and proposed operations would adversely affect reptile and bird species of concern, particularly if permanent changes in the composition of wetland vegetation occur. Permanent loss of upland habitat, including upland trees, grassland, and coastal scrub, would result in significant impacts on several bird and mammal species of concern. Serpentine- and grassland-associated plant species unable to tolerate extended periods of inundation would be lost. (PSM)	Same as proposed program (PSM)	Same as proposed program (PSM)	Same as proposed program (PSM)
• Common Habitats and Species	Due to the extent of area involved, impacts on common habitats and species would be significant. (PSM)	Same as proposed program (PSM)	Same as proposed program (PSM)	Same as proposed program (PSM)

**TABLE 8.7 (Continued)
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE
WSIP VARIANTS COMPARED TO EXISTING CONDITION – PENINSULA WATERSHED**

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.5.6, Terrestrial Biological Resources (cont.)				
Impact 5.5.6-2: Impacts on biological resources in San Andreas Reservoir				
• Sensitive Habitats	Minor changes in reservoir levels and operation would not substantially affect sensitive habitats. Minimal impacts would occur during maintenance drawdown. (LS)	Same as proposed program (LS)	Same as proposed program (LS)	Same as proposed program (LS)
• Key Special Status Species	Minor changes in reservoir levels and operation would not significantly affect the composition and extent of suitable wetland habitat for San Francisco garter snake and California red-legged frog. No impacts on terrestrial upland special-status species such as Mission blue butterfly would result. (LS)	Same as proposed program (LS)	Same as proposed program (LS)	Same as proposed program (LS)
• Other Species of Concern	Minor changes in monthly reservoir levels would not significantly affect habitat for other bird, mammal, reptile, and amphibian species of concern. (LS)	Same as proposed program (LS)	Same as proposed program (LS)	Same as proposed program (LS)
• Common Habitats and Species	Impacts on common habitats and species would be negligible. (LS)	Same as proposed program (LS)	Same as proposed program (LS)	Same as proposed program (LS)
Impact 5.5.6-3: Impacts on biological resources along San Mateo Creek below Lower Crystal Springs Dam				
• Sensitive Habitats	At the program level, potential changes in the structure and extent of freshwater marsh below the dam due to reduced instream flows would be significant. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program (LS)
• Key Special Status Species	Alterations in the extent and quality of freshwater marsh habitat for California red-legged frog could be significant. No key special-status plant species would be affected. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program (LS)
• Other Species of Concern	Impacts on riparian- and creek-associated species of concern would be minimal. (LS)	Same as proposed program (LS)	Same as proposed program (LS)	Same as proposed program (LS)
• Common Habitats and Species	Impacts on common upland habitats would be minimal. (LS)	Same as proposed program (LS)	Same as proposed program (LS)	Same as proposed program (LS)

SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITION – PENINSULA WATERSHED

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.5.6, Terrestrial Biological Resources (cont.)				
Impact 5.5.6-4: Impacts on biological resources in Pilarcitos Reservoir				
• Sensitive Habitats	Reduced water elevations could slightly reduce the extent of areas supporting sensitive freshwater marsh habitat. (LS)	Similar to proposed program (LS)	Same as proposed program (LS)	Similar to proposed program (LS)
• Key Special Status Species	Proposed operations would be within the same range as existing conditions, although replacement Measure 5.5.3-2a would cause Pilarcitos Reservoir to be drawn down earlier in the summer compared to existing conditions. This would reduce the extent of suitable habitat for California red-legged frog and San Francisco garter snake. Special status species that utilize adjacent upland vegetation would not be affected. (PSM)	Similar to proposed program (PSM)	Similar to proposed program (PSM)	Similar to proposed program (PSM)
• Other Species of Concern	The extent of suitable riparian habitat for reptile and bird species of concern would be slightly reduced. Species of concern that utilize adjacent upland vegetation would not be affected. (LS)	Similar to proposed program (LS)	Similar to proposed program (LS)	Similar to proposed program (LS)
• Common Habitats and Species	Changes in reservoir elevations would minimally affect common habitats and species. (LS)	Same as proposed program (LS)	Same as proposed program (LS)	Same as proposed program (LS)
Impact 5.5.6-5: Impacts on biological resources along Pilarcitos Creek below Pilarcitos Reservoir				
• Sensitive Habitats	Proposed operations would result in flows within the range of historical conditions, to which sensitive habitats have adapted. (LS)	Similar to proposed program (LS)	Similar to proposed program (LS)	Similar to proposed program (`LS)
• Key Special Status Species	Changes to suitable riparian habitat for foothill yellow-legged frog would be minimal. (LS)	Same as proposed program (LS)	Same as proposed program (LS)	Same as proposed program (LS)
• Other Species of Concern	Would result in slight reduction in extent of suitable for bird, mammal, and reptile species of concern that utilize open water and emergent vegetation. (LS)	Similar to proposed program (LS)	Similar to proposed program (LS)	Similar to proposed program (LS)
• Common Habitats and Species	Changes in operations would result in minor impacts to common species. (LS)	Same as proposed program (LS)	Same as proposed program (LS)	Same as proposed program (LS)
Impact 5.5.6-6: Impacts on biological resources along Pilarcitos Creek below Stone Dam				
• Sensitive Habitats	Slight incremental reduction in channel-forming processes and riparian habitat quality due to reduced stream flow. (LS)	Similar to but greater than proposed program because spills reduced compared to proposed program (LS)	Similar to proposed program (LS)	Similar to proposed program (LS)

TABLE 8.7 (Continued)

Section 5.5.6, Terrestrial Biological Resources (cont.)				
Impact 5.5.6-6 (cont.)				
• Key Special Status Species	Slight reduction in habitat quality for foothill yellow-legged frog due to reduced stream flow. (LS)	Similar to but greater than proposed program (LS**)**	Similar to proposed program (LS)	Similar to proposed program (LS)
• Other Species of Concern	Slight reduction in habitat quality for amphibian and bird species of concern due to reduced stream flow. (LS)	Similar to proposed program (LS)	Similar to proposed program (LS)	Similar to proposed program (LS)
• Common Habitats and Species	Changes in operations would result in minor impacts to common species. (LS)	Same as proposed program (LS)	Same as proposed program (LS)	Same as proposed program (LS)
Impact 5.5.6-7: Conflicts with the provisions of adopted conservation plans or other approved biological resource plans	Proposed program as a whole was found to be consistent with the provisions of the Peninsula WMP. (LS)	Same as proposed program (LS)	Same as proposed program (LS)	Same as proposed program (LS)
Section 5.5.7 Recreational and Visual Resources				
Impact 5.5.7-1: Effects on recreational facilities and/or activities	The WSIP would have no impact on water-related recreational facilities or other recreational activities in the Peninsula watershed. (LS)	Same as proposed program (LS)	Same as proposed program (LS)	Same as proposed program (LS)
Impact 5.5.7-2: Visual effects on scenic resources or the visual character of water bodies	Although elevated water levels in Crystal Springs Reservoir could change the visual appearance of the reservoir at close range, it would not change the scenic quality of the reservoir, either at close range or from distant viewpoints. (LS)	Same as proposed program (LS)	Same as proposed program (LS)	Same as proposed program (LS)

LS = Less than Significant, no mitigation required.
SM or PSM = Significant or Potentially Significant, can be Mitigated to less than significant.
SU or PSU = Significant Unavoidable or Potentially Significant Unavoidable, cannot be mitigated to less than significant.

TABLE 8.8
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITION — WESTSIDE GROUNDWATER BASIN

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.6, Westside Groundwater Basin				
Impact 5.6-1: Basin overdraft due to pumping from the Westside Groundwater Basin				
• North Westside Groundwater Basin	Proposed pumping could cause basin overdraft and result in potentially adverse impacts to groundwater resources. (PSM)	No impact because local groundwater projects would not be implemented. (N/A)	Same as proposed program. (PSM)	Same as proposed program. (PSM)
• South Westside Groundwater Basin	Proposed pumping in the South Westside Groundwater Basin for the regional conjunctive use program would comply with an operational agreement(s) to limit pumping to the "banked" quantity of water stored through in-lieu recharge so that pumping would not cause basin overdraft. (LS)	Similar to the proposed program (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
Impact 5.6-2: Changes in water levels in Lake Merced and other surface water features, including Pine Lake, due to decreased groundwater levels in the Westside Groundwater Basin				
• North Westside Groundwater Basin	Although pumping from the primary production aquifer would not have a direct effect on lake levels, it could potentially indirectly cause shallow groundwater levels to decline due to vertical leakage and affect water levels in Lake Merced and other surface water features. (PSM)	No impact because local groundwater projects would not be implemented. (N/A)	Same as proposed program. (PSM)	Same as proposed program. (PSM)
• South Westside Groundwater Basin	No major surface features in the South Westside Groundwater Basin would be affected by decreased groundwater levels. (N/A)	Same as proposed program. (N/A)	Same as proposed program. (N/A)	Same as proposed program. (N/A)
Impact 5.6-3: Seawater intrusion due to decreased groundwater levels in the Westside Groundwater Basin				
• North Westside Groundwater Basin	The shallow aquifer is in direct connection with the ocean from approximately Lake Merced to the north, and pumping could potentially cause saltwater intrusion. (PSM)	No impact because local groundwater projects would not be implemented. (N/A)	Same as proposed program. (PSM)	Same as proposed program. (PSM)
• South Westside Groundwater Basin	Saltwater intrusion in this aquifer has not been detected. Proposed pumping in the South Westside Groundwater Basin for the regional conjunctive use program would comply with an operational agreement(s) to limit pumping to the "banked" quantity of water stored through in-lieu recharge so that pumping would not cause basin overdraft or saltwater intrusion. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
Impact 5.6-4: Land subsidence due to decreased groundwater levels in the Westside Groundwater Basin if the historical low water levels are exceeded				
• North Westside Groundwater Basin	Land subsidence would not be expected because the aquifer materials are primarily composed of sands and dewatering of the fine-grained aquitards separating the aquifers would not occur (LS)	No impact because local groundwater projects would not be implemented. (N/A)	Same as proposed program. (LS)	Same as proposed program. (LS)

TABLE 8.9
SUMMARY OF WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR THE WSIP VARIANTS COMPARED TO EXISTING CONDITION — CUMULATIVE WATER SUPPLY IMPACTS

Impact	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Section 5.7, Cumulative Impacts Related to Water Supply and System Operations				
Impact 5.7.2-1: Tuolumne River – Hetch Hetchy Reservoir to Don Pedro Reservoir.	Contribution to impacts on hydrology, geomorphology, surface water quality, groundwater, fishery resources, and recreation/visual quality would not be cumulatively considerable. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
	Contribution to impacts on montane meadow habitat in Poopenaut Valley would be cumulatively considerable. (PSU)	Similar to but greater than proposed program. (PSU)	Similar to but less than proposed program. (PSU)	Similar to but greater than proposed program. (PSU)
Impact 5.7.2-2: Tuolumne River – Don Pedro Reservoir to San Joaquin River.	Contribution to impacts on hydrology, surface water quality, groundwater, fishery resources, terrestrial biological resources, and recreation/visual quality would not be cumulatively considerable. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.7.2-3: San Joaquin River, Stanislaus River, and Delta.	Contribution to impacts on hydrology, surface water quality, water supply availability, and fishery resources would not be cumulatively considerable. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.7.3-1: Alameda Creek watershed.	No cumulative impact on hydrology. (N/A)	Same as proposed program (N/A)	Same as proposed program (N/A)	Same as proposed program (N/A)
	Contribution to impacts on geomorphology, surface water quality, groundwater, terrestrial biological resources, and recreation/visual quality would not be cumulatively considerable. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.7.4-1: San Mateo Creek watershed.	Contribution to impacts on hydrology, geomorphology, surface water quality, groundwater, fishery, terrestrial biological resources, and recreation/visual quality would not be cumulatively considerable. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.7.4-2: Pilarcitos Creek watershed.	Contribution to impacts on hydrology, geomorphology, surface water quality, groundwater, fishery, terrestrial biological resources, and recreation/visual quality would not be cumulatively considerable. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)	Similar to proposed program. (LS)
Impact 5.7.5-1: North Westside Groundwater Basin.	Contribution to basin overdraft would not be cumulatively considerable. (LS)	Similar to but less than the proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)
Impact 5.7.5-2: South Westside Groundwater Basin.	Contribution to basin overdraft would not be cumulatively considerable. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)	Same as proposed program. (LS)

8.5.1 Water Supply Impacts of Variant 1

With *WSIP Variant 1 – All Tuolumne*, the water supply strategy would be the same as the proposed program, except to meet the estimated 35-mgd average annual increase in purchase request (from 265 to 300 mgd) by the year 2030, customers would be served entirely with additional water from the Tuolumne River watershed. As with the proposed program, a transfer from TID and MID and implementation of the Westside Basin conjunctive-use program would provide water during droughts. No additional water would be obtained from groundwater, additional conservation, or recycling projects in San Francisco.

Tuolumne River Watershed

With Variant 1, an annual average of 2.2 percent more water would be diverted from the Tuolumne River as compared to the WSIP.

Water levels in Lake Lloyd and Lake Eleanor would be essentially the same with Variant 1 and the WSIP. Releases from the reservoirs to Cherry and Eleanor Creeks would also be the same with Variant 1 and the WSIP.

Most of the time, more water would be diverted from the Tuolumne River at Hetch Hetchy Reservoir with Variant 1 than with the WSIP; as a result, storage in the reservoir would be drawn down farther just before the advent of the spring snowmelt. A greater proportion of snowmelt runoff would be needed to refill the reservoir, and consequently releases to the Tuolumne River in the spring would be delayed and reduced. The delay in release would usually be greater with Variant 1 than with the WSIP. Almost all of the differences in releases between Variant 1 and the WSIP would occur in May and June, with the greatest differences occurring in below-normal and dry years. With Variant 1, average monthly flow in some spring months would be 33 percent less than under the existing condition; the corresponding value with the WSIP would be 30 percent. The greatest reduction in average monthly flow in the 82-year period of hydrologic record would be 90 percent with both Variant 1 and the WSIP. The minimum required release below Hetch Hetchy Reservoir would be maintained or exceeded in all circumstances.

With Variant 1, more water would be diverted at Hetch Hetchy Reservoir and less would flow downstream to Don Pedro Reservoir than with the WSIP. Because of this reduction in inflow Don Pedro Reservoir would be drawn down farther with Variant 1 than it would with the WSIP. In a subsequent period, a higher proportion of winter and spring runoff would need to be captured to replenish Don Pedro Reservoir with Variant 1 than with the WSIP, and releases to the Tuolumne River below La Grange would be reduced. Most of the reductions in releases would occur between December and March in wet, above-normal, and below-normal years. With Variant 1, average monthly flow in some months between November and June would be 32 percent less than under the existing condition; the corresponding value with the WSIP would be 25 percent less. The greatest reduction in average monthly flow in the 82-year period of hydrologic record would be about 95 percent with both Variant 1 and the WSIP.

Alameda Watershed

The effects of Variant 1 in the Alameda watershed would be very similar to those of the WSIP. The magnitude and timing of diversions from Alameda Creek to Calaveras Reservoir and spills to Alameda Creek past the diversion dam would be the same with Variant 1 and the WSIP.

Storage in Calaveras and San Antonio Reservoirs and releases to Calaveras and San Antonio Creeks would be the same with Variant 1 and the WSIP most of the time. Storage in the two reservoirs would be drawn down more with Variant 1 than with the WSIP.

Seasonal summertime peak demand in 2030 in the Bay Area will exceed the capacity of the conveyance system from the Tuolumne River. Because of this, with the WSIP, water must be drawn from the local reservoirs to supplement the supply from the Tuolumne River. The need to draw water from local reservoirs during summertime peak demand would be greater with Variant 1 than with the WSIP. With the WSIP, additional conservation and recycling projects would effectively reduce demand for water in the Bay Area. Because Variant 1 does not include additional conservation and recycling projects, the demand for water in the Bay Area would be greater than it is for the WSIP. To meet the greater demand in the Bay Area, the local reservoirs would be drawn down further than they would be with the WSIP. Occasionally, with Variant 1, storage in Calaveras and San Antonio Reservoirs would exceed storage under the WSIP during periods when rationing is occurring or when the Westside Basin Groundwater Program is providing more water with the variant than with the WSIP. The changes in storage in the reservoirs with Variant 1 compared to the WSIP would have little or no effect on releases to Calaveras and San Antonio Creeks.

Peninsula Watershed

Storage in Crystal Springs Reservoir would be drawn down more with Variant 1 than with the WSIP fairly frequently, for the same reason noted above for Calaveras Reservoir. At certain times with Variant 1, the capacity of the conveyance system would limit the amount of water that could be conveyed from the Tuolumne River, and demand in the Bay Area would be met from local reservoirs, including Crystal Springs Reservoir. Average storage in Crystal Springs Reservoir with Variant 1 would be about 475 million gallons (1,457 acre-feet) less than with the WSIP. Because Crystal Springs Reservoir would be operated at a lower level with Variant 1, more storage capacity would be available in the reservoir to accommodate runoff during sudden storms. Releases to San Mateo Creek currently occur intermittently, primarily in wet and above-normal years, and would continue to do so with Variant 1 and with the WSIP. Current average wet-year releases are estimated to be 2.06 billion gallons (6,336 acre-feet). Releases with Variant 1 would be less frequent and smaller in magnitude than with the WSIP. Average wet-year releases to the creek would total 0.99 billion gallons (3,049 afy) with Variant 1; with the WSIP they would total 1.43 billion gallons (4,397 afy). In all cases, the estimated releases from Crystal Springs Reservoir are probably greater than the actual releases that occur because some model does not capture all of the operational flexibility available to system operators to minimize reservoir releases.

Storage in Pilarcitos Reservoir and releases to Pilarcitos Creek below the reservoir would be similar to but not identical with Variant 1 and the WSIP. Average storage in Pilarcitos Reservoir would be slightly greater for Variant 1, and releases to Pilarcitos Creek slightly less than for the WSIP. The reason for the difference is that rationing would be slightly more severe with Variant 1 than with the WSIP (See Table 8-2). Because Coastside County Water District would be subject to slightly more severe rationing with Variant 1 than with the WSIP slightly less water would be released from Pilarcitos Reservoir to serve Coastside's needs.

Spills to Pilarcitos Creek over Stone Dam currently occur primarily in wet and above-normal years and would continue to do so with Variant 1 and with the WSIP. Current average wet-year releases are estimated to be 2.29 billion gallons (7,065 acre-feet). Releases with the WSIP would be less frequent and smaller in magnitude than under the existing condition. With Variant 1 they would be less than with the WSIP. This is because with Variant 1, Crystal Springs Reservoir would be operated at a lower level than with the WSIP, enabling greater diversions from Pilarcitos Creek.

Westside Groundwater Basin

Under Variant 1, the Local Groundwater Projects (part of SF-2) would not be implemented, although the regional conjunctive-use project would continue to be implemented. In the absence of the Local Groundwater Projects, there would be no increase in pumping in the North Westside Groundwater Basin, and pumping rates would remain at about 2.5 mgd, well within the safe yield of the basin. However, without the Local Groundwater Projects, the monitoring and management of groundwater production would not occur, and the existing monitoring network would not be expanded. Overall, as shown in Table 8.8, impacts on the North Westside Groundwater Basin would be less for Variant 1 compared to the proposed program. Effects on the South Westside Groundwater Basin would be almost identical for Variant 1 and the proposed program, since both would rely on the Westside Basin conjunctive-use program as a supplemental dry-year water supply for an average of 6 mgd over the design drought. However, extraction of supplemental supplies would occur slightly more frequently with the variant in anticipation of drought.

Cumulative Water Supply Impacts

As shown in Table 8.9, cumulative water supply impacts associated with Variant 1 would be similar to those identified for the proposed program and described in Chapter 5, Section 5.7. However, due to the increased diversion from the Tuolumne River, the contribution to cumulative impacts on the terrestrial biological resources in the Poopenaut Valley would be greater than that for the WSIP. On the other hand, under Variant 1, the Local Groundwater Projects in San Francisco (part of SF-2) would not be implemented, so that the contribution to cumulative impacts related to basin overdraft in the North Westside Groundwater Basin would be less than that for the WSIP.

8.5.2 Water Supply Impacts of Variant 2

With *WSIP Variant 2 – Regional Desalination for Drought*, almost all of the additional water needed in 2030 under normal hydrologic conditions would be obtained from the Tuolumne River or from groundwater, additional conservation, and recycling in San Francisco. A small amount would come from the Bay Area watersheds through restoration of Calaveras and Crystal Springs Reservoirs. During droughts, up to 23 mgd (25,765 afy) of water would be provided from a regional desalination plant under Variant 2. Variant 2 would operate the same way as the WSIP under normal conditions, but during droughts water from the desalination plant would substitute for the water that would be transferred from TID and MID with the WSIP.

Tuolumne River Watershed

With Variant 2, about the same amount of water would be diverted from the Tuolumne River in wet, above-normal, below-normal, and dry years as with the WSIP. Much less water would be diverted in critically dry years. Average annual diversions from the Tuolumne River with Variant 2 would be 2.9 percent less than with the WSIP.

Water levels in Lake Lloyd and Lake Eleanor would be essentially the same with Variant 2 and the WSIP. Releases from the reservoirs to Cherry and Eleanor Creeks would also be the same with Variant 2 and the WSIP.

Most of the time, the same amount of water would be diverted from the Tuolumne River at Hetch Hetchy Reservoir with Variant 2 as it would with the WSIP; as a result, storage in the reservoir would be about the same with Variant 2 and the WSIP. Releases to the Tuolumne River below Hetch Hetchy Reservoir would also be about the same most of the time.

Differences would occur both during and following droughts under Variant 2. During droughts, the SFPUC would take water from the desalination plant in the Bay Area, rather than taking water from the Tuolumne River via a transfer from MID and TID. Consequently, larger amounts of water would be retained in storage in Hetch Hetchy Reservoir during droughts under Variant 2 than with the WSIP, and a smaller proportion of the spring snowmelt would be needed to refill the reservoir. As a result, releases to the Tuolumne River from Hetch Hetchy Reservoir in years following droughts would be greater with Variant 2 than with the WSIP and would be less delayed than with the WSIP. However, the differences in releases would be relatively small. With both Variant 2 and the WSIP, average monthly flow in some spring months would be 30 percent less than under the existing condition. The greatest reduction in average monthly flow in the 82-year period of hydrologic record would be 90 percent with both Variant 2 and the WSIP.

With Variant 2, storage in Don Pedro Reservoir would be almost the same as with the WSIP most of the time. During droughts under Variant 2, the SFPUC would obtain water from a desalination plant in the Bay Area. During droughts under the WSIP, Don Pedro Reservoir would be drawn down to supply water needed by the SFPUC, TID, and MID. In a series of dry years, water deficiencies would accumulate and Don Pedro Reservoir would be drawn down much farther than it is under the existing condition. With Variant 2, water deficiencies would accumulate in

Don Pedro Reservoir in a series of dry years, but to a lesser degree than with the WSIP. A smaller proportion of winter and spring runoff would need to be captured to refill Don Pedro Reservoir with Variant 2 than with the WSIP. Releases to the Tuolumne River below La Grange Dam would be greater with Variant 2 than with the WSIP. With Variant 2, average monthly flow in some months between November and June would be 21 percent less than under the existing condition. The corresponding value with the WSIP would be 25 percent less. The greatest reduction in average monthly flow in the 82-year period of hydrologic record with Variant 2 would be 78 percent; with the WSIP it would be 92 percent.

Alameda Watershed

The effects of Variant 2 in the Alameda watershed would be very similar to those of the WSIP. The magnitude and timing of diversions from Alameda Creek to Calaveras Reservoir and spills to Alameda Creek over the diversion dam would be the same with Variant 2 and the WSIP. Storage in Calaveras and San Antonio Reservoirs and releases to Calaveras and San Antonio Creeks would be the same with Variant 2 as with the WSIP.

Peninsula Watershed

Storage in Crystal Springs Reservoir would be greater at times with Variant 2 than with the WSIP. On occasion, Crystal Springs Reservoir would be drawn down with the WSIP, because the need for water in the Bay Area exceeds the amount of water that can be conveyed to the Bay Area from the Tuolumne River. This would include the occasions every five years when the conveyance system from the Tuolumne River would be shut down for a few weeks for maintenance. Because the desalination plant would meet some of the demand for water in the Bay Area during droughts, drawdown of Crystal Springs Reservoir would be less at times with Variant 2 than with the WSIP.

Average storage in Crystal Springs Reservoir with Variant 2 would be about 330 million gallons (1,014 acre-feet) more than with the WSIP. Because Crystal Springs Reservoir would be operated at a higher level with Variant 2, less storage capacity would be available in the reservoir to accommodate runoff during sudden storms. Releases to San Mateo Creek with Variant 2 would be more frequent and greater in magnitude than with the WSIP. Current total average wet year releases are estimated to be 2.06 billion gallons (6,336 acre-feet). Average wet-year releases to the creek would total 1.96 billion gallons (6,017 acre-feet) with Variant 2; with the WSIP they would total 1.43 billion gallons (4,397 acre-feet). In all cases, the estimated releases from Crystal Springs Reservoir are probably greater than the actual releases that occur because some model does not capture all of the operational flexibility available to system operators to minimize reservoir releases.

Storage in Pilarcitos Reservoir and releases to Pilarcitos Creek below the reservoir would be the same with Variant 2 and the WSIP. Spills to Pilarcitos Creek over Stone Dam currently occur primarily in wet and above-normal years and would continue to do so with Variant 2 and with the WSIP. Current average wet-year releases are estimated to be 2.29 billion gallons (7,065 acre-feet). Releases with Variant 2 would be similar in magnitude to those with the WSIP but slightly less than under the existing condition.

Westside Groundwater Basin

As shown in Table 8.8, effects on both the North and South Westside Groundwater Basins would be the same for Variant 2 and the proposed program. Both Variant 2 and the proposed program would rely on an annual average of 10 mgd of recycled water/groundwater/additional conservation projects in San Francisco during drought and nondrought periods. Similarly, both Variant 2 and the proposed program would rely on the Westside Basin conjunctive-use program as a supplemental dry-year water supply for an average of 6 mgd over the design drought.

Cumulative Water Supply Impacts

As shown in Table 8.9, cumulative water supply impacts associated with Variant 2 would be similar to those identified for the proposed program and described in Chapter 5, Section 5.7. However, due to the decreased diversion from the Tuolumne River, the contribution to cumulative impacts on the terrestrial biological resources in the Poopenaut Valley and other similar habitats below O'Shaughnessy Dam would be less than that for the WSIP. All other cumulative impacts would be similar to those for the WSIP.

8.5.3 Water Supply Impacts of Variant 3

With *WSIP Variant 3 – 10% Rationing*, almost all of the additional water needed in 2030 under normal hydrologic conditions would be obtained from the Tuolumne River or from groundwater, additional conservation, and recycling in San Francisco. A small amount would come from the Bay Area watersheds through restoration of Calaveras and Crystal Springs Reservoirs. Variant 3 would operate in the same way as the WSIP under normal conditions, but rationing during droughts would be limited to 10 percent rather than the 20 percent permitted with the WSIP. As with the WSIP, a transfer of water from TID and MID would provide water during droughts. Because rationing would be limited to 10 percent, the transfer from TID and MID would have to be greater with Variant 3 than with the WSIP. With Variant 3, the transfers would be 35 mgd (39,207 afy); with the WSIP they would be 23 mgd (25,765 afy).

Tuolumne River Watershed

With Variant 3, slightly more water would be diverted from the Tuolumne River than with the WSIP.

Because almost the same amount of water would be diverted from the Tuolumne River at Hetch Hetchy Reservoir with Variant 3 as it would with the WSIP, storage in the reservoir would be almost the same with Variant 3 and the WSIP. Releases to the Tuolumne River below Hetch Hetchy Reservoir would also be about the same. With both Variant 3 and the WSIP, average monthly flow in some spring months would be 30 percent less than under the existing condition. Compared to the existing condition, the delay in springtime releases from Hetch Hetchy

Reservoir with Variant 3 and the WSIP would be very similar. The greatest reduction in average monthly flow in the 82-year period of hydrologic record would be 90 percent with both Variant 3 and the WSIP.

Water levels in Lake Lloyd and Lake Eleanor would be essentially the same with Variant 3 and the WSIP. Releases from the reservoirs to Cherry and Eleanor Creeks would also be the same with Variant 3 and the WSIP.

With Variant 3, storage in Don Pedro Reservoir would be almost the same as with the WSIP most of the time. As with the WSIP, additional water would be obtained with Variant 3 via a transfer from TID and MID, although with Variant 3 the transfer would be larger. The effect of the transfer would be to draw down storage in Don Pedro Reservoir. In most years, the effect of the increased drawdown attributable to Variant 3 would be small relative to the size of the reservoir. Its effect on releases to the river below La Grange Dam would also be small. In a series of dry years, water deficiencies would accumulate and Don Pedro Reservoir would be drawn down farther with Variant 3 than it would be with the WSIP. A greater proportion of winter and spring runoff would need to be captured to refill Don Pedro Reservoir with Variant 3 than with the WSIP. Releases to the Tuolumne River below La Grange Dam would be somewhat less during droughts than with the WSIP in years following droughts, but the difference would be too small to have much effect on long-term averages. With both Variant 3 and the WSIP, average monthly flow in some months between November and June would be 30 percent less than under the existing condition. The greatest reduction in average monthly flow in the 82-year period of hydrologic record would be 92 percent with Variant 3 and with the WSIP.

Alameda Watershed

The effects of Variant 3 in the Alameda watershed would be very similar to those of the WSIP. The magnitude and timing of diversions from Alameda Creek to Calaveras Reservoir and spills to Alameda Creek over the diversion dam would be the same with Variant 3 and the WSIP. Storage in Calaveras and San Antonio Reservoirs and releases to Calaveras and San Antonio Creeks would be the same with Variant 3 and the WSIP.

Peninsula Watershed

Storage in Crystal Springs Reservoir would be slightly greater at times with Variant 3 than with the WSIP. Average storage in Crystal Springs Reservoir with Variant 3 would be about 112 million gallons (344 acre-feet) more than with the WSIP. Because Crystal Springs Reservoir would be operated at a slightly higher level with Variant 3, less storage capacity would be available in the reservoir to accommodate runoff during sudden storms. Releases to San Mateo Creek with Variant 3 would be slightly more frequent and slightly greater in magnitude than with the WSIP. Current total average wet year releases are estimated to be 2.06 billion gallons (6,336 acre-feet). Average wet-year releases to the creek would total 1.5 billion gallons (4,623 acre-feet) with Variant 3; with the WSIP they would total 1.43 billion gallons (4,397 acre-feet). In all cases, the estimated releases from Crystal Springs Reservoir are probably greater than actual releases because some of the modeled releases would likely be avoided by reservoir operators.

Storage in Pilarcitos Reservoir and releases to Pilarcitos Creek below the reservoir would be similar but not identical under Variant 3 and WSIP. With Variant 3, storage in Pilarcitos Reservoir and releases to Pilarcitos Creek would differ slightly from those with the WSIP because the Coastside County Water District would be subject to a different pattern of shortages/rationing during droughts. Spills to Pilarcitos Creek over Stone Dam currently occur primarily in wet and above-normal years and would continue to do so with Variant 3 and with the WSIP. Current average wet-year releases are estimated to be 2.29 billion gallons (7,065 acre-feet). Releases with Variant 3 would be similar in magnitude to those with the WSIP but slightly less than under the existing condition.

Westside Groundwater Basin

As shown in Table 8.8, effects on both the North and South Westside Groundwater Basins would be the same for Variant 2 and the proposed program. Both Variant 2 and the proposed program would rely on an annual average of 10 mgd of recycled water/groundwater/additional conservation projects in San Francisco during drought and nondrought periods. Similarly, both Variant 2 and the proposed program would rely on the Westside Basin conjunctive-use program as a supplemental dry-year water supply for an average of 6 mgd over the design drought.

Cumulative Water Supply Impacts

As shown in Table 8.9, cumulative water supply impacts associated with Variant 3 would be similar to those identified for the proposed program and described in Chapter 5, Section 5.7. However, due to the slightly increased diversion from the Tuolumne River, the contribution to cumulative impacts on the terrestrial biological resources in the Poopenaut Valley and other similar habitats below O'Shaughnessy Dam would be slightly greater than that for the WSIP. All other cumulative impacts would be similar to those for the WSIP.

8.6 Comparison of the Proposed Program and Variants

Table 8.10 summarizes the major impacts of the variants and compares them to those of the proposed program. The table focuses on the significant unavoidable or potentially significant unavoidable impacts identified in Chapters 4, 5 and 7 for the proposed program and indicates the same for each variant. The table distinguishes between facilities-related impacts (under the general categories of construction, footprint, and operational impacts) and water supply and system operation impacts. With the exception of the BARDP component of Variant 2, all three variants would have the same significant unavoidable or potentially significant unavoidable impacts as the proposed program, although in some cases, there would be slight differences in severity of the impact. The greatest differences among the proposed program and the variants are associated with facilities-related impacts of the BARDP; other differences in facilities-related impacts are minor. Similarly, as stated previously, although the water supply and system operations impacts of the variants differ somewhat from those of the proposed program, the magnitude of the differences is small and not sufficient to change either the significance determinations or the mitigation measures identified for the WSIP.

TABLE 8.10
COMPARISON OF MAJOR IMPACTS – PROPOSED PROGRAM AND VARIANTS

Impact Area	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Facilities-Related Impacts	All potential impacts could be reduced to less than significant with implementation of mitigation measures, except for potentially significant and unavoidable impacts below:	Same impacts as proposed program in all respects, except there would be fewer impacts on the west side of San Francisco because Recycled Water (SF-3) and Local Groundwater Projects (part of (SF-2) would not be implemented.	Same impacts as proposed program in all respects except there would be additional impacts associated with implementation of a regional desalination plant, including additional potentially significant and unavoidable impacts below.	Same impacts as proposed program in all respects.
▪ Construction impacts associated with construction activities	▪ Disruption of land uses during construction (PSU for New Irvington Tunnel, SV-4) ▪ Construction-related noise increases (PSU for all projects) and temporary noise disturbance along haul routes (PSU for Advanced Disinfection, SJ-1; San Joaquin Pipeline System, SJ-3; Rehabilitation of Existing San Joaquin Pipelines, SJ-4; Tesla Portal Disinfection Station, SJ-5; Bay Division Pipeline Reliability Upgrade, BD-1; BDPL Nos. 3 and 4 Crossovers, BD-2; Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault, BD-3; Baden and San Pedro Valve Lots Improvements, PN-1; HTWTP Long-Term Improvements, PN-3; San Andreas Pipeline No. 3 Installation, SF-1; Groundwater Projects, SF-2; and Recycled Water Projects, SF-3) ▪ Construction-related vibration disturbance (PSU for San Joaquin Pipeline System, SJ-3; Rehabilitation of Existing San Joaquin Pipelines, SJ-4; Additional 40-mgd Treated Water Supply, SV-3; Bay Division Pipeline Reliability Upgrade, BD-1; BDPL Nos. 3 and 4 Crossovers, BD-2; Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault, BD-3; Baden and San Pedro Valve Lot Improvements, PN-1; San Andreas Pipeline No. 3 Installation, SF-1; Groundwater Projects, SF-2; and Recycled Water Projects, SF-3) ▪ Collective, multi-regional increase in construction traffic (PSU) ▪ Cumulative traffic increases on local and regional roads (PSU) ▪ Collective, multi-regional increase in construction-related air pollutant emissions (PSU)	Same as proposed program except for PSU construction noise impact associated with Local Groundwater Projects, SF-2, and Recycled Water Projects, SF-3, would not occur.	Same as proposed program plus additional impacts associated with BARDP construction.	Same as proposed program.

TABLE 8.10 (Continued)
COMPARISON OF MAJOR IMPACTS – PROPOSED PROGRAM AND VARIANTS

Impact Area	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
▪ Construction impacts associated with construction activities (cont.)	▪ Cumulative impacts on cultural resources (PSU) ▪ Cumulative increases in construction-related air pollutant emissions (PSU) ▪ Localized, cumulative increases in emissions of diesel particulate matter (PSU) ▪ Collective, overlapping construction noise in San Joaquin, Bay Division, Peninsula, and San Francisco regions (PSU) ▪ Cumulative increases in construction-related noise and vibration (PSU) ▪ Collective impacts on land uses during construction in Bay Division Region (PSU) ▪ Collective impacts on land uses during construction in Bay Division Region (PSU)			
▪ Footprint impacts associated with siting of facilities	▪ Permanent displacement or long-term disruption of existing land uses (PSU for San Joaquin Pipeline System, SJ-3; Additional 40-mgd Treated Water Supply, SV-3; San Antonio Backup Pipeline, SV-6; Bay Division Pipeline Reliability Upgrade, BD-1; Crystal Springs/ San Andreas Transmission Upgrade, PN-2; Groundwater Projects, SF-2; and Recycled Water Projects, SF-3). ▪ Impacts on scenic resources associated with new permanent aboveground structures (PSU for Calaveras Dam Replacement, SV-2) ▪ Impacts on the historical significance of a historic district or a contributor to a historic district (PSU for Calaveras Dam Replacement, SV-2 and Crystal Springs/San Andreas Transmission Upgrade, PN-2), and impacts on historical significance of individual facilities (PSU for Calaveras Dam Replacement, SV-2; New Irvington Tunnel, SV-4; Crystal Springs/San Andreas Transmission Upgrade, PN-2; and Lower Crystal Springs Dam Improvements, PN-4).	Same as proposed program.	Same as proposed program plus additional footprint and siting impacts associated with the BARDP: ▪ Effects of BARDP construction on sensitive aquatic habitats and species and possibly special-status species (PSU)	Same as proposed program.

TABLE 8.10 (Continued)
COMPARISON OF MAJOR IMPACTS – PROPOSED PROGRAM AND VARIANTS

Impact Area	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
▪ Footprint impacts associated with siting of facilities (cont.)	▪ Collective impacts on sensitive biological resources in Sunol Valley and Peninsula regions (PSU) ▪ Collective impacts on cultural resources in Sunol Valley and Peninsula regions (PSU)			
▪ Operational impacts	No PSU or SU operational impacts.	Same as proposed program.	▪ Effects of BARDP operation on water quality associated with discharge of brine concentrate (PSU) ▪ Long-term effects of BARDP operation on sensitive biological resources, including special-status marine species (PSU) ▪ Long-term energy demand of BARDP (PSU)	Same as proposed program.
Water Supply and System Operations Impacts	All impacts could be reduced to less than significant with implementation of mitigation measures, except for potentially significant and unavoidable impacts below:			
Tuolumne River Watershed	No significant and unavoidable impacts	Similar impacts to proposed program.	Similar impacts to proposed program.	Similar impacts to proposed program.
Alameda Creek Watershed	Reduction in flow in Alameda Creek between the diversion dam and confluence with Calaveras Creek. (SU)	Similar impacts to proposed program.	Similar impacts to proposed program.	Similar impacts to proposed program.
Peninsula Watershed (San Mateo Creek and Pilarcitos Creek Watersheds)	Effects on fishery resources in Crystal Springs Reservoir. (PSU)	Similar impacts to proposed program.	Similar impacts to proposed program.	Similar impacts to proposed program
Westside Groundwater Basin	No significant and unavoidable impacts.	Same impacts as proposed program on South Westside Groundwater Basin, but PSM impacts on North Westside Groundwater Basin would be avoided	Same impacts as proposed program.	Same impacts as proposed program

TABLE 8.10 (Continued)
COMPARISON OF MAJOR IMPACTS – PROPOSED PROGRAM AND VARIANTS

Impact Area	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Growth Inducement	Indirect effects of growth include the following significant and unavoidable impacts: ▪ Loss of open space (to development) on visual quality ▪ Alteration of the visual setting or degradation of existing views and cumulative visual quality impacts ▪ Conversion of agricultural land to nonagricultural uses ▪ Cumulative loss of agricultural land ▪ Increases in air pollutant emissions and/or ozone precursors or violation of air quality standards ▪ Cumulative air quality impacts ▪ Impacts on natural habitat ▪ Individual or cumulative loss of wetlands ▪ Cumulative impacts on cultural resources ▪ Exposure to seismic or geologic hazards ▪ Exposure to soil or groundwater contamination ▪ Cumulative effects from increased exposure to man-made hazards ▪ Increases in impervious surfaces and/or alterations to drainage resulting in exposure to flood hazards and/or the need for new drainage facilities ▪ Water pollution from stormwater runoff ▪ Land use impacts ▪ Cumulative impacts from the depletion of nonrenewable resources and the alteration of landforms ▪ Noise impacts, including increases in traffic noise, exposure to construction noise, and exposure to aircraft noise ▪ Impacts related to population growth (directly or indirectly induced) and jobs/housing balance	Same impacts as proposed program.	Same impacts as proposed program, plus growth-inducement effects associated with the BARDP.	Same impacts as proposed program

TABLE 8.10 (Continued)
COMPARISON OF MAJOR IMPACTS – PROPOSED PROGRAM AND VARIANTS

Impact Area	Proposed Program	Variant 1 – All Tuolumne	Variant 2 – Regional Desalination for Drought	Variant 3 – 10% Rationing
Growth Inducement (cont.)	▪ Increased demand for schools and/or other public facilities ▪ Loss of recreational open space ▪ Cumulative impacts on recreational facilities ▪ Local and regional traffic impacts ▪ Cumulative traffic impacts ▪ Impacts on landfill capacity ▪ Increases in water demand ▪ Large and wasteful increase in energy consumption and cumulative energy-related impacts ▪ Greenhouse gas emissions			

With respect to facilities-related impacts, all three variants would have essentially the same impacts and require the same mitigation measures as described for the 22 WSIP facility improvement projects evaluated in Chapter 4. Variant 1 would have slightly fewer impacts than the proposed program or Variant 3, because the Recycled Water Projects (SF-3) and Local Groundwater Projects (part of SF-2) would not be implemented. Variant 3 would have the identical facilities-related impacts as the proposed program. Variant 2 would have the most impacts due to implementation of the BARDP in addition to the WSIP facility improvement projects. Construction and operation of the BARDP would result in other environmental effects not related to the WSIP projects, including potentially significant and unavoidable impacts associated with water quality, biological resources, and long-term energy consumption, as described above in Section 8.3, and would also require additional mitigation measures beyond those described for the proposed program.

With respect to water supply and system operations, all three variants would result in similar impacts to those of the proposed program with two exceptions. First, the difference in significance determination would be the potentially significant but mitigable impacts on the North Westside Groundwater Basin associated with the proposed program; under Variant 1, this impact would be avoided since local groundwater projects would not be implemented. Second, Variant 2 would result in potentially significant impacts on another water (either San Francisco Bay or the Pacific Ocean) and related resources, in addition to all of the impacts identified for the WSIP. As described above, for impacts on all other water resources, there would be some degree of difference in physical effects among the variants and the proposed program, with some greater and some lesser effects on different aspects of the affected water resources, but these differences do not appear sufficient to warrant a change in impact significance. Similar mitigation strategies would be required for the variants and the proposed program, although there could be slight differences in the specific design and implementation of the mitigation measures under each variant.

The variants and the proposed program would have the same impacts related to growth inducement and indirect effects of growth, as described previously in this chapter. In addition, with the exception of the BARDP component of Variant 2, the variants would have the same areas of controversy, the same unavoidable effects, and the same irreversible environmental changes as the proposed program.

9 CEQA Alternatives

CHAPTER 9
CEQA Alternatives

9.1 Introduction

9.1.1 CEQA Guidance for Alternatives Analysis

The California Environmental Quality Act (CEQA) Guidelines, Section 15126.6(a), state that an environmental impact report (EIR) must describe and evaluate a reasonable range of alternatives to the proposed project that would feasibly attain most of the project's basic objectives, but that would avoid or substantially lessen any significant adverse environmental effects of the project. An EIR is not required to consider every conceivable alternative to a proposed project. Rather, it must consider a reasonable range of potentially feasible alternatives that will foster informed decision-making and public participation. CEQA Guidelines Section 15126.6(e) states that, "The specific alternative of 'no project' shall also be evaluated along with its impact" (which, in the case of this Program EIR, is referred to as the No *Program* Alternative). The EIR must evaluate the comparative merits of the alternatives and include sufficient information about each alternative to allow meaningful evaluation, analysis, and comparison with the proposed project.

9.1.2 WSIP Goals and Objectives

Program alternatives were evaluated for their ability to attain most of the basic objectives of the proposed Water System Improvement Program (WSIP or program), consistent with CEQA. The WSIP goals, objectives, and proposed levels of service (presented in Chapter 3, Program Description, Section 3.3) are repeated here for ease of reference. The goals and objectives, based on a planning horizon through 2030, are founded on two fundamental principles pertaining to the existing regional water system: (1) maintaining a clean, unfiltered water source from the Hetch Hetchy system, and (2) maintaining a gravity-driven system. The overall goals of the WSIP for the regional water system are to:

- Maintain high-quality water
- Reduce vulnerability to earthquakes
- Increase delivery reliability and improve the ability to maintain the system
- Meet customer water supply purchase requests in nondrought and drought periods
- Enhance sustainability in all system activities
- Achieve a cost-effective, fully operational system

To further these program goals, the WSIP includes objectives that address system performance in the areas of water quality, seismic reliability, delivery reliability, and water supply through the year 2030. The system performance objectives provide design guidelines for facility improvement projects and provide the basis for the proposed system operations and water supply option. **Table 9-1** presents the WSIP goals and objectives, and **Table 9-2** summarizes and compares the levels of service under the existing condition and the proposed program.

9.1.3 Organization of this Chapter

This chapter presents the key alternatives analysis and results, then describes the background process and evaluation that led to those results, as follows:

- Section 9.2 presents the alternatives selected for inclusion in the PEIR based on CEQA criteria. The section describes each alternative, including the No Program Alternative, and discusses San Francisco Public Utilities Commission (SFPUC) actions as well as possible wholesale customer actions associated with each alternative. For each alternative, the section also describes feasibility issues associated with its implementation, as well as its ability to meet WSIP objectives and its effectiveness in avoiding or reducing environmental impacts. Section 9.2 then compares the environmental effects of each alternative with the effects of the WSIP.

- Section 9.3 summarizes and compares the alternatives, identifying trade-offs and the environmentally superior alternative.

- Section 9.4 describes the process used to identify program alternatives. It summarizes the significant adverse impacts of the WSIP, identifies strategies to avoid or substantially lessen these effects that could be implemented through an alternative to the WSIP rather

TABLE 9-1
WSIP GOALS AND OBJECTIVES

Program Goal	System Performance Objective
Water Quality – *maintain high water quality*	▪ Design improvements to meet current and foreseeable future federal and state water quality requirements. ▪ Provide clean, unfiltered water originating from Hetch Hetchy Reservoir and filter all other surface water sources. ▪ Continue to implement watershed protection measures.
Seismic Reliability – *reduce vulnerability to earthquakes*	▪ Design improvements to meet current seismic standards. ▪ Deliver basic service to the three regions in the service area (East/South Bay, Peninsula, and San Francisco) within 24 hours after a major earthquake. Basic service is defined as average winter-month usage, and the performance objective for the regional system is 229 million gallons per day (mgd). The performance objective is to provide delivery to at least 70 percent of the turnouts (i.e., water diversion point) in each region, with 104, 44, and 81 mgd delivered to the East/South Bay, Peninsula, and San Francisco regions, respectively. ▪ Restore facilities to meet average-day demand of 300 mgd within 30 days after a major earthquake.
Delivery Reliability – *increase delivery reliability and improve ability to maintain the system*	▪ Provide operational flexibility to allow planned maintenance shutdown of individual facilities without interrupting customer service. ▪ Provide operational flexibility to minimize the risk of service interruption due to unplanned facility upsets or outages. ▪ Provide operational flexibility and system capacity to replenish local reservoirs as needed. ▪ Meet the estimated average annual demand of 300 mgd for 2030 under the conditions of one planned shutdown of a major facility for maintenance concurrent with one unplanned facility outage.
Water Supply – *meet customer water needs in nondrought and drought periods*	▪ Meet average annual water purchase requests of 300 mgd from retail and wholesale customers during nondrought years for system demands through 2030. ▪ Meet dry-year delivery needs through 2030 while limiting rationing to a maximum 20 percent systemwide reduction in water service during extended droughts. ▪ Diversify water supply options during nondrought and drought periods. ▪ Improve use of new water sources and drought management, including use of groundwater, recycled water, conservation, and transfers.
Sustainability – *enhance sustainability in all system activities*	▪ Manage natural resources and physical systems to protect watershed ecosystems. ▪ Meet, at a minimum, all current and anticipated legal requirements for protection of fish and other wildlife habitat. ▪ Manage natural resources and physical systems to protect public health and safety.
Cost-effectiveness – *achieve a cost-effective, fully operational system*	▪ Ensure cost-effective use of funds. ▪ Maintain gravity-driven system. ▪ Implement regular inspection and maintenance program for all facilities.

TABLE 9-2
EXISTING AND PROPOSED REGIONAL SYSTEM LEVELS OF SERVICE[a]

Operating Parameter	Existing Level of Service (2005)	Proposed Level of Service with WSIP (2030)
Water Quality	Meet all existing local, state, and federal water quality requirements	Meet all local, state, and federal water quality requirements in 2030
Seismic Response After Major Earthquake	Not defined	Provide basic service[b] of 229 mgd within 24 hours; average-day service of 300 mgd within 30 days
Delivery During System Maintenance	Not defined	Average day demand of 300 mgd
Average Annual Water Supply	265 mgd	300 mgd
Regional System Firm Yield[c]	219 mgd	256 mgd
Drought-Year Rationing	No maximum limit to rationing	Up to 20 percent systemwide rationing

a Level of service flow rates are defined on a systemwide basis and are not specific to any customer turnout (i.e., water diversion point).
b Basic service is defined as winter-month demand, estimated to be 229 mgd systemwide in 2030.
c System firm yield is defined as the average annual water delivery that can be sustained by the regional water system during an extended drought. The SFPUC uses an 8.5-year design drought for planning purposes. Currently, due to operating restrictions imposed on Calaveras Dam by the California Division of Safety of Dams in December 2001, the system firm yield is reduced from its normal system firm yield of 226 mgd to about 219 mgd.

than through mitigation measures, and reviews suggestions and concepts for alternatives that were raised during the scoping period. Section 9.4 presents the rationale and screening process used for accepting or rejecting potential alternatives and summarizes the reasons for eliminating alternatives from further consideration.

- Section 9.5 provides additional background information about and more detail on the reasons for rejecting alternative concepts identified in Section 9.4 that were considered but rejected either as part of the WSIP development process or as part of the CEQA alternatives analysis process.

9.2 Alternatives Analysis

9.2.1 Selected Alternatives for Comparative Analysis

In accordance with CEQA, appropriate alternatives for EIR analysis are those that meet most of a project's basic objectives *and* avoid or substantially lessen the significant environmental impacts of the proposed project. As described in more detail in Section 9.4, several steps were taken to identify potential alternatives and assemble a reasonable range of alternatives for evaluation in the PEIR in comparison in the WSIP, including:

1. Review the significant effects resulting from the WSIP and identify possible strategies to avoid or lessen such impacts.

2. Review ideas and alternative concepts suggested during the PEIR scoping process.

3. Categorize and evaluate strategies and concepts for the ability to both meet the basic project objectives and avoid or lessen significant impacts.

4. Develop preliminary alternatives based on strategies and concepts retained from preliminary screening. Evaluate feasibility with respect to technical, institutional, cost, and regulatory considerations.

5. Select and refine a final set of alternatives for CEQA analysis.

From this process seven alternatives, in addition to the required No Program Alternative, were selected for further evaluation and comparison to the WSIP. Together, this set of eight alternatives represents a broad range of options in terms of how key aspects of the proposed program could be implemented. Each alternative in the set differs from the WSIP in one or more of the following important ways:

- *Demand level served*. The WSIP plans to meet an average annual delivery requirement of 300 mgd by 2030 reflecting the customer purchase request increase of 35 mgd over current average annual demand. Two alternatives do not fully satisfy customer purchase requests in 2030.

- *Water supply source(s) / level of additional Tuolumne River diversion*. The WSIP proposes to increase Tuolumne River diversion under the CCSF's existing water rights coupled with development of additional recycled water, conservation, and local groundwater in San Francisco, a conjunctive groundwater use program in the Westside Basin (San Mateo County), and acquisition of a dry-year surface water transfer. Two alternatives include a smaller increase in diversion of Tuolumne River water compared to the WSIP and two alternatives include no increase in Tuolumne River water diversion; one of these alternatives looks at demand management strategies (conservation and water recycling) while the other evaluates an alternative supply source – seawater desalination. Another alternative considers a new point of diversion on the lower Tuolumne River, which, although it is still Tuolumne River water, represents an alternative source of supply in terms of shifting from a Sierra Nevada supply source to a Central Valley supply source.

- *Level of drought rationing.* As part of implementing the WSIP the SFPUC proposes to meet an objective of up to 20 percent maximum systemwide rationing in any year of a drought. Two alternatives require higher levels of rationing.

- *Facilities – number of projects required / extent of facilities construction.* The WSIP includes implementation of 22 facility improvement projects evaluated in this PEIR. One alternative, the No Program Alternative, includes only a few of these facility improvement projects. Seven of the eight alternatives include all 22 of the facility improvement projects plus additional required facilities ranging from a new desalination plant and transmission pipelines to additional recycled water treatment plants, groundwater wells, and distribution facilities.

As noted in Section 9.4, many other alternative concepts were identified that would modify the WSIP in one of the key areas identified in the bullet list above. However, the set of eight alternatives selected for further evaluation was judged to best represent the range of identified strategies and concepts. For example, a Delta water supply source was one of the supply source concepts proposed as an alternative to increasing diversion from the Tuolumne River. However, an alternative to divert water off the lower Tuolumne River better represents the concept of diverting, in effect, Tuolumne River water from a point downstream in the valley, lower in the watershed. Similarly, a seawater desalination alternative is included in the range of alternatives evaluated as a supply source alternative that involves no additional Tuolumne River water. Section 9.4, below, describes the alternatives development and screening process in further detail and explains the reasons for eliminating various strategies and concepts from further evaluation.

This section evaluates the comparative merits of the selected alternatives relative to the WSIP. Since the alternatives are generally conceptual, the evaluation is based on the available information and reasonable assumptions about how each alternative would be implemented. For each alternative, this section presents the following:

- Description of the alternative, including associated facility improvement projects, water supply sources, and system operations. The descriptions include SFPUC actions as well as reasonable expectations regarding the wholesale customer actions that would occur under each alternative. The description includes a review of potential feasibility issues as well.

- Ability to meet primary WSIP goals and objectives

- Environmental impacts of each alternative compared to those of the WSIP. This section is divided into three groups: facility impacts (construction and operation), water supply and system operations impacts, and growth-inducement impacts. Under the facility impacts, impacts associated with each alternative are compared to those described in Chapter 4 of this PEIR for the proposed WSIP facility improvement projects; additionally, impacts of other facilities that would or could be required under an alternative but not under the WSIP are described, along with associated potential impacts on other water bodies and associated resources not affected by the WSIP. Under the water supply and system operations impacts, the potential impacts within the SFPUC regional system under each alternative are compared to those analyzed for the WSIP in Chapter 5 of this PEIR.[1] The comparative evaluation of growth-inducement impacts is discussed based on the analysis presented in Chapter 7 of this PEIR.

Table 9-3 identifies the eight CEQA alternatives evaluated in detail in this PEIR. There are seven main alternatives but there are also two variations of the Aggressive Conservation / Water Recycling and Local Groundwater Alternative that are each evaluated in detail in comparison to the WSIP; thus these are counted as two separate alternatives, for a total of eight. The table provides a brief description of each alternative and highlights how it differs from the WSIP and what impact areas it is intended to address.

---

[1] The potential impacts of the WSIP on water supply and system operations were determined based on modeling results of the Hetch Hetchy/Local Simulation Model, as described in Section 5.1. Modeling results for the CEQA alternatives are discussed in Appendices H1 through H3. It should be noted that development of the conceptual alternatives continued after the performance of modeling for the CEQA alternatives; however, results presented in this PEIR are adequate to assess the comparative impacts of the alternatives and the WSIP. In particular, the modeling results of the CEQA alternatives do not account for restoration of the historical capacity of Crystal Springs Reservoir (i.e., implementation of the Lower Crystal Springs Dam project, PN-4) and the associated 1 mgd of system firm yield; however, the comparative analysis qualitatively addresses the change in system operations that would occur with implementation of PN-4.

TABLE 9-3
SELECTED ALTERNATIVES FOR CEQA ANALYSIS

Alternative / Description	How Does This Alternative Differ From The WSIP?	What WSIP Impacts Is The Alternative Intended to Address?
No Program –SFPUC would implement only those WSIP facility improvement projects driven by regulatory requirements or existing agreements with regulatory agencies. It would endeavor to meet increasing customer purchase requests through the year 2030 by diverting additional Tuolumne River water only when available under CCSF's existing water rights. The wholesale customers would have to pursue supplemental supply sources and/or conservation measures to make up the supply shortfall/reduced reliability under this alternative.	▪ *2030 Avg. Annual Delivery Target:* Same ▪ *Supply Sources*: Tuolumne River. No dry-year water transfer, Westside Groundwater basin, or 10 mgd recycled water / conservation / groundwater in SF ▪ *Additional Tuolumne River diversion*: Less ▪ *Level of Rationing*: Allow for greater than 20% systemwide rationing ▪ *Facility projects*: Fewer	▪ Required by CEQA ▪ Fewer facilities construction impacts (fewer facilities would be constructed)
No Purchase Request Increase – SFPUC would implement all of the proposed WSIP facility improvement projects but would limit wholesale customers' future purchases to the terms of the existing Master Water Sales Agreement instead of providing all of their 2030 purchase requests. The wholesale customers would have to pursue supplemental supply sources and/or conservation measures to make up the supply shortfall under this alternative.	▪ *2030 Avg. Annual Delivery Target:* Less ▪ *Supply Sources*: Same ▪ *Additional Tuolumne River diversion*: Less ▪ *Level of Rationing*: Same ▪ *Facility projects*: Same	▪ Growth inducement potential and associated secondary effects of growth ▪ Impacts on Pilarcitos Creek
Aggressive Conservation/Water Recycling and Local Groundwater – The SFPUC would implement all of the proposed WSIP facility improvement projects and endeavor to serve the projected 2030 delivery target of 300 mgd solely through additional conservation, water recycling, and local groundwater projects. A maximum of 19 mgd of the 25 mgd projected annual average increase in purchase requests might be met through such local projects, as feasible. Since this alternative would not meet the full 2030 customer purchase request, the SFPUC would have to either (a) limit future deliveries to the level that can be met under this alternative (estimated to be 294 mgd or less) or (b) supplement supply to make up the delivery shortfall. Two variations of this alternative are evaluated as follows: ***No Supplemental Tuolumne River Supply*** – The SFPUC would not provide supplemental water from the Tuolumne River to augment this alternative to meet the 2030 customer purchase requests of 300 mgd. ***With Supplemental Tuolumne River Supply*** – The SFPUC would supplement this alternative with additional Tuolumne River diversions under its existing water rights.	***No Supplemental Tuolumne River Supply*** ▪ *2030 Avg. Annual Delivery Target:* Less ▪ *Supply Sources*: More recycled water and local groundwater. No additional Tuolumne River; no dry-year water transfer; no Westside Groundwater Basin ▪ *Additional Tuolumne River diversion*: None ▪ *Level of Rationing*: Requires greater than 20 percent rationing ▪ *Facility projects*: Same ***With Supplemental Tuolumne River Supply*** ▪ *2030 Avg. Annual Delivery Target:* Same ▪ *Supply Sources*: More recycled water and local groundwater. Less additional Tuolumne River; no dry-year water transfer; no Westside Groundwater Basin ▪ *Additional Tuolumne River diversion*: Less ▪ *Level of Rationing*: Same	▪ Impacts on the Tuolumne River, Alameda Creek and Peninsula Watershed water resources including Pilarcitos Creek

TABLE 9-3 (continued)
SELECTED ALTERNATIVES FOR CEQA ANALYSIS

Alternative / Description	How Does This Alternative Differ From The WSIP?	What WSIP Impacts Is The Alternative Intended to Address?
Lower Tuolumne River Diversion – The SFPUC would implement all of the proposed WSIP facility improvement projects and would serve the projected increase in customer purchase requests through 2030 through diversions on the lower Tuolumne River per an agreement with the Turlock and Modesto Irrigation Districts (TID and MID) and construction of conveyance and treatment facilities to blend the new supply into the regional system.	▪ *2030 Avg. Annual Delivery Target:* Same ▪ *Supply Sources*: Same but new Tuolumne River diversion point ▪ *Additional Tuolumne River diversion*: Same ▪ *Level of Rationing*: Same ▪ *Facility projects*: More	▪ Impacts on the Tuolumne River
Year-round Desalination at Oceanside – The SFPUC would implement all of the proposed WSIP facility improvement projects and construct a 25-mgd desalination plant in San Francisco at Oceanside to serve the projected increase in customer purchase requests through 2030. The plant would provide year-round supplies during all hydrologic year types to blend into the regional system.	▪ *2030 Avg. Annual Delivery Target:* Same ▪ *Supply Sources*: Desalinated seawater ▪ *Additional Tuolumne River diversion*: None ▪ *Level of Rationing*: Same ▪ *Facility projects*: More	▪ Impacts on the Tuolumne River, Alameda Creek and Peninsula watershed water resources including Pilarcitos Creek
Regional Desalination for Drought – The SFPUC would implement all of the proposed WSIP facility improvement projects and would partner with other Bay Area water agencies to develop a regional desalination plant that would provide supplemental supply to the SFPUC during drought years.	▪ *2030 Avg. Annual Delivery Target:* Same ▪ *Supply Sources*: Desalinated brackish bay water ▪ *Additional Tuolumne River diversion*: Less ▪ *Level of Rationing*: Same ▪ *Facility projects*: More	▪ Impacts on the Tuolumne River, Alameda Creek and Peninsula watershed water resources including Pilarcitos Creek
Modified WSIP – The SFPUC would implement all of the proposed facility improvement projects. This alternative would modify proposed system operations to minimize environmental effects and increase conservation, water recycling and local groundwater development as part of the water supply option.	▪ *2030 Avg. Annual Delivery Target:* Same ▪ *Supply Sources*: Additional conservation, water recycling and/or local groundwater ▪ *Additional Tuolumne River diversion*: Similar ▪ *Level of Rationing*: Same ▪ *Facility projects*: Additional regional water recycling and groundwater facilities ▪ Modifies proposed system operations	▪ Impacts on the Tuolumne River, Alameda Creek and Peninsula watershed water resources including Pilarcitos Creek and Crystal Springs Reservoir

The following series of tables provides summary information about key aspects of each alternative in comparison to the proposed WSIP and supports the description and evaluation of each of the eight alternatives that follows in this section. The tables provide summary information and evaluations that are explained in detail in the text.

Table 9-4 describes the characteristics of each of these alternatives in comparison with existing conditions and the proposed program. **Table 9-5** indicates the estimated average annual diversions from the Tuolumne River that would occur under each alternative compared to the WSIP over the modeled 82-year period of hydrologic record and presents estimates of the extent of drought-year shortages associated with each alternative based on modeling results. Two estimates of drought-year shortages are presented. First presented is the total number of years over the modeled 82-year hydrologic record that there would be shortages of 10, 20, and/or greater than 20 percent. Second, the table shows the number of years during the 8.5-year design drought that shortages of 10, 20, or greater than 20 percent would occur. The information in these two tables is used to evaluate how each alternative performs with respect to some of the key level of service goals and system performance objectives established for the WSIP. This information is also used in the subsequent discussion of the extent to which each alternative meets the program objectives. **Table 9-6** summarizes the ability of each alternative to meet the objectives established by the SFPUC for the WSIP. This table uses the following terms to simplify and abbreviate the detailed information provided on each alternative in the following sections:

> "Yes" indicates that an alternative fully meets one of the specific sub-objectives.
>
> "No" indicates that an alternative does not meet the sub-objective.
>
> "Partial" indicates that an alternative could meet the sub-objective in part but it would not fully meet the sub-objective of a level of service equivalent to the WSIP; this may be because the alternative would only serve a reduced 2030 delivery target, and/or would increase the facility requirements.
>
> "Uncertain" reflects the fact that there are questions about supply availability and reliability in addition to outstanding feasibility, cost, regulatory and public acceptance issues.

With respect to environmental impacts, **Tables 9-7**, **9-8**, and **9-9** summarize the comparison of significant water supply and system impacts (identified in Chapter 5) between the proposed WSIP and each alternative. No tables are used to illustrate how the alternatives compare to the WSIP in terms of impacts resulting from facility improvement projects or growth inducement potential and the associated secondary effects of growth, but these topics are evaluated for each alternative in the following text.

Planning Year	2005	2030	2030	2030	2030	2030	2030	2030	2030	2030
Target Delivery Level (annual average)	265 mgd	300 mgd	300 mgd	275 mgd	300 mgd	300 mgd	300 mgd	300 mgd	300 mgd	300 mgd
Water Supply Sources (during nondrought and drought periods)	▪ Local watersheds (with Calaveras and Lower Crystal Springs Reservoirs operating at reduced levels based on Division of Safety of Dams restrictions) ▪ Tuolumne River	▪ Local watersheds (with Calaveras and Lower Crystal Springs Reservoirs restored) ▪ Tuolumne River, with increased average annual diversions ▪ Recycled water/ groundwater/additional conservation in San Francisco, 10 mgd	▪ Local watersheds (with Calaveras and Lower Crystal Springs Reservoirs restored) ▪ Tuolumne River, with increased average annual diversions	▪ Local watersheds (with Calaveras and Lower Crystal Springs Reservoirs restored) ▪ Tuolumne River, with increased average annual diversions ▪ Recycled water/ groundwater/additional conservation in San Francisco, 10 mgd ▪ *Wholesale customers expected to pursue supplemental supply or conservation to make up for 2030 supply shortfall*	▪ Local watersheds (with Calaveras and Lower Crystal Springs Reservoirs restored) ▪ Tuolumne River, with no increase in average annual diversions ▪ Recycled water/ groundwater/additional conservation in San Francisco, 10 mgd ▪ Regional recycled water/ groundwater/ conservation in service area outside of San Francisco, 19 mgd ▪ *Wholesale customers expected to pursue supplemental supply (e.g., water transfer) to make up for 2030 supply shortfall*	▪ Local watersheds (with Calaveras and Lower Crystal Springs Reservoirs restored) ▪ Tuolumne River (during nondrought years), with increased average annual diversions ▪ Recycled water/ groundwater/additional conservation in San Francisco, 10 mgd ▪ Regional recycled water/ groundwater/ conservation in service area outside of San Francisco, 19 mgd ▪ *Wholesale customers expected to pursue supplemental supply (e.g., water transfer) to make up for 2030 supply shortfall*	▪ Local watersheds (with Calaveras and Lower Crystal Springs Reservoirs restored) ▪ Tuolumne River, with increased average annual diversions ▪ Recycled water/ groundwater/additional conservation in San Francisco, 10 mgd	▪ Local watersheds (with Calaveras and Lower Crystal Springs Reservoirs restored) ▪ Tuolumne River, with no increase in average annual diversion ▪ Recycled water/ groundwater/additional conservation in San Francisco, 10 mgd ▪ Potable water from SFPUC desalination plant	▪ Local watersheds (with Calaveras and Lower Crystal Springs Reservoirs restored) ▪ Tuolumne River, with increased average annual diversions ▪ Recycled water/ groundwater/additional conservation in San Francisco, 10 mgd	▪ Local watersheds (with Calaveras and Lower Crystal Springs Reservoirs restored, but with managed use of the restored historical capacity of Lower Crystal Springs Reservoir) ▪ Tuolumne River, with increased average annual diversions ▪ Recycled water/ groundwater/additional conservation in San Francisco, 10 mgd ▪ 5 – 10 mgd of regional recycled water / groundwater / conservation in regional service area
Supplemental Dry-Year Water Supply Sources (for implementation during drought periods only)	None	▪ Additional Tuolumne River diversions from Turlock and Modesto Irrigation District (TID and MID) transfers of 23 mgd (average over design drought) ▪ Westside Basin conjunctive use, 6 mgd (average over design drought)	None ▪ *Wholesale customers expected to pursue supplemental dry-year supply (e.g., water transfer) to make up for drought period supply shortfalls*	▪ Additional Tuolumne River diversions from TID and MID transfers of 1 mgd (average over design drought) ▪ Westside Basin conjunctive use, 6 mgd (average over design drought) ▪ *Wholesale customers expected to pursue supplemental dry-year supply (e.g., water transfer) to make up for drought period supply shortfalls*	None ▪ *Wholesale customers expected to pursue supplemental dry-year supply (e.g., water transfer) to make up for drought period supply shortfalls*	None ▪ *Wholesale customers expected to pursue supplemental dry-year supply (e.g., water transfer) to make up for drought period supply shortfalls*	▪ Additional Tuolumne River diversions from TID and MID transfers of 23 mgd ▪ Westside Basin conjunctive use, 6 mgd (average over design drought)	▪ Westside Basin conjunctive use, 6 mgd (average over design drought)	▪ Potable water from regional desalination plant, 23 mgd (average over design drought) ▪ Westside Basin conjunctive use, 6 mgd (average over design drought)	▪ Additional Tuolumne River diversions from TID and MID transfers of 23 mgd – conserved water only[1] ▪ Westside Basin conjunctive use, 6 mgd (average over design drought)
Maximum Drought Rationing Policy	No defined limit, but assumed incidental rationing of up to 25%	20%	No defined limit, but assumes 30% would be needed during design drought conditions	20% at reduced target delivery level	25%	20%	20%	20%	20%	20%
System Firm Yield	219 mgd	256 mgd	226 mgd	233 mgd	226 mgd	226 mgd	256 mgd	256 mgd	256 mgd	~ 256 mgd
WSIP PEIR Facility Improvement Projects	None	All projects	▪ Advanced Disinfection (SJ-1) ▪ Alameda Creek Fishery Enhancement (SV-1) ▪ Calaveras Dam Replacement (SV-2) ▪ SVWTP – Treated Water Reservoirs (SV-5)	All projects, but facilities reevaluated and sized appropriately for a reduced target delivery level	All projects, but facilities reevaluated and sized appropriately for a reduced target delivery level	All projects, but facilities reevaluated and sized appropriately given the different supply sources	All projects, but facilities reevaluated and sized appropriately given the different supply sources	All projects, but facilities reevaluated and sized appropriately given the different supply sources	All projects	All projects

TABLE 9-4 (Continued)
DESCRIPTION OF CEQA ALTERNATIVES

Program Element	Existing Condition	Proposed Program	No Program Alternative	No Purchase Request Increase Alternative	Aggressive Conservation/Water Recycling and Local Groundwater Alternative: No Supplemental Tuolumne River Water	Aggressive Conservation/Water Recycling and Local Groundwater Alternative: With Supplemental Tuolumne River Water	Lower Tuolumne River Diversion Alternative	Year-round Desalination at Oceanside Alternative	Regional Desalination for Drought Alternative (Variant 2)	Modified WSIP Alternative
WSIP PEIR Facility Improvement Projects (cont.)			▪ Lower Crystal Springs Dam Improvements (PN-4)							
Other Facility Improvements	None	None	None by the SFPUC *Wholesale customers expected to develop other facilities or projects to secure supplemental supply to improve water supply reliability, including drought supplies*	None by the SFPUC *Wholesale customers expected to develop other facilities or projects to meet additional demands*	Additional regional and local recycled water and groundwater projects in the wholesale customer service area, outside of San Francisco. *Wholesale customers expected to develop other facilities or projects to meet additional demands*	Additional regional and local recycled water and groundwater projects in the wholesale customer service area, outside of San Francisco	▪ Intake pipeline in lower Tuolumne River and pumping plant ▪ 2.5-mile raw water pipeline ▪ Lower Tuolumne River water treatment plant ▪ Treated water pump station	▪ SFPUC desalination plant in San Francisco and associated seawater intake structure, intake pipeline, pump stations, and treatment facilities ▪ Treated water pump station ▪ 2.4-mile treated water pipeline	▪ Bay Area regional desalination plant(s) and associated pumping plant(s) and pipelines needed for intertie facilities	▪ Alameda Creek bypass structure ▪ Additional facilities for regional recycled water/ groundwater/ conservation projects in the wholesale service area
Delivery, Operations, and Maintenance	As described in Chapter 2, Section 2.3	Improved to meet WSIP goals and objectives (as described in Chapter 3, Section 3.8)	Similar to existing conditions, except increased frequency of shortages and need for rationing; during drought years, rationing could be up to 30% Lack of comprehensive maintenance program and likely increased emergency repairs and replacement projects.	Similar to proposed program (but adjusted for the reduced target delivery level)	Similar to proposed program, except increased water demands served with regional recycled water, conservation and groundwater projects that would require operation and maintenance by wholesale customers in coordination with the SFPUC	Similar to proposed program, except increased water demands served with regional recycled water, conservation and groundwater projects that would require operation and maintenance by wholesale customers in coordination with the SFPUC	Similar to proposed program, except for additional operation and maintenance requirements for lower Tuolumne River diversion, conveyance, treatment, and blending facilities.	Similar to proposed program, except for additional operation and maintenance requirements for desalination and blending facilities. Customers on the westside of San Francisco would receive predominantly desalinated water.	Same as proposed program except for participation in additional operation and maintenance requirements for regional desalination facilities and any interties or transfers among the participating agencies.	Similar to proposed program, but with modified operations, specifically at the Alameda Creek Diversion Tunnel and at Crystal Springs Reservoir
Permits, Approvals, and other Decisions/Actions	As described in Chapter 2, Sections 2.4 and 2.5	▪ San Francisco Planning Commission certifies final PEIR ▪ SFPUC adopts CEQA findings/mitigation monitoring and reporting program and approves and adopts the WSIP ▪ Water transfer agreements with TID and MID ▪ Operating agreements with Daly City, San Bruno, and California Water Service Company for Westside Basin conjunctive-use program ▪ Water sales agreements with retail and wholesale customers (see Chapter 3, Section 3.13)	Same as existing conditions, except SFPUC would be required to submit an explanation describing reason for change in the proposed program to the California Department of Health Service and Seismic Safety Commission for AB 1823 compliance	Same as proposed program except: ▪ Transfer agreements with TID and MID for 1 mgd instead of 23 mgd during drought years ▪ Agreements with California Department of Health Services for any new drinking water sources developed by wholesale customers that would be introduced into the regional system	Same as proposed program except: ▪ Addition of various permits and agreements with wholesale customers to develop and implement recycled water, conservation, and groundwater projects ▪ No agreements with Daly City, San Bruno, and California Water Service. There would be no Westside Basin conjunctive-use program ▪ No water transfer agreements with TID and MID ▪ Agreements with California Department of Health Services for any new drinking water sources	Same as proposed program except: ▪ Addition of various permits and agreements with wholesale customers to develop and implement recycled water, conservation, and groundwater projects ▪ No agreements with Daly City, San Bruno, and California Water Service, There would be no Westside Basin conjunctive-use program ▪ No water transfer agreements with TID and MID ▪ Agreements with California Department of Health Services for any new drinking water sources	Same as proposed program except: ▪ The State Water Resources Control Board could require additional water appropriation permit or license ▪ Right-of-way purchase and permits to construct pipelines through levees, access the river, and protect the river and fish ▪ Agreement/coordination with TID/MID regarding operational schedule for releases at La Grange Dam ▪ Agreements with California Department of Health Services for any new drinking water sources	Same as proposed program except: ▪ Brine disposal would require a National Pollutant Discharge Elimination System permit ▪ Watershed sanitary survey needed, in accordance with California Department of Health regulations ▪ Impingement and entrainment study for the California Coastal Commission would be required to determine impacts on aquatic resources ▪ Project review and approval by the U.S. Army Corps of Engineers ▪ Agreements with California Department of Health Services for any new drinking water sources. ▪ No water transfer agreements with TID and MID	Same as proposed program except: ▪ Agreements with partners in Bay Area regional desalination project ▪ See Table 8.4 for a list of potential permits for the Bay Area regional desalination plant ▪ No water transfer agreements with TID and MID ▪ Agreements with California Department of Health Services for any new drinking water sources	Same as proposed program except: ▪ Agreements for participation in regional recycled water / conservation/ local groundwater projects that could offset SFPUC supply

Italic text indicates expected action by wholesale customers.

[1] In this alternative the water transfer of conserved water would be acquired for use every year, not just for dry-year supplement; this would avoid all impacts below La Grange Dam associated with the SFPUC's increased diversion of Tuolumne River water.

SOURCE: SFPUC, 2007b.

TABLE 9-5
AVERAGE ANNUAL TUOLUMNE RIVER DIVERSIONS AND DROUGHT-YEAR SHORTAGES FOR THE CEQA ALTERNATIVES (2030)

	Estimated Tuolumne River Diversions Over the 82-Year Period of Hydrologic Record		**Drought-Year Shortages Based on 82-Year Period of Hydrologic Record**				**Drought-Year Shortages During Design Drought (8.5 years)**		
Program/Alternative	Average Annual Increase by the SFPUC[1] (mgd)	Average Annual Diversions by the SFPUC (mgd)	Years of Shortages (10% Shortage)	Years of Shortages (20% Shortage)	Years of Shortages >20% Shortage)	No. of Years Drought-Year Supplies Triggered	Years of Shortages (10% Shortage)	Years of Shortages (20% Shortage)	Years of Shortages (25% to 30% Shortage)
Existing Conditions	N/A	218	6 out of 82 (1 in 14 years)	8 out of 82 (1 in 10 years)	None	N/A	1	5	1.5
Proposed Program	27	245	6 out of 82 (1 in 14 years)	2 out of 82 (1 in 41 years)	None	24	3	3.5	None
No Program Alternative	8	226	24 out of 82 (1 in 3 years)	10 out of 82 (1 in 8 years)	8 out of 82 (1 in 10 years)	No drought supplies. Rationing would be needed 42 out of 82 years	0	1	6.5
No Purchase Request Increase Alternative	3	221	9 out of 82 (1 in 9 years)	2 out of 82 (1 in 41 years)	None	17	3	3.5	None
Aggressive Conservation/Water Recycling and Local Groundwater Alternative – No Supplemental Tuolumne River Water	0	218	N/A	N/A	15 at 25%	There are no supplemental drought supplies	N/A	N/A	7.5
Aggressive Conservation/Water Recycling and Local Groundwater Alternative – With Supplemental Tuolumne River Water	5	223	7 out of 82 (1 in 12 years)	8 out of 82 (1 out of 10 years)	None	There are no supplemental drought supplies	1	6.5	None
Lower Tuolumne River Diversion	27	245	6 out of 82 (1 in 14 years)	2 out of 82 (1 in 41 years)	None	24	3	3.5	None
Year-round Desalination at Oceanside Alternative	0	218	6 out of 82 (1 in 14 years)	2 out of 82 (1 in 41 years)	None	24	3	3.5	None
Regional Desalination for Drought Alternative (Variant 2)	20	238	6 out of 82 (1 in 14 years)	2 out of 82 (1 in 41 years)	None	23	3	3.5	None
Modified WSIP Alternative (assumes no reduction in WSIP levels of service performance	~27	~245	Approximately the same as the WSIP				Approximately the same as the WSIP		None

[1] Represents the difference in average annual diversion modeled over 82-year historical hydrology, but does not represent year-to-year variation. Thus, even with zero average annual increase in diversions, there would still be year-to-year variations in diversions compared to the existing condition due primarily to modified system operations for maintenance and implementation of the conjunctive use program.

TABLE 9-6
SUMMARY OF ABILITY OF ALTERNATIVES TO MEET PROGRAM OBJECTIVES[1]

Objectives	Proposed Program	No Program Alternative	No Purchase Request Increase Alternative	Aggressive Conservation/Water Recycling and Local Groundwater Alternative		Lower Tuolumne River Diversion Alternative	Year-round Desalination at Oceanside Alternative	Regional Desalination for Drought Alternative	Modified WSIP Alternative
				No Supplemental Tuolumne River Water	With Supplemental Tuolumne River Water				
Water Quality									
Design improvements to meet current and foreseeable future federal and state water quality requirements?	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Provide clean, unfiltered water originating from Hetch Hetchy Reservoir and filter all other surface water sources?	Yes	Yes	Yes	Yes	Yes	Partial	Yes	Yes	Yes
Continue to implement watershed protection measures?	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Seismic Reliability									
Complies with current seismic standards?	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Capable of delivering basic service to all regions in the service area following a major earthquake?	Yes	No	Partial	Uncertain	Uncertain	Uncertain	Yes	Yes	Yes
Facilities restored to meet average-day demand within 30 days of a major earthquake?	Yes	No	Partial	Partial	Partial	Partial	Yes	Yes	Yes
Delivery Reliability									
Provides operational flexibility to allow for planned maintenance without service interruptions?	Yes	No	Yes	Yes	Yes	Partial	Partial	Yes	Yes
Provides operational flexibility and system capacity to replenish local reservoirs, as needed?	Yes	No	Yes	Uncertain	Uncertain	Uncertain	Yes	Yes	Yes
Capable of minimizing risk of service interruption due to unplanned facility upsets or outages?	Yes	No	Yes	Uncertain	Uncertain	Uncertain	Yes	Yes	Yes

Objectives	Proposed Program	No Program Alternative	No Purchase Request Increase Alternative	Aggressive Conservation/Water Recycling and Local Groundwater Alternative: No Supplemental Tuolumne River Water	Aggressive Conservation/Water Recycling and Local Groundwater Alternative: With Supplemental Tuolumne River Water	Lower Tuolumne River Diversion Alternative	Year-round Desalination at Oceanside Alternative	Regional Desalination for Drought Alternative	Modified WSIP Alternative
Cost-effectiveness									
Ensure cost-effective use of funds?	Yes	No and likely greater cost	Unknown, but greater cost	Unknown, but greater cost	Unknown, but greater cost	Unknown, but greater cost	Unknown, but greater cost	Unknown, but greater cost	Same, but greater cost
Maintains gravity-driven system?	Yes	Yes	Yes	Partial	Partial	Partial	Partial	Partial	Partial
Implement regular inspection and` maintenance program for all facilities?	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes

NOTES: 1. This assessment is based on SFPUC actions under each alternative only and does not account for the actions that BAWSCA and/or the wholesale customers might take in order to make up for any shortfall in the regional system's ability to meet the program objectives. See text for full discussion of ability of each alternative to meet objectives. In general, the terms in the table are used as follows:

Yes: Indicates that the alternative would fully meet the sub-objective at an equivalent level to the WSIP.

Partial: Indicates that the alternative could meet the objective in part, but it would not fully meet the objective at an equivalent level to the WSIP, due to variation associated with an alternative such as the reduced delivery targets, increased facility requirements and associated issues.

No: Indicates the alternative would not meet the sub-objective.

Uncertain: Indicates that there are outstanding questions regarding supply availability and reliability; feasibility, cost or other issues that require further study; and/or institutional, regulatory or permitting issues to be resolved.

TABLE 9-7
SUMMARY OF SIGNIFICANT WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR CEQA ALTERNATIVES – TUOLUMNE RIVER WATERSHED

Impact	Proposed Program	No Program Alternative	No Purchase Request Increase Alternative	Aggressive Conservation/Water Recycling and Local Groundwater Alternative		Lower Tuolumne River Diversion Alternative	Year-round Desalination at Oceanside Alternative	Regional Desalination for Drought Alternative	Modified WSIP Alternative
				No Supplemental Tuolumne River Water	**With Supplemental Tuolumne River Water**				
Section 5.3.6, Fisheries									
Impact 5.3.6-4: Effects on fishery resources along the Tuolumne River below La Grange Dam									
	In wet or above-normal years when Don Pedro Reservoir is being filled, changes in the timing and duration of releases from the reservoir would decrease average monthly flows along the lower Tuolumne River beneath La Grange Dam. The greatest average flow reductions would occur during June and could potentially result in elevated water temperatures. Changes to stream flow and water temperature would result in a reduction in the linear extent of suitable habitat for rearing Chinook salmon and oversummering steelhead/rainbow trout, potentially adversely affecting these fish populations in the lower Tuolumne River. (PSM)	Similar to but less than proposed program. (PSM)	Similar to but much less than proposed program. (LS)	Similar to existing condition. (LS)	Similar to but much less than proposed program. (LS)	Similar to proposed program. (PSM)	Similar to existing condition. (LS)	Similar to but less than proposed program (PSM)	Similar to existing condition (LS)
Section 5.3.7, Terrestrial Biological Resources									
Impact 5.3.7-2: Impacts on meadow / alluvial features along the Tuolumne River below O'Shaughnessy Dam									
▪ Sensitive habitats	Delayed snowmelt releases, reductions in flow, and the resulting reduction in groundwater recharge would result in an incremental reduction in the extent and diversity of wetland and riparian habitats, including sensitive wetland and riparian habitats in the Poopenaut Valley. (PSM)	Similar to but less than proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to proposed program (PSM)	Similar to proposed program (PSM)
▪ Key special status species	A reduction in wetland and riparian habitat would reduce suitable breeding habitat for key special-status species potentially occurring along this reach (e.g., foothill yellow-legged frog, California red-legged frog, and willow flycatcher), the populations of which are already critically reduced in the Sierra Nevada. (PSM)	Similar to but less than proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to proposed program (PSM)	Similar to proposed program (PSM)
▪ Other species of concern	A reduction in the extent and diversity of wetland and riparian habitats would reduce habitat quality and extent for animal and plant species of concern. (PSM)	Similar to but less than proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to proposed program (PSM)	Similar to proposed program (PSM)
▪ Common habitats and species	All habitats affected by the WSIP are considered sensitive. A large number of common animal species depend on sensitive meadows and larger riparian areas potentially affected by the WSIP for food and cover. (PSM)	Similar to but less than proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to proposed program (`PSM)	Similar to proposed program (PSM)
Impact 5.3.7-6: Impacts on biological resources along Tuolumne River below La Grange Dam									
▪ Sensitive habitats	Delayed spring releases and reductions in average and total flow (particularly during and following an extended drought) below La Grange Dam would reduce or eliminate suitable conditions for recruitment of some riparian species along the river. (PSM)	Similar to but less than proposed program. (PSM)	Similar to but much less than proposed program. (LS)	Similar to existing condition. (LS)	Similar to but much less than proposed program. (LS)	Similar to proposed program. (PSM)	Similar to existing condition. (LS)	Similar to but less than proposed program (PSM)	Similar to existing condition (LS)
▪ Key special status species	Because of the known presence of key special-status species and the very limited amount of remaining suitable habitat along this reach of the Tuolumne River, this incremental impact would be potentially significant. (PSM)	Similar to but less than proposed program. (PSM)	Similar to but much less than proposed program. (LS)	Similar to existing condition. (LS)	Similar to but much less than proposed program. (LS)	Similar to proposed program. (PSM)	Similar to existing condition. (LS)	Similar to but less than proposed program (PSM)	Similar to existing condition (LS)
▪ Other species of concern	Species of concern that would be adversely affected by changes in the extent and quality of suitable riparian habitat include western pond turtle, several bat species, and a wide variety of riparian- and marsh-associated bird species. (PSM)	Similar to but less than proposed program. (PSM)	Similar to but much less than proposed program. (LS)	Similar to existing condition. (LS)	Similar to but much less than proposed program. (LS)	Similar to proposed program. (PSM)	Similar to existing condition. (LS)	Similar to but less than proposed program (PSM)	Similar to existing condition (LS)
▪ Common habitats and species	The populations of common species that depend on riparian habitat could be adversely affected by the alteration of habitat. (PSM)	Similar to but less than proposed program. (PSM)	Similar to but much less than proposed program. (LS)	Similar to existing condition. (LS)	Similar to but much less than proposed program. (LS)	Similar to proposed program. (PSM)	Similar to existing condition. (LS)	Similar to but less than proposed program (PSM)	Similar to existing condition (LS)

LS = Less than Significant, no mitigation required
SM or PSM = Significant or Potentially Significant, can be Mitigated to less than significant
SU or PSU = Significant Unavoidable or Potentially Significant Unavoidable, cannot be mitigated to less than significant

TABLE 9-8
SUMMARY OF SIGNIFICANT WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR CEQA ALTERNATIVES – ALAMEDA WATERSHED

Impact	Proposed Program	No Program Alternative	No Purchase Request Increase Alternative	Aggressive Conservation/Water Recycling and Local Groundwater Alternative		Lower Tuolumne River Diversion Alternative	Year-round Desalination at Oceanside Alternative	Regional Desalination for Drought Alternative	Modified WSIP Alternative
				No Supplemental Tuolumne River Water	With Supplemental Tuolumne River Water				
Section 5.4.1, Stream Flow and Reservoir Water Levels									
Impact 5.4.1-2: Effects on flow along Alameda Creek below diversion dam.									
	In all year types, system operations under the WSIP would increase diversions from Alameda Creek to Calaveras Reservoir between the months of December and May, nearly eliminating low and moderate (1 to 650 cubic feet per second) flows in Alameda Creek downstream of the diversion dam and substantially reducing many higher (greater than 650 cubic feet per second) flows that have occurred since 2002. The resultant reduction in stream flows and alteration of the stream hydrograph is considered an adverse effect. (SU)	Similar to proposed program, but winter diversions from Alameda Creek would be greater. (SU)	Similar to proposed program, but winter diversions would be slightly less. (SU)	Similar to proposed program, but winter diversions would be slightly less. (SU)	Similar to proposed program, but winter diversions would be slightly less. (SU)	Similar to proposed program. (SU)	Similar to proposed program. (SU)	Similar to proposed program (SU)	Similar to proposed program (SU)
Section 5.4.5, Fisheries									
Impact 5.4.5-3: Effects on fishery resources.									
	Following implementation of the Calaveras Dam Replacement project (SV-2), operation of Calaveras Reservoir and the Alameda Creek Diversion Dam would be restored to pre-2002 conditions. A substantial increase in diversions from Alameda Creek to Calaveras Reservoir would reduce flows in this stretch of the creek. Diversion of most or all flows during late winter and spring months would reduce the ability of resident rainbow trout to spawn and for eggs to incubate. In addition, the increased diversion of flows to the reservoir would divert fish from Alameda Creek to the reservoir, prevent fish passage to downstream reaches of the creek, and increase the potential for fish entrainment since there are currently no screens on the diversion. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program (PSM)	Much less than proposed program (LS)
Section 5.4.6, Terrestrial Biological Resources									
Impact 5.4.6-1: Impacts on riparian habitat and related biological resources in Calaveras Reservoir.									
▪ Sensitive Habitats	Increased reservoir storage elevations would result in inundation and permanent loss of seasonal wetlands, seeps, perennial freshwater marsh, and riparian habitat that have established since 2002. (PSM)	Same as proposed program. (PSM)	Same as proposed program. (PSM)	Same as proposed program. (PSM)	Same as proposed program. (PSM)	Same as proposed program. (PSM)	Same as proposed program. (PSM)	Same as proposed program (PSM)	Same as proposed program (PSM)
▪ Key Special Status species	Since 2002, yellow-legged frogs have occupied approximately 10,000 linear feet of stream channel along Arroyo Hondo between the maximum reservoir elevation mandated by the Division of Safety of Dams and the spillway elevation. Higher maintained reservoir levels would reduce the length of this high-quality habitat along the creek and adversely affect existing populations of foothill yellow-legged frog. (PSM)	Same as proposed program. (PSM)	Same as proposed program. (PSM)	Same as proposed program. (PSM)	Same as proposed program. (PSM)	Same as proposed program. (PSM)	Same as proposed program. (PSM)	Same as proposed program (PSM)	Same as proposed program (PSM)
Impact 5.4.6-2: Effects on riparian habitat and related biological resources along Alameda Creek from below the diversion dam to the confluence with Calaveras Creek.									
▪ Key special status species	A reduction in the frequency, duration, and magnitude of flows below the diversion dam would reduce the total available aquatic breeding habitat and food sources for California red-legged frog and foothill yellow-legged frog populations that currently occupy this reach of Alameda Creek. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program (PSM)	Similar to proposed program (PSM)
Impact 5.4.6-3: Effects on riparian habitat and related biological resources along Calaveras Creek from Calaveras Reservoir to the confluence with Alameda Creek.									
▪ Key special status species	Future outlet works at Calaveras Dam would have the capacity to make higher volume releases than under existing conditions. Depending on the timing and volume of operational releases, they could adversely affect the reproductive success of special-status amphibian species along this reach (e.g., California red-legged frog and foothill yellow-legged frog). (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program (PSM)	Similar to proposed program (PSM)
Impact 5.4.6-4: Effects on riparian habitat and related biological resources along Alameda Creek from Calaveras Creek to San Antonio Creek,									
▪ Key special status species	Depending on annual rainfall and localized site conditions along this creek segment, changes in winter and summer flows along this reach could result in both beneficial and adverse impacts on habitat for California red-legged frog and foothill yellow-legged frog populations. SUMMARY OF SIGNIFICANT WATER SUPPLY AND SYSTEM OPERATIONS IMPACTS FOR CEQA ALTERNATIVES – ALAMEDA WATERSHED

Impact	Proposed Program	No Program Alternative	No Purchase Request Increase Alternative	Aggressive Conservation/Water Recycling and Local Groundwater Alternative: No Supplemental Tuolumne River Water	Aggressive Conservation/Water Recycling and Local Groundwater Alternative: With Supplemental Tuolumne River Water	Lower Tuolumne River Diversion Alternative	Year-round Desalination at Oceanside Alternative	Regional Desalination for Drought Alternative	Modified WSIP Alternative
Section 5.4.7, Recreational and Visual Resources									
Impact 5.4.7-1: Effects on recreation									
	Operations under the WSIP would substantially reduce flows along Alameda Creek in the Sunol Regional Wilderness during winter and early spring months and adversely affect the recreational experience of hikers; however, with the changes in project description for the Calaveras Dam Replacement (SV-2) project, bypass flows would be reduced from the diversion dam when flows are present. Section 5.5.3, Surface Water Quality									
Impact 5.5.3-2: Water quality in Pilarcitos Reservoir									
	Proposed operations would generally be within the same range as existing conditions although replacement Measure 5.5.3-2a would cause Pilarcitos Reservoir to be drawn down earlier in the summer compared to existing conditions. Water temperature could increase and dissolved oxygen content could be reduced. During dry years, summertime releases from Pilarcitos Reservoir to Pilarcitos Creek would be eliminated or reduced to a low level for a longer period of time with the WSIP, which would increase the temperature of instream flows between Pilarcitos Creek and Stone Dam and reduce the creek's ability to support designated cold freshwater habitat along this reach. (PSM)	Similar to proposed program. (PSM)	Similar to but much less than proposed program. (LS)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSU)	Same as proposed program (PSU)	Similar to proposed program (PSU)
Impact 5.5.5-4: Effects on fisheries resources in Pilarcitos Reservoir									
	Proposed operations would be within the same range as existing conditions although replacement Measure 5.5.3-2a would cause Pilarcitos Reservoir to be drawn down earlier in the summer compared to existing conditions. This would reduce the volume and quality of coldwater habitat available for resident fish species. (PSM)	Similar to proposed program. (PSM)	Similar to but much less than proposed program. (LS)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program (PSM)	Similar to existing condition (LS)
Impact 5.5.5-5: Effects on fisheries resources along Pilarcitos Creek below Pilarcitos Reservoir									
	Under the WSIP, the extended period of no or very little flow in Pilarcitos Creek below Pilarcitos Reservoir during summer months of dry years would result in significant impacts on resident trout, other resident fish species and aquatic resources, and habitat quality and availability for anadromous steelhead. Increased drawdown of Pilarcitos Reservoir would increase the temperature of releases in summer and fall and reduce the quality and availability of habitat for coldwater fish species. A reduction in the frequency and magnitude of spills over Stone Dam would reduce flows along the lower reach. Reduced instream flows during winter months would adversely affect migratory fish habitat. (PSM)	Similar to proposed program. (PSM)	Similar to but less than proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program. (PSM)	Similar to proposed program (PSM)	Similar to existing condition (LS)
Section 5.5.6, Terrestrial Biological Resources									
Impact 5.5.6-1: Impacts on biological resources in Upper and Lower Crystal Springs Reservoirs									
▪ Sensitive Habitats	Implementation of the Lower Crystal Springs Dam Improvements project (PN-4) would raise average monthly water levels in Crystal Springs Reservoir and result in a short-term reduction in the overall extent of freshwater marsh as the reservoir fills. Proposed changes in operations would maintain maximum reservoir levels during summer for longer periods than under existing conditions, which could affect the composition and structure of riparian habitats. In addition, sensitive upland habitats that are unable to tolerate these longer periods of inundation would be lost. (PSM)	Same as proposed program. (PSM)	Same as proposed program. (PSM)	Same as proposed program. (PSM)	Same as proposed program. (PSM)	Same as proposed program. (PSM)	Same as proposed program. (PSM)	Same as proposed program (PSM)	Similar to pre-1983 conditions (LS)
▪ Key special status species	Elevated reservoir levels would inundate existing populations of special-status plant species, including serpentine-associated fountain thistle and Marin western flax, and their habitat could be permanently lost. The extent of available habitat for San Francisco garter snake and California red-legged frog would be temporarily reduced during reservoir refill, but wetland habitat that would establish at higher elevations could potentially be more extensive. Raised reservoir levels would provide greater opportunities for largemouth bass and other predators to access frogs and snakes. Periodic drawdown during planned maintenance could adversely affect San Francisco garter snake foraging habitat. (PSM)	Same as proposed program. (PSM)	Same as proposed program. THIS PAGE INTENTIONALLY LEFT BLANK

9.2.2 No Program Alternative

The No Program Alternative is the scenario that would most likely unfold between now and 2030 if the WSIP were not implemented. CEQA Guidelines Section 15126.6(e) provides the following guidance on the "no project" alternative:

- The specific alternative of "no project" shall also be evaluated along with its impact. The purpose of describing and analyzing a no project alternative is to allow decision-makers to compare the impacts of approving the proposed project with the impact of not approving the proposed project.
- The no project alternative is not the baseline for determining whether the proposed project's environmental impacts may be significant, unless it is identical to the existing environmental setting analysis, which does establish that baseline.
- The no project analysis shall discuss the existing conditions at the time the Notice of Preparation is published as well as what would be reasonably expected to occur in the foreseeable future if the project were not approved, based on current plans and consistent with available infrastructure and community services.
- When the proposed project is the revision of an ongoing operation, the no project alternative will be the continuation of the existing operation into the future.
- If the proposed project is a development project on identifiable property, the no project alternative is the circumstance under which the project does not proceed.

Consistent with the above guidance, the No Program Alternative reflects continued operation of the regional system and system upgrades and maintenance as well as implementation of actions that are reasonably expected to occur if the WSIP as a comprehensive program or policy is not approved. Compared to the WSIP this alternative would develop less in terms of new water supplies for the regional system and would implement far fewer of the proposed facility improvement project.

Description of SFPUC and Wholesale Customer Actions

SFPUC Actions

Under the No Program Alternative, the SFPUC would continue to rely on water supply sources from local watersheds and the Tuolumne River. Similar to existing conditions, the SFPUC would have no supplemental dry-year water supply sources and there would be no diversification of water supply sources from groundwater development, recycled water projects, water transfers, or additional conservation beyond what is occurring now and what is mandated by regulation (i.e., the plumbing code). This alternative assumes that the SFPUC would endeavor to serve the projected 2030 increase in purchase requests when water is available. The additional water demand would be served from increased diversions from the Tuolumne River under the City and County of San Francisco's (CCSF) existing water rights as well as increased use of local watershed supplies, primarily associated with the restoration of Calaveras and Lower Crystal Springs Reservoirs (discussed below). Under the No Program Alternative, the SFPUC would continue its existing operation of the regional water system and associated facilities, including compliance with all regulatory requirements and ongoing system maintenance. Thus, under this alternative, it is assumed that by 2030 the SFPUC would implement the following WSIP facility improvement projects that have been mandated or previously agreed to by regulatory agencies:

- *Advanced Disinfection (SJ-1)*. This project must be implemented to comply with the Long Term 2 Enhanced Surface Water Treatment Rule under the federal Safe Drinking Water Act.

- *Alameda Creek Fishery (SV-1)*. This water recapture project would ensure compliance with the 1997 Memorandum of Understanding (MOU) between the SFPUC and California Department of Fish and Game (described in Chapter 2, Section 2.5.3) following completion of the Calaveras Dam project (SV-2). The MOU, which stipulates the magnitude and timing of flows released from Calaveras Reservoir for the purpose of improving habitat conditions for fisheries along Alameda and Calaveras Creeks, also states that the water released to meet minimum flow requirements may be recaptured downstream for consumptive use in the SFPUC service area. Although the Alameda Creek Fishery project would not in itself increase the firm yield of the system, it is necessary to avoid the loss of yield associated with fishery releases from Calaveras Reservoir.

- *Calaveras Dam (SV-2)*. The existing dam is currently operating under California Division of Safety of Dams (DSOD) interim restrictions, as described in Chapter 2, Section 2.2.3. The DSOD restrictions include maximum operating levels, with the provision that the SFPUC pursue an aggressive schedule for remediation of Calaveras Dam. Therefore, long-term operation of the reservoir at this restricted level is not an option (Verigin, 2003). The proposed replacement dam would not increase the delivery capacity of the regional water system above its historical (pre-2002) value and would restore the reservoir's operating storage to the level allowed before the DSOD placed restrictions on the reservoir. Use of local watershed supplies provided by Calaveras Dam and Reservoir is a fundamental part of the SFPUC's existing system operations, and restoring Calaveras Reservoir to historical storage levels is thus considered a continuation of the existing operation into the future.

- *Treated Water Reservoirs (SV-5)*. This project is needed in order to comply with requirements of the California Department of Health Services for water quality and public health purposes.

- *Lower Crystal Springs Dam (PN-4)*. The DSOD has placed operational restrictions on Lower Crystal Springs Dam due to concerns regarding the ability of the dam to provide adequate protection from the probable maximum flood (described in Chapter 2, Section 2.2.5). The DSOD has indicated that if the SFPUC does not implement improvements to the dam, it would likely impose further, more severe restrictions on reservoir operations due to updated calculations of the probable maximum flood (Mavroudis, 2007). The extent of these more severe restrictions would result in substantial adverse effects on water supply and delivery reliability and reduce existing water quality reliability, severely limiting continuation of existing system operations into the future.

Implementation of the above projects would be subject to environmental review under CEQA as determined by the San Francisco Planning Department. However, if any of the regional system facilities were to fail in the future, such as in the event of an earthquake or other disaster, the SFPUC would proceed with the necessary emergency repairs/replacements, which may not be subject to CEQA, and those repairs or replacements would be conducted on an individual basis and not as part of a comprehensive and coordinated program. The No Program Alternative also assumes that the SFPUC would proceed with implementation of other capital improvement projects and related activities funded under the WSIP but not considered part of the program analyzed in this PEIR (as described in Chapter 3, Sections 3.13 and 3.4.6). Under the No Program Alternative, it is assumed that the SFPUC would continue to maintain water sales agreements with wholesale and retail customers to meet the supply assurance of 184 mgd and make further sales to the wholesale customers on an interruptible, as-available basis to reduce the rate impact on City retail customers.

If the SFPUC were to adopt a change in the proposed program, such as the No Program Alternative, the CCSF would be required to submit an explanation to the California Department of Health Services and the Seismic Safety Commission as described in Assembly Bill No. 1823 (the Wholesale Regional Water System Security and Reliability Act).

Wholesale Customer Actions

As described in more detail below under Ability to Meet Program Objectives, the regional water system would have reduced seismic, delivery, and water supply reliability under the No Program Alternative compared to the WSIP. According to hydrologic modeling, regional system customers could experience water shortages as often as every one in two years (refer to Table 9-5) compared to one in ten years for the proposed program, and wholesale customers (as well as retail customers) would likely need to implement water rationing, up to 30 percent.

The wholesale customers have obligations, through laws, contracts, and other legal instruments, to provide water service to their customers. The ability of wholesale customers to impose limits on urban growth as a means of controlling demand is limited. Consequently, in the absence of reliable water service from the SFPUC, the wholesale customers would likely pursue other projects, either individually or collectively,[2] to meet their water needs for both drought and nondrought periods. Numerous factors inhibit the ability of the wholesale customers to address the decreased reliability associated with this alternative, including the following:

- The WSIP addresses sudden (emergency) as well as gradual changes in water availability. The ability of the wholesale customers to meaningfully influence the reliability of their water supplies is very limited in the event of emergency conditions (for example, if part of the regional system failed due to an earthquake). Under the No Program Alternative, most of the key projects needed to improve the seismic reliability would not be implemented.

- Water demand among all customers is highest when supplies are most constrained (i.e., during dry years and warm-weather periods) and therefore more difficult to secure. Securing water supplies in California is increasingly difficult, particularly in dry years, as overall demand increases and conflicts among competing interests for water supply arise.

- A major new water supply project can take as many as 20 to 25 years to complete (Johnson and Loux, 2004).

[2] Bay Area Water Supply and Conservation Agency (BAWSCA) has the authority to pursue and secure water supplies on behalf of the SFPUC wholesale customers (its members) as well as to coordinate recycled water and conservation projects to benefit its members. While it is likely that BAWSCA would lead any effort to secure water supplies, either BAWSCA or individual SFPUC wholesale customer agencies could pursue such actions.

- Some wholesale customers are wholly reliant on SFPUC for water, whereas others have multiple sources of supplies. Customers with diverse water supply portfolios would likely have more flexibility to augment supplies from sources other than the SFPUC. Under existing conditions, the SFPUC meets more than 50 percent of the demand for all but three of the wholesale customers; 16 wholesale customers rely entirely on the SFPUC for water purchases to meet existing demand.

- The wholesale customers' purchase requests already include a foreseeable level of increased conservation and recycling in addition to existing conservation and recycling. (The next subsection describes the opportunities for, and challenges to implementing, aggressive conservation and recycling programs.)

- The current urban water management plans for the wholesale customers do not address the issue of developing substitute supplemental supplies, since the customers anticipate receiving and have requested supplemental supply from the SFPUC.

In short, the ability of the wholesale customers to develop additional water supplies is uncertain, and further studies would be required to evaluate technical and institutional feasibility. Determining (a) the specific projects that each wholesale customer would pursue and (b) the likelihood that the wholesale customers could successfully implement the projects is speculative and outside the control of the SFPUC. A discussion of representative projects that the wholesale customers might pursue is presented below. This discussion is intended to provide decision-makers and other interested parties with information about the potential options that exist, the challenges associated with each, and attendant environmental impacts.

The basic water management strategies that the wholesale customers could pursue to offset the severely reduced reliability under the No Program Alternative involve increasing supplies and decreasing demand. Among the options associated with these strategies are water purchases or transfers, groundwater management/use, aggressive recycling and conservation, and desalination. Water purchases/transfers and conjunctive use are discussed below. Currently, some of the wholesale customers are already actively developing recycled water/groundwater/ conservation projects to address their increasing demands and it is assumed that the wholesale customers will continue to do so in the future. Additional aggressive recycling, groundwater, and conservation is described separately under its own alternative (presented in Section 9.2.4). Similarly, there are two separate alternatives addressing desalination (presented in Sections 9.2.6 and 9.2.7).

Regarding water purchases or transfers, statewide trends indicate that while urban water use is increasing, agricultural water use is decreasing, in part because agricultural water users are selling water rights or contracts to urban agencies (Department of Water Resources, 2005). Potential sources of supplies for the wholesale customers include water-rights holders north of the Delta, in the Delta, or south of the Delta. The agencies with the rights to the greatest quantities of water in the state, the U.S. Bureau of Reclamation (USBR) and California Department of Water Resources (DWR), would not be sources of new water supply contracts/agreements because of their commitments to existing contractors and to the protection, restoration, and enhancement of fish and wildlife habitat. Challenges to water purchases and transfers pertain to restrictions associated with entitlements, contracts, and water rights; permitting requirements; effects caused by the cessation of water application to an area (e.g., land fallowing, economic impacts); Delta pumping restrictions; and wheeling arrangements[3] (Johnson and Loux, 2004). Existing water delivery infrastructure could theoretically be used through agreements with other agencies (such DWR, USBR, SFPUC, East Bay Municipal Utility District, Alameda County Water District, or Santa Clara Valley Water District) to convey water to the wholesale customers, if and when system capacity is available. Construction or expansion of interties or connecting pipelines in urban areas would likely be required.

A supplemental water supply must be available concurrent with annual and seasonal demands or must be stored during periods of adequate supply and low demand. An agency could pursue its own storage project, either through conjunctive use of a groundwater basin or through construction of a new storage facility. Conjunctive use of a groundwater basin is likely a potential option only for agencies that currently utilize groundwater. Review of current urban water management plans for the wholesale customers indicates that seven customers currently rely on groundwater for part of their supply; however, the ability of these agencies to implement additional conjunctive-use projects beyond any existing or planned projects to help offset any supply shortfall under this alternative is uncertain. Challenges to implementing conjunctive-use projects pertain to the sustainable yield of the groundwater basin, restrictions on appropriative rights, and existing regional and local groundwater management policies, ordinances, and practices. Regarding construction of new storage facilities for surface water supplies, very few agencies have constructed major reservoirs in Northern California in recent decades due to ecological impacts, cost, availability of suitable sites, and other issues, although several proposals to increase storage at existing reservoirs that provide water to the Bay Area are currently under study. The ability of a wholesale customer to acquire, through agreements with other agencies, use of a portion of an existing storage facility is uncertain; the terms of such agreements favor the dry-year and seasonal supply needs of the reservoir owner/operator. A key issue associated with use of existing storage is whose water spills first and is therefore “lost” before it can be used.

Feasibility Issues

While the No Program Alternative would present no engineering or technical feasibility issues, it would raise some fundamental institutional issues regarding the ability of the SFPUC to fulfill its basic mission to provide reliable, high quality and affordable water to its customers. The No Program Alternative would place the regional system at significant risk to seismic hazards, increased facility failures, and increased supply shortages on a day-to-day basis, as well as result in prolonged service disruptions to many customers in the event of an earthquake or other emergency due to inadequate facility redundancy and operational flexibility. The SFPUC customers would likely seek alternatives, as described above, and it is unlikely that the public would support this alternative. In addition, this alternative could add substantial long-term costs due to the increased likelihood of facility failures and increased need for emergency repairs or replacement in the event of an earthquake or other emergency. This unknown and likely substantial additional cost raises questions about cost and financing feasibility and customer rate impacts.

---

[3] Wheeling arrangements are agreements to use existing infrastructure owned by a third party to transport/convey water from a source to a customer.

The feasibility of rationing at levels of 20 percent or more and the effects of such rationing are key issues facing the regional system customers raised by the No Program Alternative and several of the other alternatives that require the wholesale customers to address average annual supply shortfalls and/or less dry-year reliability from the regional system on top of being prepared for dry-year rationing. Since the last drought (1987 – 1992), the state's population has increased and the amount of agricultural plantings that require water during drought years (i.e., vineyards and orchards) has increased. At the same time virtually all of the State's largest water agencies have implemented conservation and other demand management actions. Residential, commercial and industrial sectors have reduced water demand through conservation, and to a lesser extent, water recycling. The SFPUC wholesale customers already implement some level of conservation and some have existing water recycling projects; they have factored additional conservation and water recycling into their projections and used these as the basis for determining their 2030 purchase request from the SFPUC regional system. To the extent that water conservation is already being practiced and will increase in the future, the more difficult it will be to implement adequate cutbacks in water use in the future to achieve the rationing that may be required during a drought period. Demand hardening refers to the increasing difficulty and expense of achieving short-term water conservation levels during shortages as more long-term conservation measures are implemented and water-use efficiency is maximized. As described by the California Department of Water Resources, demand hardening:

> "occurs when agencies implement water conservation programs that result in permanent reductions in water use, such as retrofitting plumbing fixtures or installing low-water-use landscaping. These measures lessen agencies ability to implement rationing to reduce water use during droughts, and can result in great impacts to urban water users (e.g., loss of residential landscaping) when rationing is imposed. For example, the extensive Los Angeles retrofit program helped the city maintain reductions in urban per capita water use it achieved during the last drought. These permanent water use reductions will make it more difficult for the city to duplicate its previous 15 percent water use reduction goal during a future drought" (Department of Water Resources (DWR), 2005)

With respect to the effects of droughts and rationing on customers, droughts gradually affect water service. The socioeconomic effects of drought-related shortages depend on many factors, including the frequency, size, and duration of the supply shortage; types of water use affected; the options available to an agency and water users for managing shortages; the drought management strategies implemented, customer response to drought management strategies, and the costs of contingency water management and losses associated with shortages (DWR, 2000). From a statewide perspective, examples of drought impacts include (DWR, 2000):

- Lost jobs and revenue in landscaping / nursery industries
- Homeowner costs for replacing lawns and landscaping
- Unemployment and other socioeconomic impacts in farming-dependent communities
- Increased wildfire damages
- Widespread loss of trees in the Sierra Nevada
- Declines in fish populations

- Lost revenues to water-based recreation business
- Reduced hydroelectric power generation

The most recent prolonged drought lasted six years (1987 – 1992). Much of the information available about the economic consequences of this drought focuses on the agricultural sector. At the time, little information was available on the comprehensive, statewide impacts to urban customers from droughts. The California Urban Water Agencies (CUWA) formed in 1990 in part to study such effects and to promote the need for reliable, high quality water supplies for current and future urban water users. CUWA commissioned several reports on the adverse consequences of drought to urban customers.[4] Findings from those studies, as well as other literature reviewed are summarized in the following bullet item list. The experiences among water suppliers and their customers during the 1987-1992 drought varied considerably:

- *Distribution of Water Shortage Impacts.* Water shortages were not evenly distributed throughout the state. The cumulative deficit was worst in the Central Coast region. The degree of water shortage varied among agencies and, although target cutbacks ranged from 15 to 30 percent, there were differences between planned and actual cutbacks.

- *Drought Management Strategies.* The different drought management policies implemented by water suppliers created different consumption patterns and attendant economic losses.[5] For example, the City of Santa Barbara implemented mandatory conservation directives with steeply rising tiered water rates, resulting in a 62 percent reduction in consumption for single-family residences; neighboring Goleta Water District implemented quantity restrictions and higher flat rates for water, resulting in a 40 percent reduction in consumption for single-family residences (Rand, 1993).

- *Impacts Among Customer Types*. Cutbacks were not evenly distributed among residential, commercial, and industrial customers. Residential customers typically were cut back more than industrial or commercial users, although the horticulture sector of commercial customers suffered substantial losses.

- *Exterior and Interior Water Use.* Urban rationing programs typically shift the worst impacts to residential exterior and commercial landscaping uses and away from industrial use, commercial non-landscaping use, and residential interior use (DWR, 2005). Consequently a 30 percent shortage overall can translate to a 35 percent shortage for residential users, for example.

- *Other effects.* Because there was an economic recession in 1990-1991, water use and production output reductions in the commercial and industrial sectors during these years may not have been due to drought.

---

4 The CUWA-commissioned studies include: *Assessment of the Economic Impacts of California's Drought on Urban Areas, A Research Agenda* (RAND, 1993); *Drought Management Policies and Economic Effects in Urban Areas of California, 1987 – 1992* (RAND, 1996); *Cost of Industrial Water Shortages* (Wade, et al, 1991); *The Value of Water Supply Reliability: Results of a Contingent Valuation Survey of Residential Customers* (Barakat & Chamberlin, Inc, August 1994); Water Reliability Analysis and Planning (WRAP) (Barakat & Chamberlin, Inc, August 1993); and *CUWA Survey of 1991 Drought Management Measures*, June 1991.

5 Examples of the drought management policies implemented during the 1987 – 1992 drought include: quantity restrictions, type-of-use restrictions, public education programs, device distribution program (e.g., low-flow shower heads), price increases, supply augmentation strategies (greater groundwater pumping, greater use of recycled water, and water transfers) (Rand, 1993).

According to DWR, genuine health and safety concerns (i.e., running out of water for drinking, sanitation, and firefighting) during the past recorded droughts generally have been limited to small, rural communities relying on marginal water sources. Estimated losses to residences from droughts vary, and studies of actual monetary losses sustained by residential customers are uncommon. A survey of impacts to residents in Alameda County Water District, which modeled household response to steeply increasing water rate structure, calculated average welfare losses per household in the range of $14-$23 per household for the period July 1991 to December 1992.

Because of the challenges in quantifying economic losses in the residential sector, CUWA determined that contingent valuation, or willingness to pay, was the best available method for studying residential water shortage losses. Contingency valuation is based on estimating how much people will pay for something that is not available on the private market, in this case, how much people are willing to pay to avoid water shortages of varying magnitude and frequency (Barakat and Chamberlain, 1994). Using the willingness to pay methodology, the 1994 survey found concluded that California residents were willing to pay $12 to $17 more per month per household for water to avoid the kinds of water shortages that occurred in the 1987–1992 drought. An estimate of impacts to Orange County residents used the same methodology to estimate economic losses by residents from 20 percent cutbacks over three years at about $13 billion in 2002 dollars (Orange County Business Council, 2003). As noted in DWR (2005), property values for residential users and their quality of life may be lower in an area with less reliable dry-year water services if the expected cost of shortage-related landscaping replacement is high enough to discourage planting high-investment landscaping.

Based on data collected in a 1990 industry survey, the report *Cost of Industrial Water Shortages* (Spectrum Economics, Inc., 1991) indicated that direct losses in industry production from a 30 percent shortage in 1990 dollars would be $0.93 billion for Alameda County, $5.3 billion for Santa Clara County, $0.9 billion for San Francisco County, and $7.6 billion for San Mateo County. In May 2005, BAWSCA submitted a report to the SFPUC regarding the economic consequences to the Bay Area of water shortages (Wade, 2005). The report, which advocates that the SFPUC reconsider the 20 percent maximum systemwide rationing goal established for the WSIP, characterizes water use in the industrial sector of wholesale customer communities as follows:

> The companies that account for the majority of industrial sector water use are those in the computer equipment and electronic component manufacturing categories. These water-dependent industries are the backbone of the Bay Area economy. In some industries, water is an essential element of the production process, not ancillary to plant production and employee use. For example, 75 percent of the water use in the food products industry is employed directly in the process. Water essentially is the product for many beverage processors. Microchips are manufactured in a wet environment. … Biotechnology, an emerging industry in the Bay Area requires water. Genentech, for example, is the largest industrial user of water in South San Francisco. Over 75 percent of the water used in its South San Francisco plant is employed directly in the manufacturing process, while research and development uses account for most of the remainder.

The report estimates the value of production losses (lost value of shipments in 2001 dollars) in water-critical industries located in the BAWCA service area caused by water shortage of up to 20 percent at $2.5 billion to $7.7 billion per year, and notes that this estimate is conservative because of demand hardening. The report also cited the following information from an SFPUC report to the Federal Energy Regulatory Commission (FERC) (Hetch Hetchy Water and Power Department, 1993)

- "The economic impact resulting from a water supply cutback will be concentrated in two industries: electronic components and accessories, and computer office equipment. Other industries could experience larger production cutbacks, but their economic impact will be small by comparison, except for the beverage industry.
- A 15 percent cutback in water supply could reduce direct shipments from the electronic component industry in 1990 dollars by $68 million and $163 million from the computer industry. The secondary impact could increase loss from these two industries by $294 million.
- A 15 percent cutback in water supply could result in more than 2,000 jobs lost in the two industries and their ancillary service areas.
- At a 15 percent cutback in water supply, the beverage industry would experience the largest production cutback of 10.4 percent and lost sales of approximately $72.4 million (1990 dollars)."

Although the information on the effects of water shortages during drought is limited, studies completed to date indicate that rationing cutbacks of 15 to 20 percent can have substantial economic impact on commercial, industrial and residential sectors and well as lifestyle effects on residents. To date, these studies have not identified significant environmental impacts resulting from such rationing in urban areas and the economic consequences do not appear to have resulted in major physical changes such businesses and/or residents leaving the area to an extent that land use patterns change. However, requiring rationing of up to 20 percent during a drought of customers who have already implemented aggressive conservation and water recycling would result in more severe economic and lifestyle effects.

Ability to Meet Program Objectives

Tables 9-5 and 9-6, above, show how the No Program Alternative would perform in terms of meeting the level of service goals and system performance objectives established for the WSIP (no assumptions are made regarding the ability of the wholesale customers to develop alternative supplies to offset water supply shortages or reduced system reliability). While this alternative could occasionally satisfy the 2030 customer purchase requests of 300 mgd, the alternative would fail to meet the WSIP level of service goals with respect to seismic, delivery, and water supply reliability. The water quality level of service goal would be achieved, since the SFPUC would implement required facility improvements to meet federal and state water quality regulations for the regional system (assuming no new supply would be wheeled through the SFPUC's system from wholesale customer actions; the SFPUC would not be responsible for regulatory compliance for any new sources obtained by wholesale customers).

Under the No Program Alternative, the regional system could not reliably meet the average 2030 demand of 300 mgd during nondrought years. With the restoration of Calaveras and Lower Crystal Springs Reservoirs under this alternative, water supply reliability would be somewhat improved over existing conditions, but this alternative would still not meet the WSIP level of service goals for seismic and delivery reliability due to other system deficiencies related to water availability during maintenance or outages, storage, conveyance, and treatment. In addition, this alternative would fail the WSIP objective of limiting drought-year rationing to a maximum of 20 percent systemwide. Systemwide shortages of greater magnitude and frequency would occur compared to both existing conditions and the proposed program. Using the Hetch Hetchy/Local Simulation Model (HH/LSM) and assuming a maximum rationing of 30 percent, the regional system would experience shortages during 42 years of the 82-year period of hydrologic record—as much as one in every two years. There would be no supplemental dry-year sources (e.g., the Westside Groundwater Program) to potentially forestall customer shortages.

With the exception of the Calaveras Dam project (SV-2), key WSIP facility improvement projects that were identified as needed to meet the seismic reliability performance objectives would not be implemented.[6] As a result, the system would continue to be subject to seismic hazards. In the event of a major earthquake, critical facilities could fail, leading to prolonged outages; customers could be without water service (including drinking water supplies and water for firefighting) for more than 14 days and possibly more than 30 days. Furthermore, without the WSIP facility improvement projects, the system would not have sufficient redundancy to reliably maintain or quickly restore basic service following a major earthquake.

Under the No Program Alternative, comprehensive maintenance and repair of the regional system would continue to be deferred, resulting in an increasing risk of failure and service disruption; in addition, some facilities (such as the Irvington Tunnel) could not be inspected, serviced, or repaired without loss of service to customers. The system would also have a limited ability to respond to unplanned outages resulting from power failures, earthquakes, or water quality events at Hetch Hetchy Reservoir. Aging infrastructure and substandard maintenance under the No Program Alternative would severely compromise overall delivery reliability[7] compared to existing conditions, due to increased demand on the system coupled with a greater likelihood of facility failure. Facilities would not be in place to replenish local reservoirs as needed to prepare for drought, and, as previously stated, customers would be subject to more severe and more frequent shortages and rationing.

6 Key WSIP projects needed to meet seismic reliability levels of service include Calaveras Dam (SV-2), New Irvington Tunnel (SV-4), BDPL Reliability Upgrade (BD-1), BDPL 3 and 4 Seismic Upgrade at Hayward Fault (BD-3), Baden and San Pedro Valve Lots (PN-1), CS/SA Transmission (PN-2), HTWTP Long-Term (PN-3), and SAPL 3 Installation (SF-1). In addition, two WSIP projects identified as having independent utility—New Crystal Springs Bypass Tunnel and Bay Division Pipelines Nos. 3 and 4 Crossover/Isolation Valve at Hayward Fault—would be required (SFPUC, 2006).

7 Key WSIP projects needed to meet delivery reliability levels of service during maintenance conditions include SJPL System (SJ-3), 40-mgd Treated Water (SV-3), New Irvington Tunnel (SV-4), BDPL Reliability Upgrade (BD-1), CS/SA Transmission (PN-2), and HTWTP Long-Term (PN-3). Key WSIP projects needed to meet delivery reliability levels of service during a Hetch Hetchy water quality event or unplanned outage include Calaveras Dam (SV-2), 40-mgd Treated Water (SV-3), and HTWTP Long-Term (PN-3) (SFPUC, 2006).

If the wholesale customers and/or BAWSCA were to pursue supplemental water sources to compensate for the reduced reliability of the SFPUC's regional system under the No Program Alternative, additional studies would be required to determine both the technical and institutional feasibility of such supplemental sources. The resultant ability of the alternative to meet the program objectives would then depend in part on the wholesale customer actions and would be outside the control of the SFPUC.

While the SFPUC would continue to provide watershed protection and meet legal requirements for protection of fish and other wildlife, under the No Program Alternative, the system would not be managed in a comprehensive and coordinated manner to best manage natural resources and physical systems; therefore, the system would not meet all the sustainability objectives. Similarly, while the system would maintain its gravity-driven attributes, the system would not meet all of the WSIP cost-effectiveness objectives because the increased risk of facility failures and outages and likely increased need for emergency repairs and replacement would not be considered efficient or cost-effective use of resources or funds and the SFPUC would not be able to implement a regular inspection and maintenance program for all facilities.

Environmental Impacts Compared to those of the WSIP

Facility Construction and Operations Impacts

WSIP Facilities

Under the No Program Alternative, only five WSIP facility improvement projects would be constructed—Advanced Disinfection (SJ-1), Alameda Creek Fishery (SV-1), Calaveras Dam (SV-2), Treated Water Reservoirs (SV-5), and Lower Crystal Springs Dam (PN-4). None of the impacts attributable to the other WSIP facility projects would occur. The construction and operational impacts of these five facilities would be identical to those described in Chapter 4, Sections 4.3 to 4.15. As with the WSIP, the program-level analysis indicates that implementation of these five projects would result in potentially significant and unavoidable construction-related noise increases. In addition, implementation of the Advanced Disinfection project would result in potentially significant and unavoidable impacts related to temporary noise disturbance along construction haul routes; the Calaveras Dam project would result in potentially significant and unavoidable impacts related to visual resources as well as to historic districts and the historical significance of individual facilities; the Lower Crystal Springs Dam project would result in potentially significant impacts related to the historical significance of individual facilities. All other identified program-level impacts for these five projects would either be less than significant or could be mitigated to a less-than-significant level with implementation of identified mitigation measures.

Potentially significant unavoidable impacts associated with construction noise would be avoided at the 17 remaining WSIP facility improvement project sites. Impacts in the San Joaquin Region would be limited to the Tesla Portal area, and potentially significant unavoidable land use and/or vibration impacts associated with the SJPL System (SJ-3) and SJPL Rehabilitation (SJ-4) projects would be avoided. Impacts in the Sunol Valley Region would be limited to the Alameda Creek, Calaveras Dam, and Sunol Valley Water Treatment Plant (WTP) areas; and potentially significant unavoidable land use and/or cultural resource impacts associated with the 40-mgd Treated Water (SV-3), New Irvington Tunnel (SV-4), and SABUP (SV-6) projects would be avoided. There would be no construction or operations impacts in the Bay Division Region, and potentially significant unavoidable land use and/or vibration impacts associated with the three projects in this region would be avoided. Impacts in the Peninsula Region would be limited to the Crystal Springs Reservoir area, and potentially significant unavoidable land use and cultural resource impacts associated with the CS/SA Transmission project (PN-2) as well as potentially significant unavoidable vibration impacts associated with the Baden and San Pedro Valve Lots project (PN-1) would be avoided. There would be no construction or operations impacts in the San Francisco Region, and potentially significant unavoidable land use and/or vibration impacts associated with the three projects in this region would be avoided.

Under the No Program Alternative, all potentially significant collective impacts (with the exception of cultural resources) would be less than significant or avoided due to the greatly reduced number of projects. Only two of the three projects in the Sunol Valley—Alameda Creek Fishery (SV-1) and Calaveras Dam (SV-2)—would have overlapping construction schedules, and project-specific mitigation measures would be adequate to reduce any combined effects of construction activities on Calaveras Road to a less-than-significant level. Thus, multi-regional and overlapping collective impacts under the No Program Alternative would be less than significant.

Unlike the proposed program, the contribution of facilities impacts under the No Program Alternative to cumulative impacts on traffic and biological resources would be mitigated through project-specific mitigation; other WSIP-related activities such as the Habitat Reserve Program (if implemented, see Chapter 3, Section 3.12) would also reduce cumulative impacts on biological resources. However, similar to the proposed program, the contribution of the No Program Alternative's impacts to cumulative impacts on air quality and cultural resources would be cumulatively considerable, particularly due to the extent of construction activities associated with the Advanced Disinfection (SJ-1) and Calaveras Dam (SV-2) projects.

Other Facilities Potentially Implemented Under this Alternative

The ability of the wholesale customers to develop additional water supplies is uncertain and outside the control of the SFPUC. The types of projects that the wholesale customers might pursue and the potential facility and operations impacts associated with such projects are presented in **Table 9-10** for consideration by decision-makers and other interested parties. In general, certain types of impacts are common to water supply transfers/acquisition and include: the cessation of water application to lands irrigated by the water being transferred; changes related to flows, fisheries, and water quality; and impacts caused by the use of existing or the construction of new infrastructure. Typically, the water rights-holder previously applied the water to agricultural land. The transfer can result in the conversion of agricultural land to nonagricultural land. Beneficial environmental effects (related to retiring drainage-impaired lands, reducing the application of pesticides, etc.) can also occur. The need for new facilities and/or changes in the operations of existing facilities depend on the source of supply (e.g.,

TABLE 9-10
SUMMARY OF POTENTIAL IMPACTS AND MITIGATION STRATEGIES ASSOCIATED WITH REPRESENTATIVE WATER SUPPLY ACQUISITION PROJECTS

Actions Associated with Water Supply Acquisition Projects	Potential Impacts	Mitigation Strategy
Supplemental Water Supply Source		
Increased Water Use Efficiency/Conservation (e.g., conversion to drip irrigation); tiered water pricing	Reduced groundwater recharge. Exposure of soils to wind erosion leading to air quality impacts. Could lead to increased groundwater pumping.	None required. See below regarding increased groundwater pumping.
Conversion of More Water-Intensive to Less Water-Intensive Crops, Land Fallowing	Land fallowing could create pressure to convert land to urban uses and loss of agricultural land. Economic impacts to community.	Include consideration of farming interests in decision-making process for transfer.
Increased Groundwater Pumping/Conjunctive Use of Groundwater	Groundwater level reductions and overdraft if there is insufficient sustainable yield to accommodate increased pumping. Water quality issues include decreased aesthetic quality in drinking water (hardness, tastes, odors), health risk from potential contaminants in groundwater basin.	Determine sustainable yield of the basin, implement monitoring program, regulate groundwater pumping to preserve safe yield, provide treatment and/or blending if necessary to remove contaminants and control taste and odor. Local assistance programs for remediation of affected wells.
Delta Diversions	Potential impacts on sensitive Delta fisheries including: winter-run, spring-run Chinook salmon, Delta smelt, steelhead trout, and Delta splittail.	Compliance with existing and future pumping requirements related to threatened and endangered species protection.
	Changes in Delta inflow, outflow. Potential impacts on flows associated with wheeling Delta transfers through the Delta, resulting in secondary impacts on Delta fisheries and other biological resources.	Transfer would require review/approval by applicable regulatory agencies. Analysis of flow impacts and commitment to minimize adverse secondary impacts on biological resources (e.g., through transfer timing, pumping restrictions).
	Water quality for the Delta and downstream water users (including salinity, bromides, potential contaminants from agricultural and industrial run-off, taste and odor problems, disinfection byproducts, and temperature).	Compliance with existing and future applicable water quality control. Regulations. Treatment to bring up to water quality equitable to Tuolumne River.
	Water quality for the Delta and downstream water users (including salinity, bromides, and temperature).	Transfer would require review/approval by applicable regulatory agencies. Analysis of flow impacts and commitment to minimize adverse impacts on other water users (e.g., through transfer timing, pumping restrictions).

TABLE 9-10 (Continued)
SUMMARY OF POTENTIAL IMPACTS AND MITIGATION STRATEGIES ASSOCIATED WITH REPRESENTATIVE WATER SUPPLY ACQUISITION PROJECTS

Actions Associated with Water Supply Acquisition Projects	Potential Impacts	Mitigation Strategy
Facilities Required		
Conveyance	Mostly temporary impacts from construction of pipelines, valves, and pumps (disturbance of soils, surface water quality, biological resources, cultural resources, air quality, traffic, noise, land use, hazardous materials, aesthetics).	Most impacts associated with facility construction could be mitigated to a less-than-significant level with the types of measures identified in Chapter 6. As is the case with the proposed WSIP facilities, some impacts (e.g., short-term noise and traffic) could be unavoidable.
Pumping	Noise, energy consumption, air pollutant emissions from energy consumption.	Muffle noise. Use energy-efficient pumps and alternative energy sources.
Treatment	Temporary construction impacts, including land use, traffic, noise and air quality impacts. Potential long-term impacts could include increase in energy consumption, air pollutant and greenhouse gas emissions from energy consumption.	Use standard construction mitigations. Use energy-efficient pumps and alternative energy sources.
Groundwater Basin Storage of Surface Water	Potential degradation of groundwater quality, hydrofracturing (injection).	Pretreatment, groundwater quality monitoring, groundwater basin modeling, modifications to recharge and pumping practices.
Storage – Development of New Offstream Storage	Temporary and long-term impacts from construction of dam, pipelines, pumps, and appurtenant features (direct and indirect impacts on wetland and upland fish and wildlife and attendant habitat; impacts related to cultural resources, air quality, traffic, noise, land use, aesthetics, etc.).	Most impacts associated with facility construction could be mitigated to a less-than-significant level with the types of measures identified in Chapter 6. Some impacts would likely be unavoidable.

Tuolumne River through transfers with TID and MID, water-rights holders north of the Delta, in the Delta, or south of the Delta), the quantity of supply, and the means of conveyance. Construction or expansion of interties or connecting pipelines could be required, potentially resulting in impacts similar to those described for WSIP pipeline projects. The use of existing infrastructure to convey water to the wholesale customer would require extensive hydrologic, hydraulic and seismic reliability modeling to confirm that there would be no adverse consequences to the supply availability of other system users under all normal and emergency conditions. Without the WSIP improvements, capacity is already extremely limited, so ability to provide additional conveyance capacity is unlikely.

Water Supply and System Operations Impacts

Under the No Program Alternative, the estimated average annual diversions from the Tuolumne River would be 226 mgd, based on HH/LSM modeling of the no-program assumptions over the 82-year hydrologic record. This amount is 19 mgd less than the 245 mgd average annual diversions from the Tuolumne River under the WSIP, but 8 mgd more than the 218 mgd average annual diversions under existing conditions, as shown in Table 9-5, above. The potential impacts on water resources in the Tuolumne River, Alameda Creek, and Peninsula watersheds associated with this level of diversion are described below and compared to the impacts that would occur under the WSIP.

Tuolumne River Watershed

Currently, water storage in Hetch Hetchy Reservoir follows a seasonal pattern. The SFPUC typically draws the reservoir down in the summer, fall, and winter. During the summer, fall, and winter, only the minimum required release is made to the Tuolumne River below O'Shaughnessy Dam. The SFPUC refills Hetch Hetchy Reservoir with snowmelt in the spring and, once it is full, or in anticipation of it filling, releases excess to the river. The amount of the release in any particular year depends on the mass of snow that has accumulated in the previous winter.

Based on projected increases in customer water demand in 2030 the amount of water delivered to customers by the SFPUC regional system under the WSIP would be greater than under the existing condition. To meet the increased demand under the WSIP, the SFPUC would draw down Hetch Hetchy Reservoir to a greater extent in the summer, fall, and winter compared to the existing condition. A higher proportion of the snowmelt runoff would be required to refill the reservoir in the spring, and a smaller proportion would be released to the Tuolumne River below O'Shaughnessy Dam. Average annual releases to the Tuolumne River would be reduced by about 3.5 percent. The reduction in average annual releases to the river would manifest itself as a delay in the start of the spring release. The average delay would be 1 day, the maximum delay would be 8 days and a delay greater than 2 day would occur about once every 4 years.[8] The delay in spring releases would have a significant adverse effect on terrestrial biological resources in streamside meadows, particularly in the Poopenaut Valley, as described in Section 5.3.7.

8 The estimates of delay in spring releases are based on the assumption that operators would release water from Hetch Hetchy Reservoir at a rate of 3,000 cfs. Review of past practice indicates that this a typical springtime release rate. If the release rate was reduced, as might happen in a dry year, the delay would be extended.)

The No Program Alternative would also result in a delay in spring releases from Hetch Hetchy Reservoir. This delay would occur because, under the No Program Alternative, water demand would increase (as it would with the WSIP), and the SFPUC would attempt to satisfy the increase in demand by drawing more water from Hetch Hetchy Reservoir. The SFPUC would not draw as much water from Hetch Hetchy Reservoir with the No Program Alternative as it would with the WSIP because it would not provide the same level of delivery reliability during drought it would with the WSIP. This substantial reduction in delivery reliability during drought results in more frequent reductions to full deliveries during nondrought years. The average annual release of water to the Tuolumne River below O'Shaughnessy Dam would still be reduced (by about 1.3 percent). The delay in spring releases would be less with the No Program Alternative than with the WSIP. With the No Program Alternative the average delay would about half a day and the maximum delay would be 5.5 days. Delays of more than two days would occur about once every six years. The delays would still have a significant adverse effect on terrestrial biological resources.

Water storage in Don Pedro Reservoir also follows a seasonal pattern. The Turlock Irrigation District (TID) and Modesto Irrigation District (MID) typically draw the reservoir down in the summer and early fall by diversion to their service areas and releases from La Grange Dam to the Tuolumne River. During the summer and fall, typically only the minimum required release is made to the Tuolumne River below La Grange Dam. TID and MID replenish storage in Don Pedro Reservoir with rainfall runoff from the watershed in the winter and snowmelt in the spring. Because one of the purposes of Don Pedro Reservoir is flood control, space must be retained in the reservoir through the winter to capture runoff from large winter storms. In years when runoff exceeds the available capacity of the reservoir, TID and MID release the excess to the river below La Grange Dam. The amount of the release in any particular year depends on the size and frequency of winter storms and the mass of snow that has accumulated in the upper watershed in the previous winter. Releases may occur in a series of pulses rather than in a single defined spring release as typically occurs at Hetch Hetchy Reservoir.

As noted above, water demand in 2030 would be greater than under the existing condition. To meet the increased demand, with the WSIP the SFPUC would divert more water from the Tuolumne River at Hetch Hetchy Reservoir than under the existing condition. There would be a corresponding reduction in inflow to Don Pedro Reservoir. As a result, Don Pedro Reservoir would be drawn down farther by the late fall than it is under the current condition. A higher proportion of the rainfall and snowmelt runoff would be required to replenish storage in Don Pedro Reservoir in the winter and spring, and a smaller proportion would be released to the Tuolumne River below La Grange Dam. The reduction in average annual releases to the river with the WSIP would manifest itself as a delay in the start of pulse releases in the winter and spring. The combination of a reduction in the average annual volume of releases (of about 4 percent) and a delay in releases would have a significant adverse effect on fisheries in the Tuolumne River and on terrestrial biological resources in the riparian corridor, as described in Sections 5.3.6 and 5.3.7.

As noted above, water demand would increase with the No Program Alternative (as it would with the WSIP), and the SFPUC would attempt to satisfy the increase in demand by drawing more water from Hetch Hetchy Reservoir. Withdrawal of more water from Hetch Hetchy Reservoir would reduce inflow into Don Pedro Reservoir and result in a greater drawdown of storage in that reservoir compared to the existing condition. The No Program Alternative would reduce the average annual release of water to the Tuolumne River below La Grange Dam (by about 1.3 percent) and delay the initial release, but to a much lesser extent than with the WSIP. The reduction in total releases and the delay in the initial release would have an adverse effect on fisheries in the Tuolumne River and on terrestrial biological resources in the riparian corridor, but the impact would be less than significant.

Alameda Creek Watershed

The proposed improvements to Calaveras Dam included under the WSIP would also occur under the No Program Alternative. As a result of the improvements and associated modification in system operations, the maximum water level in Calaveras Reservoir would rise by about 50 feet. The rise in water level would have significant adverse impacts on terrestrial biological resources, as described in Section 5.4.6.

Under the No Program Alternative, as with the WSIP, restoration of historical water levels at Calaveras Reservoir would enable greater diversions of water from Alameda Creek into the reservoir. The consequent reductions in flow would have significant and unavoidable impacts on the hydrology of the creek below the diversion dam and significant adverse impacts on fisheries and terrestrial biological resources. The improvements to Calaveras Dam would also lead to changes in flow in Calaveras Creek and Alameda Creek below the Calaveras Creek confluence, which would have significant adverse impacts on terrestrial biological resources. The changes in water level in Calaveras Reservoir and changes in flow in the creeks would have a significant adverse effect on recreational and visual resources. Under the No Program Alternative, the SFPUC would operate its facilities in the Alameda Creek watershed in a similar manner as it would with the WSIP. Consequently, the environmental impacts of the No Program Alternative would be similar to those of the WSIP.

Peninsula Watershed

Currently, water storage in Pilarcitos Reservoir follows a seasonal pattern. The SFPUC typically draws the reservoir down in the summer. During the summer, water is released from the reservoir to Pilarcitos Creek to supply the Coastside County Water District (CWD). Coastside CWD diverts water from Pilarcitos Creek at Stone Dam. By late summer, Pilarcitos Reservoir is typically drawn down to its minimum, and the SFPUC supplies Coastside CWD from Crystal Springs Reservoir. The SFPUC refills Pilarcitos Reservoir in the winter and spring.

Water demand in 2030 would be greater than under the existing condition, including water demand in the Coastside CWD service area. To meet the increased demand in the Coastside CWD service area, the SFPUC would draw down Pilarcitos Reservoir more rapidly in the summer than under the existing condition and end stored water releases to Pilarcitos Creek at an earlier date. The more rapid drawdown and the earlier cessation of releases to Pilarcitos Creek would have a significant adverse effect on water quality, fisheries, and terrestrial biological resources in the reservoir and the creek, as described in Sections 5.5.3, 5.5.5, and 5.5.6.

Water demand would increase with the No Program Alternative, as it would with the WSIP. The SFPUC would try to serve increased demand in the Coastside CWD service area from Pilarcitos Reservoir, exactly as it would with the WSIP. The consequent, more rapid drawdown of Pilarcitos Reservoir and the earlier cessation of stored water releases to Pilarcitos Creek would have a significant adverse effect on water quality, fisheries, and terrestrial biological resources in the reservoir and the creek.

The improvements to Lower Crystal Springs Dam that would occur with the WSIP would also be part of the No Program Alternative. As a result of the improvements and associated modification in system operations, the maximum water level in Crystal Springs Reservoir would rise by about 20 feet. The rise in water level would have significant adverse impacts on terrestrial biological resources, as described in Section 5.5.6. Because the No Program Alternative would include the same improvements to Lower Crystal Springs Dam as the WSIP, the SFPUC would generally operate its facilities in the Peninsula watershed in a similar manner as it would with the WSIP. Consequently, the environmental impacts of the No Program Alternative would be similar to those of the WSIP.

Growth-Inducement Potential and Secondary Effects of Growth

The growth-inducement potential for this alternative is expected to be similar to that of the proposed program. Under this alternative, the SFPUC would not be able to provide a water supply with a reliability comparable to the WSIP in all nondrought years, or in dry years and drought periods; nonetheless, it is reasonable to expect that the SFPUC wholesale customers (either separately or together through BAWSCA) would seek to acquire supplemental dry-year water supplies to complement the supply increases the SFPUC is able to deliver under this alternative and to provide a comparable level of supply reliability. As a result, this alternative would have the same indirect, secondary effects of growth as the proposed program. As discussed in Chapter 7, growth has occurred in some communities, such as San Francisco, without a corresponding increase in water supply. In the future, the projected population and/or employment growth for some communities are clearly greater than the corresponding projected increase in water supply need, indicating that water use efficiency is increasing and that additional supply is not necessarily required for growth to occur. It is possible that approval of additional development within the SFPUC’s wholesale customer service areas might be slowed somewhat in some communities because the wholesale customers would have to pursue other projects and actions to achieve adequate dry-year supplies and reliability, but it is not expected that this would deter communities from taking actions to support planned growth.

9.2.3 No Purchase Request Increase Alternative

Under the No Purchase Request Increase Alternative, the SFPUC would implement all of the proposed WSIP facility improvement projects but would limit wholesale customers’ future purchases to terms of the existing Master Water Sales Agreement instead of providing for their 2030 purchase requests. The wholesale customers would have to pursue supplemental supply sources and/or conservation measures to make up the supply shortfall under this alternative. This alternative assumes there would be no increase in the existing level of supply assurance

(275 mgd, annual average which reflects the wholesale customer supply assurance under the Master Water Sales Agreement of 184 and a demand of 91 mgd in the SFPUC retail service area), but there would be a slight increase in demand compared to the existing purchase request level of 265 mgd. With the inclusion of 10 mgd of recycled water, groundwater and conservation projects in San Francisco, there would be limited need for additional Tuolumne River diversions except for drought supplies.

This alternative was included in the PEIR alternatives analysis to evaluate the consequences of the SFPUC not meeting the future increase requested by its customers in an effort to avoid or minimize the potential growth-inducing effects and secondary effects of growth associated with providing more water to the regional customers.

Description of SFPUC and Wholesale Customer Actions

SFPUC Actions

Table 9-4 summarizes the main characteristics of this alternative in comparison to those of the proposed program. Under the No Purchase Request Increase Alternative, the SFPUC would implement the same water supply option and facility improvement projects as those proposed under the WSIP; however, instead of serving the full 2030 purchase requests of 300 mgd (average annual), the SFPUC would limit customer deliveries to 275 mgd (as compared to current deliveries of 265 mgd), with 184 mgd for wholesale customers and 91 mgd for retail customers.
Master Water Sales Agreement Terms

Currently, the SFPUC's wholesale customers purchase an annual average of 170 mgd from the regional water system. The wholesale customers estimate that, by 2030, they will need to purchase an annual average of 209 mgd from the regional system. Under the WSIP, the regional system would meet the needs of wholesale customers for water. The No Purchase Request Increase Alternative assumes that the SFPUC would be able to limit the wholesale customers' future purchases to the terms of the existing Master Water Sales Agreement it holds with the wholesale customers, who are represented by BAWSCA (see Chapter 2, Section 2.5.5 for a description of the agreement). Under this agreement, the CCSF has agreed that the wholesale customers may collectively purchase up to 184 mgd on an average annual basis, subject to reductions in the event of a drought, water shortage, earthquake, other natural disaster, or rehabilitation and maintenance of the system ("the supply assurance"). Additional sales are made on an interruptible basis to San Jose and Santa Clara. The current master contract expires in 2009, but in the event the contract is not renewed or renegotiated, or the parties agree to a new contract without an increase in the supply assurance, the current supply assurance of the contract would remain in force. Thus, under the No Purchase Request Increase Alternative, it is assumed that the SFPUC and its customers would choose not to negotiate a new contract and instead would continue with the existing contract in which the customer water delivery for 2030 would be 184 mgd for the wholesale customers instead of 209 mgd and would be the same as under the WSIP for retail customers (91 mgd). Therefore, under the No Purchase Request Increase Alternative, the wholesale customers would receive 25 mgd (average annual) less than under the WSIP. It is assumed that the wholesale customers, either individually or collectively, would seek sources other than the SFPUC, through alternative supply sources, additional conservation, water recycling, or other demand management approaches, as described below. The SFPUC would need to work closely with BAWSCA to define where the additional 10 mgd would be served, and would need to redefine level of service objectives for seismic and delivery reliability based on the decreased supply and revised supply distribution.

Water Supply Characteristics

Under the No Purchase Request Increase Alternative, it is assumed that the total customer purchase requests to be served by the regional system by 2030 would be 275 mgd, consisting of 184 mgd for the wholesale customers and 91 mgd for the retail customers. As shown in Table 9-4, the increased water demand would be served through additional Tuolumne River diversions under existing CCSF water rights, increased use of local watershed supplies due to restoration of Calaveras and Crystal Springs Reservoirs, and 10 mgd from recycled water, groundwater, and conservation projects in San Francisco. During drought sequences, this supply would be supplemented by additional Tuolumne River diversions through a water transfer with TID and MID, similar to the proposed program, but for 1 mgd instead of 23 mgd. The supplemental dry-year supplies would also include implementation of the Westside Basin conjunctive-use program for 6 mgd (same as under the proposed program).

WSIP Facility Improvement Projects

The No Purchase Request Increase Alternative assumes that the SFPUC would implement all 22 WSIP facility improvement projects to meet the water quality, seismic reliability, and delivery reliability objectives of the WSIP. However, the design of some of the WSIP facilities would need to reevaluated and sized appropriately to meet the reduced delivery levels and corresponding adjusted performance objectives under this alternative. In addition, the No Purchase Request Increase Alternative assumes that the SFPUC would proceed with implementation of other capital improvement projects and related activities not considered part of the program analyzed in this PEIR (as described in Chapter 3, Sections 3.13 and 3.4.6).

Wholesale Customer Actions

Under this alternative, the SFPUC would serve 184 mgd out of the 209 mgd in wholesale customer purchase requests (demand) by 2030. BAWSCA and/or individual SFPUC wholesale customers could pursue supplemental water supplies on their own to compensate for the 25 mgd in additional demand, or possibly develop additional conservation programs or other demand management approaches. A potential approach for BAWSCA and the wholesale customers to secure supplemental water supplies and associated issues are described under the No Program Alternative. However, unlike the No Program Alternative (under which the SFPUC could at times meet the full purchase requests but with uncertain reliability), the No Purchase Request Increase Alternative would on average provide 184 mgd, or 88 percent, of wholesale customer demand with a high level of reliability. Nevertheless, the wholesale customers might elect to obtain supplemental supplies to meet the additional 25 mgd in demand using an approach similar to that described above under the No Program Alternative.

Feasibility Issues

Similar to the No Program Alternative, the No Purchase Request Increase would present no engineering or technical feasibility issues, but it would likely result in institutional and legal issues since it assumes that the SFPUC and it customers would collectively agree to maintain the current Master Water Sales Agreement contract provisions (and other individual contracts). However, without such an agreement BAWSCA and/or wholesale customers would likely pursue legal remedies to compel the SFPUC to meet the 2030 customer purchase request. Whether or not the SFPUC could agree with its customers on such an alternative, BAWSCA and/or wholesale customers would also likely seek other water supply sources to meet customer water needs; each alternate water source would have its own set of technical, cost, legal, and regulatory considerations that would require additional studies. With respect to public acceptance, it is unlikely that the SFPUC's regional system customers would support this alternative. In addition, depending on the outcome of customer actions, this alternative could add substantial capital and/or operation and maintenance costs as a result of having to accommodate alternate water sources in addition to the costs of the 22 facility improvement projects included in the WSIP. This unknown but possibly substantial additional cost raises questions about total program cost and financing feasibility and customer rate impacts.

Ability to Meet Program Objectives

Table 9-6, above, shows how the No Purchase Request Increase Alternative would perform in terms of meeting the WSIP level of service goals and system performance objectives compared to the proposed program. This alternative would fully meet the WSIP level of service goal with respect to water quality for the SFPUC system (although the SFPUC would not be responsible for regulatory compliance of new water sources obtained by wholesale customers; in addition, if new sources are to be "wheeled" through the SFPUC system, then the water quality objective may not be achieved). Seismic reliability would be improved over existing conditions, but due to the reduced target delivery level, the alternative would not meet the WSIP objective of providing 300 mgd average day demand but would meet a reduced objective of 275 mgd average day demand. In addition, there is no certainty about where the distribution of the additional 10 mgd would occur, so the seismic performance objectives of serving 70 percent of turnouts and meeting average day demand in the three customer regions (South Bay, Peninsula and San Francisco) could not be guaranteed and would need to be reevaluated to determine if the WSIP performance objective could be achieved. Delivery reliability of the regional system would be improved similar to the proposed program; however, this alternative would only partially meet those objectives, since it would not meet the average annual demand of 300 mgd under maintenance or outage conditions but instead meet the reduced target delivery level of 275 mgd. Comprehensive and regular repair and maintenance of the regional system would occur without service interruptions, and the risk of service interruptions due to unplanned facility upsets or outages would be minimal. Facilities would be in place to replenish local reservoirs as needed to prepare for drought, and the system would remain essentially gravity-driven.

The No Purchase Request Increase Alternative would fail to achieve the WSIP's water supply level of service goal during nondrought and drought periods and would not meet the 2030 customer purchase requests of 300 mgd. Under this alternative, the regional system would be capable of serving average annual purchase requests of 275 mgd during nondrought conditions (compared to 265 mgd delivered on average under existing conditions). Deliveries would be limited to an annual average of 275 mgd. Similarly, while this alternative would meet the WSIP objective of limiting drought-year rationing to a maximum of 20 percent systemwide, it would achieve this objective at the reduced demand level of 275 mgd. Unless wholesale customers were to obtain alternative supplies from other sources to supplement the SFPUC deliveries, the combined effect of reduced deliveries from the SFPUC and 20 percent rationing during droughts could effectively require rationing of over 20 percent of total demand during an extended drought sequence. However, the No Purchase Request Increase Alternative would succeed in diversifying the SFPUC water supply portfolio and improve use of new water sources during nondrought and drought periods.

In order to reevaluate levels of service objectives at a target delivery level of 275 mgd, system modeling using the hydrologic, hydraulic and seismic reliability models would need to be performed, and the level of service objectives would need to be revised to become compatible with the lower system delivery target. The distribution of future demands would need to be evaluated in order to determine if the seismic criteria of 70 percent of turnouts and average day demand to the three regional customer groups following a seismic event could be achieved.

If the wholesale customers and/or BAWSCA were to pursue supplemental water sources to compensate for the reduced supply provided by the SFPUC's regional system under this alternative, additional studies would be required to determine both the technical and institutional feasibility of such supplemental sources. The resultant ability of the alternative to meet the WSIP water supply and delivery reliability objectives would then depend in part on the wholesale customer actions and would be outside the control of the SFPUC.

Similarly, the No Purchase Request Increase Alternative would meet the WSIP sustainability objectives, within the bounds of the SFPUC actions, but it would be unknown with respect to the wholesale customer actions. If the wholesale customers were to take independent action from the SFPUC under this alternative, this would result in inefficient use of resources and funds and would not meet the WSIP objective for cost-effectiveness. The capital, operation and maintenance cost of the 22 facility improvement projects would be the same as the WSIP, but additional costs would be incurred from conservation or supply projects implemented by customers in place of the WSIP supply.

Environmental Impacts Compared to those of the WSIP

Facility Construction and Operations Impacts

WSIP Facilities

The No Purchase Increase Alternative assumes that all WSIP facility improvement projects would be implemented to meet the intent of the water quality, seismic reliability, and delivery reliability objectives of the WSIP. Therefore, the identical facility-related impacts described in Chapter 4 would occur under this alternative.

Other Facilities Potentially Implemented Under this Alternative

The ability of the wholesale customers to develop additional water supplies is uncertain and outside the control of the SFPUC. A potential approach for BAWSCA and the wholesale customers to secure supplemental water supplies is described under the No Program Alternative. The types of projects that the wholesale customers might pursue and the potential facility and operations impacts associated with such projects are presented in Table 9-10, above, for consideration by decision-makers and other interested parties.

This alternative could result in construction and operation of extensive additional recycled water, groundwater, and water conveyance facilities in the wholesale customer service areas; thus, collective impacts in the Bay Division and Peninsula Regions and associated cumulative effects (such as traffic, air quality, noise and vibration) would be more severe than those of the WSIP.

Water Supply and System Operations Impacts

Under the No Purchase Request Increase Alternative, the estimated average annual diversions from the Tuolumne River would be 221 mgd, based on HH/LSM modeling of this alternative over the 82-year hydrologic record. This amount is 24 mgd less than the 245 mgd average annual diversions from the Tuolumne River under the WSIP, but 3 mgd more than the 218 mgd average annual diversions under existing conditions, as shown in Table 9-5, above. The slight increase in diversions is due to the small increase in purchase request and the improvement in delivery reliability. The potential impacts on water resources in the Tuolumne River, Alameda Creek, and Peninsula watersheds associated with this level of diversion are described below and compared to the impacts that would occur under the WSIP.

Tuolumne River Watershed

Under the No Purchase Request Increase Alternative, the SFPUC would meet more purchase requests by 2030 than under the existing condition, but less than it would under the WSIP or any of the other alternatives analyzed in Section 9.2. The No Purchase Request Increase Alternative would result in a small reduction (less than 0.5 percent) in average annual releases to the Tuolumne River from Hetch Hetchy Reservoir and some reduction and delay in the spring releases on occasion compared to the existing condition. The reduction and delay in spring releases would occur because storage deficits in a series of dry years would accumulate in Hetch Hetchy Reservoir. The reduction and delay in spring releases would be less than with the WSIP, and a delay of more than two days would occur much less frequently, about once in every 10 years, with the No Purchase Request Increase Alternative than with the WSIP. The delay is still judged to be sufficient to have a significant adverse effect on terrestrial biological resources because of the ecological sensitivity of riverside meadows and their flora and fauna.

The No Purchase Request Increase Alternative would result in a small reduction in average annual releases to the Tuolumne River from La Grange Dam (less than 0.5 percent) and some reduction and delay in the winter/spring releases compared to the existing condition. The delay in winter/spring releases would have an adverse effect on fisheries in the Tuolumne River and on terrestrial biological resources in the riparian corridor, but the impact would be less than significant.

Alameda Creek Watershed

The improvements to Calaveras Dam that would occur with the WSIP would also be part of the No Purchase Request Increase Alternative. Furthermore, under this alternative, the SFPUC would operate its facilities in the Alameda Creek watershed in a similar manner as with the WSIP. Consequently, the environmental impacts of the No Purchase Request Increase Alternative would be similar to those of the WSIP.

Peninsula Watershed

Average annual system delivery to the wholesale customers would increase with the No Purchase Request Increase Alternative compared to the existing conditions, but to a much lesser degree than with the WSIP (10 mgd more rather than 25 mgd). The SFPUC would try to serve the smaller increase in demand in the Coastside CWD service area from Pilarcitos Reservoir, as it would with the WSIP. Drawdown of Pilarcitos Reservoir would occur more rapidly than under the existing condition but less rapidly than with the WSIP under the No Purchase Request Increase Alternative. Stored water releases to Pilarcitos Creek would cease earlier in the summer than under the existing condition but later than with the WSIP. The changes attributable to the No Purchase Request Increase Alternative would adversely affect water quality, fisheries, and terrestrial biological resources in the reservoir and the creek, but the impact would be less than significant.

The improvements to Lower Crystal Springs Dam that would occur with the WSIP would also be part of the No Purchase Request Increase Alternative. As a result of the improvements and associated modifications in system operations, the maximum water level in Crystal Springs Reservoir would rise by about 20 feet. The rise in water level would have significant adverse impacts on terrestrial biological resources, as described in Section 5.5.6. Since the No Purchase Request Increase Alternative would include improvements to Lower Crystal Springs Dam, the SFPUC would generally operate its facilities in the Peninsula watershed in a similar manner as it would with the WSIP. Consequently, the environmental impacts of this alternative would be similar to those of the WSIP.

Growth-Inducement Potential and Secondary Effects of Growth

This alternative, would have less growth-inducement potential than the WSIP, because the SFPUC would only provide additional water to its wholesale customers up to the existing contract amount of 184 mgd (average annual), compared with 209 mgd (average annual) under the WSIP. Under this alternative, the SFPUC would only improve system reliability for existing customers, providing for water delivery in accordance with the existing Master Sales Agreement between the SFPUC and the wholesale customers. As discussed above in the description of this alternative, it is reasonable to assume that the SFPUC wholesale customers would seek to acquire (either separately or together through BAWSCA) supplemental water supplies to meet their projected needs, as represented by the increased purchase requests they submitted to the SFPUC.

As discussed in Chapter 7, growth has occurred in some communities, such as San Francisco, without a corresponding increase in water supply. In the future, the projected population and/or employment growth in some communities are clearly greater than the corresponding projected increase in water supply needs, indicating that water use efficiency is increasing and that additional supply is not necessarily required for growth to occur. It is possible that approval of additional development within the SFPUC's wholesale customer service area might be slowed somewhat in some communities because the wholesale customers would have to pursue other projects and actions to achieve adequate dry-year supplies and reliability, but it is not expected that this would deter communities from taking actions to support planned growth. Thus, the growth-inducement potential under this alternative could be similar to that of the proposed program. The difference is that the WSIP would not support this additional growth, but the growth would occur anyway as a result of SFPUC wholesale customers and/or BAWSCA pursuing substitute supplemental water supplies.

Even assuming that growth potential under this alternative were appreciably reduced within Bay Area communities served by the regional system, it is nonetheless likely that growth pressure would increase elsewhere in the Bay Area, such as eastern Contra Costa County, Solano and Sonoma Counties, and southern Santa Clara County, or beyond to tributary areas in the Central Valley. It is also likely that growth in these outlying areas would have similar types of environmental impacts but of potentially greater magnitude and consequence due to the effects of new development or "sprawl" versus the infill that would occur in the existing Bay Area communities served by the SFPUC's regional system.

9.2.4 Aggressive Conservation/Water Recycling and Local Groundwater Alternative (with and without Tuolumne River Supplement)

The Aggressive Conservation/Water Recycling and Local Groundwater Alternative examines the potential for the SFPUC and the wholesale customers to meet the 2030 service goals for the regional system, including serving the 2030 customer purchase requests of 300 mgd average annual supply through a combination of additional conservation efforts and recycled water and local groundwater projects. Since the WSIP already includes some conservation, water recycling, and local groundwater projects, this alternative would require aggressive efforts in these three areas that go beyond those proposed as part of the WSIP. This alternative represents alternate sources of supply and different target delivery levels for the regional system compared to the WSIP. This alternative is evaluated to address the impacts to the Tuolumne River, Alameda Creek, and the Peninsula watershed, including Pilcarcitos Creek.

Conservation, water recycling, and local groundwater projects are already included in the proposed program in three ways. First, the effects of plumbing codes currently in place in the SFPUC service area (which provide passive conservation savings) are already incorporated into the projected total service area demand. Second, in the development of their 2030 purchase requests, the wholesale customers incorporated their current and anticipated future conservation programs and water recycling projects as well as local groundwater projects. The estimated 2030 purchase requests to the SFPUC reflect the wholesale customers' current assessment of the conservation, groundwater, and water recycling potential in their service areas. In addition, the proposed WSIP water supply option includes a combination of conservation, water recycling, and groundwater use in San Francisco to achieve an additional offset of 10 mgd of potable water demand from the regional system by the year 2030 (under the Groundwater and Recycled Water Projects, SF-2 and SF-3).

It is assumed that the wholesale customers would continue to actively participate in developing additional local and/or regional recycled water/groundwater/conservation projects to reduce the increased demand on surface water supplies during nondrought and drought periods in addition to the groundwater, recycled water, and conservation projects they are already committing to implement locally.

The SFPUC undertook a study, in coordination with its wholesale customers and BAWSCA, to assess the potential for more aggressive conservation coupled with local recycled water and naturally renewable groundwater projects[9] for potential regional development within the SFPUC service area. In preparing the *Investigation of Regional Water Supply Option No. 4 Technical Memorandum*, the SFPUC interviewed representatives of 27 wholesale customers to identify potential recycled water and groundwater projects that were not already considered implemented locally prior to estimating SFPUC regional water system purchases through the year 2030, and that could potentially be implemented regionally to offset SFPUC regional water system deliveries. In all, 53 recycled water and groundwater projects were identified for investigation of the potential to offset demand on the SFPUC regional water system. In addition, regional conservation programs consisting of between 8 and 23 conservation measures were evaluated. The regional conservation measures evaluated for the programs included a subset of the original 32 conservation measures evaluated in the 2004 conservation potential study (all but 8 of the original 32 measures that involved city of county ordinances or would be difficult to implement regionally), as well as four new measures and two revised original measures. The measures were evaluated individually and grouped into three regional programs. These conservation programs and the identified groundwater and recycled water projects were then screened to identify the feasibility and likelihood of implementation for each project/program.

The SFPUC assessed the likelihood of implementation on the basis of the degree to which various milestones in the project development and approval process had been completed by the local sponsoring agency, including: feasibility studies, cost estimate, conceptual engineering, CEQA environmental review, user commitments, community support, plans, and specifications. The projects identified as being eligible for the program (those that could potentially offset SFPUC regional water system deliveries) fell into three categories according to the likelihood of implementation with up to about 11 mgd in Category 1 (likely to be implemented), up to about 15.2 mgd in Category 2 (in early planning stages), and up to about 2.25 mgd in Category 3 (projects considered potentially eligible for future consideration). Due to their higher likelihood of implementation, the SFPUC incorporated the Category 1 San Francisco local projects into the WSIP's proposed water supply option for 10 mgd of additional supply (see Chapter 3, Section 3.6 for a description of these projects). The remaining projects in Categories 1, 2 and 3 have varying

9 Naturally renewable groundwater was defined as groundwater that, when pumped out of the ground, is naturally recharged in such a way that there is minimal or immeasurable effect on the beneficial uses of surface water. Further, this is groundwater that can be withdrawn from the ground at a sustainable rate without requiring imported surface water for recharge and without adversely affecting the local water resource.

degrees of feasibility; because most remain in the early stages of development and evaluation, information about their yield and ability to be implemented in a reasonable timeframe is limited, as well as their ability to ultimately offset SFPUC regional water system deliveries. This is likely the reason the SFPUC customers did not include them in their original SFPUC regional water system purchases estimates.

Table 9-11 lists the identified potential conservation, recycled water, and groundwater projects that could potentially provide for up to 19 mgd of water supply to meet the increasing delivery requests assuming it is determined that they can offset SFPUC regional water system supplies and are implementable. The 19 mgd is an optimistic, high estimate that combines the estimated high-range yield of remaining Category 1 projects as well as both projects in Categories 2 and 3, including some projects only at a conceptual stage. The implementation of the identified projects is uncertain due to numerous unknown factors, including water quality issues, end-users, long-term sustainable yield, production rates, feasibility, institutional arrangements, and permitting. Among many unknown factors, for example, is the degree to which other water agencies that serve some of the same customers as the SFPUC may choose to pursue the same actions and seek to reduce their use of other water supplies. Therefore, while the list of identified projects illustrates that there are opportunities within the service area to develop more conservation, recycled water, and local groundwater, the total yield of these potential projects is unknown. For purposes of analysis, this PEIR evaluates a maximum supply/supply offset of 19 mgd, identified as the high-range of potential yield that might offset SFPUC purchases, might be developed through this alternative over the planning horizon.

This discussion is intended to provide decision-makers and interested parties with information about the potential options that exist, the challenges associated with each, and (as discussed in a subsequent section) attendant environmental impacts. Even assuming that 19 mgd could be developed through these projects, this alternative could meet approximately 75 percent of the additional projected 2030 average annual water supply need. However, at least 6 mgd of the projected average annual 2030 demand would be unmet, and this alternative would also provide less drought supply reliability compared to the WSIP, requiring increased frequency of rationing at 20 percent.

Tuolumne River Supplement

For purposes of the analysis of alternatives, the PEIR considers a second scenario for this alternative in which the SFPUC would provide supplemental Tuolumne River water to fully meet the 2030 customer purchase requests.

In the first scenario, the SFPUC would not divert additional water from the Tuolumne River. SFPUC rationing of its deliveries would increase above the 20 percent objective during a drought. It is expected that the wholesale customers would pursue a supplemental supply, such as a water transfer, to augment this alternative to serve their 2030 purchase requests. Potential effects of pursuing a water transfer are described generally under Section 9.2.2 No Program Alternative, above. In the second scenario, the SFPUC would provide for the full 2030 customer purchase requests of 300 mgd by augmenting the 19 mgd of additional conservation, water recycling, and

TABLE 9-11
REGIONAL RECYCLED WATER, GROUNDWATER, AND CONSERVATION PROJECTS INCLUDED IN THE AGGRESSIVE CONSERVATION/WATER RECYCLING AND LOCAL GROUNDWATER ALTERNATIVE

Location/Jurisdiction	Type of Supply	Description	Low Range Yield (mgd)	High-Range Yield (mgd)
Category 1 – Projects Likely to be Implemented				
City of Daly City	Recycled Water	Expansion of recycled water uses from an existing facility to irrigate an additional park and landscape medians.	-	0.01
North Coast County Water District/San Francisco	Recycled Water	Various irrigation uses for school grounds and highway uses.	0.15	0.58

SOURCE: SFPUC, 2007b.

conservation with additional diversions from the Tuolumne River when available. In many years, alternative could fully meet the 2030 customer purchase requests by diverting the additional required amount from the Tuolumne River under the SFPUC's existing water rights. This would require diversion of some additional water from the Tuolumne River (at least approximately 5 mgd, average annual) compared to the existing condition, but substantially less than proposed under the WSIP (27 mgd, average annual). There would continue to be a shortfall in firm water supply during drought which would lead to more frequent need to ration water deliveries at 20 percent. Alternatively, the SFPUC could develop additional water through a desalination project to serve the remaining 6 mgd of average annual delivery demand (see Section 9.2.6 for a discussion of the year-round desalination supply alternative).

For purposes of the analysis of alternatives, the PEIR considers two possible scenarios for this alternative: one in which the SFPUC would not provide supplemental Tuolumne River water and one in which the SFPUC would provide supplemental Tuolumne River water to fully meet the 2030 customer purchase requests.

Description of SFPUC and Wholesale Customer Actions

SFPUC Actions

Under this alternative, the SFPUC would implement all of the same WSIP facility improvement projects as proposed for the WSIP, although the capacities of some of the facilities might be somewhat reduced since some of the supply would be provided by customers. The design of some of the WSIP facilities would need to reevaluated and sized appropriately to meet the delivery levels and performance objectives under this alternative. In addition, the SFPUC would proceed with implementation of other capital improvement projects and related activities not considered part of the program analyzed in this PEIR (as described in Chapter 3, Sections 3.13 and 3.4.6). The SFPUC would also implement the same system maintenance program and similar operational changes in the regional system as those proposed under the WSIP.

The SFPUC's role in helping its customers develop more aggressive conservation, recycled water, and local groundwater programs under this alternative could range from one of coordination and facilitation, to funding support, to full partnership with one or more customer in the design, construction, and/or operation of regional projects. The SFPUC's role in such projects would need to be defined on a case-by-case basis.

As discussed above, the maximum potential SFPUC regional water system delivery offset identified in the study is about 19 mgd (not including the 10 mgd of San Francisco local projects in the WSIP proposed program). The ability for the SFPUC and its customers to achieve this 19 mgd of yield by the year 2030 is highly uncertain, particularly the Category 3 project portion (2.25 mgd), for which the offset potential has not been determined even if the projects move forward. Assuming the 19 mgd is realized, this alternative still does not fully offset the regional water system increase of 25 mgd average annual supply needed to meet the 2030 purchase requests. In this case, the SFPUC could consider augmenting this alternative by providing an incremental increase in Tuolumne River supply to make up the potential delivery shortfall in years when water is available under their existing water rights. This would involve increasing the average annual Tuolumne River diversion by at least approximately 5 mgd over the existing average annual diversion. Alternatively, the SFPUC could provide a different supplemental source, such as potable water from a new desalination plant (described in Section 9.2.6).

This alternative includes the SFPUC implementing projects in San Francisco to achieve a 10-mgd offset on regional system demand through a combination of conservation, recycled water, and groundwater projects, as in the WSIP proposed program. However, without some additional Tuolumne River diversion there would be no supplemental dry-year water supply sources from water transfers or from the Westside Basin conjunctive-use program which would lead to delivery shortfalls during drought.

Wholesale Customer Actions

For this alternative, it is assumed that the wholesale customers would actively participate in developing additional recycled water/groundwater/conservation projects in their local service areas to reduce the increased regional demand on surface water supplies during nondrought and drought periods in addition to the groundwater, recycled water, and conservation projects they are already committing to implement locally. As indicated in Table 9-11, under this alternative, various wholesale customers, in partnership with the SFPUC and/or BAWSCA, would develop a variety of programs to increase local groundwater extraction and recycled water through more aggressive conservation efforts to offset 19 mgd of increased water demand on the SFPUC regional water system. It is also assumed that the wholesale customers, in coordination with the

SFPUC, would implements these actions in a timely manner so that the water supply/offset would be available as the estimated customer increase in purchase requests are realized.

If the SFPUC does not supplement this alternative with additional Tuolumne River water in order to fully meet the 2030 customer purchase requests, it is expected that the wholesale customers would pursue additional supplemental supply, such as a water transfer.

Feasibility Issues

The Aggressive Conservation/Water Recycling and Local Groundwater Alternatives, (with and without supplemental Tuolumne River supply), would have numerous technical, institutional, financial, and public acceptance issues to overcome prior to implementation. As described above, the estimated 19 mgd from regional conservation/water recycling and local groundwater projects represents an optimistic, high-end estimate based on very preliminary studies. There are numerous uncertainties with regard to water quality issues, end-users, long-term sustainable yield, and production rates; furthermore, in some communities, there remain public acceptance issues with regard to use of recycled water for non-potable uses. Institutional arrangements, funding sources, and permitting requirements for these programs are also unknown. Furthermore, even if these obstacles were overcome, this alternative would have questionable feasibility to require customers 20 percent rationing during drought periods due to demand hardening. It is unlikely that the SFPUC's regional system customers would support this alternative. In addition, this alternative would add substantial cost to overall program as a result of having to implement additional regional conservation/water recycling and local groundwater projects in addition to the costs of the 22 facility improvement projects included in the WSIP. This unknown but substantial additional cost raises questions about cost and financing feasibility and customer rate impacts.

Ability to Meet Program Objectives

The Aggressive Conservation/Water Recycling and Local Groundwater Alternative would meet the WSIP objectives for water quality only for the SFPUC actions; however, the objective could not be guaranteed for new sources provided by customers, nor if new sources are wheeled through the SFPUC's system, unless developed in cooperation with the SFPUC. As shown in Table 9-6, seismic reliability would be improved over existing conditions since all WSIP facility improvement projects would be implemented, but this alternative cannot meet the objective of providing basic service to all regions following a major earthquake with certainty, even with supplemental Tuolumne River water, since the reliability of new sources to be developed by customers is unknown. In addition, there is no certainty about where the distribution of the new sources would occur, so the seismic objectives of serving 70 percent of turnouts and meet basic service in the three customer regions (South Bay, Peninsula and City) could not be guaranteed. However, with implementation of all WSIP facility improvement projects, it is likely that facilities would be restored within 30 days of a major earthquake and the SFPUC could at least partially meet the average day demand.

Based on input from the wholesale customers throughout the SFPUC service area, aggressive conservation, recycled water, and local groundwater projects could partially but not fully meet the

WSIP delivery reliability and water supply performance objectives. Under this alternative, it might be possible to provide for much of (estimated up to approximately 19 mgd but with unknown certainty) but not all of the projected 25 mgd increase in customer purchase requests by 2030. To fully meet the 2030 purchase requests, a supplemental supply of at least 6 mgd would need to be provided to augment this alternative; otherwise, the SFPUC would not be able to fully serve the 2030 customer purchase requests. Even with the Tuolumne River water, the delivery reliability objectives could not be guaranteed due to the lack of SFPUC control over and the uncertainty of the wholesale customers' new sources of supply. Implementation of all the facility improvement projects would permit operational flexibility under planned maintenance conditions, when customer demands are low, but there is uncertainty over the reliability and availability of the full 19 mgd of regional recycled water /groundwater / conservation programs to provide sufficient operational flexibility when needed to replenish local reservoirs or during unplanned facility outages.

In addition, this alternative would provide less dry-year/drought supply reliability than the WSIP and would not meet the WSIP objective for system firm yield. As shown on Table 9-5, customers would experience rationing under this alternative of up to 20 percent (for the Tuolumne River supplemental supply scenario) or 25 percent (for the no supplemental supply scenario) with notably greater frequency than would customers under the WSIP. Furthermore, this degree of rationing would have different implications for customers under the Aggressive Conservation/Water Recycling and Local Groundwater Alternative compared to the WSIP. Demand hardening[10] refers to the increasing difficulty and expense of achieving short-term water conservation levels during shortages as more long-term conservation measures are implemented and water-use efficiency is maximized and is a concern among water conservation agencies regarding aggressive conservation programs. As a result of the water use efficiency or demand "hardening" that would be further institutionalized through this alternative, customers would have limited options for accommodating a period requiring 20 percent or more rationing in terms of what water uses they could cut back. Customers would have already increased their water use efficiency and eliminated less efficient uses such as many types of conventional outdoor use (e.g., landscape irrigation, car washing). In these cases, the water use cutbacks required to achieve 20 percent or more rationing would involve reductions in more essential water uses, such as indoor uses for cleaning and bathing, which could cause greater hardship on customers. This alternative would only partially meet the objective of diversifying water supply, since it does not provide for any dry year water sources.

This objective would meet the WSIP sustainability objectives, within the bounds of the SFPUC actions, but it would be unknown with respect to the wholesale customer actions. If the wholesale customers were to take independent action from the SFPUC under this alternative, this would

[10] As described by the California Department of Water Resources, demand hardening "occurs when agencies implement water conservation programs that result in permanent reductions in water use, such as retrofitting plumbing fixtures or installing low-water-use landscaping. These measures lessen agencies' ability to implement rationing to reduce water use during droughts, and can result in greater impacts to urban water users (e.g., loss of residential landscaping) when rationing is imposed. For example, the extensive Los Angeles retrofit program helped the city maintain reductions in urban per capita water use it achieved during the last drought. These permanent water use reductions will make it more difficult for the city to duplicate its previous 15 percent water use reduction goal during a future drought" (Department of Water Resources, 2005).

result in inefficient use of resources and funds and would not meet the WSIP objective for cost-effectiveness. While the system would remain largely gravity-driven, implementation of additional water recycling and groundwater projects would increase the pumping requirements of the overall system. The capital, operation and maintenance cost of the 22 facility improvement projects would be the same as the WSIP, but unknown and likely substantial additional costs would be incurred from conservation or supply projects implemented by customers in place of the WSIP supply.

Environmental Impacts Compared to those of the WSIP

Facility Construction and Operations Impacts

WSIP Facilities

The Aggressive Conservation/Water Recycling and Local Groundwater Alternative assumes that the same 22 facility improvement projects proposed under the WSIP would be implemented to meet the water quality, seismic reliability, and delivery reliability objectives of the WSIP; therefore, all of the impacts described in Chapter 4 would also occur under this alternative. Although the capacities of some of the proposed facilities, such as those under the SJPL System (SJ-3) and BDPL Reliability Upgrade (BD-1) projects, might be reduced compared to the WSIP, the impacts of constructing and operating these projects would be largely the same under this alternative as with the WSIP. This alternative relies on 19 mgd supply from the wholesale customers. However, as described below, this alternative could result in construction and operation of extensive additional recycled water and groundwater facilities in the wholesale customer service areas; thus, collective impacts in the Bay Division and Peninsula Regions and associated cumulative effects (such as traffic, air quality, noise, energy use, waste disposal, and vibration) would be more severe than those of the WSIP.

If the SFPUC were to supplement this alternative with additional Tuolumne River supply, no additional facilities beyond the proposed WSIP facilities and new customer facilities would be needed, except for recycling facilities or a possible desalination plant, as detailed in the next section. If the SFPUC were to supplement this alternative with a desalinated water supply, it would have to construct and operate a new desalination plant and conveyance facilities to connect to the regional system (see Section 9.2.6 for the discussion of a desalination alternative).

Other Facilities Potentially Implemented Under this Alternative

No significant environmental impacts would be expected from implementation of water conservation measures. However, implementation of the recycled water and groundwater projects listed in Table 9-11 would result in a full range of construction and operational impacts, similar to those described in Chapter 4 for the WSIP facilities, in the South Bay and Peninsula areas. The types of impacts associated with implementation of the local recycled water and groundwater projects are summarized in **Table 9-12** and generally relate to construction of new infrastructure, water quality, and groundwater resources and operational uses of energy and long-term air quality emissions.

TABLE 9-12
SUMMARY OF POTENTIAL IMPACTS AND MITIGATION STRATEGIES FOR RECYCLED WATER AND GROUNDWATER PROJECTS

Potential Impact	Mitigation Strategy
Groundwater Resources. Potential for increased groundwater pumping, groundwater level reductions, and overdraft if there is insufficient sustainable yield to accommodate increased pumping.	Determine sustainable yield of the basin, implement monitoring program, regulate groundwater pumping to preserve safe yield.
Surface Water, Groundwater Quality, and Public Health Issues. Recycled water applied to the irrigated lands would infiltrate through the subsurface levels, potentially affecting surface and groundwater quality. Groundwater may have contaminants with potential health effects. Groundwater lowers the aesthetic quality of the water through increased hardness, and potential for tastes and odors.	Comply with Title 22 Water Recycling Criteria. Groundwater may require disinfection, treatment and/or blending.
Energy use. Operation of both recycled water and groundwater projects would require increased energy use for treatment and distribution, and pumping. Increased energy production to support these activities along with plant operation would, in turn, generate additional air pollutant emissions, including greenhouse gases emissions.	Energy efficiency measures.
Treatment. Temporary construction impacts (disturbance of soils, surface water quality, biological resources, cultural resources, air quality, traffic, noise, land use, hazardous materials). Potential long-term impacts could include odor, depending on treatment processes and location relative to sensitive receptors. Plant operations could also generate long-term noise, traffic, and visual impacts depending on facility site location(s)and increased energy consumption and air pollutant emissions. **Pumping.** (groundwater pumping station)	Most impacts associated with facility construction could be mitigated to a less-than-significant level with the types of measures identified in Chapter 6. As is the case with the proposed WSIP facilities, odor control features (scrubbers) could reduce any odor impacts to a less-than-significant level.
Conveyance. Mostly temporary impacts from construction of pipelines, valves, and pumps (disturbance of soils, surface water quality, biological resources, cultural resources, air quality, traffic, noise, land use, hazardous materials, aesthetics).	Most impacts associated with facility construction could be mitigated to a less-than-significant level with the types of measures identified in Chapter 6. As is the case with the proposed WSIP facilities, some impacts (e.g., short-term noise and traffic) could be unavoidable.
Storage. Temporary construction impacts (disturbance of soils, surface water quality, biological resources, cultural resources, air quality, traffic, noise, land use, hazardous materials) and potential long-term impacts based on site-specific characteristics (e.g., slope stability, location within a scenic viewshed).	Most impacts associated with facility construction could be mitigated to a less-than-significant level with the types of measures identified in Chapter 6. As is the case with the proposed WSIP facilities, some impacts (e.g., short-term noise and traffic) could be unavoidable. Prepare and implement recommendations from a geotechnical study, implement measures to reduce visual contrast with surroundings (e.g., backfilling, earth-tone paint).

If the wholesale customers were to supplement this alternative with additional water through a water purchase, additional storage and/or limited conveyance facilities might be required. See the discussion of this topic under the No Program Alternative.

Water Supply and System Operations Impacts

This discussion addresses both alternative scenarios—the scenario in which the SFPUC would not supplement this alternative with additional supplies (could be anything), and the scenario in which the SFPUC would supplement this alternative with additional Tuolumne River diversions.

Aggressive Conservation/Water Recycling and Local Groundwater Alternative with No Supplemental Tuolumne River Water

Tuolumne River Watershed. Water demand would increase under the Aggressive Conservation/Water Recycling and Local Groundwater Alternative, but for this analysis, it is assumed that none of it would be met with water from the Tuolumne River. There would be no change in average annual releases to the Tuolumne River from Hetch Hetchy Reservoir with the Aggressive Conservation/Water Recycling and Local Groundwater Alternative compared to the existing condition. There may be changes in the pattern of releases from Hetch Hetchy Reservoir because of the improvements to conveyance facilities and improved maintenance practices. These changes could lead to year to year differences in the amount of water diverted from the Tuolumne River. There would be changes in the pattern of spring releases from Hetch Hetchy Reservoir, but these changes would be expected to have less severe impacts than the WSIP. However, the delay would still be enough to have a potentially significant adverse effect on terrestrial biological resources because of the ecological sensitivity of riverside meadows and their flora and fauna.

Similarly, the Aggressive Conservation/Water Recycling and Local Groundwater Alternative would result in no change in average annual releases to the Tuolumne River from La Grange Dam. The net effect of the small increases and decreases in the initial winter/spring releases would have a less-than- significant effect on fisheries in the Tuolumne River and the terrestrial biological resources in the riparian corridor.

Alameda Creek Watershed. The improvements to Calaveras Dam that would occur with the WSIP would also be part of the Aggressive Conservation/Water Recycling and Local Groundwater Alternative. Furthermore, under this alternative, the SFPUC would operate its facilities in the Alameda Creek watershed in a similar manner as the WSIP. Consequently, the environmental impacts of the Aggressive Conservation/Water Recycling and Local Groundwater Alternative would be similar to those of the WSIP.

Peninsula Watershed. Water demand would increase with the Aggressive Conservation/Water Recycling and Local Groundwater Alternative, as it would with the WSIP. The SFPUC would try to serve increased demand in the Coastside CWD service area from Pilarcitos Creek, exactly as it would with the WSIP. The consequent, more rapid drawdown of Pilarcitos Reservoir and the earlier cessation of stored water releases to Pilarcitos Creek would have a significant adverse effect on water quality, fisheries, and terrestrial biological resources in the reservoir and the creek.

The improvements to Lower Crystal Springs Dam that would occur with the WSIP would also be part of the Aggressive Conservation/Water Recycling and Local Groundwater Alternative. As a result of the improvements and associated modifications in system operations, the maximum water level in Crystal Springs Reservoir would rise by about 20 feet. The rise in water level would have significant adverse impacts on terrestrial biological resources, as described in Section 5.5.6. Since this alternative would include improvements to Lower Crystal Springs Dam, the SFPUC would generally operate its facilities in the Peninsula watershed in a similar manner as with the WSIP. Consequently, the environmental impacts of this alternative would be similar to those of the WSIP.

Aggressive Conservation/Water Recycling and Local Groundwater Alternative with Supplemental Tuolumne River Water

Tuolumne River Watershed. Water demand would increase under the Aggressive Conservation/Water Recycling and Local Groundwater Alternative, but a greater portion of the increase would be met by conservation, recycling, and groundwater than under the WSIP. This alternative would result in a small reduction in average annual releases to the Tuolumne River from Hetch Hetchy Reservoir (less than 1 percent) and some reduction and delay in the spring releases on occasion as compared to the existing condition. The reduction and delay in spring releases would occur because storage deficits in a series of dry years would accumulate in Hetch Hetchy Reservoir. The reduction and delay in spring releases would be less than with the WSIP, and a delay of more than two days would occur much less frequently, about once in every 10 years, with the Aggressive Conservation/Water Recycling and Local Groundwater Alternative than with the WSIP. The delay would still be enough to have a significant adverse effect on terrestrial biological resources because of the ecological sensitivity of riverside meadows and their flora and fauna.

The Aggressive Conservation/Water Recycling and Local Groundwater Alternative would result in a small reduction in average annual releases to the Tuolumne River from La Grange Dam (less than 1 percent) and some reduction and delay in the winter/spring releases as compared to the existing condition. The reduction and delay in winter/spring releases would have an adverse effect on fisheries in the lower Tuolumne River and on terrestrial biological resources in the riparian corridor, but the impact would be less than significant.

Alameda Creek Watershed. The improvements to Calaveras Dam that would occur with the WSIP would also be part of the Aggressive Conservation/Water Recycling and Local Groundwater Alternative. Furthermore, under this alternative, the SFPUC would operate its facilities in the Alameda Creek watershed in a similar manner as with the WSIP. Consequently, the environmental impacts of the Aggressive Conservation/Water Recycling and Local Groundwater Alternative would be similar to those of the WSIP.

Peninsula Watershed. Water demand would increase with the Aggressive Conservation/Water Recycling and Local Groundwater Alternative, as it would with the WSIP. The SFPUC would try to serve increased demand in the Coastside CWD service area from Pilarcitos Creek, exactly as it would with the WSIP. The consequent, more rapid drawdown of Pilarcitos Reservoir and the earlier cessation of stored water releases to Pilarcitos Creek would have a significant adverse effect on water quality, fisheries, and terrestrial biological resources in the reservoir and the creek.

The improvements to Lower Crystal Springs Dam that would occur with the WSIP would also be part of the Aggressive Conservation/Water Recycling and Local Groundwater Alternative. As a result of the improvements and associated modifications in system operations, the maximum water level in Crystal Springs Reservoir would rise by about 20 feet. The rise in water level would have significant adverse impacts on terrestrial biological resources. Since this alternative would include improvements to Lower Crystal Springs Dam, the SFPUC would generally operate its facilities in the Peninsula watershed in a similar manner as with the WSIP. Consequently, the environmental impacts of this alternative would be similar to those of the WSIP.

Growth-Inducement Potential and Secondary Effects of Growth

The growth-inducement potential for the Aggressive Conservation/Water Recycling and Local Groundwater Alternative would be similar to that described above for the No Program Alternative. As discussed above under Ability to Meet Program Objectives, this alternative would meet the 2030 purchase request increase but would not provide the same level of supply reliability as the proposed program. As a result, it is expected that SFPUC wholesale customers and/or BAWSCA would pursue other projects and actions to provide the desired level of reliability. While the need to develop additional projects beyond the WSIP might have some slowing effect on development approvals in some communities, it is not expected to impede growth from continuing in accordance with adopted plans. As a result, this alternative would have similar secondary effects of growth as those described for the proposed program.

9.2.5 Lower Tuolumne River Diversion Alternative

Under the Lower Tuolumne River Diversion Alternative, the SFPUC would implement all of the proposed facility improvement projects and would serve the projected increase in customer purchase requests through 2030 through diversions from the lower Tuolumne River, in accordance with an agreement with TID and MID, and construction of conveyance and treatment facilities to blend the new supply into the regional system. This alternative is based on an alternative developed by the SFPUC planning studies conducted for the WSIP water supply option (SFPUC, 2007b). Compared to the WSIP, this alternative represents an alternative source of supply and is evaluated to address impacts to the Tuolumne River.

Description of SFPUC and Wholesale Customer Actions

SFPUC Actions

Table 9-4 summarizes the main characteristics of the Lower Tuolumne River Diversion Alternative in comparison to those of the proposed program. Under this alternative, the SFPUC would rely on the same water supply sources as it would under the WSIP during both drought and nondrought periods. The increase in purchase requests would be served through the restored capacity of Calaveras and Crystal Springs Reservoirs, increased diversions from the Tuolumne River, and an equivalent of 10 mgd of supply from recycled water, groundwater, and conservation projects in San Francisco. Unlike the proposed program, however, the SFPUC would secure the increased diversions from the Tuolumne River at a downstream location near the confluence with the San Joaquin River. To meet the increase in purchase requests under this alternative, the SFPUC would release about 25 mgd (average annual) water from Hetch Hetchy Reservoir, allow it to flow to Don Pedro Reservoir, and release it from the New Don Pedro Dam to the lower Tuolumne River, in accordance with an agreement with TID/MID. A new SFPUC diversion facility located near the confluence of the San Joaquin and Tuolumne Rivers would recover the 25 mgd. From the diversion point, the recovered water would be pumped to a new treatment plant near Tesla Portal where it would be filtered and disinfected prior to blending with unfiltered Hetch Hetchy water. The lower Tuolumne River water would require treatment prior to blending into the Coast Range Tunnel because it would not meet the federal or state filtration exemption requirements. A conceptual schematic of this diversion is shown in **Figure 9.1**.

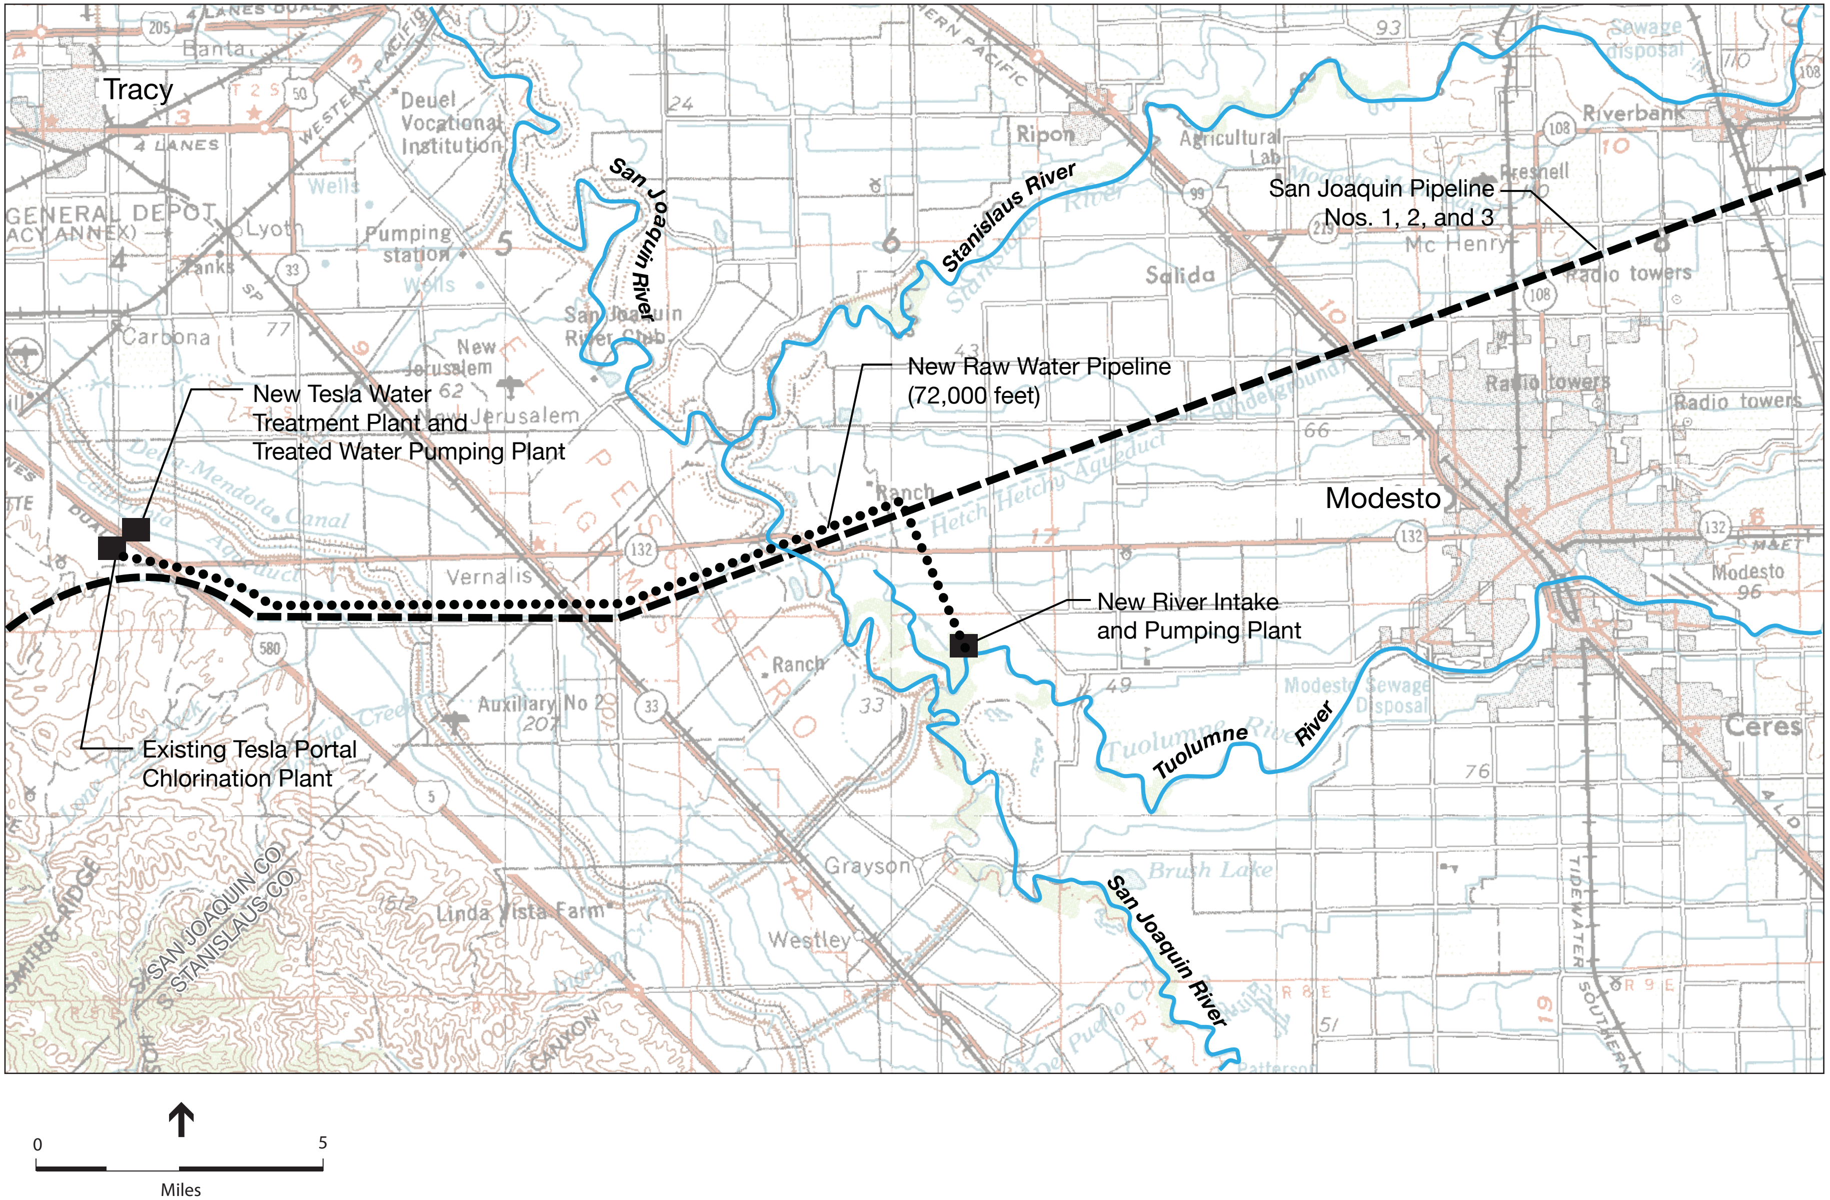
The Lower Tuolumne River Diversion Alternative assumes that all 22 WSIP facility improvement projects would be implemented. However, the design of some of the WSIP facilities would need to reevaluated and sized appropriately to meet the delivery levels and performance objectives under this alternative. In addition, the SFPUC would proceed with implementation of other capital improvement projects and related activities not considered part of the program analyzed in this PEIR (as described in Chapter 3, Sections 3.13 and 3.4.6). The SFPUC would also implement the same system maintenance program and similar operational changes in the regional system as those proposed under the WSIP with the addition of operation and maintenance of the additional facilities described below.

This alternative would require that the SFPUC construct and operate additional facilities not included under the WSIP, as summarized below:

- *Lower Tuolumne River Intake and Pumping Plant*. A new lower Tuolumne River intake and pumping plant would divert the 25 mgd (average annual) and lift the water to a new treatment plant near Tesla Portal. Depending on the suitability of the gravel bed, it is possible that the intake structure would be similar to that of the TID Infiltration Gallery Project, which consists of an array of perforated pipes installed in the lower Tuolumne River bed. If this design is not appropriate, the intake structure would be equipped with a fish screen designed to meet state and federal fish screen criteria. Two sites for the lower Tuolumne River intake and pumping plant have been considered at locations where the flood levels are not in place or already compromised. The facility would be sized appropriately (e.g., 55 mgd) to provide for seasonal diversions.

- *15-Mile Pipeline*. Diverted lower Tuolumne River flows would be pumped to the new treatment plant via a 15-mile, 48-inch-diameter welded steel pipe, the majority of which would run parallel to the existing San Joaquin Pipelines.

- *Lower Tuolumne Water Treatment Plant*. The Lower Tuolumne WTP would filter and disinfect the lower Tuolumne River water. The WTP would be located just north of Tesla Portal within the SFPUC property boundary and have a sustainable capacity of 55 mgd.



SOURCE: ESA+Orion, 2006

SFPUC Water System Improvement Program . 203287

Figure 9.1
Lower Tuolumne River Diversion Alternative Facilities and Pipeline Alignment

- *Tesla Treated Water Pumping Plant*. The pumping plant would pump treated lower Tuolumne River water to Tesla Portal, where it would be combined with Hetch Hetchy water via a new vertical shaft to the Coast Range Tunnel. However, if the Advanced Disinfection project (SJ-1) is sited at Tesla Portal, a blending structure could be added to the new facility, and a new vertical shaft to the Coast Range Tunnel would not be required.

Wholesale Customer Actions

Like the proposed program, the Lower Tuolumne River Diversion Alternative would fully meet the WSIP delivery reliability and water supply level of service goals. Therefore, the SFPUC would serve the projected 2030 purchase requests for all customers, and wholesale customers would not be required to implement any additional conservation and/or recycled water projects or develop supplemental water supplies from other sources beyond what is identified in their respective urban water management plans.

Feasibility Issues

The Lower Tuolumne Diversion Alternative would pose a number of technical and institutional challenges and there is uncertainty regarding the availability of water at this location. The availability of water on the lower Tuolumne River to the SFPUC would be dependent upon: (1) agreements with TID and MID for making the necessary releases from Don Pedro Reservoir, (2) approval by the State Water Resources Control Board for a change in the point of diversion and possibly additional appropriation license to recover this water, (3) and regulatory constraints under the state and federal Endangered Species Act. Construction of the intake in the lower Tuolumne River and crossing the San Joaquin River could affect critical habitat for steelhead and Chinook salmon. There could also be water quality issues with the new source, depending on the location of the intake and the design of the treatment facility, and the overall quality of the regional system water would be reduced with the addition of treated water from the lower Tuolumne River. This alternative would likely arouse public opposition result in the San Joaquin Valley due to substantial construction and operational impacts, outside of the SFPUC service area. In addition, this alternative would add substantial cost to overall program as a result of having to build and operate a new intake, treatment plant, and transmission pipelines in addition to the costs of the 22 facility improvement projects included in the WSIP. This substantial additional cost raises questions about cost and financing feasibility and customer rate impacts.

Ability to Meet Program Objectives

Table 9-6 shows how the Lower Tuolumne River Diversion Alternative would perform in terms of meeting the WSIP level of service goals and performance objectives compared to the proposed program. This alternative is dependent on agreements with TID/MID to make the requisite water releases from New Don Pedro Dam; State Water Resources Control Board appropriation licenses, if applicable; and regulatory constraints under the California and Federal Endangered Species Acts. Thus, water from the Tuolumne River is reliable but not necessarily available under this scenario.

The Lower Tuolumne River Diversion Alternative would only partially meet the level of service goal related to water quality, since it would require full treatment prior to blending with other Hetch Hetchy supplies. Although both the WSIP and this alternative would meet all applicable water quality requirements, there would be a deterioration in water quality, including potentially more contaminants in the water, and reduced aesthetic quality (tastes and odor, hardness) under the Lower Tuolumne River Diversion Alternative compared to the WSIP.

The Lower Tuolumne River Diversion Alternative would include implementation of the 22 facility improvement projects as proposed under the WSIP needed to meet the seismic and delivery reliability level of service goals. However, due to the unknown availability of the lower Tuolumne River as a year-round source, there is uncertainty of the capability of this alternative to provide adequate delivery to all regions following a major earthquake or to serve average day demand during an unplanned facility outage. Similarly, while the facilities could be restored within 30 days after a major earthquake, this alternative could partially restore service to the customer but the availability of the full average day demand of 300 mgd would depend on the lower Tuolumne River diversion. With implementation of all the facility improvement projects, the system would have increased operational flexibility for planned maintenance, but the extensive increase in facility requirements under this alternative would add additional constraints to systemwide operational flexibility. Comprehensive and regular repair and maintenance of the regional water system would generally occur without interruption, and the risk of service interruptions due to unplanned facility upsets or outages would be minimal, assuming availability of water from the lower Tuolumne River diversion location.

With respect to water supply reliability, the Lower Tuolumne River Diversion Alternative would increase system firm yield to 256 mgd, thus meeting the level of service goals for water supply during drought and nondrought periods. This assumes that diversions from the lower Tuolumne River are feasible during all water years and all seasons, as proposed under this scenario, and that the water transfer from TID/MID could be implemented.

It is uncertain if the Lower Tuolumne River Diversion Alternative would meet the WSIP sustainability objectives, since there are numerous regulatory and permitting issues to be resolved, including effects on steelhead and Chinook salmon, and would require significant increase in long-term energy use compared to the proposed program. While the system would remain largely gravity-driven, the new source of water under this alternative would increase the pumping requirements of the overall system. This alternative would result in inefficient use of resources and funds compared to the WSIP, and would not meet the WSIP objective for cost-effectiveness. The capital, operation and maintenance cost of the 22 facility improvement projects would be the same as the WSIP, but substantial additional capital, operation and maintenance costs would be incurred from the diversion, pumping, conveyance and treatment facilities needed for this alternative.

Environmental Impacts Compared to those of the WSIP

Facility Construction and Operations Impacts

WSIP Facilities

The Lower Tuolumne River Diversion Alternative would include implementation of all 22 WSIP facility improvement projects. Although implementation of the SJPL System project (SF-3) would be slightly different than under the WSIP, the impacts associated with this project would be about the same under both scenarios. Thus, the environmental impacts of constructing and operating each of the 22 WSIP facility projects would be about the same as those described in Chapter 4 for the proposed program. However, as discussed below, this alternative would require the construction and operation of extensive additional facilities in the San Joaquin Valley; thus, collective impacts in the San Joaquin Region and associated cumulative effects (such as traffic, air quality, noise, and vibration) would be more severe than those of the WSIP, depending on the construction schedule for these facilities.

Other Facilities and Actions Potentially Implemented Under this Alternative

In addition to the impacts related to construction and operation of the 22 WSIP facility improvement projects, implementation of the Lower Tuolumne River Diversion Alternative would also result in substantial additional impacts related to the construction and operation of additional facilities, including an intake structure and pumping plant, a new 55-mgd water treatment plant, a 15-mile pipeline to convey diverted flows from the point of diversion to the water treatment plant, and a new Tesla treated water pumping plant to transmit the treated water to Tesla Portal. These facilities would result in the full range of impacts at the proposed facility locations as those described in Chapter 4 for the WSIP facilities and would increase the construction and operational impacts in the San Joaquin Region. Impacts of these facilities would be similar to and in addition to those identified for the WSIP; construction and operational impacts would include effects on biological resources (described below), water quality, air quality, noise, traffic, visual, and recreation.

A primary concern with respect to these additional facilities is the potential for adverse effects on biological resources. Construction activities could affect wetlands and riparian habitat, alkali grasslands, valley oak woodland, agricultural areas, and grassland/ruderal habitat as well as special-status animal and plant species such as Swainson's hawk, vernal pool invertebrates, California tiger salamander, burrowing owl, Valley elderberry longhorn beetle, San Joaquin kit fox, California red-legged frog, and Delta button-celery. Construction of the intake structure at the Tuolumne River and across the San Joaquin River could adversely affect fishery resources, including Central Valley fall- and late-fall-run Chinook salmon and Central Valley steelhead.

The key operational issues associated with the Lower Tuolumne River Diversion Alternative would center around the effects of withdrawals on the Tuolumne River. Operation of the intake could result in the entrainment or impingement of species of concern (Central Valley steelhead and Chinook salmon). If an intake structure similar to that of the TID Infiltration Gallery Project were found to be inappropriate, the intake would be designed with state-of-the art fish screens. In addition, implementation of this alternative could potentially cause changes in hydrologic conditions along the lower Tuolumne River. Future evaluations would be required to assess hydrologic regime impacts. When compared to the proposed program, the Lower Tuolumne River Diversion Alternative would result in increased annual energy demand related to the operation of new pumping and treatment facilities, which in turn could result in secondary air quality and greenhouse gas emission, depending on the source of power.

Water Supply and System Operations

Under the Lower Tuolumne River Diversion Alternative, the total average annual diversions from the Tuolumne River would be essentially the same as with the WSIP, based on HH/LSM modeling over the 82-year hydrologic record, as shown in Table 9-5. However, due to the change in the point of diversion, system operations would be modified under this alternative compared to the WSIP. The potential impacts on water resources in the Tuolumne River, Alameda Creek, and Peninsula watersheds associated with this modified operation are described below and compared to the impacts that would occur under the WSIP.

Tuolumne River Watershed

Water demand would increase under the Lower Tuolumne River Diversion Alternative, as it would with the WSIP. The increased demand would be met, as it would be with the WSIP, by a combination of conservation, recycling, and groundwater storage and water from the Tuolumne River. However, with the Lower Tuolumne River Diversion Alternative, most of the increased diversion from the Tuolumne River would occur at a point just upstream of the Tuolumne River's confluence with the San Joaquin River, rather than at Hetch Hetchy Reservoir. This alternative would result in an increase in average annual releases to the Tuolumne River from Hetch Hetchy Reservoir of about 5 percent compared to the existing condition. Most of the time, releases to the river would be increased compared to the existing condition with the Lower Tuolumne River Diversion Alternative. Under the existing condition, the minimum required release would be made from Hetch Hetchy Reservoir 84.2 percent of the time (837 months in the 987-month hydrologic record). With the Lower Tuolumne River Diversion Alternative, the minimum required release would be made in many fewer months. The minimum releases would be supplemented by water released from Hetch Hetchy Reservoir for subsequent diversion near the Tuolumne River's confluence with the San Joaquin River in about half of the months in the 82-year hydrologic record. The increase in flow in the river between O'Shaughnessy Dam and Don Pedro Reservoir would benefit resident fish, riparian vegetation, fauna of the riparian corridor and whitewater recreation.

The Lower Tuolumne River Diversion Alternative would increase the average annual releases of water to the Tuolumne River below La Grange Dam, but would reduce and delay winter/spring releases by essentially the same amount as the WSIP. Under the existing condition, the minimum required release would be made from La Grange Dam 72.6 percent of the time (717 months in the 987-month hydrologic record). With the Lower Tuolumne River Diversion Alternative, the minimum required release would be made in fewer months. The minimum releases would be supplemented by water released from La Grange Dam for subsequent diversion near the

Tuolumne River's confluence with the San Joaquin River in many months. The increase in flow in the river between La Grange Dam and the San Joaquin River confluence would benefit resident and migratory fish, riparian vegetation, fauna of the riparian corridor and recreation. As with the WSIP, the reduction and delay in winter/spring releases would have a significant adverse effect on fisheries in the Tuolumne River and terrestrial resources in the riparian corridor.

Alameda Creek Watershed

The improvements to Calaveras Dam that would occur under the WSIP would also be part of the Lower Tuolumne River Diversion Alternative. Furthermore, under this alternative, the SFPUC would operate its facilities in the Alameda Creek watershed in a similar manner as with the WSIP. Consequently, the environmental impacts of the Lower Tuolumne River Diversion Alternative would be similar to those of the WSIP.

Peninsula Watershed

Water demand would increase with the Lower Tuolumne River Diversion Alternative, as it would with the WSIP. The SFPUC would try to serve increased demand in the Coastside CWD service area from Pilarcitos Creek, exactly as it would with the WSIP. The consequent, more rapid drawdown of Pilarcitos Reservoir and the earlier cessation of stored water releases to Pilarcitos Creek would have a significant adverse effect on water quality, fisheries, and terrestrial biological resources in the reservoir and the creek.

The improvements to Lower Crystal Springs Dam that would occur under the WSIP would also be part of the Lower Tuolumne River Diversion Alternative. As a result of the improvements and associated system operations, the maximum water level in Crystal Springs Reservoir would rise by about 20 feet. The rise in water level would have significant adverse impacts on terrestrial biological resources, as described in Section 5.5.6. Since this alternative would include improvements to Lower Crystal Springs Dam, the SFPUC would generally operate its facilities in the Peninsula watershed in a similar manner as with the WSIP. Consequently, the environmental impacts of the Lower Tuolumne River Diversion Alternative in the Peninsula watershed would be similar to those of the WSIP.

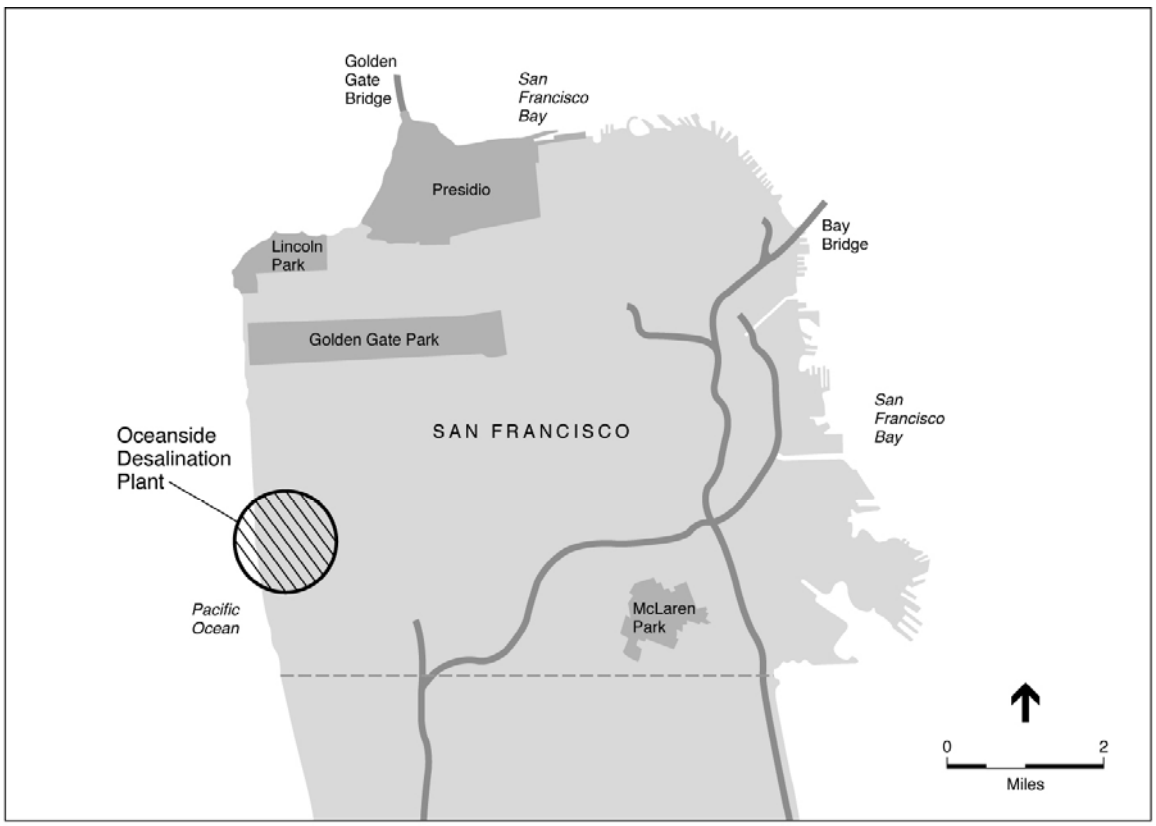
Growth-Inducement Potential and Secondary Effects of Growth

The growth-inducement potential for the Lower Tuolumne River Diversion Alternative would be similar to that of the proposed program, as described in Chapter 7. Since this alternative would meet the WSIP system performance objectives for delivery reliability and water supply, the water service and populations served would be identical. The minor difference in water quality would not affect the growth-inducement potential.

9.2.6 Year-round Desalination at Oceanside Alternative

Under the Year-round Desalination at Oceanside Alternative, the SFPUC would implement all of the proposed facility improvement projects and would construct a 25-mgd desalination plant in San Francisco to serve the projected increase in customer purchase requests. The plant would provide year-round supplies during all hydrologic year types to blend with the regional system water. This alternative is based on an alternative developed by the SFPUC planning studies conducted for the WSIP water supply option (SFPUC, 2007b). Compared to the WSIP this alternative represents and alternative source of supply and is evaluated to address the impacts to the Tuolumne River, Alameda Creek, and the Peninsula watershed, including Pilcarcitos Creek.

The Year-round Desalination at Oceanside Alternative would involve the construction of the Oceanside Seawater Desalination Plant (OSDP) on the west side of San Francisco near the existing Oceanside Water Pollution Control Plant (WPCP) (see **Figure 9.2**). Under this alternative, 25 mgd of potable water supplies produced by reverse-osmosis technologies would be provided year-round to retail customers in San Francisco during all hydrologic year types to the regional water system. The desalinated water would be introduced into the regional water system at Sunset Reservoir; this reservoir serves only customers in San Francisco and these customers would receive predominantly desalinated water.



SOURCE: ESA+Orion, 2006

SFPUC Water System Improvement Program . 203287

Figure 9.2
Year-Round Desalination at Oceanside Alternative

The Year-round Desalination at Oceanside Alternative assumes that seawater would be pumped through an offshore intake structure and pipeline to the OSDP, which would be designed with a sustainable capacity of 25 mgd. Based on a water recovery rate of approximately 50 percent in modern-day desalination plants, the capacity of the seawater intake structure and pipeline is estimated at 55 mgd. The conceptual process for the desalination plant includes pretreatment using advanced technologies to remove pathogens and suspended solids, a dual-stage reverse-osmosis system to remove salts, and post-treatment to stabilize and disinfect the product water and make it suitable for mixing in drinking water systems. The OSDP would make use of the existing wastewater outfall at the Oceanside WPCP for the discharge of the reverse-osmosis and pretreatment brine.

Description of SFPUC and Wholesale Customer Actions

SFPUC Actions

Table 9-4 summarizes the main characteristics of the Year-round Desalination at Oceanside Alternative in comparison to those of the proposed program. Under this alternative, the SFPUC would accommodate the projected increase of 35 mgd in customer purchase requests through 2030 through construction and operation of the OSDP (25 mgd), increased utilization of Bay Area watershed supplies associated with the restoration of storage in Calaveras Reservoir (SV-2) and Lower Crystal Springs Reservoir (PN-4), and an equivalent of 10 mgd of supply from recycled water, groundwater, and conservation projects in San Francisco. Supplemental drought-year supplies would consist of 25 mgd of desalination water and 6 mgd from implementation of the Westside Groundwater Basin conjunctive-use program.

The Year-round Desalination at Oceanside Alternative would implement all facility improvement projects proposed under the WSIP. However, the design of some of the WSIP facilities would need to reevaluated and sized appropriately to meet the delivery levels and performance objectives under this alternative. In addition, the SFPUC would proceed with implementation of other capital improvement projects and related activities not considered part of the program analyzed in this PEIR (as described in Chapter 3, Sections 3.13 and 3.4.6). The SFPUC would also implement the same system maintenance program and similar operational changes in the regional system as those proposed under the WSIP with the addition of operation and maintenance of the additional facilities described below.

Additional facilities that would be required under this alternative are summarized below:

- *55-mgd Concrete Seawater Intake Structure*. The new concrete intake structure would be located southwest of the desalination plant, approximately one to two miles offshore, at a depth of approximately 40 to 50 feet, depending on the extent of the existing sandbar. The intake structure would be sited and designed so as to minimize sediment intrusion, minimize the entrainment and/or impingement of marine organisms, and maximize water quality.

- *60-inch-Diameter Intake Pipeline*. The intake pipeline would convey 55 mgd of seawater from the intake structure to a new raw water pump station.

- *Seawater Intake Pump Station*. The seawater intake pump station, located onshore next to the OSDP, would be designed with a pumping capacity of 55 mgd and would pump raw water to pretreatment facilities.

- *Oceanside Seawater Desalination Plant*. The OSDP would be located near the existing Oceanside WPCP and would use the existing ocean outfall pipeline for brine disposal. The new plant would include pretreatment facilities, reverse-osmosis modules, and post-treatment facilities, as well as pipelines and pumps needed to convey the brine to the ocean outfall. There are feasibility issues associated with siting of the plant at this location due to space constraints for this plant as well as the proposed WSIP recycled water treatment facilities for the Recycled Water projects (SF-3).

- *25-mgd Treated Water Pump Station*. The treated water pump station would pump the treated water to the Sunset Reservoir for distribution via a new treated water pipeline.

- *48-Inch-Diameter Treated Water Pipeline*. A 2.4-mile 48-inch-diameter pipeline would convey the treated water through city streets to the Sunset Reservoir.

Implementation of the Year-round Desalination at Oceanside Alternative would require numerous additional permits and approvals, including preparation of a watershed sanitary survey in accordance with California Department of Health's safety regulations, approval by the U.S. Army Corps of Engineers for construction of structures in coastal areas, and approval by the Regional Water Quality Control Board for brine disposal. In addition, as required by Clean Water Act Section 316(b), the SFPUC would be required to submit a study to the California Coastal Commission describing the potential impingement and entrainment impacts on aquatic resources.

Wholesale Customer Actions

Like the proposed program, the Year-round Desalination at Oceanside Alternative would fully meet the WSIP delivery reliability and water supply level of service goals. Therefore, the SFPUC would serve the projected 2030 purchase requests for all customers, and wholesale customers would not be required to implement any additional conservation and/or recycled water projects or develop supplemental water supplies from other sources beyond what is identified in their respective urban water management plans.

Feasibility Issues

The major technical feasibility issue of implementing a year-round desalination plant at the Oceanside Water Pollution Control Plant site is due to the limited space available at this location. The site was selected to take advantage of the existing ocean outfall structure at this location, but there are other competing uses for this space, including the recycled water treatment facilities proposed as one of the WSIP facility improvement projects and recreational uses at and near the San Francisco Zoo. While there would be no restrictions on the availability of seawater, there remain site-specific uncertainties regarding the permit conditions for brine disposal and for minimizing impacts on aquatic resources. This alternative would also result in a direct impact on residents on the westside of San Francisco who are served from Sunset Reservoir and would essentially receive desalinated water instead of regional system water. Other public acceptance issues include potential conflicts with nearshore recreational uses in the Ocean Beach area. In addition, this alternative would add substantial cost to overall program as a result of having to build and operate a new intake structures, pump station, treatment plant, transmission pipelines, and any associated mitigation measures in addition to the costs of the 22 facility improvement projects included in the WSIP. This substantial additional cost raises questions about cost and financing feasibility and customer rate impacts.

Ability to Meet Program Objectives

Table 9-6 shows how the Year-round Desalination at Oceanside Alternative would perform in terms of meeting the WSIP level of service goals and performance objectives compared to the proposed program. Because there are no restrictions on the amount of seawater taken from the Pacific Ocean, this alternative does not have the same supply availability and reliability constraints as the surface water options.

The Year-round Desalination at Oceanside Alternative would increase system firm yield to approximately 256 mgd, thus meeting the level of service goals for water supply during drought and nondrought periods. This alternative would include implementation of all key projects needed to meet the seismic reliability and delivery reliability objectives of the WSIP, although the increase in facility maintenance and operational requirements associated with the desalination facilities would add additional constraints to systemwide operational flexibility. Although the Year-round Desalination at Oceanside Alternative would also meet the level of service objectives related to water quality, assuming the desalinated water would be treated to meet drinking water standards. As discussed above, this alternative would require that the SFPUC conduct a watershed sanitary survey and an impingement/entrainment study to comply with the requirements of the California Department of Health Services and the California Coastal Commission, respectively.

It is uncertain if the Year-round Desalination at Oceanside Alternative would meet the WSIP sustainability objectives, since there are numerous regulatory and permitting issues to be resolved associated with the desalination process, including protection of aquatic resources, water quality, and brine disposal issues, and it would require significant increase in long-term energy use compared to the proposed program. While the system would remain largely gravity-driven, the new source of water under this alternative would increase the pumping requirements of the overall system. This alternative would result in inefficient use of resources and funds compared to the WSIP, and would not meet the WSIP objective for cost-effectiveness. The capital, operation and maintenance cost of the 22 facility improvement projects would be the same as the WSIP, but substantial additional capital, operation and maintenance costs would be incurred from the intake, pumping, conveyance, treatment, and brine disposal facilities needed for this alternative.

Environmental Impacts Compared to those of the WSIP

Facility Construction and Operations Impacts

WSIP Facilities

The Year-round Desalination at Oceanside Alternative would include implementation of all 22 WSIP facility improvement projects. Although depending on a reevaluation of facilities sizing, some of the facilities could be slightly different than as proposed under the WSIP; however, the facilities impacts would be about the same under both scenarios. Thus, the environmental impacts of constructing and operating each of the 22 WSIP facility projects would be about the same as those of the proposed program. However, as discussed below, this alternative would require the construction and operation of extensive additional facilities on the west side of San Francisco; thus, collective impacts in the San Francisco Region and associated cumulative effects (such as traffic, air quality, noise, and vibration) would be more severe than those of the WSIP.

Other Facilities and Actions Potentially Implemented Under this Alternative

The Year-round Desalination at Oceanside Alternative would involve the construction of the OSDP, an intake structure and pipeline, intake pump station, a treated water pump station, and a treated water pipeline. A project-specific EIR would be required for the desalination plant and associated infrastructure. These facilities would result in a full range of construction and operations impacts at the proposed facility locations, similar to those described in Chapter 4 for the WSIP facilities, and would increase the construction and operational impacts in the San Francisco Region.

Construction Impacts. The primary environmental concerns during construction of the desalination plant and transmission pipelines are adverse impacts on sensitive receptors at the San Francisco Zoo and in nearby residential neighborhoods. Dust, noise and traffic generated during construction could affect nearby sensitive receptors, including animals and patrons at the zoo and residents who live along the pipeline routes. Depending on the location of the desalination plant, construction could also result in the displacement of parking at the San Francisco Zoo, result in temporary traffic impacts along pipeline alignments, and/or adversely affect recreational users at Fort Funston. In addition, the construction of the intake structure and pipeline would have a localized impact on marine organisms. Other potential construction-related effects would include cultural resources, hazardous materials, solid waste disposal impacts.

Operational Impacts. The primary concerns related to operation of the OSDP and related transmission facilities are potential impacts on aquatic resources, water quality, energy consumption, air quality, visual resources, geology and soils, land use and planning, traffic, and greenhouse gas emissions related to both traffic and energy use.

With respect to aquatic resources and water quality, operation of the OSDP could result in the entrainment and/or impingement of marine organisms in the intake pipeline and the discharge of potentially toxic substances into the Pacific Ocean from the existing outfall structure, including high-salinity discharges related to brine disposal as well as discharges of chemical and cleaning compounds. It is expected that significant entrainment and/or impingement impacts could be addressed by installing fine screens at the intake structure and by reducing the velocity of water intake. Discharge toxicity could be reduced by minimizing the use of chemicals during filter backwashing. Dilution modeling would be required to determine whether the new discharge, which would be a mixture of brine and wastewater from the Oceanside WPCP, would meet National Pollutant Discharge Elimination System discharge requirements and whether modifications to the outfall would be required. In addition, although blending of desalinated water with the regional system water would continue to meet all federal and state drinking water standards, there would be a noticeable change in water quality, particular residents in the westside of San Francisco who would receive predominantly desalinated water.

The energy consumption of desalination depends on the quality of the water produced and the feed water composition. The amount of electric power needed to produce potable water is proportional to the salinity of the source water. For this reason, when compared to the proposed program, operation of the Year-round Desalination at Oceanside Alternative would result in substantial increases in energy consumption and greenhouse gas emissions.

Potential impacts on cultural resources would result if the OSDP were sited at the Fleishhacker site or the National Guard Armory site. Construction of the OSDP at the Fleishhacker site would require the removal or modification of the Fleishhacker Bathhouse, which was constructed in the 1920s and thus potentially eligible for historic status. It is uncertain whether the National Guard Armory site has been evaluated for inclusion in the National Register of Historic Places. Cultural resource surveys would be completed during CEQA review and any identified cultural resources would be avoided to the extent feasible.

With respect to geology and soils, the proposed intake structure and pipeline would terminate in or near the surface rupture zone of the active San Andreas fault, which is located on the ocean floor about two miles west of the Oceanside WPCP. In addition, areas along the coast (such as ocean bluffs) can be unstable and are subject to erosion. Geotechnical studies would be conducted to characterize potential geologic and seismic hazards and to develop appropriate design measures.

Operation of the OSDP could also result in land use and planning issues related to the siting of the desalination plant near the coastal zone and potential land use conflicts with the San Francisco Zoo, the Oceanside WPCP, and/or the National Guard Armory.

Water Supply and System Operations

Under the Year-round Desalination at Oceanside Alternative, the total average annual diversions from the Tuolumne River would be essentially the same as the existing condition, based on HH/LSM modeling over the 82-year hydrologic record, as shown in Table 9-5. However, system operations would be modified under this alternative to accommodate the year-round addition of desalinated water to the regional water supply sources as well as to provide for regular system inspection and maintenance, similar to the WSIP. The potential impacts on water resources in the

Tuolumne River, Alameda Creek, and Peninsula watersheds associated with this modified operation are described below and compared to the impacts that would occur under the WSIP.

Tuolumne River Watershed

Water demand would increase under the Year-round Desalination at Oceanside Alternative by the same amount as with the WSIP. The increase in demand would be met with water from a new desalination plant. This alternative would not result in changes in average annual releases to the Tuolumne River from Hetch Hetchy Reservoir compared to the existing condition but changes could occur due to changes in operations attributed to conveyance system maintenance. The changes in spring releases would occur because of storage changes accumulating in Hetch Hetchy Reservoir leading to the delay or earlier initiation in spring releases. These changes would be less than with the WSIP and typically result in greater releases. Compared to current conditions, there could be a delay or an earlier initiation of the day of excess release. The delay would still be enough to have a potentially significant adverse effect on terrestrial biological resources because of the ecological sensitivity of riverside meadows and their flora and fauna.

Similarly, the Year-round Desalination at Oceanside Alternative would result in an occasional difference in the winter/spring releases from La Grange Dam compared to current conditions, sometimes greater and sometimes less year to year with no difference in the average annual releases to the Tuolumne River. In those years when the WSIP resulted in a delay in winter/spring releases it would have an adverse effect on fisheries in the Tuolumne River and on terrestrial biological resources in the riparian corridor, but the impact would be less than significant because this delay represents a minor variation in the flow release pattern.

Alameda Creek Watershed

The improvements to Calaveras Dam that would occur under the WSIP would also be part of the Year-round Desalination at Oceanside Alternative. Furthermore, under this alternative, the SFPUC would operate its facilities in the Alameda Creek watershed in a similar manner as with the WSIP. Consequently, the environmental impacts of the Year-round Desalination at Oceanside Alternative would be similar to those of the WSIP.

Peninsula Watershed

Water demand would increase with the Year-round Desalination at Oceanside Alternative, as it would with the WSIP. The SFPUC would try to serve increased demand in the Coastside CWD service area from Pilarcitos Creek, exactly as it would with the WSIP. The consequent, more rapid drawdown of Pilarcitos Reservoir and the earlier cessation of stored water releases to Pilarcitos Creek would have a significant adverse effect on water quality, fisheries, and terrestrial biological resources in the reservoir and the creek.

The improvements to Lower Crystal Springs Dam that would occur under the WSIP would also be part of the Year-round Desalination at Oceanside Alternative. As a result of the improvements and associated modifications in system operations, the maximum water level in Crystal Springs Reservoir would rise by about 20 feet. The rise in water level would have significant adverse impacts on terrestrial biological resources, as described in Section 5.5.6. Since the Year-round

Desalination at Oceanside Alternative would include improvements to Lower Crystal Springs Dam, the SFPUC would generally operate its facilities in the Peninsula watershed in a similar manner as with the WSIP. Consequently, the environmental impacts of the Year-round Desalination at Oceanside Alternative would be similar to those of the WSIP.

Growth-Inducement Potential and Secondary Effects of Growth

The growth-inducement potential for the Year-round Desalination at Oceanside Alternative would be similar to that of the proposed program, as described in Chapter 7. Since this alternative would meet the WSIP level of service goals for delivery reliability and water supply, the water service and populations served would be identical. The minor difference in water quality would not affect the growth-inducement potential.

9.2.7 Regional Desalination for Drought Alternative (Variant 2)

Under the Regional Desalination for Drought Alternative, the SFPUC would implement all of the proposed WSIP facility improvement projects and would partner with other Bay Area water agencies to construct and operate a proposed regional desalination plant. The SFPUC would receive supplemental supply from the regional desalination plant during drought years. This scenario is the same as WSIP Variant 2, as described in Chapter 8, Section 8.3, and is repeated here as a CEQA alternative because it would reduce impacts associated with increased diversions from the Tuolumne River.

The Regional Desalination for Drought Alternative (WSIP Variant 2) is similar to the WSIP, except that the SFPUC would receive supplemental drought-year supplies from a proposed regional desalination plant instead of from water transfers from TID and MID. The SFPUC, through its participation in the Bay Area Regional Desalination Project (BARDP), would receive additional water supply of up to 26 mgd during drought periods (an average annual yield of 23 mgd over the 8.5-year design drought). The SFPUC would not need to develop water transfer agreements with TID and MID for supplemental dry-year water, and, as a result, the overall increase in average annual water diversions from the Tuolumne River under this alternative would be less than that required for the proposed program. On an average annual basis, over the 82-year period of hydrologic record, this alternative would result in a 20-mgd increase in diversions from the Tuolumne River over existing conditions, compared to an increase of 27 mgd for the proposed program.

The BARDP involves a partnership among regional water agencies, including the SFPUC, Contra Costa Water District, East Bay Municipal Utility District, and Santa Clara Valley Water District, for the purpose of developing desalination as a regional water supply to improve supply reliability for over 5 million people served by the four agencies. The BARDP would develop and implement one or two desalination plants and associated facilities capable of producing about 65 to 71 mgd of potable water from ocean water, seawater, or brackish water. Participating agencies would either directly receive desalination product water into their water systems or would receive transfers from other agencies that directly receive desalination product water. A more detailed description of the BARDP is provided in Chapter 8, Section 8.3.

At the time of PEIR preparation, the institutional commitments and arrangements to implement a full-scale desalination plant as well as the necessary technical and feasibility studies had not been completed. However, in 2005, participating agencies received a grant from the California Department of Water Resources to complete a feasibility study to evaluate the institutional feasibility of the BARDP, and, in 2006, participating agencies received a second grant from the California Department of Water Resources to construct a desalination pilot plant. The pilot plant and related studies are scheduled to be implemented from 2007 to 2009.
