Table 9-4 summarizes the main characteristics of the Regional Desalination for Drought Alternative in comparison to those of proposed program. As previously discussed, with the exception of supplemental drought-year supply sources, this alternative is similar to the proposed program in that the SFPUC would accommodate the projected increase of 35 mgd in customer purchase requests through an increase in average annual diversions from the Tuolumne River (20 mgd), increased utilization of Bay Area watershed supplies associated with the restoration of Calaveras Reservoir (SV-2) and Lower Crystal Springs Reservoir (PN-4), and an equivalent of 10 mgd of supply from recycled water, groundwater, and conservation projects in San Francisco. Unlike the proposed program, however, supplemental drought-year supplies would consist of up to 26 mgd (average annual yield of 23 mgd over the 8.5-year design drought) of desalination water from the BARDP and 6 mgd from implementation of the Westside Groundwater Basin conjunctive-use program.

The Regional Desalination for Drought Alternative would include implementation of all of the 22 facility improvement projects proposed in the WSIP. In addition, the SFPUC would proceed with implementation of other capital improvement projects and related activities not considered part of the program analyzed in this PEIR (as described in Chapter 3, Sections 3.13 and 3.4.6). The SFPUC would also implement the same system maintenance program and similar operational changes in the regional system as those proposed under the WSIP with the addition of participation in the operation and maintenance of the BARDP and related facilities.

The SFPUC is currently participating in the development of feasibility studies and pilot testing to determine the viability of the BARDP. If the project is found to be feasible, the SFPUC would contribute funds towards environmental review, project construction, and operation of the BARDP. Depending on the site(s) selected for development of the full-scale BARDP, the desalination project could require multiple components, including raw water supply/intake facilities, process and treatment facilities, and concentrate disposal facilities/outfall structures. To convey the product water from the desalination plant to the regional water agencies, transmission pipelines and pump station(s) would also be required. It is assumed that the BARDP would use or modify existing distribution and transmission facilities to the extent possible. Under the Regional Desalination for Drought Alternative, the SFPUC would receive transfer water from other participating water agencies, unless the facility were sited in San Francisco.

Wholesale Customer Actions

Like the proposed program, the Regional Desalination for Drought Alternative would fully meet the WSIP delivery reliability and water supply level of service goals. Therefore, the SFPUC would serve the projected 2030 purchase requests for all customers, and wholesale customers would not be required to implement any additional conservation and/or recycled water projects or develop supplemental water supplies from other sources beyond what is identified in their respective urban water management plans.

Feasibility Issues

A feasibility study is currently underway to refine the institutional, technical, environmental and scientific merits of a regional desalination facility. A pilot plant is proposed to test pretreatment options, membrane performance, and approaches for brine disposal. The technical feasibility of this alternative is dependent upon the outcome of these studies and pilot testing, and if determined to be fully feasible, implementation of a full-size regional desalination facility will require institutional arrangements to be formalized among the four partnering agencies as well as completion of environmental studies and permitting negotiations with numerous jurisdictions and resource agencies. In addition, this alternative would add costs to the overall program as a result of having to build and operate a new intake, treatment plant, transmission pipelines, and associated mitigation measures in addition to the costs of the 22 facility improvement projects included in the WSIP. Depending on the institutional and financial arrangements between the partnering agencies, this additional cost raises questions about cost and financing feasibility and customer rate impacts.

Ability to Meet Program Objectives

The Regional Desalination for Drought Alternative would include implementation of the same 22 regional system facility improvement projects as proposed under the WSIP needed to meet the water quality, seismic reliability, and delivery reliability performance objectives of the WSIP. Although this alternative would meet the level of service goals related to water quality, the desalinated water would require treatment to produce potable water supplies and would site-specific regulatory and permitting conditions for the desalination process. This alternative would increase system firm yield to 256 mgd, thus meeting the level of service goals for water supply during drought and nondrought periods.

However, it is uncertain if the Regional Desalination for Drought Alternative would meet the WSIP sustainability objectives, since there are numerous regulatory and permitting issues to be resolved associated with the desalination process, including protection of aquatic resources, water quality, and brine disposal issues, and it would require significant increase in long-term energy use compared to the proposed program. While the system would remain largely gravity-driven, the new source of water under this alternative would increase the pumping requirements of the overall system. This alternative would result in higher costs compared to the WSIP. The capital, operation and maintenance cost of the 22 facility improvement projects would be the same as the WSIP, but substantial additional capital, operation and maintenance costs—to be shared among the partnering agencies—would be incurred from the intake, pumping, conveyance, treatment, and brine disposal facilities needed for this alternative.

Environmental Impacts Compared to those of the WSIP

Facility Construction and Operations Impacts

WSIP Facilities

Potential impacts related to construction and operation of the WSIP facilities would be the same as those of the proposed program described in Chapter 4. However, as discussed below and in Chapter 8, this alternative would require the construction and operation of extensive additional facilities, and, depending on their location, could contribute to collective and cumulative effects (such as traffic, air quality, noise, and vibration), resulting in more severe collective and cumulative impacts than those of the WSIP.

Other Facilities and Actions Potentially Implemented Under this Alternative

As discussed in Chapter 8, Section 8.3.3, potential impacts resulting from the construction of desalination facilities and appurtenances include temporary conflicts with established uses during construction, temporary degradation of scenic resources, geologic and/or seismic hazards associated with facility siting, short-term impacts on water quality and the potential for short-term depletion of groundwater resources from construction dewatering, impacts on biological resources during construction and/or associated with facility siting, construction-related traffic impacts, increased air quality emissions and odors, construction-related noise, temporary impacts on agricultural resources, and potential impacts associated with encountering hazardous materials in soil and groundwater during construction.

The primary operational concerns would be the entrainment and/or impingement of special-status aquatic organisms in the intake pipeline, the discharge of potentially toxic substances from the outfall structure, and potential impacts on wetlands, marshlands, and other sensitive habitats. In addition, implementation of the BARDP would result in the substantial use of nonrenewable energy resources during construction and operation as well as the generation of greenhouse gases. Additional impacts associated with operation of the desalination plant and facilities include permanent conflicts with existing land uses or permanent degradation of visual resources/scenic views, operational air quality emissions and odors, and permanent increases in noise and vibration. A more detailed discussion of construction and operational impacts related to the BARDP is provided in Chapter 8, Section 8.3.3.

Water Supply and System Operations Impacts

As described in Chapter 8, the Regional Desalination for Drought Alternative would essentially have all the same water supply and system operations impacts as the WSIP. In the Tuolumne River, Alameda Creek, and Peninsula watersheds, all the same impacts would occur as with the proposed program and all the same mitigation measures would apply. During drought, SFPUC would supplement supplies with the desalination supply. However, in nondrought years the SFPUC would serve the customer requests with additional diversions from the Tuolumne River.

While impacts on Tuolumne River resources would be somewhat reduced compared to the proposed program, the significance determination of the impacts would remain the same as those for the proposed program. Refer to Chapter 8, Section 8.5 for further discussion of the water supply and system operations impacts of this alternative.

Growth-Inducement Potential and Secondary Effects of Growth

As described in Chapter 8, the growth-inducement potential under the Regional Desalination for Drought Alternative would be essentially the same as that for the WSIP insofar as the SFPUC's component of the BARDP would be used to serve the 2030 purchase requests of SFPUC customers. Any growth-inducement effects associated with the BARDP beyond this component would be determined as part of the CEQA review of the BARDP.

9.2.8 Modified WSIP Alternative

The Modified WSIP Alternative incorporates changes in the proposed WSIP primarily to modify the proposed water supply and system operations so as to minimize environmental effects.[11] Most of these changes are also proposed as mitigation measures for potentially significant or significant impacts identified in Chapter 5 – Water Supply and System Operations. In addition, the Modified WSIP Alternative includes other supply and operational modifications and actions that would further reduce impacts identified in Chapter 5. As discussed below under Ability to Meet Program Objectives, these supply and system operation modifications could, in some cases, compromise the level of service goals and system performance objectives established for the WSIP.

Description of SFPUC and Wholesale Customer Actions

SFPUC Actions

Under the Modified WSIP Alternative, the SFPUC would implement the identical facility improvement projects as those proposed under the WSIP. In addition, the SFPUC would proceed with implementation of other capital improvement projects and related activities not considered part of the program analyzed in this PEIR (as described in Chapter 3, Sections 3.13 and 3.4.6). The SFPUC would also implement the same system maintenance program and similar operational changes in the regional system as those proposed under the WSIP. The SFPUC would also implement largely the same water supply option package as proposed under the WSIP, but would endeavor to increase the amount of recycled water, conservation, and local groundwater contributing to meeting the regional system demand. Under this alternative, the SFPUC would also implement the following changes in the proposed system operations and supply options:

- <u>*Dry-year water transfer*</u>. The proposed WSIP includes acquisition of a water transfer from TID/MID to provide supplemental dry-year water for the regional system. The specific terms of this water transfer have not been established. Under this alternative, the terms of any water transfer from TID, MID or other agency(ies) would be conditioned such that it involves a transfer of conserved water only, rather than a transfer of stored water. This proposed condition is explained in Measure 5.3.6-4a. Under this alternative, a transfer of conserved water would be acquired for use every year, not only as a dry-year supplement,

[11] The description and analysis of the Modified WSIP Alternative has been updated in the Comment and Responses document. Please see Section **14.10, Master Response on the Modified WSIP Alternative** (Vol. 7, Chapter 14) for detailed information.

and doing so would avoid the WSIP impacts on the lower Tuolumne River below La Grange that result from the SFPUC increasing its diversions from the Tuolumne River.

- *Alameda Creek minimum flow requirement for trout between the Alameda Creek Diversion Dam and the confluence with Calaveras Creek*. To support trout spawning and egg incubation following the replacement of Calaveras Dam and the resumption of flow diversion from Alameda Creek, the SFPUC will meet a minimum flow requirement in the creek reach below the Alameda Creek Diversion Dam to the confluence with Calaveras Creek between December 1 and April 30 at times when precipitation would naturally generate unimpaired flow in this reach. The SFPUC will conduct the necessary site-specific studies to determine the specific minimum flow requirement. Allowing flow to bypass the diversion dam in order to meet this minimum flow requirement would result in some reduction in supply that would otherwise be available to the regional system, and this could compromise the system firm yield level of service objective under the WSIP's water supply goal. This proposed condition is explained in Measure 5.4.5-3a.

- *Water Delivery to Coastside County Water District – modified operations for Pilarcitos Reservoir*. Under the WSIP, the SFPUC would meet increased 2030 demand from Coastside CWD by drawing the additional water from Pilarcitos Reservoir. This would result in a variety of significant or potentially significant impacts on the water quality and fish, aquatic, and terrestrial resources associated with the reservoir and Pilarcitos Creek downstream of the reservoir (see Section 5.5 for a discussion of these impacts). Under this alternative, the SFPUC would serve Coastside CWD's increase in demand from Crystal Springs Reservoir rather than from Pilarcitos Reservoir, which would allow the SFPUC to continue to operate Pilarcitos Reservoir in a manner similar to existing conditions. Under this alternative approach, the SFPUC and Coastside CWD would need to work together to expand conveyance capacity to Coastside CWD to accommodate increased supply delivery from Crystal Springs Reservoir. Serving Coastside CWD from Crystal Springs Reservoir instead of Pilarcitos Reservoir, as proposed under the WSIP, would require additional water from the Hetch Hetchy system (combined Alameda watershed, Crystal Springs watershed, and Tuolumne River supplies) to substitute for the local Pilarcitos watershed supply that would have been used. This proposed condition is explained in Measure 5.5.3-2.

- *Crystal Springs Reservoir – modified operation to manage inundation levels*. As discussed in Section 5.5, the WSIP would result in significant effects on the biological resources associated with and surrounding Crystal Springs Reservoir as a result of increasing water storage levels within the reservoir and maintaining these higher water levels in the reservoir for a longer period each year than was the case under historic operations. The oak woodland habitat that occurs in the proposed reservoir inundation zone would not survive the extended period of inundation each year. The PEIR identifies mitigation measures to reduce these effects to a less-than-significant level, primarily through habitat compensation. One strategy that could substantially lessen these environmental effects would be to operate the regional system such that the water storage levels in Crystal Springs Reservoir would not be increased over existing levels for prolonged periods during the year. Although reservoir water levels still would be increased to the historical maximum under this Modified WSIP Alternative, modifying the proposed future reservoir operation to ensure that the water level fluctuates seasonally and is lowered for some period each year to create conditions that the oak woodland habitat could survive. The proposed modified operations would be similar to the operating conditions in effect prior to 1983, which the oak woodland was apparently able to survive. Because with this modification the water level in the reservoir would not be maintained as full for as long each year as proposed under the WSIP, this modified operation would reduce the amount of water in storage on the Peninsula and could compromise the system firm yield level of service objective under the WSIP's water supply goal. This is a new operation that SFPUC would implement under this alternative.

- *Increased Recycled Water, Conservation, and Local Groundwater*. Under this alternative, the SFPUC would institute a program to work with the wholesale customers to develop approximately 5 to 10 mgd of supply contribution, as feasible, from recycled water, conservation, and local groundwater projects within the regional wholesale service area. While the analysis of the Aggressive Conservation / Water Recycling and Local Groundwater Alternative in Section 9.2.4 indicates that it does not appear feasible to develop enough additional recycled water, water conservation and local groundwater to serve all or even a majority of the 25 mgd needed to meet the projected 2030 delivery demand for the regional system, it does appear feasible to develop at least some additional increment of supply / supply offset through these types of local projects. Based on the list of potential projects provided by the wholesale customers (see Table 9-11), a target goal of 5 to 10 mgd is proposed under this Modified WSIP Alternative. This is a new program that SFPUC would implement under this alternative.

  Developing additional water supply/ supply offset for the regional system through local water conservation, water recycling and groundwater projects would reduce the amount of additional Tuolumne River diversion required. At a minimum, it is expected that developing this level of additional local supply / supply offset could compensate for the reduction in available system supply resulting from the following operation modifications incorporated into this alternative to lessen or avoid environmental impacts: the Alameda minimum flow requirement, providing water delivery to Coastside CWD from Crystal Springs Reservoir, and the modified operation of Crystal Springs Reservoir. As a result, this alternative is not expected to require increases in Tuolumne River diversion that are greater than those proposed under the WSIP, and it is possible that the diversion increase would be less under this alternative than the WSIP.

  The SFPUC together with its wholesale customers have identified opportunities to expand supply contributions from water recycling, conservation and groundwater. While some of these projects are not cost-effective to pursue at the local level by a single agency or community, they may be more economically viable if developed and funded as regional projects contributing to the overall regional system. This alternative calls for the SFPUC to establish and fund, in conjunction with BAWSCA and the wholesale customers, a proactive regional program that will be supported by the SFPUC and its customers, promotes customer participation, and ultimately benefits the SFPUC regional water system. Based on a review of regional programs being implemented by other water agencies and consideration that the SFPUC provides water to both retail and wholesale customers, the SFPUC has identified several potential approaches for the program, shown in the bullet list below. One of these approaches, or a hybrid alternative featuring a combination of approaches, may best suit the SFPUC, its customers and the set of potential projects. The approaches include:

  – *Regional Entity Provides Financial Incentives.* This approach is structured such that the regional entity provides financial incentives for customers to apply for implementing their projects through the program. This financial assistance may include staff and material support.

  – *Regional Entity Implements Programs Directly.* This approach is structured such that the regional entity directly implements those projects or programs selected.

- *Regional Entity Implements Programs in Cooperation with Local Customers.* This approach is structured such that the regional entity implements those projects or programs selected in cooperation with the individual wholesale customer.

- *Regional Entity Implements a Grant Program.* This approach is structured such that the regional entity provides grants to individual wholesale customers, which are used by the individual wholesale customers to implement the projects.

Wholesale Customer Actions

Like the proposed program, the Modified WSIP Alternative would fully meet the WSIP delivery reliability and water supply level of service goals during nondrought years, and the SFPUC would serve the projected 2030 purchase requests for all customers. The wholesale customers would need to participate with the SFPUC in developing more recycled water, conservation, and local groundwater to contribute to meeting the needs of the regional system. The types of projects that would need to be pursued are discussed above under the Aggressive Conservation/Water Recycling and Local Groundwater Alternative.

Feasibility Issues

The Modified WSIP Alternative would have few feasibility issues, since in large part, this alternative represents the same actions and elements as the WSIP, for which the SFPUC has resolved major feasibility issues. Technical issues would be the same as the WSIP except for the design and implementation of facilities to permit bypass flows on Alameda Creek past the diversion dam. The institutional issues would be essentially the same as under the WSIP, including establishing agreements with local agencies for the regional groundwater conjunctive-use program in Northern San Mateo County and with TID, MID or other agency for water transfer agreements. The only difference would be that the water transfer agreement with TID, MID or other agency(ies) specify *conserved* water. Under this alternative the SFPUC would actively engage in developing regional recycled water, conservation, and local groundwater programs with the wholesale customers. While there remain feasibility issues associated with each specific water recycling, conservation and groundwater project (as discussed in Section 9.2.4, above), pursuing a goal of developing 5 to 10 mgd over time through a coordinated regional program appears achievable. Developing this additional increment of conservation, water recycling, and groundwater projects requires agreement between BAWSCA, the wholesale customers and the SFPUC as well as cooperation from several local agencies including wastewater agencies, stormwater management agencies, and planning departments, among others. Each project also will have its own feasibility questions, such as cost, facility siting, permitting and public acceptance, to resolve.

Ability to Meet Program Objectives

The Modified WSIP Alternative would include implementation of all of the proposed facility improvement projects needed to meet the water quality, seismic reliability, and delivery reliability goals of the WSIP, and would meet these objectives similar to the proposed program. Although the modified operation under this alternative would include actions that would affect the water supply and system firm yield (i.e., minimum flow requirements on Alameda Creek, reduced use of Pilarcitos Reservoir, and managed inundation levels in Crystal Springs Reservoir), the Modified WSIP Alternative also includes 5 to 10 mgd of regional recycled water / groundwater / conservation that is not part of the proposed program. Long-term implementation of these regional recycled water/local groundwater/conservation projects would offset impacts of the operational modifications proposed under the Modified WSIP Alternative on the Tuolumne River such that it is expected that this alternative would meet all of the water supply level of service goals and system performance objectives of the WSIP.

The Modified WSIP Alternative would meet the WSIP sustainability objective, and would be expected to have slightly greater costs than the WSIP, since there would be additional conservation, water recycling and local groundwater projects within the regional service area than under the WSIP. The water recycling and groundwater elements would add some pumping requirements to the overall regional system. However, it is assumed that planning and implementation of regional recycled water/groundwater/conservation projects in partnership with the wholesale customers would be conducted to incorporate the WSIP objectives for cost-effective use of funds.

Environmental Impacts Compared to those of the WSIP

Facility Construction and Operations Impacts

WSIP Facilities

Potential impacts related to construction and operation of the WSIP facilities would be the same as those of the proposed program, as described in Chapter 4.

Other Facilities Potentially Implemented Under this Alternative

No significant environmental impacts would be expected from implementation of water conservation measures. Implementation of recycled water and groundwater projects would result in a full range of construction and operational impacts in the South Bay and Peninsula areas, similar to those described in Chapter 4 for the WSIP facilities. The types of impacts associated with implementation of the local recycled water and groundwater projects are summarized in Table 9-12, above, and generally relate to construction of new infrastructure, water quality, and groundwater resources.

Water Supply and System Operations Impacts

This alternative incorporates mitigation measures to address some of the impacts identified for the WSIP, namely the effects on fish and riparian habitat in the lower Tuolumne River (Impacts 5.3.6-4 and 5.3.7-6), the effects on trout in Alameda Creek below the diversion dam (Impact 5.4.5-3), the effects on Pilarcitos Reservoir and Creek and associated resources (Impacts 5.5.3-2, 5.5.5-4, 5.5.5-5, 5.5.6-4, and 5.5.6-5), and the effects on fish and terrestrial biological resources around Crystal Springs Reservoir (Impacts 5.5.5-1 and 5.5.6-1). Otherwise, this alternative would have the same water supply and system operations impacts as the WSIP in the Tuolumne River, Alameda Creek, and Peninsula watersheds and would require the same mitigation measures.

The proposal to modify the proposed operations of Crystal Springs Reservoir would allow storage levels to be returned to their historical maximum; however, the reservoir would have to be operated to allow water levels to fluctuate annually and to provide for a seasonal lowering of the water level so that the oak woodland and other habitat on the periphery of the reservoir would not be inundated throughout the year. Historical vegetation mapping and accounts of habitat in the vicinity of Upper and Lower Crystal Springs Reservoirs (Oberlander, 1952) indicate that the prevailing reservoir levels in the 1950s resulted in more extensive freshwater marsh than at present. An increase in freshwater marsh habitat would benefit San Francisco garter snake and California red-legged frog. Although the overall increase in reservoir elevation under this alternative could still affect the populations of fountain thistle and other sensitive plants that now exist below the proposed maximum reservoir level, the habitat around the reservoir would return to conditions that existed before 1983, and these plant populations would therefore be expected to regain their former extent and distribution. Maintaining reservoir levels similar to historical patterns prior to 1983—and without the more lengthy periods when the reservoir is nearly full as proposed under the WSIP—would reduce or eliminate the adverse impacts on upland habitats such as oak woodland, which could experience extensive mortality if inundated for long periods of time.

With the WSIP, average monthly water levels would rise by 2 to 8 feet compared with existing conditions. Except for periodic drawdowns, all areas below the current maximum reservoir elevation of 283 feet would be permanently inundated, resulting in the loss of all existing freshwater marsh and riparian vegetation below this elevation. The maximum reservoir elevation of 291 feet would be maintained for several weeks longer than maximum elevations under existing and pre-1983 operations. Upland vegetation growing below 291 feet along the reservoir shoreline could not tolerate these longer periods of inundation and would be lost, including oak woodland, mixed evergreen forest, serpentine grassland, valley needlegrass grassland, and exotic forest.

The “bathtub ring” that is a trademark of reservoirs occurs because water remains high enough, for long enough, to exceed the flood tolerance of most woody and shrubby perennial vegetation and is not present long enough for emergent aquatic vegetation to persist. Inundation replaces the air-filled pores in the soil, which limits the amount of oxygen roots can obtain, resulting in increased stress, reduced growth, and eventually mortality. This PEIR predicts that implementation of the WSIP would result in a bathtub ring at some regional water system reservoirs, but this outcome is not inevitable. Most woody plants have some tolerance to flooding, which is a natural phenomenon. It would therefore be possible for the SFPUC to “manage” the inundation zone to allow selected species to survive, while still utilizing the restored historical reservoir capacity. Flood tolerance has been studied for several species. For example, 70 percent of valley oak (*Quercus lobata*) have been shown to survive inundation of over 40 days during the growing season (Walters, 1980). Under a managed inundation scenario, the maximum reservoir elevation would be periodically adjusted to limit inundation to the maximum tolerance of the least flood-tolerant species that are considered to provide valuable habitat components. Since these tolerances are not known for all of the species currently present, the Modified WSIP Alternative would require a period of adaptive management, during which growth and stress would be studied for a number of years to establish a balance between woody vegetation vigor and diversity and the needs of the proposed program for storage. Although this alternative would not likely avoid impacts on grasslands, much of the biological productivity of the area between 283 and 291 feet elevation would be retained.

Growth-Inducement Potential and Secondary Effects of Growth

The growth-inducement potential for this alternative would be identical to that of the proposed program, as described in Chapter 7.

9.3 Comparison of Alternatives

Based on the information presented in Section 9.2, the following discussion highlights the key similarities and differences between the WSIP and the eight alternatives evaluated in detail in this PEIR with respect to their ability to meet the program objectives and to lessen the severity of the WSIP's environmental impacts. The environmentally superior alternative is also identified from among the proposed WSIP and the alternatives.

9.3.1 Comparison of Alternatives

Ability to Meet Program Objectives

As summarized in Table 9-6, above, three alternatives to the WSIP appear to meet most of the basic project objectives: the Lower Tuolumne River Diversion Alternative, Year-round Desalination at Oceanside Alternative, and Regional Desalination for Drought Alternative. Each of these three alternatives develops additional water supplies to meet the 2030 average annual increase in delivery demand, drought-year needs, and support the 20 percent maximum systemwide rationing goal. There are questions associated with each of these alternatives, including questions of technical and institutional feasibility, cost, and public support as well as regulatory permit challenges; however, assuming these alternatives could be implemented, it appears that they could each largely meet the program objectives. All of them would cost more than the WSIP because each would require implementation of all 22 WSIP facility improvement projects as well as construction and operation of additional major facilities for water diversion, transmission, treatment and distribution. Costs for these alternatives would include all the WSIP facility improvement project costs plus the substantial additional costs for planning, environmental review, design, construction, operation, and mitigation of the additional facilities. All of these alternatives would also require an incremental increase in treatment and pumping facilities to the regional system; they would introduce a water source with different water quality into the system and would involve additions to the system that are not gravity-driven.

Four alternatives – the No Program Alternative, No Purchase Request Increase Alternative, and the Aggressive Conservation / Water Recycling and Local Groundwater Alternative (without and with supplemental Tuolumne River water), would each fail to meet one or more key program objectives. The No Program Alternative would meet the fewest of the program objectives. Under the No Program Alternative only those facility improvement projects required by current regulation or agreement with regulatory agencies would be implemented, thus, only a few of the many needed repairs and improvements would be made to the regional system. Many other facility improvement projects and supply development actions needed to improve seismic and delivery reliability, and provide adequate supplies to meet both average annual delivery demand and drought-year needs would not be implemented, leaving these objectives wholly or substantially unmet under the No Program Alternative.

The No Program Alternative leaves the SFPUC and its customers at significant risk of supply reduction or disruption during an earthquake or other emergency, or during a drought. This is not a feasible or acceptable alternative for the SFPUC. The SFPUC is responsible for maintaining and upgrading the regional system as needed to meet, at a minimum, the public health and safety needs of its customers. If the SFPUC cannot repair and improve its water system in a planned, comprehensive program like the WSIP, then it will be forced to do so in a piecemeal, reactive, emergency response manner, repairing parts of an aging system as facilities reach the end of their useful life or fail. This alternative is analyzed as required by CEQA to disclose the potential environmental impacts of not implementing the WSIP compared to implementation of the program but is not a practical alternative for the SFPUC.

The No Purchase Request Increase Alternative is designed to serve wholesale customers only the amount of water required under the existing Master Water Sales Agreement; therefore it would not fully meet the purchase request increase by the SFPUC wholesale customers for additional supply through the year 2030. Under this alternative, the SFPUC would choose not to meet the future water requests from its current customers – one of its key program objectives. This alternative was included in this alternatives analysis to evaluate the consequences of the SFPUC not meeting the future increase requested by its customers in an effort to avoid or minimize the potential growth-inducing effects and secondary effects of growth associated with providing more water to the regional customers. Neither BAWSCA nor its member agencies is expected to allow their customer needs to go unmet. Therefore, under this alternative, while the SFPUC would not achieve the program objective of meeting customer water delivery needs in 2030, it is expected that customer needs would nonetheless be met through other efforts by BAWSCA and/or the wholesale customers. Likely action by BAWSCA and wholesale customers would be to pursue a water transfer from another agency, similar to that proposed by the SFPUC as part of the WSIP. Consequently, the No Purchase Request Increase Alternative would not avoid the potential growth inducement effects of meeting the 2030 customer purchase requests.

The Aggressive Conservation / Water Recycling and Local Groundwater Alternatives (without and with supplemental Tuolumne River water) appear to meet, or almost meet the supply delivery and reliability objectives. This alternative, without supplemental Tuolumne River water, appears to almost meet the average annual 2030 delivery target of 300 mgd. With supplemental Tuolumne River water (5 mgd) it would meet the 300 mgd target. However, there are significant questions about the feasibility of producing up to 19 mgd of supply / supply offset with this alternative. As discussed in Section 9.2.4, while projects that might produce up to 19 mgd of potential supply/supply offset were identified within the wholesale customer service area, there are many steps still required to confirm the actual potential yield of each of the projects and assess the technical, cost, and permitting feasibility in addition to public acceptance associated with specific conservation, recycled water and groundwater projects within the wholesale customer service area.

As shown on Table 9-11, above, producing up to 19 mgd of supply/supply offset under this alternative could involve implementation of more than 14 separate conservation/water recycling/ groundwater projects in the wholesale customer service area. This requires coordinated action by the SFPUC and multiple partner agencies to plan, evaluate, design, permit, finance, construct and operate these projects. It also requires community approval and fairly extensive public participation. Of the 19 mgd of potential supply/supply offset shown on Table 9-11, 8.35 mgd or almost half could be recycled water, and conservation represents another 7 mgd; thus the majority would come from increased water recycling and conservation. These two water supply management approaches, perhaps more than any other, require significant community support and participation to implement. Water recycling is becoming more and more common throughout the Bay Area, yet it is not universally accepted by all communities and for all permitted uses. Community support for increasing the recycled water supply and using it primarily for non-potable uses throughout the SFPUC service areas is a critical component for implementing this alternative.

Similarly, implementing aggressive additional conservation actions, beyond existing conservation levels and the planned conservation efforts (already factored into the future water demand estimates by each wholesale customer), also requires widespread community support, participation and compliance. Further, if an aggressive level of conservation can be implemented to reduce the average day water demands, then the question arises, will the community also be able to further reduce its water use enough to achieve the WSIP goal of 20 percent rationing during a drought? As discussed in Section 9.2.2 under the discussion of feasibility for the No Program Alternative, effective, lasting water conservation leads to demand "hardening" such that there may be little flexibility remaining for customers to further reduce water use during a drought without experiencing substantial economic and personal hardship.

From the information gathered by the SFPUC and the wholesale customers to develop and assess this potential alternative it is apparent that there is the potential to implement additional conservation, recycled water projects, and local groundwater projects within the regional service area. However, given the uncertainties in implementing many of the projects assumed under this alternative, it is also apparent that there is not sufficient, reasonably foreseeable potential for these types of projects to fully meet the program objectives for 2030 supply and delivery reliability and drought reliability. As shown on Figure 5.1-2, based on the wholesale customers water demand projections and purchase request increase, planning estimates indicate about half of the total 35 mgd requested increase in water delivery would be needed by 2015. It is unlikely that this much additional supply/supply offset could be developed under this alternative in this short a time. Consequently, the Aggressive Conservation/Water Recycling and Local Groundwater Alternative, as a stand-alone program, would not meet the key program objectives. However, developing some more conservation, recycled water and local groundwater within the regional service area than is proposed under the WSIP does appear possible and this possibility has been incorporated into the proposed Modified WSIP Alternative. Developing more local conservation efforts, recycled water and local groundwater projects would also contribute to meeting the objective of diversifying the water supply and demand management portfolio for the regional system.

The Modified WSIP Alternative would meet all the program objectives, similar to the WSIP. This alternative was developed to avoid or substantially lessen some of the significant impacts of water system operations under the WSIP. Some of the operational changes included in this alternative would also be implemented if the WSIP and all mitigation measures presented in this PEIR are approved. This alternative also proposes that the SFPUC, in partnership with its wholesale customers, implement more conservation, water recycling and local groundwater projects than are proposed as part of the WSIP. The additional conservation, recycling, and local groundwater projects would offset the increase in diversion from the Tuolumne River made necessary by the operational modifications included in the Modified WSIP Alternative. While there remain feasibility issues associated with each specific water recycling, conservation and groundwater project (as discussed in Section 9.2.4, above), pursuing a goal of developing 5 to 10 mgd over time through a coordinated regional program appears achievable. Developing this additional increment of conservation, water recycling, and groundwater projects requires agreement between BAWSCA, the wholesale customers and the SFPUC as well as cooperation from several local agencies including wastewater agencies, stormwater management agencies, and planning departments, among others. Each project also will have its own feasibility questions, such as cost facility siting, permitting and public acceptance, to resolve.

Environmental Impacts Compared to Those of the WSIP

The following summarizes the chief differences between the WSIP and the alternatives with respect to potential environmental impacts. In some cases an alternative would result in more or less impacts on a particular environmental resource compared to the WSIP, and in other cases an alternative would affect an altogether different geography and environmental resource than the WSIP. This section frames the environmental impact trade-offs raised by each of the alternatives in comparison to the WSIP.

Water Resources Impacts

As summarized below some alternatives would lessen significant impacts of the program on the Tuolumne River, but all alternatives would continue to have significant impacts within the Alameda Creek and Peninsula watersheds because these impacts would result primarily from implementation of two facility improvement projects (Calaveras Dam Replacement Project (SV-2) and Lower Crystal Springs Dam Improvement Project (PN-4)) that are included in each alternative since they must be completed in order to meet regulatory requirements for public safety reasons. In addition, three alternatives would impact other water bodies not affected by the WSIP and three other alternatives might affect other water bodies depending on how they are implemented.

Tuolumne River Watershed

Under the WSIP, the SFPUC would increase average annual diversions from the Tuolumne River by 27 mgd to meet 2030 service area needs; this increase can be served from the CCSF's existing water rights on the Tuolumne River. Six of the eight alternatives considered also involve some level of increased average annual diversion from the Tuolumne River. Two alternatives, the Lower Tuolumne River Diversion Alternative and the Modified WSIP Alternative would require the same or greater increase in average annual Tuolumne River diversions compared to the WSIP. Under four alternatives the increase in average annual Tuolumne River diversion would be less then the WSIP, ranging from an increase of 20 mgd down to an increase of 3 mgd (in descending order): Regional Desalination for Drought Alternative, No Program Alternative, Aggressive Conservation / Water Recycling and Local Groundwater Alternative with supplemental Tuolumne River water, and the No Purchase Request Increase Alternative (see Table 9-5, above). Two alternatives, Aggressive Conservation / Water Recycling and Local Groundwater Alternative without supplemental Tuolumne River water and the Year-round Desalination at Oceanside Alternative, would not require an increase in average annual diversion from the Tuolumne River over the existing condition.

Table 9-7 summarizes the potentially significant impacts on the Tuolumne River and its associated environmental resources that would result from implementation of the WSIP and from each of the alternatives in comparison to the WSIP. Although some alternatives would result in less increase in Tuolumne River diversion than the WSIP (in some cases notably less), none of them would substantially lessen the potential impact on meadows between O'Shaughnessy Dam and Don Pedro Reservoir. All of the alternatives could still result in a potentially significant impact on meadows, in particular in the Poopenaut Valley, as a result of delaying the higher volume spring releases from Hetch Hetchy Reservoir (see Impact 5.3.7-2), similar to the WSIP. Three alternatives — Regional Desalination for Drought, Lower Tuolumne River Diversion, and the Modified WSIP – would involve increasing the average annual diversions by 20 mgd or more, similar to the WSIP and thus would have a similar impact to that described for the WSIP, requiring mitigation. Five other alternatives – No Program, No Purchase Request Increase, Year-round Desalination at Oceanside and the two Aggressive Conservation/Water Recycling and Local Groundwater Alternatives (without and with Supplemental Tuolumne River Water) – would involve either a diversion increase of less than 10 mgd or no increase in average annual diversion (see Table 9.5) and would result in shorter delays that occur less frequently than with the WSIP. Nonetheless, in order to meet the delivery reliability level of service goals, these alternatives would involve a change in system operations that would still result in a delay in spring releases due to the change in diversion patterns. For all but the No Program Alternative and the two Aggressive Conservation/Water Recycling and Local Groundwater Alternatives, the implementation of the Westside Basin Project would also affect the year to year diversions from the Tuolumne River thus potentially affecting spring flow releases. This delay in spring releases was deemed to still result in a significant adverse impact on mountain meadows and associated resources (i.e., sensitive habitats and species). As a result, the analysis determined that the impact would be potentially significant and that mitigation would still be required for these alternatives.

Although the Lower Tuolumne River Diversion Alternative would provide environmental benefits to water quality, habitat, fish, and recreation during most summers, winters and early spring as a result of flow being released to the river below O'Shaughnessy Dam for diversion further downstream, this alternative would still result in delays in the late spring (May and June) releases from O'Shaughnessy Dam, the same as and possibly greater than the WSIP. Therefore, despite the benefits at other times of the year, this delay was deemed to still result in a significant adverse impact on mountain meadows and associated resources (i.e., sensitive habitats and species). As a result, the analysis determined that the impact would be potentially significant and that mitigation would still be required for this alternative.

On the lower reach of the Tuolumne River below La Grange Dam, the WSIP would result in significant impacts on fisheries and riparian habitat, again as a result of reducing the volume and delaying the release of the higher spring flows from Don Pedro Reservoir (see Impacts 5.3.6-4 and 5.3.7-6). Most alternatives would have less impact on these resources in this river reach than the WSIP, except for the Lower Tuolumne River Diversion Alternative. The Lower Tuolumne Diversion Alternative would also result in additional fisheries impacts, including potential impacts on listed Chinook salmon and steelhead, as a consequence of constructing a new water intake facility in the lower river and diverting flow in the reach where listed Chinook salmon and steelhead occur, and would require supplemental mitigation for those effects in addition to the mitigation required under the WSIP. Four alternatives – the Aggressive Conservation / Water Recycling and Local Groundwater Alternative Without Supplemental Tuolumne River Water, the No Purchase Request Increase, the Year-round Desalination at Oceanside, and the Modified WSIP, would avoid this significant impact associated with the delay in spring releases.

Alameda Creek Watershed

In the Alameda Creek Watershed, all alternatives but the Modified WSIP Alternative would have the same significant impacts on fisheries in Alameda Creek below the diversion dam as the WSIP. This is because the impacts in this watershed are associated primarily with the replacement of Calaveras Dam (SV-2), as required by DSOD, and the subsequent revised system operations associated with restoration of storage capacity in the reservoir and are not related to which supply source(s) is selected to meet future customer delivery needs. The Calaveras Dam Replacement Project is required by DSOD to meet regulatory requirements, therefore it would occur under every alternative. Impacts would occur once the SFPUC resumes normal operation of that reservoir. The Modified WSIP Alternative would incorporate, as part of its description, the provision of a minimum flow in Alameda Creek below the Alameda Creek Diversion Dam to support resident trout spawning and egg incubation. (This minimum flow requirement is also proposed as mitigation for the WSIP.) Implementing the minimum flow requires the SFPUC to relinquish some of its supply that otherwise would have been available to customers. This supply reduction would have to be made up through more Tuolumne River diversion or more conservation, recycled water and local groundwater projects. The Modified WSIP Alternative proposes that the SFPUC develop more conservation, recycled water and local groundwater projects to both compensate for operational modifications that reduce supply for customers and reduce the amount of additional diversion required from the Tuolumne River to fully meet the WSIP program objectives, if possible.

Peninsula Watershed

In the Peninsula Watershed all alternatives but the No Purchase Request Increase Alternative and the Modified WSIP Alternative would have the same significant environmental impacts as the WSIP. This is because the impacts in this watershed are not a result of which water supply source is selected but are primarily associated with two actions proposed under the WSIP. The first is increased service to Coastside County Water District (Coastside CWD) to serve its 2030 purchase request and the second is implementation of the Lower Crystal Springs Dam Replacement Project (PN-4).

Coastside CWD assessed its future water supply needs and developed its 2030 customer purchase request from the SFPUC regional system. Coastside CWD requests a supply increase of 1.22 mgd by 2030. Coastside CWD serves Half Moon Bay and surrounding communities on the San Mateo County coast. The SFPUC currently serves Coastside CWD with about equal quantities of water from Pilarcitos Creek and Crystal Springs Reservoir. In order to meet Coastside's purchase request increase, under the WSIP the SFPUC would use more water from the Pilarcitos Creek watershed. However, as discussed in Section 5.5, this could result in significant environmental impacts on resources in and around Pilarcitos Reservoir and Creek. Two alternatives address these impacts; the other six alternatives would have the same impacts on Pilarcitos Reservoir and Creek resources. Under the No Purchase Request Increase Alternative, the SFPUC would not serve Coastside's 2030 purchase request increase and therefore this alternative would lessen the impacts on Pilarcitos Reservoir and Creek identified for the WSIP. Under the Modified WSIP Alternative, the SFPUC would serve Coastside's 2030 purchase request increase but it would modify its proposed system operation within the Peninsula Watershed to provide additional supply to Coastside CWD from Crystal Springs Reservoir instead of the Pilarcitos Creek watershed. As a result, under this alternative Pilarcitos Reservoir would be operated similarly to the way it is under existing conditions and none of the significant impacts associated with the WSIP would occur. However, this operational modification would require the SFPUC to provide Coastside CWD with some additional increment of supply from outside of the Pilarcitos Reservoir watershed from the rest of the regional water system. As discussed under the Alameda Creek Watershed above, this additional supply requirement would have to be made up through either more Tuolumne River diversion or more conservation, recycled water and local groundwater projects. The Modified WSIP Alternative proposes that the SFPUC develop more conservation, recycled water and local groundwater projects to both compensate for operational modifications that increase use of Crystal Springs Reservoir to serve Coastside CWD customers and to reduce the amount of additional diversion required from the Tuolumne River to fully meet the WSIP program objectives, if possible.

With respect to the significant environmental impacts associated with the Lower Crystal Dam Replacement Project and subsequent operation of Crystal Springs Reservoir to utilize the restored historical storage capacity, these impacts would occur under all alternatives because this project must be implemented under all alternatives in order to meet DSOD regulatory requirements. However, the Modified WSIP Alternative includes a modification to the proposed operation of this reservoir that would lessen the significant effects of increasing the reservoir water level on the oak woodland habitat and associated species. With this modification, the reservoir water levels would be allowed to fluctuate to a greater degree over the year than proposed under the WSIP such that the woodland trees would be able to survive the annual increase in inundation. This operational modification may require that the SFPUC sacrifice some of the increases in system delivery and drought reliability it would gain under the WSIP because it would not be able to store as much water in Crystal Springs Reservoir for as long each year. Additional modeling of this alternative would be needed to determine how it would specifically perform against the WSIP goals and objectives and if other system modifications could compensate for this change.

Westside Groundwater Basin

Three alternatives—No Program Alternative and the two Aggressive Conservation/Water Recycling and Local Groundwater Alternatives—would not include the Westside Basin conjunctive use program as a dry-year supplemental supply. Therefore, these alternatives would not result in potential overdraft or seawater intrusion in the North Westside Groundwater Basin or in the potential to affect Lake Merced levels due to implementation of the WSIP as proposed; however, as stated above, these three alternatives could all result in increased local groundwater pumping within the wholesale customer service area, with similar impacts as the WSIP. The remaining five alternatives would include the conjunctive use program, so groundwater impacts would be the same as for the WSIP.

Other Water Bodies

Three alternatives would affect other water bodies and their associated environmental resources in addition to those affected by the WSIP. The Lower Tuolumne River Diversion Alternative would result in direct impacts on the lower Tuolumne River from construction and operation of a new diversion facility. At the same time, compared to the WSIP this alternative would provide some benefit to both the upstream reach of the Tuolumne River below Hetch Hetchy Reservoir to Don Pedro Reservoir and the downstream reach below La Grange as a result of more water being released from Hetch Hetchy Reservoir for subsequent diversion downstream. However, while the upstream reach of the Tuolumne River supports a resident trout fishery, the downstream reach in the lower Tuolumne supports listed Chinook salmon and steelhead. This alternative would trade-off environmental benefits to both reaches of the river with adverse environmental impacts on the lower Tuolumne River.

The Regional Desalination for Drought Alternative would result in impacts on upper San Francisco Bay (along the eastern Contra Costa County shoreline based on the proposed plant location in the Pittsburg-Antioch area) in addition to the same water bodies affected by the WSIP. Under this alternative, water would be diverted from the bay, treated for use and the brine concentrate would then be discharged back to the Bay. The SFPUC has partnered with other Bay Area water agencies to evaluate the feasibility of this project which will include the ability to mitigate potential impacts to the Bay to a level that is less than significant. Alameda County Water District has successfully implemented a brackish groundwater desalination project to supplement its supply. Marin Municipal Water District is currently evaluating a potential desalination facility and has proceeded with a pilot project. Thus, several agencies are pursuing this type of water supply project. It may be possible to design and operate the proposed regional desalination facility in a manner that does not have significant, unavoidable effects on the Bay, but additional detailed pilot testing and environmental study are required to assess the site-specific feasibility and environmental effects of the proposed regional desalination facility. This alternative represents a trade-off in terms of environmental effects; it would slightly reduce the amount of additional Tuolumne River to be diverted compared to the WSIP and thus lessen the impact on the river, but it would introduce impacts on San Francisco Bay that would not occur under the WSIP.

Under the Year-round Desalination at Oceanside Alternative, seawater from the Pacific Ocean offshore of the City and County of San Francisco would be diverted for treatment and use in a portion of San Francisco on a year-round basis and the concentrated brine byproduct would be discharged back into the ocean. As described above for the Regional Desalination for Drought Alternative, many water agencies are currently studying potential seawater desalination facilities along the coast of California. It may be possible to design and operate the proposed seawater desalination facility required under this alternative in a manner that does not have significant, unavoidable effects on the ocean, but additional detailed feasibility and environmental study is required to assess whether this is possible. This alternative represents a trade-off in terms of environmental effects; it would substantially reduce the amount of additional Tuolumne River to be diverted compared to the WSIP and thus lessen the impact to the river, but it would introduce impacts on the offshore waters of the Pacific Ocean that would not occur under the WSIP.

The four alternatives that do not fully meet the supply reliability and/or drought reliability objectives - the No Program Alternative, the No Purchase Request Increase Alternative and the Aggressive Conservation / Water Recycling and Local Groundwater Alternative, with and without supplemental Tuolumne River water, would each likely prompt BAWSCA and/or the wholesale customers to pursue alternative supplies to meet their communities' needs through 2030. Actions taken by BAWSCA and/or individual wholesale customers could result in impacts to other water bodies including more pumping of local groundwater supplies, or water transfers from other surface water sources. BAWSCA and/or the wholesale customers would likely pursue water transfers from other water agencies. If BAWSCA and/or wholesale customers were to pursue a water transfer from Modesto Irrigation District or Turlock Irrigation District, it would affect the Tuolumne River and associated resources much as the WSIP (though there would be institutional complexities associated with wheeling water through third party facilities). If BAWSCA and/or wholesale customers were to pursue a water transfer from other entities, this could result in environmental effect on other rivers north or south of the Delta as well as the Delta, itself. Alternatives that result in water transfers from water sources other than as proposed under the WSIP also present environmental impact trade-offs; they could potentially lessen the effects of the WSIP on the Tuolumne River and, in one case to Pilarcitos Reservoir and Creek, but they introduce potential impacts on other water bodies and their associated resources and require additional mitigation.

Under the Aggressive Conservation / Water Recycling and Local Groundwater Alternatives (both without supplement supply and with supplemental Tuolumne River water) and possibly under the No Program and No Purchase Request Increase Alternatives, the wholesale customers would implement groundwater projects, which could result in overdraft and associated impacts to local groundwater basins, including seawater intrusion, similar to the effects described in Section 5.6 for the Westside Groundwater Basin. These alternatives also present environmental impact trade-offs; they could potentially lessen the effects of the WSIP on the Tuolumne River but they could introduce potential impacts to other water bodies and their associated resources and require additional mitigation.

Facility Impacts

Seven alternatives, except for the No Program Alternative, would involve the construction of all the same 22 facility projects on the SFPUC regional system as proposed under the WSIP. These projects are needed to repair and improve the system to meet the supply delivery and seismic reliability objectives regardless of target delivery demand level or source of supply. The sizing of some facilities would need to be evaluated under the various alternatives and might be revised / reduced from that proposed under the WSIP, but no facility project would be eliminated from the program. As a result all alternatives but the No Program Alternative would have, at a minimum, the same facility construction and operation impacts as the WSIP.

Under the No Program Alternative only five projects required to meet regulatory requirements are assumed to be implemented. Because far fewer facility improvement projects would be built under this alternative there would be much less facility construction and operation impact compared to the WSIP. However, it is expected that there would be much more emergency facility repair under this alternative as the system continued to age without proactive improvement and thus, ultimately, through required repair and rehabilitation efforts, a similar level of facility improvement projects might have to be carried out, resulting in much of the same facility impacts as the WSIP but possibly occurring over a longer period of time and in a less planned and comprehensive manner.

All eight alternatives would require construction and operation of other new facilities in additional to all the WSIP facility improvement projects. The two Aggressive Conservation / Water Recycling and Local Groundwater Alternatives (without and with Tuolumne River supplement), and to a lesser extent the Modified WSIP Alternative, would require the SFPUC and/or the wholesale customers to construct and operate additional water recycling treatment plants and distribution pipelines along with groundwater wells and distribution lines throughout the wholesale customer service area. The number and location of these facilities is not known but several new and/or expanded facilities would be required. Similarly, under the No Program and No Purchase Request Increase alternatives, the wholesale customers might decide to develop additional water recycling and/or groundwater facilities and, in addition, might pursue other surface water supplies that could require new treatment, storage or transmission facilities.

Both desalination alternatives require construction and operation of a new treatment plant, a water intake structure, transmission and distribution pipelines and possible storage. The Lower Tuolumne River Diversion Alternative requires construction and operation of a new water diversion structure on the river, a new water treatment plant and new pipelines. These alternatives would involve substantial additional facility construction and operation impacts, including impacts on land use, traffic, air quality, noise, energy and others. In addition, these alternatives would use greater amounts of energy than the WSIP and, as a consequence, could contribute additional greenhouse gas emissions along with other air pollutant emissions. The desalination process is particularly energy intensive; thus, the two alternatives that include desalination plants would make a more substantial contribution to increasing energy use and associated greenhouse gas emissions than the other alternatives.

Growth Inducement and Secondary Effects of Growth

As discussed in Chapter 7, the WSIP would provide water supply to some customers to use in supporting additional growth within their communities and, as such, water supply would be less of a potential constraint to growth. The communities within the regional system service area have evaluated their growth plans (i.e., through General Plans and Urban Water Management Plans) and found that there are some significant and, in some cases, significant and unavoidable impacts that could or would occur as a result of planned growth. One alternative, the No Purchase Request Increase Alternative, specifically attempts to reduce or avoid the growth inducing effects of the WSIP and two other alternatives (the No Program Alternative and the Aggressive Conservation, Recycled Water and Local Groundwater Alternative) also appear to have less growth inducement potential than the WSIP

The No Purchase Request Increase Alternative was included in the range of alternatives evaluated in the PEIR specifically to consider the consequences of the SFPUC not fully providing for future water supply needs of its customers in an attempt to avoid or minimize the significant secondary effects associated with planned growth in the service area. As discussed above, while the SFPUC would plan not to fully meet the future 2030 water purchase request from its wholesale customers under this alternative, it is expected that the customers would pursue and secure the additional supplies they require. Thus, with respect to the SFPUC’s actions, this alternative would have less growth inducement potential than the WSIP but combined with the wholesale customers actions, the same planned growth is ultimately expected to occur resulting in largely the same secondary effects of growth as would occur with the WSIP. While it is possible that approval of additional development and growth within the wholesale customer service area might be slowed somewhat in some communities as wholesale customers require more time to pursue other water supply and reliability projects, it is not expected that this would deter communities from ultimately taking the actions needed to support planned growth. As a result, this alternative is not an effective approach to avoiding or reducing the significant secondary effects of growth.

The No Program Alternative and the Aggressive Conservation, Recycled Water and Local Groundwater Alternative would both provide additional supplies to partially meet the 2030 average annual delivery demand and drought year needs but the supply would not be as reliable as that provided by the WSIP. As a result, as with the No Purchase Request Alternative, it is expected that the SFPUC wholesale customers and/or BAWSCA would pursue other projects and actions to provide the desired level of supply and supply reliability. While the need to develop additional projects beyond the WSIP might have some slowing effect on development approvals in some communities, it is not expected to impeded growth from continuing in accordance with adopted plans. As a result, this alternative would have similar secondary effects of growth as those described for the proposed program.

The other four alternatives would each have the same growth inducement potential and associated secondary effects of growth as the WSIP.

9.3.2 Environmentally Superior Alternative

CEQA requires the identification of an environmentally superior alternative from among the proposed project and the set of alternatives evaluated. The CEQA Guidelines further state that if the No Program Alternative is the environmentally superior alternative, then the EIR must also identify which of the action alternatives is the environmentally superior alternative. In this case, the No Program Alternative is not the environmentally superior alternative.

Although it appears that fewer facility improvement projects would be implemented under the No Program Alternative and that, as a result, there would be fewer facility and construction impacts, it is expected that there would be much more emergency facility repair and replacement projects under this alternative as the system continues to age without proactive improvement. Ultimately, through required repair and replacement efforts, a similar level of facility improvement projects as that proposed under the WSIP might have to be conducted under the No Program Alternative, resulting in much of the same facility impacts as the WSIP; however, these repair and replacement projects would likely occur over a longer period of time and in a less coordinated and comprehensive manner. In addition, implementing system improvements through a piecemeal and largely emergency response approach could result in greater environmental impacts and less mitigation for such impacts; when projects are implemented under emergency conditions, they often require little or no environmental review and thus could be implemented without the same level of mitigation and mitigation compliance monitoring that would be required for the WSIP. Furthermore, piecemeal implementation could also increase the cumulative effects of multiple, sequential facility repair and replacement projects throughout the system.

With respect to impacts on water resources, the No Program Alternative's effects on the Tuolumne River would be similar to but less than those of the WSIP because river diversions would not increase quite as much as with the WSIP; however, the No Program Alternative would result in the same significant impacts on the Tuolumne River as the WSIP and would require the same mitigation. As summarized above, the No Program Alternative would also have the same impacts as the WSIP on the Alameda Creek / Alameda watershed resources and on the Peninsula watersheds (including Pilarcitos Creek) resources. The No Program Alternative would have the same growth-inducement potential and associated secondary effects of growth as the WSIP because BAWSCA and the wholesale customers would be expected to secure supplemental supplies to meet any supply delivery and reliability shortfall from the regional system that would result under the No Program Alternative.

Finally, under this alternative, the SFPUC, BAWSCA and/or the wholesale customers might have to construct and operate additional facilities in order to develop supplemental surface water supplies, recycled water, or groundwater. Required facilities could include new treatment plants, storage and transmission facilities, and groundwater wells. The impacts of constructing and operating these facilities would be in addition to those resulting from improvement and repair of the regional system. Thus, the No Program Alternative could result in greater facility impacts than the WSIP. Because the No Program Alternative would not appreciably lessen the environmental impacts of the WSIP, might result in additional impacts due to the need for supplemental supply development and associated facility construction, and would not meet most of the basic program objectives, it is not considered the environmentally superior alternative.

In addition to having many of the same environmental impacts as the WSIP, under the No Program Alternative, the SFPUC would be unable to meet most of the program objectives. The No Program Alternative would leave the SFPUC and its customers at significant risk of supply reduction or disruption during an earthquake or other emergency, or during a drought. This is not a feasible or acceptable alternative for the SFPUC.

The Modified WSIP Alternative is considered to be the environmentally superior alternative. It would reduce key impacts of the proposed WSIP on natural resources along the lower Tuolumne River, along Alameda Creek below the diversion dam, at Pilarcitos Reservoir and along Pilarcitos Creek, and in Crystal Springs Reservoir, but it would continue to meet the WSIP's primary goals and objectives. Like the WSIP, this alternative would maximize the use of existing facilities and the largely gravity-driven system without also requiring the construction of additional major facilities called for under many other alternatives, or substantially increasing the energy demand of the system or need for pumping. While some of the other alternatives would avoid or lessen certain WSIP impacts, they would also result in substantial additional impacts that the WSIP would not generate, because these alternatives would require substantial additional major facilities and affect other environmental resources in different geographic locations in addition to those affected by the WSIP. For example, while the Year-round Desalination at Oceanside Alternative would meet the program objectives and lessen some of the impacts associated with the WSIP, it would also cause impacts to the marine environment associated with brine disposal, potential land use compatibility impacts due to space limitations in the vicinity of the proposed shoreline site, and require substantial energy use for the desalination process which would likely make a greater contribution to greenhouse gas and other pollutant emissions than the WSIP or other alternatives.

The Modified WSIP Alternative includes implementation of more conservation, water recycling and local groundwater projects within the regional service area than under the WSIP, which would require construction of some additional facilities in some areas not affected by the WSIP. However, while construction of these facilities would cause temporary construction disruption and related environmental impacts, long-term implementation of these regional conservation, water recycling, and local groundwater projects would offset impacts of the operational modifications proposed under the Modified WSIP Alternative on the Tuolumne River. Depending on the extent of these projects implemented by wholesale customers in collaboration with the SFPUC, they could also help reduce the amount of additional diversion required from the Tuolumne River to serve the 2030 customer purchase requests.

9.4 Alternatives Identification and Screening

This section presents the process and results of identifying and screening alternative concepts and strategies in order to develop the range of alternatives analyzed in Section 9.2.

9.4.1 Process for Identifying Alternative Concepts

Alternatives to be considered under CEQA are those that can avoid or substantially lessen one or more of the significant environmental effects identified for the proposed program. Many of the adverse environmental impacts of the WSIP described in Chapters 4 and 5 were judged to be less than significant. Other adverse impacts were judged to be significant or potentially significant but could be reduced to a less-than-significant level through the application of mitigation measures. Still others were judged to be significant and unavoidable, even with the application of mitigation measures described in Chapter 6. This section summarizes the chief significant environmental impacts identified for the WSIP and discusses potential strategies to avoid or lessen these significant effects. It also describes the process used to develop and identify the alternatives analyzed above in Section 9.2 and includes descriptions of preliminary alternatives as well as the concepts, strategies, and other elements used to develop the alternatives. The basic process is described below:

1. Review potentially significant/significant mitigable (PSM/SM) and potentially significant/significant unavoidable (PSU/SU) impacts identified in Chapters 4 and 5 of this PEIR and identify strategies to lessen or avoid impacts.

2. Review ideas and alternative concepts suggested during PEIR scoping.

3. Conduct preliminary screening of identified strategies and alternative concepts by determining if the strategy/concept meets <u>both</u> of the following criteria:

   - Does it meet any of the basic WSIP goals and objectives?
   - Would it lessen or reduce identified significant impacts?

   If the answer to either question was “no,” the concept was eliminated from further consideration. If the answer to both questions was “yes,” the concept was retained for further consideration.

4. Develop preliminary alternatives based on strategies and concepts retained for further consideration. Review feasibility issues with respect to technical, institutional, and regulatory concerns. If the preliminary alternative was determined to be infeasible, the conceptual alternative was eliminated from further consideration.

5. Develop and refine final alternatives for CEQA analysis in Section 9.2 and identify preliminary feasibility issues to be considered as part of the alternatives analysis.

Each step in this process is further described below. Section 9.5 provides a more detailed description of the concepts and strategies that were eliminated from further consideration and the reasons for their elimination.

9.4.2 Identified Impacts and Potential Strategies to Avoid or Lessen Significant Effects

Significant Facilities-Related Impacts and Strategies to Avoid or Lessen Effects

As described throughout Chapter 4, implementation of the WSIP would have potentially significant construction and/or operations impacts associated with the 22 facility improvement projects in the five regions analyzed in this PEIR. Chapter 4 identifies potentially significant construction impacts for individual facility improvement projects at and near individual project sites; potentially significant collective effects due to concurrent construction of WSIP facilities in the same and multiple regions (overlapping and multi-regional); and potentially significant impacts related to the WSIP facilities' contribution to cumulative impacts. Potentially significant mitigable (PSM) and potentially significant unavoidable (PSU) impacts were identified for one or more facility improvement project(s), as described below.

Significant Facilities Construction Impacts

- Land Use – temporary disruption of existing land uses, including PSU impact for New Irvington Tunnel (SV-4); and PSU impact for collective, overlapping effects in the Bay Division Region
- Geology – slope instability, squeezing ground/subsidence during tunneling, expansive or corrosive soils
- Hydrology – short-term depletion of groundwater resources
- Biological Resources – impacts on wetlands, aquatic resources, sensitive habitats, common habitats, heritage trees, special-status species, including PSU collective impacts in the Sunol Valley and Peninsula Regions
- Traffic – impacts related to roadway capacity, traffic delays, impaired access, parking, and safety hazards, including PSU collective and cumulative impacts
- Air Quality – emission of air pollutants, and exposure to diesel particulate matter, including PSU collective and cumulative impacts
- Noise and Vibration – disturbance adjacent to sites and haul routes, including PSU construction noise impacts for all projects, PSU vibration impacts for multiple projects, as well as PSU and PSM collective impacts in all regions and PSU cumulative impact
- Public Services and Utilities – impacts related to utility disruption, landfill capacity, compliance with solid waste regulations
- Recreational and Agricultural Resources – temporary conflicts with established uses
- Hazards – temporary exposure to hazardous materials
- Energy – construction energy use

Significant Facilities Siting/Design Impacts

- Land Use – permanent displacement or long-term disruption of existing land uses, including PSU impacts for SJPL System (SJ-3), 40-mgd Treated Water (SV-3), SABUP (SV-6), BDPL Reliability Upgrade (BD-1), CS/SA Transmission (PN-2), Groundwater Projects (SF-2), and Recycled Water Projects (SF-3)

- Visual Quality – effects on scenic vistas or visual character, including PSU impact for Calaveras Dam (SV-2); new sources of light and glare

- Hydrology and Water Quality – flooding impacts, increases in impervious surfaces

- Biological Resources – conflicts with adopted conservation plans

- Cultural Resources – impacts on paleontological resources, archaeological resources, and historic resources, including PSU impacts for Calaveras Dam (SV-2), New Irvington Tunnel (SV-4), CS/SA Transmission (PN-2), and Lower Crystal Springs Dam (PN-4), and PSU collective impacts in the Sunol Valley and Peninsula Regions, and PSU cumulative impacts

- Public Services and Utilities – relocation of utilities

- Recreational and Agricultural Resources – long-term conflicts with established uses

Significant Facilities Operational Impacts

- Biological Resources – water discharge effects on riparian/aquatic resources

- Energy – operational energy use

Strategies to Avoid or Lessen Significant Facilities-Related Impacts

Mitigation measures identified in Chapter 4 and described in Chapter 6 would reduce most of the facilities-related impacts listed above to a less-than-significant level, and include measures that would be implemented at the project level, such as construction controls or footprint or project design features. However, this PEIR identifies many impacts as PSU. Although SFPUC construction measures and additional mitigation measures would be applied to these impacts, the remaining environmental impacts would remain significant or potentially significant and therefore unavoidable. However, in many cases, the PSM and PSU impacts were identified as such because there was not enough site-specific information at this program level of analysis to determine definitively whether the impact would be less than significant or whether the identified mitigation measures could reduce the severity of the impact to a less-than-significant level. Separate, project-level CEQA evaluation of the WSIP projects could either confirm that the impact is less than significant or that mitigation is available to reduce the impact to a less-than-significant level. For the purpose of the PEIR analysis, a conservative determination regarding the level of impact has been made, and the designation of PSU is applied to disclose the potential for such effects.

Regardless of mitigation measures, programmatic strategies that would meet one or more of the basic WSIP objectives and might avoid or lessen the significant facilities impacts include:

- Reduce the number and/or extent of facility improvement projects to avoid construction, siting, or operational impacts associated with one or more project (possibly reducing the ability of the WSIP to fully meet the level of service goals for water quality, seismic reliability, delivery reliability, or water supply). This strategy could also lessen the collective and overlapping effects of multiple WSIP projects.

- Phase/extend the WSIP construction schedule such that fewer projects, especially those with geographic overlap, occur concurrently to lessen the collective regional and multi-regional impacts associated with the effects of multiple WSIP projects.

- Refine project site selections and/or facility layout designs to avoid or minimize impacts on sensitive resources (e.g., biological resources, cultural resources, land use, or agricultural lands).

Significant Water Supply/System Operations Impacts and Strategies to Lessen or Avoid Effects

As described in Chapter 5, implementation of the WSIP would have potentially significant impacts on water bodies and associated resources due to the changes in water supply and system operations. Chapter 5 identifies potentially significant impacts that would occur in the Tuolumne River, Alameda Creek, Peninsula watersheds (San Mateo and Pilarcitos Creeks) and in the Westside Groundwater Basin. Potentially significant water supply and system operations impacts, both mitigable and unavoidable, were identified, as described below.

Significant Tuolumne River Watershed and Downstream Impacts

- Effects on fishery resources below La Grange Dam

- Effects on alluvial features that support montane meadow and riparian habitat between Hetch Hetchy and Don Pedro Reservoirs and on riparian resources below La Grange Dam

Significant Alameda Creek Watershed Impacts

- Changes in flow in Alameda Creek below the diversion dam (significant and unavoidable)

- Effects on fishery resources in Alameda Creek below the diversion dam

- Effects on biological resources in Calaveras Reservoir, Calaveras Creek, and Alameda Creek

- Effects on recreational and visual resources in the Sunol Regional Wilderness near Alameda Creek below the diversion dam

Significant Peninsula Watershed Impacts

- Effects related to water quality, fisheries, and biological resources in Pilarcitos Reservoir and along Pilarcitos Creek

- Effects on fishery resources in tributaries to Crystal Springs Reservoir (PSU)

- Effects on biological resources around Upper and Lower Crystal Springs Reservoirs

Significant Westside Groundwater Basin Impacts

- Potential overdraft in the North Westside Groundwater Basin and related effects, including changes in Lake Merced water levels and seawater intrusion
- Water quality effects on drinking water due to groundwater pumping in the North and South Westside Groundwater Basin

Strategies to Avoid or Lessen Significant Water Supply and System Operations Impacts

Mitigation measures identified in Chapter 5 and described in Chapter 6 would reduce most of the effects listed above to a less-than-significant level, although a few of the impacts were identified as PSU. As an alternative to mitigation measures, programmatic strategies that would meet one or more of the basic WSIP objectives that might avoid or lessen the significant water supply and system operations impacts are presented below.

Reducing the amount of additional water diverted from the Tuolumne River could avoid or substantially lessen the significant impacts of the WSIP on the Tuolumne River watershed. Strategies include:

- Use an alternative supplemental supply source instead of the Tuolumne River to meet future purchase requests and/or dry-year water supply reliability needs.
- Use Tuolumne River water to meet additional water supply needs, but alter the point of diversion to a location downstream from the potentially affected fisheries and biological resources.
- Reduce service, thereby reducing the ability to fully meet the level of service goals for water supply. Specifically, do not meet some or all of the future purchase requests and/or dry-year water supply reliability needs.
- Implement demand management to meet increased purchase requests and dry-year water supply reliability needs through aggressive conservation and water recycling only.

Strategies to avoid or lessen impacts in the Alameda Creek watershed include:

- Do not resume diversions from Alameda Creek above the diversion dam to Calaveras Reservoir after Calaveras Dam is restored (possibly reducing the ability of the WSIP to fully meet the level of service goals for water supply and delivery reliability).
- Do not resume diversions from Alameda Creek above the diversion dam to Calaveras Reservoir to historical (pre-2002) levels after Calaveras Dam is restored, but recapture the flows at a location downstream from the potentially affected resources and pump the recaptured water to the regional system.

Strategies to avoid or lessen impacts in the Peninsula watershed include:

- Do not increase water storage in Crystal Springs Reservoir over existing levels for prolonged periods.
- Do not fully meet the 2030 increased purchase requests from wholesale customers served from Pilarcitos Reservoir.

Strategies to avoid or lessen impacts in the Westside Groundwater Basin include:

- Use an alternative supplemental supply instead of groundwater.
- Implement demand management, including conservation and/or water recycling, to reduce demand for additional potable water and thereby avoid or reduce the need to use groundwater.

Growth-Inducement Impacts and Strategies to Avoid or Lessen Effects

As discussed in Chapter 7, the WSIP would support some additional growth within the SFPUC service area—primarily the planned growth reflected in the adopted general plans of the local communities. This growth would result in potentially significant secondary environmental effects such as increased traffic, air pollution, greenhouse gas emissions, noise, and demand for public services and utilities; loss of open space; and effects on water quality, cultural resources, and habitat and associated biological resources. Local land use jurisdictions have prepared CEQA documents on their general plans to assess the secondary effects of growth; as part of that process, these jurisdictions have adopted mitigation measures for the secondary effects of planned growth and have also adopted statements of overriding considerations in cases where they approved growth that could result in significant and unavoidable impacts.

Strategies to Avoid or Lessen Growth-Inducement Impacts

The secondary effects of growth supported by the WSIP would meet one or more of the basic WSIP objectives that could be avoided or substantially reduced by the following strategy:

- Reduce service, thereby reducing the ability to meet the 2030 customer purchase request increase; meet only purchase request levels reflected in the existing Master Water Sales Agreement with the wholesale customers.

9.4.3 Preliminary Screening of Alternative Strategies and Concepts

This section summarizes the overall alternative strategies and concepts considered in the CEQA alternatives analysis, and it provides a preliminary screening based on the ability of each alternative to meet the WSIP level of service goals. The preliminary screening includes both the strategies identified in Section 9.4.2 as well as the concepts raised during the public scoping period. All of the strategies and concepts are grouped into one of the following four main categories: strategies/concepts that affect facilities; strategies/concepts that affect system operations; strategies/concepts that affect water supply sources; and other strategies/concepts.

Summary of Strategies to Avoid or Lessen Significant Impacts

Table 9-13 summarizes and categorizes the strategies identified in Section 9.4.2 to avoid or lessen significant impacts of the proposed program. The table also indicates the ability of each strategy to meet the basic WSIP performance objectives and level of service goals as a preliminary screening of alternative strategies.

Alternative Concepts Raised During PEIR Scoping

The WSIP PEIR Scoping Report (see Appendix A) summarizes the comments made during the public scoping process for this PEIR for consideration during the environmental review process. Participants in the scoping process presented numerous suggestions for reducing potential impacts as well as possible alternatives to one or more aspect of the proposed WSIP. **Table 9-14** summarizes the alternative concepts raised during the public scoping process and indicates the ability of each idea to meet the basic WSIP performance objectives and level of service goals as a preliminary screening of these ideas.

9.4.4 Alternative Screening

Tables 9-13 and 9-14 list alternative strategies and concepts that were either developed to reduce significant impacts or suggested during the public scoping period, and indicate the ability of each strategy or concept to meet the basic WSIP objectives. All of the strategies listed in Table 9-13 would meet one or more of the basic objectives and would avoid or lessen at least one significant impact. Many of the concepts in Table 9-14 would meet one or more of the basic objectives; however, some of the concepts would meet none of the basic WSIP objectives, and those concepts were eliminated from further consideration, as indicated in the table. In a few cases where extensive scoping comments were made on a concept, further discussion of the concepts and reasons for elimination is provided in Section 9.5.

This section further develops the strategies and remaining concepts, addresses feasibility issues of each strategy and concept, and provides screening for the alternatives and concepts that were either retained for detailed study in this PEIR, or eliminated from, further consideration as CEQA alternatives. Strategies and concepts were considered in the formulation of the range of alternatives evaluated in Section 9.2 if they were determined to be both feasible to implement and potentially effective in avoiding or reducing the environmental impacts associated with the WSIP. The range of alternatives identified for further evaluation and comparison to the WSIP is presented in Section 9.2.

In this section, alternative concepts or strategies were eliminated from further consideration for one or more of the following reasons: (a) they are a variation on an alternative that is evaluated in this PEIR in detail and thus are already represented in the range of alternatives selected for evaluation, (b) they do not meet the CEQA criteria for an alternative (i.e., meet most of the basic

TABLE 9-13
STRATEGIES TO AVOID OR LESSEN SIGNIFICANT IMPACTS AND PRELIMINARY SCREENING

Strategies to Avoid or Lessen Significant Impacts	Does the Strategy Meet the WSIP Performance Objectives and Level of Service Goals? Water Quality	Seismic Reliability	Delivery Reliability	Water Supply	Preliminary Screening
Strategies that Affect Facilities and Could Reduce Facilities Impacts					
Reduce the number and/or extent of facility improvement projects.	No to partially (depends on which projects)	No to partially (depends on which projects)	No to partially (depends on which projects)	No to partially (depends on which projects)	Concept is addressed under No Program Alternative and analyzed in Section 9.2.
Phase/extend the WSIP construction schedule such that fewer projects, especially those with geographic overlap, occur concurrently to lessen the collective regional and multi-regional impacts associated with the effects of multiple WSIP projects.	Partially (could delay ability to meet water quality requirements)	Yes (but would prolong period of time system is subject to seismic risks)	Yes (but may delay regular maintenance program and ability to keep local reservoirs full)	Yes	Concept is discussed in Section 9.4.4 and screened from further consideration, as described in more detail in Section 9.5.
Refine project site selections and/or facility layout designs that avoid or minimize impacts on sensitive resources (e.g., biological, cultural, land use, or agricultural lands).	Yes	Yes	Yes	Yes	Concept is discussed in Section 9.4.4 and screened from further consideration, as described in more detail in Section 9.5.
Strategies that Affect System Operations and Could Reduce Growth or System Operations Impacts					
Reduced service – do not fully meet the WSIP project objectives for water supply. Specifically, do not meet some or all of the future purchase requests and/or dry-year water supply reliability needs. ▪ Meet purchase request levels reflected in the existing Master Water Sales Agreement with the wholesale customers only ▪ Do not fully meet 2030 purchase requests from customers served from Pilarcitos Reservoir	Yes	Yes	Yes	No	Concept is further developed under No Purchase Request Increase Alternative and analyzed in Section 9.2.
Alter the point of diversion for additional Tuolumne River water needed to meet future water supply needs to a location downstream from the potentially affected fisheries and biological resources.	No, would require treatment prior to mixing with Hetch Hetchy supplies	Yes	Yes	Yes	Concept is further developed under Lower Tuolumne River Diversion Alternative and analyzed in Section 9.2.
Do not resume diversions from Alameda Creek above the diversion dam to Calaveras Reservoir after Calaveras Dam is restored.	Yes	Yes	No	No	Concept is discussed in Section 9.4.4 and screened from further consideration, as described in more detail in Section 9.5.

TABLE 9-13 (Continued)
STRATEGIES TO AVOID OR LESSEN SIGNIFICANT IMPACTS AND PRELIMINARY SCREENING

Strategies to Avoid or Lessen Significant Impacts	Does the Strategy Meet the WSIP Performance Objectives and Level of Service Goals?				Preliminary Screening
	Water Quality	Seismic Reliability	Delivery Reliability	Water Supply	
Strategies that Affect System Operations (cont.)					
Do not resume diversions from Alameda Creek above the diversion dam to Calaveras Reservoir to historical (pre-2002) levels after Calaveras Dam is restored, but recapture the flows at a location downstream from the potentially affected resources and pump the recaptured water to the regional system.	Yes	Yes	No	No	Concept is discussed in Section 9.4.4 and screened from further consideration, as described in more detail in Section 9.5.
Do not increase water storage in Crystal Springs Reservoir over existing levels for prolonged periods.	Yes	Yes	No	No	Concept is further developed under Modified WSIP Alternative and analyzed in Section 9.2.
Strategies that Affect Water Supply Sources and Could Reduce Water Supply Impacts					
Use an alternative supplemental supply source to meet future purchase requests and/or dry-year water supply reliability needs. ▪ Use an alternative supply source instead of additional Tuolumne River water ▪ Use an alternative supply source instead of additional pumping from the North Westside Groundwater Basin	Yes	Yes	Yes	Yes	Concept of alternative supply sources is addressed under Aggressive Conservation/Water Recycling and Local Groundwater Alternative and Year-round Desalination at Oceanside Alternative and analyzed in Section 9.2.
Implement demand management to meet increased purchase requests and dry-year water supply reliability needs through aggressive conservation and water recycling only.	Yes	Yes	Yes	Yes	Concept is addressed under Aggressive Conservation/Water Recycling and Local Groundwater Alternative and analyzed in Section 9.2.

TABLE 9-14
ALTERNATIVE CONCEPTS RAISED DURING PEIR SCOPING PROCESS AND PRELIMINARY SCREENING

Alternative Concept	Does the Concept Meet the WSIP Objective and Level of Service in the following areas?				Preliminary Screening
	Water Quality	Seismic Reliability	Delivery Reliability	Water Supply	
Concepts that Affect Facilities					
Do not expand the capacity of the system to withdraw water.	Yes	No	No	No	Concept does not meet three of the basic program objectives but is discussed under the No Program Alternative – analyzed in Section 9.2.
Enlarge Calaveras Reservoir to increase storage.	Yes	No	No	Possibly	Concept is discussed in Section 9.4.4 and screened from further consideration, as described in more detail in Section 9.5.
Remove O'Shaughnessy Dam and restore Hetch Hetchy Valley and use alternative water and power supplies / Use available storage capacity at New Melones Reservoir.	No	No	No	No	Concept does not meet any of the basic program objectives – eliminated from further consideration but discussed further in Section 9.5.
Build a pump station downstream of Holm Powerhouse to pump water from Cherry Creek to Mountain Tunnel / Larger intertie to Cherry Creek / Cherry Reservoir to Mountain Tunnel.	No	No	No	Possibly	Concept is discussed in Section 9.4.4 and screened from further consideration, as described in more detail in Section 9.5.
Expand downstream and off-stream storage.	No	No	No	Possibly	Concept is discussed in Section 9.4.4 and screened from further consideration, as described in more detail in Section 9.5.
Convey water from Don Pedro Reservoir to San Joaquin Pipelines.	No	No	No	Possibly	Concept is further developed under Lower Tuolumne River Diversion Alternative and analyzed in Section 9.2.
Do not build San Joaquin Pipeline (SJPL) No. 4 / Alternative without SJPL No. 4 / Advantages, disadvantages, and impacts of cross connections among SJPLs Nos. 1, 2, and 3 / Status of crossover on the San Joaquin Pipeline system at Albers Road.	No	No	No	No	Concept does not meet any of the basic program objectives – eliminated from further consideration and not discussed further in this PEIR. The SFPUC removed the SJPL No. 4 project from the WSIP and replaced it with the SJPL System project (SJ-3), which would include improvements to the San Joaquin Pipeline system without installation of a completely new SJPL No. 4. Programmatic impacts of the SJPL System project are evaluated as part of the proposed program and as part of all alternatives analyzed in Section 9.2.
Build pump station near Tesla Portal to reduce need for fourth San Joaquin Pipeline.	No	No	No	No	Concept does not meet any of the basic program objectives – eliminated from further consideration and not discussed further in this PEIR. When compared to the proposed program, the addition of a pump station at Tesla Portal would result in increased construction and operational impacts without reducing any of the impacts identified for the WSIP. This concept was considered during development of the SJPL System project (SJ-3) and may be considered in the project-level alternatives analysis if warranted.
Repair leaky pipelines.	No	No	No	No	Concept does not meet any of the basic program objectives – eliminated from further consideration and not discussed further in this PEIR. This concept is part of the SFPUC's ongoing repair and rehabilitation activities, and while it would improve the efficiency of the existing water supply, it would not be sufficient to meet the delivery reliability or water supply objectives.

TABLE 9-14 (Continued)
ALTERNATIVE CONCEPTS RAISED DURING PEIR SCOPING PROCESS AND PRELIMINARY SCREENING

Alternative Concept	Does the Concept Meet the WSIP Objective and Level of Service in the following areas?				Preliminary Screening
	Water Quality	Seismic Reliability	Delivery Reliability	Water Supply	
Concepts that Affect System Operations					
Filtration of Sierra source water / Expansion of filtration capacity in the SFPUC system / Alternative locations for filtration equipment.	No	No	No	No	Concept does not meet any of the basic program objectives – eliminated from further consideration but discussed further in Section 9.5.
Use of water stored in other reservoirs – Lake Lloyd, Lake Eleanor, Don Pedro Reservoir.	No	No	Possibly	Possibly	Concept is incorporated into the existing conditions as well as the proposed program; under both scenarios, the SFPUC maximizes use of water stored in Lake Lloyd and Lake Eleanor as part of Hetch Hetchy Reservoir operations. Use of water stored in Don Pedro Reservoir is part of the existing condition through the water bank described in Chapter 2; it is also assumed under the WSIP for the proposed water transfers with TID and MID for a supplemental drought supply. See Chapter 3, Program Description, Section 3.6, Proposed Water Supply Sources, and analysis in Chapter 5, Section 5.3. This concept is also incorporated and evaluated as part of all alternatives selected for detailed analysis in Section 9.2.
Assume the maximum releases identified in the 1987 Agreement as the required minimum flows for the Tuolumne River.	No	No	No	No	There is presently no basis for assigning the maximum releases to particular time periods, and the concept does not meet any of the basic program objectives – eliminated from further consideration as an alternative. However, concept is considered in the cumulative impact analysis of water supply and system operations and analyzed in Chapter 5, Section 5.7.
Extend the duration of releases into Pilarcitos Creek from Pilarcitos Reservoir to create a more natural flow regime in the creek.	No	No	No	No	Concept does not meet any of the basic program objectives – eliminated from further consideration and not discussed further in this PEIR. This concept is being considered under the SFPUC's Watershed and Environmental Improvement Program, described in Chapter 3, Section 3.12.
Alternative that will provide increased amount and duration of releases from Holm Powerhouse that can be used for whitewater recreation.	No	No	No	No	Concept does not meet any of the basic program objectives – eliminated from further consideration and not discussed further in this PEIR. Releases from SFPUC facilities for whitewater recreation under the proposed program are described in Chapter 3, Section 3.7.1.
Improve freshwater flows for streams.	No	No	No	No	Concept does not meet any of the basic program objectives – eliminated from further consideration and not discussed further in this PEIR. This concept is being considered under the SFPUC's Watershed and Environmental Improvement Program, described in Chapter 3, Section 3.12.
Alternative that analyzes the maximum conveyance capacity.	No	No	Possibly	No	Operation of the regional system under existing conditions, the proposed program, and all alternatives and variants considers the maximum conveyance capacity of the transmission system in terms of optimizing system reliability at the same time as meeting customer water demands. Under the WSIP, CEQA alternatives, and WSIP variants, the maximum conveyance capacity is

TABLE 9-14 (Continued)
ALTERNATIVE CONCEPTS RAISED DURING PEIR SCOPING PROCESS AND PRELIMINARY SCREENING

Alternative Concept	Does the Concept Meet the WSIP Objective and Level of Service in the following areas?				Preliminary Screening
	Water Quality	Seismic Reliability	Delivery Reliability	Water Supply	
Concepts that Affect System Operations (cont.)					
					evaluated in terms of delivery reliability, which includes provisions for maintenance, replenishment of local reservoirs, and minimizing risk of service interruption. Therefore, this concept is incorporated and analyzed as part of the delivery reliability level of service for the proposed program and all alternatives.
Concepts that Affect Water Supply Sources					
Increased conservation, demand-side management.	No	No	Possibly	Possibly	All three concepts are incorporated into the proposed program as described in Chapter 3 and are analyzed as part of the WSIP. In addition, these concepts are further developed under the Aggressive Conservation/Water Recycling and Local Groundwater Alternative and analyzed in Section 9.2.
Increased recycling to meet demand.	No	No	Possibly	Possibly	
Local and regional groundwater.	No	No	Possibly	Possibly	
Infiltration of groundwater into Mountain Tunnel.	No	No	No	No	Concept does not meet any of the basic program objectives – eliminated from further consideration and not discussed further in this PEIR. Current operations of the regional water system account for groundwater accretions to tunnels, and there would be no change in future operations under the WSIP in this regard.
Conjunctive use / Groundwater banking options.	No	No	No	Possibly	This concept is already incorporated in the proposed program and analyzed in Chapter 5. As described in Chapter 3, the proposed program includes a conjunctive-use program in the Westside Groundwater Basin in northern San Mateo County as a supplemental dry-year water source.
Groundwater banking in Kern County	No	No	No	Possibly	The concept of groundwater banking in Kern County in the Semitropic groundwater bank is discussed in Section 9.4.4 and screened from further consideration, as described in more detail in Section 9.5.
Purchase groundwater storage rights in foothills east of and outside of MID/Central Valley.	No	No	No	Possibly	Concept is discussed in Section 9.4.4 and screened from further consideration, as described in more detail in Section 9.5.
Zero increase in imports from the Tuolumne River / No further depletions from the Tuolumne River.	No	No	No	No	Concept alone does not meet any of the basic program objectives. However, this concept is further developed in combination with other alternative water sources under the Aggressive Conservation/Water Recycling and Local Groundwater Alternative and analyzed in Section 9.2.
Supply from Delta / More interties to other water sources, such as the Delta / Connect to the State Water Project at the California Aqueduct or Central Valley Project at the Delta-Mendota Canal.	No	No	Possibly	Possibly	Concept is discussed in Section 9.4.4 and screened from further consideration, as described in more detail in Section 9.5.

TABLE 9-14 (Continued)
ALTERNATIVE CONCEPTS RAISED DURING PEIR SCOPING PROCESS AND PRELIMINARY SCREENING

Alternative Concept	Does the Concept Meet the WSIP Objective and Level of Service in the following areas?				Preliminary Screening
	Water Quality	Seismic Reliability	Delivery Reliability	Water Supply	
Concepts that Affect Water Supply Sources (cont.)					
Additional intertie with Santa Clara Valley Water District.	No	No	Possibly	Possibly	Concept is discussed in Section 9.4.4 and screened from further consideration, as described in more detail in Section 9.5.
Desalination as water supply source.	No	No	Yes	Yes	Concept is developed and analyzed as Variant 2, Regional Desalination for Drought, in Chapter 8, as well as under the Year-round Desalination at Oceanside Alternative in Section 9.2. The Aggressive Conservation/Water Recycling and Local Groundwater Alternative also includes a component of desalination and is analyzed in Section 9.2.
Purchase water from TID and MID.	No	No	Yes	Yes	Concepts are incorporated into the proposed program, which would include water transfers with TID and MID for a supplemental drought supply. See Chapter 3, Program Description, Section 3.6, Proposed Water Supply Sources, and the Modified Alternative, analyzed in Section 9.2, considers water transfers from other agencies.
Water transfers.	No	No	Yes	Yes	
Different combinations of water sources.	No	No	Yes	Yes	Concept is incorporated into the proposed program, which would augment existing supply sources with conservation, recycled water, and groundwater projects in San Francisco; water transfers with TID and MID; and conjunctive-use program in northern San Mateo County. See Chapter 3, Section 3.6, Proposed Water Supply Sources, and analysis in Chapter 5. The concept is also incorporated into the No Purchase Request Increase and Aggressive Conservation/Water Recycling and Local Groundwater Alternatives analyzed in Section 9.2 as well as WSIP Variant 2 – Regional Desalination for Drought, analyzed in Chapter 8.
Urban stormwater.	No	No	No	No	Concept does not meet any of the basic program objectives – eliminated from further consideration and not discussed further in this PEIR. This concept is considered under one component of the Groundwater Projects (SF-2) to use treated urban stormwater to maintain water levels in Lake Merced as well as under the Recycled Water Projects (SF-3), since San Francisco's combined sewer system captures urban stormwater which would be treated as part of the recycled water. This concept alone would not be sufficient to meet the delivery reliability or water supply objectives.
Other Concepts					
No Program.	No	No	No	No	Concept does not meet any of the basic program objectives but is further analyzed in Section 9.2 as required by CEQA.
Meet only seismic and water quality objectives.	Yes	Yes	No	No	Concept is further developed under the No Purchase Request Increase Alternative and analyzed in Section 9.2.

TABLE 9-14 (Continued)
ALTERNATIVE CONCEPTS RAISED DURING PEIR SCOPING PROCESS AND PRELIMINARY SCREENING

Alternative Concept	Does the Concept Meet the WSIP Objective and Level of Service in the following areas?				Preliminary Screening
	Water Quality	Seismic Reliability	Delivery Reliability	Water Supply	
Other Concepts (cont.)					
Meet only sustainability objective / Provide projects that meet the sustainability objective.	No	No	No	No	Concept does not meet any of the basic program objectives – eliminated from further consideration and not discussed further in this PEIR. However, the SFPUC would meet the sustainability objective through implementation of mitigation measures incorporated into the WSIP. This concept is being implemented through the SFPUC's Watershed and Environmental Improvement Program, described in Chapter 3, Section 3.12, as well as through the Alameda and Peninsula Watershed Management Plans.
Meet goals and objectives without a gravity-driven system.	Not defined	Not defined	Not defined	Not defined	Concept is not sufficiently defined to determine if it could meet program objectives or for it to be analyzed. At a minimum, if any alternative to the WSIP were developed that relied on pumping rather than gravity to convey water supplies from the Sierra to San Francisco, it would result in greater long-term air quality and energy impacts than the WSIP, without reducing any impacts of the WSIP. It would also require construction of additional pumping and transmission facilities, resulting in additional construction impacts. Therefore, this concept is eliminated from further consideration and is not discussed further in this PEIR.
Reduce regional per capita daily consumption / Do not fully meet all of the 2030 customer purchase requests.	Not defined	Not defined	Not defined	Not defined	Concept is further developed under No Purchase Request Increase Alternative and analyzed in Section 9.2.
Alternative rationing objectives / scenarios.	No	No	No	No	Concept alone does not meet any of the basic program objectives. However, an alternative rationing objective is developed under Variant 3, 10% Rationing, and analyzed in Chapter 8. In addition, the No Program Alternative does not define a maximum drought rationing policy, but the analysis in Section 9.2 assumes incidental rationing up to 30 percent.
Provide watershed and fish-passage projects aimed at improving habitat and restoring steelhead in the Pilarcitos Creek watershed, such as through the removal or bypass of Old Stone Dam.	No	No	No	No	Concept does not meet any of the basic program objectives – eliminated from further consideration and not discussed further in this PEIR. This concept is being considered under the SFPUC's Watershed and Environmental Improvement Program, described in Chapter 3, Section 3.12.

project objectives *and* avoid or lessen the impacts of the proposed project), or (c) they are not considered feasible to implement. However, it should be noted that SFPUC decision-makers will ultimately determine whether an alternative is feasible or infeasible at the time of program approval. At that time, decision-makers may consider, among other things, whether the alternatives are desirable from a public policy standpoint in light of the program's objectives and whether they provide a reasonable balance of relevant economic, environmental, social, and technological factors.

Strategies/Concepts that Affect Facilities and Could Reduce Facilities Impacts

Reduce the Number and/or Extent of Facility Improvement Projects

The concept of reducing the number or extent of facility improvement projects implemented as part of the WSIP is addressed under the No Program Alternative. This strategy might avoid or lessen the significant construction effects of individual and/or multiple WSIP projects (such as short-term construction traffic, noise, air quality) and still meet most of the WSIP objectives to some degree, depending on which projects would be removed from the WSIP. However, the SFPUC has a limited ability to reduce the number of facility projects and/or the extent of work proposed as part of the WSIP. Each of the proposed facility improvement projects is an important part of repairing and upgrading the regional system, and all of the projects are needed to assure the program objectives can be met. The No Program Alternative describes the effects of a greatly reduced facilities improvement program. Under this alternative, the SFPUC would still proceed with certain projects in order to comply with future water quality regulations. The No Program Alternative, which is discussed in more detail in Section 9.2, assumes that at least five projects required for current regulatory compliance would be implemented in the near term by the SFPUC, even if the SFPUC did not approve the entire program considered in this PEIR. While the No Program Alternative would reduce overall construction impacts, including avoiding some PSU impacts, this alternative would fail to meet the WSIP level of service goals for seismic, delivery, and water supply reliability.

Among the remaining WSIP PEIR projects (beyond those required for immediate regulatory compliance), the SFPUC has determined that all are critical to achieving the WSIP level of service goals. As shown in Chapter 3, Table 3.10, each of the WSIP projects would be required in order to meet some combination of the water quality, seismic reliability, delivery reliability, water supply, and sustainability objectives. The SFPUC has identified most of the WSIP projects as *key* projects for seismic and/or delivery reliability (SFPUC, 2006), but a few projects not listed as key still represent needed facilities that are critical for long-term maintenance and asset management, such as the Pulgas Balancing Reservoir project (PN-5). It might be possible to delay the few maintenance projects not identified as key, but they would ultimately be needed to ensure responsible and adequate maintenance of the system, or, if deferred too long, would possibly have to be conducted as emergency repair projects.

In some cases, a WSIP project would definitively have a significant unavoidable impact, such as the New Irvington Tunnel project (SV-4), even at this programmatic level of environmental review. Potentially significant, unavoidable impacts related to land use, visual quality, historic resources, and construction noise were identified for individual WSIP projects, but the only clear strategy to avoiding or substantially reducing the significant and unavoidable construction and siting effects would be to not implement those projects. However, this strategy would not be reasonable. As described above, each of the WSIP projects is needed to meet the proposed level of service goals, and those that are not urgent in terms of regulatory or public safety concerns would still be needed for long-term maintenance and asset management of the regional system.

Since all of the projects would eventually be required, delaying implementation of any one project would only defer rather than avoid the identified construction effects. Eliminating the few maintenance-type projects would not substantially reduce the overall construction impacts of the multiple-project WSIP and could potentially prolong the construction impacts. As a result, this PEIR does not evaluate a “reduced project” alternative beyond that represented by the No Program Alternative.

Phase/Extend the WSIP Construction Schedule

Phasing or extending the WSIP construction schedule so that fewer projects, especially those with geographic overlap, would occur concurrently is one approach that could lessen the collective regional and multi-regional impacts associated with multiple WSIP projects. However, this concept would prolong the duration of construction impacts as a trade-off for reducing impact intensity, which is not considered effective as an alternative to avoid or substantially lessen impacts associated multiple and overlapping construction projects. Therefore, this concept was eliminated from further consideration, as discussed in Section 9.5, below. To some degree, like the refinement of site and facility layouts (see immediately below), the feasibility of minimizing impacts due to concurrent construction of projects in the same geographic area would be examined as part of project-level environmental review. Detailed siting studies and construction requirements for each facility would be needed to identify further opportunities to avoid or minimize these environmental effects, and site-specific evaluations will be conducted as part of project-level CEQA review of each WSIP project. When more project-specific information becomes available, it is expected that the SFPUC would coordinate the phasing of construction schedules to minimize impacts where feasible. These project-specific issues are not evaluated in this PEIR, since these actions affect individual groups of projects only and not the WSIP as a whole and would be best addressed during project-level CEQA review. No further analysis in this PEIR is warranted.

Refine Project Site Selection or Facility Layouts

Refining the individual project site selection and/or the facility layout designs could avoid or minimize impacts on sensitive resources (e.g., biological resources, cultural resources, land use, or agricultural lands) associated with construction of individual facility improvement projects. This concept is deferred to the project-level environmental review of individual WSIP projects and was eliminated from further consideration in the PEIR.

A strategy to avoid or lessen footprint impacts associated with siting a project at a specific location would be to revise and refine individual site selection and/or facility layout designs. As this is a program EIR that provides a program-level review of the overall WSIP, detailed project siting and layout information, while in development, is not yet available for many WSIP projects. In most cases, the proposed facility improvement projects would be constructed on existing SFPUC property, at or adjacent to existing water system facilities. This basic siting approach has helped reduce the potential footprint effects of the proposed projects, but detailed siting and design studies for each facility would be needed to identify further opportunities to avoid or minimize these environmental effects. Site-specific evaluations will be conducted as part of project-level CEQA review of each WSIP project. During detailed project design and subsequent CEQA review, facility siting and layout designs will be considered. Where appropriate, project-level CEQA review will consider site and design alternatives to avoid or lessen the effects of individual projects. These specific site alternatives are not evaluated in this PEIR, since these actions affect individual projects only and not the WSIP as a whole. In addition, the SFPUC's construction measures along with the mitigation measures identified in this PEIR establish procedures and performance measures to be implemented during siting and design of WSIP projects to minimize environmental impacts where feasible. Therefore, alternatives and refinements to individual site selection would be best addressed during project-level CEQA review. No further analysis in this PEIR is warranted.

Strategies/Concepts that Affect Facilities and Could Reduce Water Supply Impacts

Enlarge Calaveras Reservoir

Enlarging Calaveras Reservoir to increase storage beyond the historical capacity could result in the capture of more water within the upper Alameda Creek watershed and could increase local water supplies. This concept also included the potential to provide pumping facilities and to store Tuolumne River water in an enlarged Calaveras Reservoir, thereby increasing local storage for use during droughts, planned or unplanned outages, or other emergencies. However, this concept would not avoid or reduce identified environmental effects associated with increased diversions from the Tuolumne River and would result in more severe environmental impacts on Alameda Creek than the proposed program; therefore, this concept was eliminated from further consideration, as discussed in Section 9.5, below.

Connect Cherry Creek Directly to Regional Water System

The Cherry Creek water supply could be connected directly to the regional water system by building a pump station downstream of Holm Powerhouse to pump water from Cherry Creek to Mountain Tunnel; this would augment supplies to the regional system to serve increased customer demand instead of increasing diversions from Hetch Hetchy Reservoir. However, this concept was eliminated from further consideration because it would result in far greater environmental effects than the proposed program, as discussed in Section 9.5, below.

Expand Downstream and Off-stream Storage

Expanding downstream and off-stream storage within the regional system could possibly augment regional system supplies to help meet increased customer demand. The SFPUC has a limited ability to develop or expand storage within the existing system beyond the facility improvement projects already incorporated into the WSIP, which are designed to restore historical storage capacity rather than expand storage (i.e., Calaveras Dam, SV-2, and Lower Crystal Springs Dam, PN-4). The concept to expand storage is incorporated into other strategies discussed below, including Enlarge Calaveras Reservoir and Recapture Upper Alameda Creek Flows Downstream, using the infiltration galleries, quarries, or Alameda County Water District (ACWD) facilities. Both concepts were eliminated from further consideration due to institutional constraints or technical infeasibility, as discussed below in Section 9.5.

Strategies/Concepts that Affect System Operations and Could Reduce System Operations Impacts

Revise Alameda Creek Diversion Dam Operations

This concept involves not resuming historical levels of diversions from Alameda Creek above the diversion dam to Calaveras Reservoir after Calaveras Dam is restored. However, this concept was eliminated from further consideration since it would not meet two fundamental WSIP objectives—water supply and delivery reliability—and would make the system more vulnerable to water supply shortages in the event of drought or Hetch Hetchy system emergency outages because Alameda Creek is a local water supply source. This concept could affect the CCSF's water rights to Alameda Creek drainage, as discussed in Section 9.5, below.

Recapture Upper Alameda Creek Flows Downstream

This concept involves not resuming the historical pattern of diversions from Alameda Creek above the diversion dam to Calaveras Reservoir, recapturing the flows downstream from the potentially affected resources, and pumping the recaptured water to the regional system. The SFPUC explored the possibility of recapturing flows downstream at the Sunol infiltration galleries, the quarries, and ACWD facilities. This concept was eliminated from further consideration because of technical infeasibility, as discussed in Section 9.5, below.

Strategies/Concepts that Affect Water Supply Sources and Could Reduce Water Supply Impacts

Both Tables 9-13 and 9-14 indicate that alternative water supply sources would be a possible strategy to meet future purchase requests and to reduce identified impacts of the WSIP. Possible water supply sources shown in these tables include increased conservation (i.e., demand management), increased water recycling, local and regional groundwater, desalination, Delta groundwater banking/conjunctive use, and interties with other agencies. Conservation, increased water recycling, local groundwater, and desalination are incorporated into alternatives discussed and analyzed in Section 9.2. The overall approach of other water supply sources reviewed are discussed below.

As described in Chapter 3, Section 3.4, the SFPUC has conducted numerous water supply studies over the last 20 years to explore strategies and options for meeting future water purchase requests and dry-year water supply reliability needs. These studies have considered a broad range of water supply alternatives. Appendix C of the *Water Supply Options* report (SFPUC, 2007b), referred to as the WSIP Option 3 study, reviewed three previous water supply reports that considered among them a total of 28 potential water supply alternative projects to meet the growing water supply needs for the SFPUC system:

- *Alternative Means of Providing Additional Water to the San Francisco Water Department* (Kennedy/Jenks Engineers, 1986) – 12 alternatives evaluated.
- *Water Supply Master Plan* (SFPUC, 2000) – 19 alternatives evaluated.
- *Bay Area Water Quality and Supply Reliability Program – Final Report* (CDM, 2005) – Seven Bay Area water agencies evaluated potential regional projects for improvement of water quality and water supply reliability. A set of 69 concepts was screened, 35 of which were selected for further evaluation.

For the WSIP Option 3 study, the SFPUC screened numerous alternatives identified in previous studies for compatibility with the current WSIP goals and levels of service performance objectives. Alternative water supply sources considered include the following: Sacramento–San Joaquin Delta, direct purchase from neighboring water agencies, desalination of seawater or brackish water, recycled water, and water conservation. In addition, the SFPUC evaluated alternative locations for future Tuolumne River diversions (one location is discussed in Section 9.2). Conservation and water recycling options were addressed separately as part of the WSIP planning process (discussed in Section 9.2.4). The 28 alternative concepts were evaluated for the following major issues:

- Environmental issues – major impacts that have a high risk of not being resolved
- Institutional issues – contractual, jurisdiction authority issues or other permitting requirements that have a high risk of not being resolved
- Operational issues – perceived operation problems, either with the SFPUC system or state/federal water systems, that have a high risk of not being resolved
- Water quality issues – water treatment issues that have a high risk of requiring costly treatment or incurring unnecessary health risks

In addition, the SFPUC's initial screening process considered the following criteria specifically related to its system needs and WSIP level of service goals:

1. Secure a reliable and sustainable 25-mgd supplemental water supply.
2. No additional flows to be diverted from the Tuolumne River above historical levels; however, for this study, additional Tuolumne River diversions could be considered at the downstream end of the lower Tuolumne River near the confluence with the San Joaquin River.
3. Corollary to Criterion 2, no additional infrastructure requirements beyond the those of the proposed program (such as a complete fourth San Joaquin Pipeline extending from Oakdale Portal to Tesla Portal or second Coast Range Tunnel).
4. Maintain "filtration avoidance" for water diverted from Hetch Hetchy Reservoir.

The SFPUC's initial screening process identified 10 alternative concepts for further evaluation. Some of these concepts represented variations rather than distinct alternatives. After further review of the remaining 10 alternative concepts, the SFPUC selected three alternatives for more in-depth evaluation: Lower Tuolumne River Diversion, Oceanside Seawater Desalination Plant, and Delta Diversion. The first two are discussed and analyzed in Sections 9.2.5 and 9.2.6, respectively, as potential CEQA alternatives. The last one, Delta Diversion, was considered and rejected as a CEQA alternative, as discussed below. The list below also includes other water sources that were reviewed or suggested during scoping as possible supplemental supplies during nondrought or drought years, but were rejected from further consideration.

Additional Intertie with Santa Clara Valley Water District

The SFPUC investigated several alternatives for an exchange or transfer with the Santa Clara Valley Water District (SCVWD) as part of the WSIP background studies exploring regional water supply opportunities. The SFPUC and SCVWD explored options using the existing intertie, a new intertie, or exchanges through delivery to the eight customers in common to both the SCVWD and SFPUC. This concept was eliminated from further consideration, as described in more detail in Section 9.5, because it would not provide a dependable future water source for the SFPUC regional system. However, the SFPUC considered this concept in combination with supplemental water supply sources, including Groundwater Banking in Kern County and Delta Exchange, as discussed below.

Groundwater Banking in Kern County

As described in Chapter 3, Section 3.4, the SFPUC explored storage in the Semitropic Water Storage District's groundwater bank near Bakersfield as a possible dry-year water supply. Under this option, during wet years, the SFPUC would deliver Tuolumne River water to the Semitropic groundwater bank using the California Aqueduct and, in dry years, would receive water through the Semitropic Water Storage District's allocations of water from the State Water Project via the Delta and South Bay Aqueduct. Direct participation by the SFPUC in this type of water banking program was determined to pose a significant risk of violation of the Raker Act, and this option was therefore eliminated from further consideration, as described further in Section 9.5. The SFPUC also considered indirect participation in this program through current Bay Area partners, including the SCVWD, Alameda County Flood Control and Water Conservation District Zone 7, and ACWD via Delta exchange, but this was determined to be infeasible, as described in Section 9.5.

Delta Exchange

The SFPUC evaluated various alternatives for exchanging water from the SFPUC regional water system for Delta water. It considered the three Bay Area water agencies that are (1) State Water Project contractors receiving Delta water, and (2) agencies to which a means for transferring SFPUC regional water system supplies was identified. The SFPUC, in collaboration with the three potentially participating agencies (ACWD, Zone 7, and SCVWD), determined that this concept is not technically feasible due to timing and capacity issues, as described below in Section 9.5.

Delta Diversion

The SFPUC explored using diversions from the Delta as a supplemental water source. This scenario would involve the following: purchasing water from a water-right holder in the Delta and/or on one of the rivers tributary to the Delta; transporting the water via the State Water Project or Central Valley Project conveyance facilities to the regional system; treating the water at a new treatment plant at Tesla Portal; and blending the treated Delta supply with the Hetch Hetchy supply in the Coast Range Tunnel. This concept was eliminated from further consideration due to uncertainties regarding the availability of water supplies and pumping capacities (which would make consistent year-round diversions highly unlikely), potential water quality issues, and the significant increase in adverse environmental impacts from facility construction and on Delta resources, as discussed in Section 9.5.

Purchase Groundwater Storage Rights in Foothills East of and Outside of MID/Central Valley

This concept was raised during the public scoping period. The SFPUC has not explored this concept because of the limited information on the infiltration rates and potential groundwater quality issues in this basin as well as potential institutional issues. Therefore, due to technical infeasibility, this concept was eliminated from further consideration as a strategy to incorporate into a CEQA alternative, as discussed further in Section 9.5.

9.5 Alternative Concepts Considered But Rejected

9.5.1 Rejected Strategies/Concepts that Affect SFPUC Facilities

Phase/Extend the WSIP Construction Schedule

Phasing or extending the WSIP construction schedule so that fewer projects, especially those with geographic overlap, would occur concurrently is one approach that could lessen the collective regional and multi-regional impacts associated with construction of multiple WSIP projects. However, this concept was eliminated from further consideration, as discussed below.

The SFPUC has a limited ability to revise the phasing or to extend the proposed WSIP multi-project construction schedule. Critical to the phasing of the construction activities is the ability to maintain full service to customers throughout the entire WSIP construction schedule. Certain projects must be completed in the appropriate sequence to provide ongoing service. In addition, the construction of many of the projects requires certain linkages, which necessarily involve overlapping construction activities and schedules between some projects; this overlap would in fact reduce the duration of construction disturbance at some locations.

As described previously, many of the proposed facility improvement projects are urgent in order to meet public health requirements and water quality objectives as well as key to achieving the seismic and delivery reliability level of service goals. As a result, these projects cannot be delayed without compromising the fundamental WSIP goals and objectives and possibly jeopardizing public health and safety. In addition, lengthening the overall WSIP construction schedule might reduce the intensity of construction impacts from multiple projects in some areas but would, conversely, increase the duration of these impacts as projects are constructed sequentially rather than concurrently. Because phasing project schedules and extending overall construction would trade potential impact intensity for impact duration, this strategy is not considered effective as an alternative to avoid or substantially lessen impacts associated with multiple and overlapping construction projects. Therefore, the concepts of either revising the phasing of the WSIP construction or extending the construction schedule were eliminated from further consideration.

Enlarge Calaveras Reservoir

Enlarging Calaveras Reservoir to increase storage beyond the historical capacity would capture more water within the upper Alameda Creek watershed and could increase local water supplies. This concept also included the potential to provide pumping facilities and to store Tuolumne River water in an enlarged Calaveras Reservoir, thereby increasing local storage for use during droughts, planned or unplanned outages, or other emergencies. However, this concept would not avoid or reduce identified environmental effects associated with increased diversions from the Tuolumne River and would result in more severe environmental impacts on Alameda Creek than the proposed program; therefore, this concept was eliminated from further consideration, as discussed below.

As part of the development of the WSIP, the SFPUC considered an alternative under which Calaveras Reservoir would be enlarged from its historical capacity of 98,800 acre-feet to 256,000 or 409,000 acre-feet. An enlarged Calaveras Reservoir would enable the SFPUC to capture more water from the Alameda Creek watershed and to store more Tuolumne River water in the Bay Area. This alternative would increase the firm yield of the regional water system.

The SFPUC rejected this concept because of uncertainties about the ability to obtain the necessary water rights and environmental permits within the timeframe needed to replace Calaveras Dam to satisfy DSOD requirements. In 2002, the DSOD imposed interim restrictions on Calaveras Dam operations, with the caveat that the SFPUC continue to pursue an aggressive schedule for the remediation of Calaveras Dam. The Calaveras Dam project (SV-2), proposed as a part of the WSIP, includes design features that would technically allow the dam to be raised in the future and the reservoir capacity to be increased if needed, and water-rights and environmental issues can be resolved at that time.

As a potential CEQA alternative, enlarging Calaveras Reservoir to store more than its original 98,800 acre-feet would not help avoid or lessen the effects to the WSIP. It would not reduce the levels of Tuolumne River diversions, if the proposal includes pumping facilities to store Tuolumne River supplies in Calaveras Reservoir. Alternatively, it could replace that supply in whole or in part with increased diversions from upper Alameda Creek, Arroyo Hondo, and Calaveras Creek. This concept would allow increased diversions from upper Alameda Creek through the Alameda Creek Diversion Tunnel compared to the proposed program, which would exacerbate the identified significant, unavoidable impact on stream flow in Alameda Creek below the diversion dam as well as worsen the potentially significant impact on fishery resources in this reach of Alameda Creek. Therefore, the alternative of enlarging Calaveras Reservoir beyond its historical capacity was eliminated from further consideration in this PEIR.

Connect Cherry Creek Directly to Regional Water System

The Cherry Creek water supply could be connected directly to the regional water system by building a pump station downstream of Holm Powerhouse to pump water from Cherry Creek to Mountain Tunnel; this would augment supplies to the regional system to serve increased customer demand instead of increasing diversions from Hetch Hetchy Reservoir. However, this concept was eliminated from further consideration because it would result in far greater environmental effects than the proposed program, as discussed below.

This concept would use Cherry Creek to augment the regional water supply sources. It could consist of a pump station downstream of Holm Powerhouse to pump water from Cherry Creek to Mountain Tunnel or, alternatively, could consist of a larger intertie to Cherry Creek and Lake Lloyd (Cherry Reservoir) to Mountain Tunnel. This concept would avoid impacts on sensitive terrestrial biological resources downstream of O'Shaughnessy Dam, such as those in the Poopenaut Valley.

To meet federal and state water quality requirements, this concept would necessitate the construction of a filtration plant, since—unlike the Hetch Hetchy watershed—the Cherry Creek watershed does not meet filtration avoidance criteria (see Chapter 2, Section 2.4). This concept would require either filtration of the Cherry Creek source water prior to blending with Hetch Hetchy water in Mountain Tunnel, or filtration of the entire Hetch Hetchy supply after blending with the Cherry Creek water. In either case, construction of a filtration plant would result in numerous additional construction and operational environmental impacts that would not occur under the proposed program. Increased use of Cherry Creek water supplies to serve customer demand would reduce flows available for whitewater rafting. Furthermore, the concept would be contrary to the fundamental operating principle of maintaining filtration avoidance for the Hetch Hetchy system. Therefore, since this concept would not effectively avoid or substantially lessen WSIP impacts without also resulting in a number of other potentially significant environmental impacts, it was eliminated from further consideration.

9.5.2 Rejected Strategies/Concepts that Affect System Operations

Filtration of Sierra Source Water

During scoping, the suggestion was raised to expand the filtration capacity in the SFPUC system and/or to explore alternative locations for necessary filtration equipment, including locating facilities at Brown Adit or Moccasin, or expanding capacity at the Sunol Valley WTP. As a stand-alone alternative, this concept would not meet any of the basic program objectives, would not avoid or lessen any of the impacts of the WSIP, and would result in adverse construction and operational impacts. As described in Chapter 2, the existing quality of Hetch Hetchy water meets the full requirements of the state and federal Safe Drinking Water Acts, and the water can be consumed without the need for filtration. Therefore, this concept as a stand-alone alternative was eliminated from further consideration.

This suggestion was likely posed in combination with the concept of removing O'Shaughnessy Dam and restoring the Hetch Hetchy Valley. That concept was rejected since it would neither meet any of the program objectives nor avoid or lessen the significance of any of the WSIP impacts, as discussed below in Section 9.5.4.

Revise Alameda Creek Diversion Dam Operations

This concept would involve not resuming historical levels of diversions from Alameda Creek above the diversion dam to Calaveras Reservoir after Calaveras Dam is restored under the WSIP. However, this concept was eliminated from further consideration since it would not meet two fundamental WSIP objectives, would result in the loss of an irreplaceable local source of water needed during droughts and Hetch Hetchy water quality events, and could affect the CCSF's water rights to Alameda Creek drainage.

As discussed in Section 5.4, the WSIP would result in some significant impacts on the Alameda Creek system and its related environmental resources. Most notably, these impacts include a significant and unavoidable reduction of stream flow in Alameda Creek in the reach below the diversion dam to the confluence with Calaveras Creek, and a significant but mitigable effect on the resident trout fishery in this reach. Since the DSOD restricted the storage capacity of Calaveras Reservoir, the SFPUC has substantially reduced the amount of water it routinely diverts each year from Alameda Creek at the diversion dam. This concept would involve proceeding with implementation of the Calaveras Dam project (SV-2), as required by the DSOD, and allowing the reservoir to resume its historical capacity; however, the Alameda Creek Diversion Tunnel would remain as currently managed and would not resume the operations in existence prior to the DSOD restriction. This concept would avoid the significant, unavoidable impact on the hydrology of Alameda Creek below the diversion dam and maintain stream flow in Alameda Creek equivalent to 2005 conditions.

However, this concept would effectively eliminate Alameda Creek drainage as a local water supply source, and only Arroyo Hondo and Calaveras Creek would drain to Calaveras Reservoir. Alameda Creek drainage to Calaveras Reservoir, under historical operating conditions, represents about one-third of the reservoir's capacity and loss of this supply would constitute a substantial reduction in the regional system's total water supply. Without the contribution of Alameda Creek to the total supply, the SFPUC would be unable to meet the delivery reliability and water supply objectives without securing a replacement water supply. Most importantly, under this concept, the regional system would be more vulnerable to water supply shortages in the event of drought or other emergency, since Alameda Creek is a local water supply source. The need for this supply is especially acute during droughts and Hetch Hetchy system emergency outages. This local supply plays a critical role in providing delivery and water supply reliability and cannot be fulfilled through nonlocal supplies (such as the Tuolumne River or the Delta), since it provides local Bay Area storage within the regional water system in proximity to customers. In addition, this concept could possibly jeopardize the CCSF's pre-1914 appropriative water rights for this supply. Therefore, this concept was eliminated from further consideration.

Recapture Upper Alameda Creek Flows Downstream

This concept involves not resuming the historical pattern of diversions from Alameda Creek above the diversion dam to Calaveras Reservoir, recapturing the flows downstream from the potentially affected resources, and pumping the recaptured water to the regional system. This concept was eliminated from further consideration because of technical infeasibility, as discussed below.

This concept is similar to the previous concept in that it would avoid the significant, unavoidable impact associated with the reduction in stream flow in Alameda Creek below the diversion dam (by not resuming historical operation of the Alameda Creek Diversion Tunnel) and would maintain current stream flow patterns below the diversion dam. However, under this concept, stream flow equivalent to the volume normally diverted to Calaveras Reservoir would be recaptured farther downstream in the creek and then returned to the regional water system. This approach would allow the SFPUC to retain its local water supply source available for use during droughts, Hetch Hetchy water quality events, and other emergency situations.

The SFPUC explored the possibility of recapturing flows downstream at the Sunol infiltration galleries, the quarries, and ACWD facilities, with a focus on recapturing high winter flows rather than low-volume summer releases (SFPUC, 2007a). (The infiltration galleries are described in Section 5.4.4, and the quarries and ACWD facilities are described in Section 5.7.3.) All of these options were determined to be technically infeasible due to physical limitations, as described below. In addition, implementation of any of these concepts would require extensive new construction in sensitive habitats and would result in a host of additional potentially adverse environmental effects. Furthermore, this concept would only avoid the significant, unavoidable impact for the reach of the creek from the Alameda Creek Diversion Dam to the infiltration galleries/quarries/ACWD facilities, but a significant, unavoidable impact on stream flow in the creek below these facilities would remain.

The Sunol infiltration galleries, built in 1901, were designed to intercept surface water from Alameda Creek into the shallow alluvium of the Sunol Valley and provide a location for temporary aquifer recharge and recovery. Historically, the SFPUC (and its predecessors) operated the Sunol infiltration galleries to divert peak flood flows, to divert releases from Calaveras Reservoir, to divert releases of Hetch Hetchy water to Alameda Creek, and to divert flows from Pleasanton/Arroyo de la Laguna; up to 50 to 60 mgd of water was historically diverted at the infiltration galleries. Use of the galleries historically required installation of seasonal gravel dams to improve percolation rates into the galleries. However, following construction of the Calaveras Pipeline in 1934, and again following construction of San Antonio Dam in 1965, the yield of the infiltration galleries declined. The current capacity of the galleries has been further reduced due to the demolition of Sunol Dam and by aggregate mining upstream. Therefore, it is unknown whether it would be feasible to use the infiltration galleries to capture the flows from upper Alameda Creek that were diverted to Calaveras Reservoir prior to the DSOD restriction. The physical hydrogeology of the Alameda Creek and groundwater system has altered since the infiltration galleries were used, and it is likely that extensive upstream facilities would be required. This concept would then result in a number of potentially adverse environmental effects downstream of the diversion dam associated with placing new facilities in a sensitive habitat. Due to the extent of additional impacts and unknown feasibility, as well as the limited reduction in adverse effects, use of the infiltration galleries was eliminated from further consideration.

Diversion of Alameda Creek flows to the quarries currently located in the Sunol Valley might be possible when a limited amount of water storage space (approximately 14,000 acre-feet) becomes available at one of the lease sites along the bank of Alameda Creek between Interstate 680 and San Antonio Creek. This diversion would require a surface impounding structure (i.e., a rubber dam) and would also have to be screened to prevent fish entrainment. Use of the quarries for water storage would also require extensive modification of the site. Due to the extent of additional impacts and unknown feasibility, as well as the limited reduction in adverse effects, use of the quarries was eliminated from further consideration.

Similarly, use of ACWD's existing downstream facilities to recapture flows from upper Alameda Creek would be questionably feasible. Flows are currently diverted into streamside intakes behind two rubber dams, and, during the winter, the ACWD must lower its rubber dams if flows exceed 200 cubic feet per second. It may not be feasible to capture additional high winter flows from upper Alameda Creek. Due to the extent of additional impacts and unknown feasibility, as well as the limited reduction in adverse effects, use of ACWD facilities was eliminated from further consideration.

9.5.3 Rejected Strategies/Concepts that Affect Water Supply Sources

Additional Intertie with Santa Clara Valley Water District

As described in Chapter 2, the existing SFPUC intertie with the SCVWD has a capacity of 40 mgd and serves as a means to transfer water between the SFPUC and SCVWD during an emergency or during periods of planned maintenance work on critical facilities. The SFPUC investigated several alternatives for an exchange or transfer with the SCVWD as part of the WSIP background studies exploring regional water supply opportunities. The SFPUC and SCVWD explored options using the existing intertie, a new intertie, or exchanges through delivery to the eight customers in common to both the SCVWD and SFPUC. In general, an exchange would involve the SFPUC advancing water in wet years to the SCVWD in exchange for supplies from the SCVWD in dry years. However, it was determined that the SCVWD does not have capacity or need for additional water supplies during wet years. At times when the SFPUC has additional supplies available for delivery to the SCVWD, the SCVWD cannot use the water directly or store it. Additionally, the SCVWD does not have excess water to transfer to the SFPUC in normal or dry years.

Thus, this intertie or any additional intertie with the SCVWD alone would not provide a dependable future water source for the SFPUC regional system, since the SCVWD is faced with similar water supply issues as the SFPUC due to its projected increase in demand and limited water supply sources. However, the SFPUC considered this concept in combination with supplemental water supply sources, including Groundwater Banking in Kern County and Delta Exchange, as discussed below.

Groundwater Banking in Kern County

Hundreds of feet of permeable geologic strata underlie the southern end of the San Joaquin Valley, creating favorable conditions for groundwater storage and recovery. Water applied to the floor of the San Joaquin Valley in Kern County rapidly percolates into the ground and can be readily recovered by pumping from existing groundwater wells.

For many years, water agencies in Kern County have practiced conjunctive use of their surface and groundwater sources; that is, they actively manage their surface and groundwater sources to take advantage of the different characteristics of the two types of water sources. The availability of surface water supplies varies greatly from year to year, but the availability of groundwater supplies typically does not. When surface water is abundant, water agencies supply their customers with surface water and percolate the excess into the ground. When surface water is scarce, water agencies in Kern County supply their customers with groundwater.

Until about 10 years ago, water agencies in Kern County managed the groundwater basin underlying the San Joaquin Valley portion of Kern County exclusively for their own benefit. In 1994, the first of several water banking projects designed to benefit water agencies outside of Kern County came into operation. The Semitropic Water Storage District (Semitropic) provides groundwater storage capacity to multiple partners, including the Metropolitan Water District of Southern California, ACWD, Zone 7, and SCVWD. The total storage capacity of the Phase I basin is nearly 1 million acre-feet. Semitropic has been pursuing development of a Phase II basin (referred to as the “New Unit”) with 650,000 acre-feet of new storage capacity. The project is operated as a storage bank; during wet periods, when the project partners do not need all of their water from the State Water Project or other Delta sources to meet current needs, it places the excess in storage in Semitropic’s groundwater bank in Kern County. In dry periods, the project partners expect to recover water from the groundwater bank, either through groundwater extraction or Semitropic’s Delta entitlements, to supplement their other supplies.

The SFPUC evaluated storing water in the Semitropic groundwater bank in order to increase the firm yield of the regional water system. Specifically, the storage proposal involved an in-lieu groundwater banking concept in which the SFPUC would supply water in non-dry years under its existing Tuolumne River water rights or use another source of non-dry-year supply to irrigators in Semitropic’s service area for surface irrigation. In exchange, the farmers would not pump groundwater, which would be credited to the SFPUC’s Semitropic groundwater bank account (less the actual losses in delivery, estimated to be 10 percent). When called on by the SFPUC, Semitropic would provide the SFPUC credited amount of water to the California Aqueduct via a proposed New Unit of the Semitropic groundwater bank, which would, in turn, allow the SFPUC to draw the equal amount of water from the State Water Project South Bay Aqueduct turnout at San Antonio Reservoir or other locations. Finally, other State Water Project contractors located south of Semitropic would use the actual SFPUC banked water delivered by Semitropic.

However, there is uncertainty regarding the ability of the SFPUC to provide water for storage in the Semitropic groundwater bank. The SFPUC determined that there would be a significant risk that conveyance of Hetch Hetchy water to irrigators in the southern San Joaquin Valley would be in violation of the Raker Act, which stipulates that the CCSF not divert any more Hetch Hetchy water beyond the limits of the San Joaquin Valley than is required for its own domestic or municipal purposes. Therefore, due the institutional and legal uncertainties, this option was screened from further consideration.

The SFPUC then evaluated the possibility of purchasing a Delta water supply through a willing seller and delivering it to Semitropic for storage. The SFPUC concluded that delivering a source of Delta water to Semitropic would be subject to extreme competition for pumping capacity, which is already constrained during the winter and spring, the time that excess water is available. Pumping capacity is least constrained during the summer, when there is less water available. In addition to pumping capacity constraints, there may be constraints on the aqueduct capacity required to transport the water south. There may also be capacity issues with the South Bay Aqueduct. Although it appears that summertime capacity is available (when State Water Project deliveries are reduced, which is most likely when the SFPUC would be transporting its return water back), there is no assurance that the SFPUC would have access to that capacity. In addition, the SFPUC would have a lower priority for use of available capacity in the Bank Pumping Facility and in the South Bay Aqueduct than existing State Water Project customers.

In both of the scenarios described above, the SFPUC would receive State Project Water from the Sacramento–San Joaquin Delta in return for the water conveyed to Semitropic. Delta water is of lower quality than Hetch Hetchy water and requires filtration prior to potable use. Use of Delta water during dry periods would create operational difficulties for the SFPUC and would incur substantial additional cost. The SFPUC rejected the alternative of storing water in Semitropic’s groundwater bank for a combination of legal, institutional, operational, and cost factors. In an effort to address these issues, the SFPUC also investigated the possibility of participating in Semitropic’s groundwater bank through the ACWD, Zone 7, or SCVWD. These options are discussed below under Delta Exchange.

Delta Exchange

The SFPUC evaluated various alternatives for exchanging water from the SFPUC regional water system for Delta water. It considered the three Bay Area water agencies that are (1) State Water Project contractors receiving Delta water, and (2) agencies to which a means for transferring SFPUC regional water system supplies was identified. These three agencies are the ACWD, Zone 7, and SCVWD.

The general concept would be to advance SFPUC regional system water during wet years to the ACWD, Zone 7, or SCVWD via direct connections or interties, or through increased deliveries to the SFPUC's and SCVWD's common customers to replace demand otherwise met by the SCVWD. This would allow these water agencies to reduce their deliveries from the State Water Project, which could then be stored in Semitropic's groundwater bank (see Groundwater Banking in Kern County, below), used to allow recharge of their local groundwater basins, or use other storage, if available. In dry years, supplies would be returned to the SFPUC either through a reduction in SFPUC demand from SFPUC/SCVWD common customers or through State Water Project deliveries via the State Water Project South Bay Aqueduct turnout at San Antonio Reservoir or other locations.

The SFPUC obtains all of its water from high-quality sources—the Tuolumne River watershed and protected Bay Area watersheds—and therefore is not required to provide the same level of water treatment as water agencies that obtain water from less high-quality sources. It is difficult for the SFPUC to accept lower quality Delta water as a supplementary source of supply during droughts because it is not well equipped to receive, treat, and deliver it to customers. Because the ACWD, Zone 7, and SCVWD already use Delta water, they are better equipped to receive, treat, and deliver it to customers.

The SFPUC, in collaboration with the potentially participating agencies, determined that a Delta Exchange alternative is not technically feasible. The feasibility of this concept is related to the analysis in the discussion above for the Groundwater Banking in Kern County concept. The constraints to feasibility include: (1) inconsistent timing regarding when SFPUC excess water supplies are available and when storage capacity is available; (2) the limited capacity at the State Water Project pumps to move wet-year water to available storage; or (3) the lack of assurance that dry-year supplies could be provided from the State Water Project. These issues are in addition to potential treatment incompatibilities with SFPUC facilities and related water quality issues. Therefore, this concept was eliminated from further consideration.

Delta Diversion

The SFPUC explored using diversions from the Delta as a supplemental water source. This would involve the following: purchasing water from a water-right holder in the Delta and/or on one of the rivers tributary to the Delta; transporting the water via the State Water Project or Central Valley Project conveyance facilities (i.e., the California Aqueduct or the Delta-Mendota Canal) to the regional system; treating the water at a new treatment plant at Tesla Portal; and blending the treated Delta supply with the Hetch Hetchy supply in the Coast Range Tunnel. This concept was eliminated from further consideration due to uncertainties regarding the availability of water supplies and pumping capacities, which would make consistent year-round diversions unlikely, as discussed below.

The SFPUC developed a Delta Diversion alternative and determined that, in addition to construction of all of the WSIP facility improvement projects, a Delta intake and pumping plant, Delta water treatment plant, and associated pipelines would be required. This alternative would be similar in concept to two ideas raised during the scoping period. One included use of the South Bay Aqueduct to convey Delta water directly to San Antonio Reservoir, and the other involved use of the California Aqueduct/Delta-Mendota Canal to convey water to the Hetch Hetchy system.

The SFPUC evaluated the Delta Diversion alternative with respect to water supply availability and reliability from the source; conveyance capacity availability for the Delta supply option; regional water system performance; operations and maintenance requirements; water quality effects; facility siting considerations, including geotechnical, right-of-way, and environmental resources; permitting requirements; and capital, operating, and life-cycle costs. Overall, the SFPUC determined that the feasibility of this alternative would be limited by the availability of Delta water supplies and the pumping capacity of existing State Water Project/Central Valley Project conveyance facilities. In addition, because of numerous institutional and regulatory uncertainties associated with this alternative (largely dependent on how and where the SFPUC would purchase the water), it is unknown if this alternative could achieve the WSIP level of service goals for delivery and water supply reliability. The quality of Delta water supplies would be lower than that of water from the Hetch Hetchy system.

While this alternative could avoid or lessen the impacts on Tuolumne River resources that would occur under the WSIP (as described in Chapter 5), it would result in other, distinct significant environmental impacts on the Delta and associated environmental resources (e.g., fisheries, aquatic habitat and species, riparian habitat, and water quality affecting other beneficial uses). The alternative would substitute one set of significant environmental impacts with another, thus representing trade-offs among environmental resources and impacts without avoiding or necessarily reducing overall environmental impacts.

Regarding impacts associated with facility construction and operation, the Delta Diversion alternative would neither avoid nor lessen the environmental effects that would result from construction and operation of the WSIP facility improvement projects, as all of the key WSIP projects for water quality, seismic reliability, and delivery reliability would still need to be implemented. At the same time, additional facilities beyond those required for the WSIP would need to be constructed and operated. These facilities would be located in a combination of open space, rural settings, and dense urban settings, resulting in a range of additional environmental impacts.

Therefore, since this alternative would have uncertain water supply reliability and an unknown ability to reduce impacts on Tuolumne River resources, as well as significant additional environmental impacts, it was eliminated from further consideration.

Purchase Groundwater Storage Rights in Foothills East of and Outside of MID/Central Valley

As described above in Section 9.4.4, this concept was raised during the public scoping period, but the SFPUC has rejected this concept due to technical infeasibility. The SFPUC did not explore this concept because of the limited information on the infiltration rates in this groundwater basin and potential sources of groundwater quality impairment associated with dibromochloropropane, chlorine, boron, nitrate, iron, and manganese. In addition, there would be institutional issues concerning the SFPUC’s ability to use this basin as a drought supply, since the SFPUC would have lowest priority in times of overdraft. Therefore, this concept is not considered as a feasible strategy and was removed from further consideration in this PEIR.

9.5.4 Other Rejected Concepts

Removal of O'Shaughnessy Dam

In 1913, Congress passed and President Woodrow Wilson signed the Raker Act, granting the CCSF the right to dam the Tuolumne River at the mouth of the Hetch Hetchy Valley in Yosemite National Park. O'Shaughnessy Dam was completed in 1923, and water first flowed to the San Francisco Peninsula in 1934.

The decision to permit flooding of the Hetch Hetchy Valley was controversial; when the Raker Act was approved in the Senate, 43 senators voted in favor, 25 were opposed, and 29 abstained (Simpson, 2005). The controversy continues today, and many parties have expressed an interest in removing O'Shaughnessy Dam and restoring the Hetch Hetchy Valley to its condition before the O'Shaughnessy Dam was completed. A number of studies have been performed to determine the feasibility and cost of removing the dam and restoring the valley. Recently, the State of California examined all prior studies and concluded that restoration was feasible, but that the costs would be between $3 and $10 billion (California Department of Water Resources/California Department of Parks and Recreation, 2006).

In 2004, Environmental Defense prepared a planning-level analysis of replacing the water supply and hydropower benefits provided by Hetch Hetchy Reservoir and O'Shaughnessy Dam (Rosekrans et al., 2004). The study was prepared with the objective of restoring the Hetch Hetchy Valley to conditions that existed prior to the construction of O'Shaughnessy Dam; the restored valley would serve as a natural resource available to the public as part of Yosemite National Park. The study proposes alternatives for water storage (such as available storage in New Melones Reservoir), conveyance and treatment, and replacement of lost hydropower, and acknowledges that these alternatives must be in place before restoration of Hetch Hetchy Valley could begin. This study is considered highly speculative in that there are unresolved legal issues inherent in the proposal regarding the Raker Act and the CCSF, TID, and MID water rights, as well as in these water agencies' obligations to their customers.

Regardless of the merits of removing O'Shaughnessy Dam, dam removal is not considered an alternative to the WSIP that must be evaluated to satisfy the requirements of CEQA in this PEIR. The CEQA Guidelines state that an EIR must describe and evaluate a reasonable range of alternatives to the proposed project that would feasibly attain most of the project's basic objectives and would avoid or substantially lessen any significant adverse environmental effects. This proposal is not reasonably related to a reduction or elimination of the significant impacts that would result with implementation of the proposed program, but suggests far greater changes than would be necessary to address any impacts that this proposed program would cause on the Tuolumne River and related resources. To the extent Tuolumne River water continues to be diverted, it is likely to continue to cause or maintain impacts similar to those that resulted from construction of O'Shaughnessy Dam and created the existing condition. The proposal itself is likely to result in numerous, significant environmental impacts associated with construction and operation of unknown new storage, conveyance and treatment facilities at unknown locations, and would likely require increased long-term energy requirements compared to the Hetch Hetchy system that is gravity-driven and not subject to water filtration requirements. In addition, there would likely be other significant impacts on diversion of Tuolumne River water elsewhere or any other surface water bodies developed to replace any Tuolumne River supply and associated resources.

In addition, removal of O'Shaughnessy Dam would fail to meet any of the WSIP's basic objectives of improving water quality, seismic reliability, delivery reliability, and water supply. The proposal does not attempt to address any of the goals and objectives of the WSIP, but instead suggests a different way to operate the water system without Hetch Hetchy Reservoir. The purpose of the WSIP is to address the inadequacies of the existing system and to provide for reasonably foreseeable future needs. Removal of O'Shaughnessy Dam would require significantly more funding than is available, significant changes in water supply strategy, construction of additional storage and transmission facilities, and operation of a different water system.

This proposal could reduce the existing level of delivery and water supply reliability to regional system customers, since the status and availability of water supplies and transmission methods to replace the existing water system are unknown. Similarly, the proposal would reduce the reliability and jeopardize the power generation facilities associated with O'Shaughnessy Dam, causing impacts on power customers.

Therefore, since this concept does not meet any of the program objectives, nor does it effectively avoid or substantially lessen WSIP impacts without also resulting in a number of other potentially significant environmental impacts, this concept was eliminated from further consideration in this PEIR.

10 Impact Overview

CHAPTER 10
Impact Overview

10.1 Significant Environmental Effects that Cannot Be Avoided if the Proposed Program Is Implemented

In accordance with Section 21067 of the California Environmental Quality Act (CEQA), and with Sections 15126(b) and 15126.2(b) of the CEQA Guidelines, the purpose of this section is to identify environmental impacts that could not be eliminated or reduced to a less-than-significant level by SFPUC construction measures included as part of the program or by other mitigation measures that could be implemented, as described in Chapter 6, Mitigation Measures. Findings in this chapter are subject to final determination by the Planning Commission as part of its certification of the PEIR.

Facility Construction Effects

The impacts associated with the facility improvement projects would occur primarily during the construction phase as opposed to the operations phase. Although most construction impacts would be short-term, they could pose significant effects. Construction of facility improvement projects could result in potential erosion and associated water quality and water resources effects, disruption of sensitive habitats and impacts on special-status species, impacts on cultural resources, short-term traffic delays and impaired access along project roadways, local and regional degradation of air quality, and short-term noise impacts. These impacts would be mitigated to less-than-significant levels by implementation of mitigation measures described in Chapter 6, Mitigation Measures, with the exception of the effects listed below. This PEIR makes a conservative determination that these effects would be potentially significant and unavoidable. When better facility siting information is available and the Major Environmental Analysis Section (MEA) of the San Francisco Planning Department completes detailed project-level CEQA review on the WSIP projects, it may be determined that these effects can be avoided or mitigated to a less-than-significant level.

- A ranch property in the Sunol Valley would be subject to 24-hour construction effects for the full duration of construction of the New Irvington Tunnel project, and such land use disruption is considered to be potentially significant and unavoidable even with implementation of traffic, noise, and air quality mitigation measures (Chapter 4, Section 4.3).

- Existing land uses could be displaced to accommodate proposed facilities at some locations under the following projects: San Joaquin Pipeline System, Additional 40-mgd Treated Water Supply, San Antonio Backup Pipeline, Bay Division Pipeline Reliability Upgrade, Crystal Springs/San Andreas Transmission Upgrade, Groundwater Projects, and Recycled Water Projects. Since final facility locations are undetermined at this time, any possible permanent displacement of existing land uses is conservatively considered to be potentially significant and unavoidable in this PEIR (Chapter 4, Section 4.3).

- Removal of a large area of existing oak woodland cover as part of the Calaveras Dam Replacement project would permanently alter a scenic vista, a potentially significant and unavoidable impact (Chapter 4, Section 4.3).

- Alteration or demolition of existing facilities under the following projects could result in potentially significant and unavoidable impacts on the historic significance of individual facilities: Calaveras Dam Replacement, New Irvington Tunnel, Crystal Springs/San Andreas Transmission Upgrade, and Lower Crystal Springs Dam Improvements (Chapter 4, Section 4.7).

- The Calaveras Dam Replacement and Crystal Springs/San Andreas Transmission Upgrade projects would result in potentially significant and unavoidable impacts on historic districts, if historic districts are determined to be present (Chapter 4, Section 4.7).

- Temporary construction-related noise impacts could occur under all facility improvement projects analyzed in the PEIR and would be potentially significant and unavoidable if excessive construction noise occurred in close proximity to sensitive receptors or audible construction noise occurred during the more noise-sensitive nighttime hours (Chapter 4, Section 4.10).

- Temporary noise disturbance could occur along construction haul routes under the following projects: Advanced Disinfection, San Joaquin Pipeline System, Rehabilitation of Existing San Joaquin Pipelines, Tesla Portal Disinfection Station, Bay Division Pipeline Reliability Upgrade, BDPL Nos. 3 and 4 Crossovers, Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault, Baden and San Pedro Valve Lots Improvements, HTWTP Long-Term Improvements, San Andreas Pipeline No. 3 Installation, Groundwater Projects, and Recycled Water Projects. This impact is conservatively considered potentially significant and unavoidable because haul routes, truck volumes, and hours of truck operations have not yet been determined for these projects (Chapter 4, Section 4.10).

- If any construction activities were to generate vibration in proximity to sensitive receptors during the nighttime hours, potentially significant and unavoidable vibration impacts could occur under the following projects: San Joaquin Pipeline System, Rehabilitation of Existing San Joaquin Pipelines, Additional 40-mgd Treated Water Supply, Bay Division Pipeline Reliability Upgrade, BDPL Nos. 3 and 4 Crossovers, Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault, Baden and San Pedro Valve Lots Improvements, San Andreas Pipeline No. 3 Installation, Groundwater Projects, and Recycled Water Projects (Chapter 4, Section 4.10).

- Combined or collective temporary impacts on residences near the Irvington Tunnel portal in Fremont (Bay Division Region) could result during construction because staging and access for both the New Irvington Tunnel and Bay Division Pipeline Reliability Upgrade projects would overlap in this vicinity. Since the feasibility of coordinating construction activities for these projects cannot be determined at this stage of project planning, such an effect is conservatively considered to be potentially significant and unavoidable (Chapter 4, Section 4.16).

- Multiple facility improvement projects in the Sunol Valley Region would have a potentially significant and unavoidable collective impact on biological resources because of the number of WSIP projects in this region and the extent of overlap in terms of construction activity timing and location (Chapter 4, Section 4.16).

- Potentially significant and unavoidable collective impacts on special-status plant species could occur during construction of the Crystal Springs/San Andreas Transmission Upgrade and Lower Crystal Springs Dam projects in the Peninsula Region; incidental disturbance of plants along the road shoulder would be difficult to completely avoid, even with proposed mitigation measures (Chapter 4, Section 4.16).

- Multiple facility improvement projects within the Sunol Valley and Peninsula Regions could collectively cause substantial adverse changes to historic districts, but until more detailed assessments are completed to determine if any historic districts exist, this potential collective impact is conservatively considered to be potentially significant and unavoidable (Chapter 4, Section 4.16).

- Even with proposed control measures, construction-related criteria air pollutant emissions associated with all of the WSIP projects would have a potentially significant and unavoidable collective impact on air quality, since the projects would contribute to the nonattainment status for ozone and particulate matter in both the San Francisco Bay Area and San Joaquin Valley Air Basins (Chapter 4, Section 4.16).

- Since the hours of construction as well as haul routes, truck volumes, and hours of truck operations have not yet been determined for all facility improvement projects within the San Joaquin, Bay Division, Peninsula, and San Francisco Regions, there is the potential that collective noise impacts could result from construction of multiple WSIP projects near Tesla Portal, Irvington Tunnel portal in Fremont, and Lower Crystal Springs Dam. Also, there could be collective truck traffic increases along any overlapping haul routes in these regions. Given these unknowns, such collective effects are conservatively considered to be potentially significant and unavoidable (Chapter 4, Section 4.16).

- Several WSIP projects and several other SFPUC projects could cumulatively affect individual historical resources or potential historic districts (if historic districts are determined to be present), and until project-level analysis is completed, this cumulative effect is conservatively considered to be potentially significant and unavoidable (Chapter 4, Section 4.17).

- Construction-related traffic generated by the WSIP projects would contribute to potentially significant and unavoidable cumulative traffic impacts (e.g., increased travel times), particularly if the travel routes of individual drivers coincided with the construction routes for the WSIP projects, other SFPUC projects, and/or other public and private projects within one or more regions, and/or when construction vehicles associated with the cumulative projects utilize regional transportation facilities (Chapter 4, Section 4.17).

- Construction emissions associated with the WSIP projects, other SFPUC projects, and other public and private projects would cumulatively contribute to the nonattainment status for ozone and particulate matter, a potentially significant and unavoidable cumulative impact (Chapter 4, Section 4.17).

- Potential overlap of the WSIP's construction truck traffic with construction truck traffic of other public and private projects could result in cumulative increases in diesel particulate matter (DPM) and noise on local roadways. Since the SFPUC would have no control over the construction schedules or traffic routes for other projects outside its jurisdiction, potential DPM and noise impacts are considered to be potentially significant and unavoidable (Chapter 4, Section 4.17).

Facility Operations Effects

As described above, implementation of WSIP facility improvement projects would primarily result in short-term effects associated with facility construction. However, operational effects would occur, associated with long-term maintenance and operations activities, such as increased vehicle trips for routine maintenance of new facilities, the long term effect of new facilities on scenic vistas or scenic resources, and the effects of treated water discharge on water quality and aquatic resources. These impacts would be mitigated to less-than-significant levels by implementation of mitigation measures described in Chapter 6.

Water Supply and System Operations Effects

Chapter 5 of this PEIR addresses the effects of the proposed water supply and system operations on the Tuolumne River system, Alameda Creek system, Peninsula system, and Westside Basin Groundwater Resources. In addition, Chapter 5 identifies the cumulative effects of implementing the WSIP water supply option and system operations in combination with other past, present, and reasonably foreseeable future projects within each of these watersheds as well as effects related to climate change.

Due to the proposed increase in diversions from the Tuolumne River and associated changes in system operations, implementation of the WSIP would result in changes in reservoir levels and associated changes in downstream flows in rivers or creeks in the three affected watersheds. In all three watersheds, these hydrologic changes could in turn result in impacts on geomorphology of the water body, groundwater, water quality, fisheries, terrestrial biological resources, and recreational and visual resources. In the Tuolumne River watershed, changes in stream flow could also affect downstream water supplies and hydropower generation. In the Alameda Creek and Peninsula watersheds, implementation of the WSIP would include restoration of the historical storage capacities in Calaveras and Lower Crystal Springs Reservoirs, respectively, resulting in impacts on reservoir levels, downstream flows, fisheries, terrestrial biological resources, and visual resources. In addition, implementation of the WSIP would include development of groundwater supplies in the North Westside Groundwater Basin as well as a conjunctive-use program in the South Westside Groundwater Basin. Identified impacts on these resources were determined to be less than significant with implementation of the mitigation measures described in Chapter 6, with the exception of the following:

- The WSIP would result in a significant and unavoidable impact in the Alameda Creek watershed on the flow along Alameda Creek below the Alameda Creek Diversion Dam (Chapter 4, Section 5.4.1)

- The WSIP would result in a potentially significant and unavoidable impact in the Peninsula watershed on fishery resources in Crystal Springs Reservoir (Chapter 4, Section 5.5.5)

10.2 Significant Irreversible Environmental Changes

In accordance with Section 21100(b)(2)(B) of the CEQA, and with Sections 15126(c) and 15126.2(c) of the CEQA Guidelines, the purpose of this section is to identify significant irreversible environmental changes that would be caused by implementation of the proposed project. Construction and operational impacts associated with implementation of the WSIP projects would result in an irretrievable and irreversible commitment of natural resources through the use of fossil fuels and construction materials. Operation of project facilities would incrementally increase power consumption associated with water facilities, even though operation of SFPUC facilities would predominantly use hydropower. The program's incremental increased use of these resources, however, would not significantly increase the overall commitment of resources associated with water treatment and distribution. The program would involve only minor incremental use of nonrenewable resources and would locate facilities primarily on lands already committed to water treatment and supply purposes. Furthermore, since the SFPUC would implement the mitigation measures identified in this PEIR in concert with other ongoing stewardship and watershed protection activities, implementation of the WSIP would not result in significant irreversible environmental changes. When completed, the program would provide a high level of public health protection against potential seismic hazards as well as increase the long-term reliability of the drinking water to customers throughout the SFPUC service area.

Agency Contact Person:	Diana Sokolove	**Telephone:** (415) 558-5971
Project Title:	Water System Improvement Program (WSIP)	
Project Sponsor:	San Francisco Public Utilities Commission	**Email:** kcapone@sfwater.org
Contact Person:	Kelley Capone	**Telephone:** (415) 934-5715
Project Address:	Various	**Assessor's Block and Lot:** Various
County:	Alameda, Santa Clara, San Francisco, San Joaquin, San Mateo, Stanislaus, and Tuolumne Counties	

Project Description: The WSIP is a program to implement the service goals and system performance objectives established by the SFPUC for the regional water system in the areas of water quality, seismic reliability, delivery reliability, and water supply through the year 2030. The key program elements include:

- Meeting or exceeding existing and anticipated federal, state, and local water quality requirements
- Providing seismic reliability in order to restore basic service (215 million gallons per day [mgd]) to the regional system within 24 hours after a major earthquake and full service within 30 days
- Providing delivery reliability (300 mgd) that allows local reservoir replenishment and adequate maintenance and repair of the system without disruption below level of service goals
- Meeting customer purchase requests through the year 2030, which increase by 35 mgd to 300 mgd over the current 265 mgd, requiring an increase in average annual water delivery of 25 mgd from the regional water system plus 10 mgd from a combination of conservation, water recycling and groundwater supply programs
- Meeting water delivery demands in normal and drought years through 2030 with a combination of Tuolumne River water, groundwater conjunctive-use programs in the Westside Basin, San Mateo County, and conservation, water recycling and groundwater supply programs
- Providing drought reliability such that rationing in any year of the design drought does not result in more than a 20 percent systemwide reduction in delivery of the 2030 purchase requests, which requires an increase in system firm yield[1] from 223 mgd to 256 mgd
- Repairing, upgrading and, in some cases, expanding the regional system facilities to meet these system goals and performance objectives.

Please see the attached for more information about the proposed WSIP, the scope of the PEIR, and the anticipated environmental issues.

THIS PROJECT MAY HAVE A SIGNIFICANT EFFECT ON THE ENVIRONMENT. AN ENVIRONMENTAL IMPACT REPORT IS REQUIRED. This determination is based upon the criteria of the Guidelines of the State Secretary for Resources, Sections 15063 (Initial Study), 15064 (Determining Significant Effect), and 15065 (Mandatory Findings of Significance).

[1] System firm yield is defined as: the maximum annual water delivery that can be sustained by the regional water system during an extended drought. The SFPUC uses an 8.5-year design drought for planning purposes. Currently, due to recent operating restrictions imposed by the California Division of Safety of Dams on the Calaveras Dam, the system firm yield is reduced from its normal system firm yield of 223 mgd to about 219 mgd.

PUBLIC SCOPING MEETINGS will be held pursuant to the State of California Public Resources Code Section 21083.9 and California Environmental Quality Act Guidelines Section 15206 to receive oral comments concerning the scope of the PEIR. Five meetings will be held at different locations along the regional system between October 5 and October 19, 2005. Please see the attached for more information.

Written comments on the scope of the PEIR will be accepted until the close of business on **October 24, 2005**. Written comments should be sent to the San Francisco Planning Department, Attn: Paul Maltzer, 30 Van Ness, Suite 4150, San Francisco, CA 94103, or sent by email to diana.sokolove@sfgov.org.

Documents relating to the proposed project are available for review, by appointment, at the San Francisco Planning Department's Major Environmental Analysis office, 30 Van Ness Avenue, Suite 4150. Please call Diana Sokolove at (415) 558-5971. Documents are also available online at www.sfwater.org (click on "PEIR").

SFPUC Water System Improvement Program

CASE NO. 2005.0159E

1.0 Overview

1.1 Water System Improvement Program

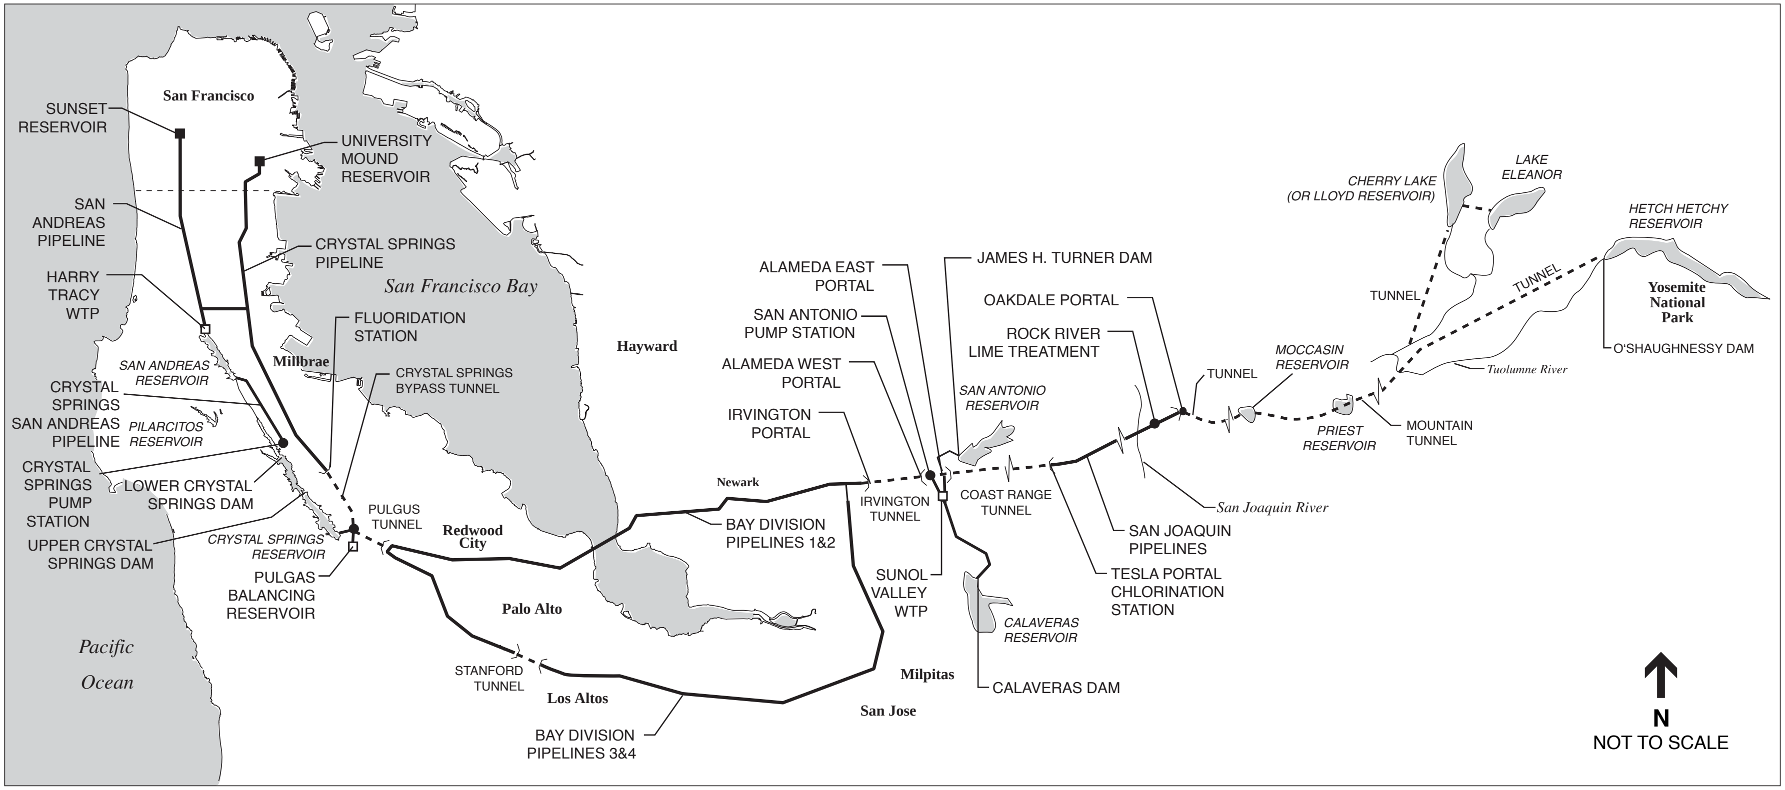
The City and County of San Francisco, through the San Francisco Public Utilities Commission (SFPUC), owns and operates a regional water system that extends from the Sierra Nevada to San Francisco, as shown in **Figure 1**. The regional water system serves 2.4 million people in San Francisco, San Mateo, Santa Clara, Alameda and Tuolumne Counties. The SFPUC has developed a Water System Improvement Program (WSIP or program) in support of its mission to serve its customers with reliable, high-quality drinking water.[2] The basic goals of the WSIP are to increase the reliability of the system with respect to water quality, seismic response, water delivery, and water supply to meet water delivery needs in the service area through the year 2030. The WSIP is a program to implement the service goals and system performance objectives established by the SFPUC for the regional water system. These goals and objectives provide the basis for a series of facility improvement projects that the SFPUC would implement throughout the regional water system and for the implementation of water supply options to meet future annual water delivery needs during normal (nondrought) years as well as current and future needs during droughts.

1.2 Environmental Review Process

The San Francisco Planning Department will prepare an environmental impact report (EIR) to evaluate the environmental effects of the proposed WSIP. The EIR on the WSIP will be a Program EIR (PEIR), as defined in the California Environmental Quality Act (CEQA) Guidelines, Section 15168, and will thus address the broad environmental effects of the program as a whole. The PEIR will analyze the effects of improving the reliability of the system, implementing additional water recycling and conservation, augmenting existing water supplies with supplemental supplies during drought periods, and accommodating increases in customer water purchase requests through the year 2030. The PEIR will also analyze the general effects of constructing and operating the facility rehabilitation and improvement projects that are necessary to meet the goals and objectives of the program. The PEIR will address the "big picture" issues (including the program's growth inducement potential and the associated secondary effects of growth, cumulative effects, system tradeoffs, and program alternatives) and will identify programmatic mitigation measures. To the extent that projects within the WSIP require further, project-level CEQA evaluation in the future, the PEIR also will provide the foundation for such environmental review. For some of the WSIP projects, project-level CEQA analysis will be prepared, as required by CEQA, on a parallel track with the PEIR.

---

This report plus additional information developed subsequently by the SFPUC has been used to prepare this Notice of Preparation (NOP).



SOURCE: San Francisco Public Utilities Commission (2005)

SFPUC Water System Improvement Program . 203287

Figure 1

SFPUC Regional Water System

The WSIP encompasses a comprehensive list of regional water system and local San Francisco system projects and actions designed to implement the program. Regional projects are designed to improve the regional system to meet needs throughout the entire service area, whereas the local San Francisco system projects would serve only customers within the City and County of San Francisco. The PEIR will primarily address the regional system projects in the WSIP and will address local San Francisco system projects to the extent that they affect the operations or capacity of the regional system or contribute to cumulative environmental effects. CEQA analysis of local projects in San Francisco will be addressed separately as appropriate.

Among the regional projects, the San Francisco Planning Department has determined that CEQA review for some of the projects in the WSIP can be conducted separately and independently from the regional projects evaluated in the PEIR, either because (1) the Planning Department completed CEQA review for those projects prior to development of the WSIP or (2) the SFPUC can proceed with implementation of these projects in advance of completing the PEIR on the remaining regional system projects with no substantial changes in the environmental issues to be evaluated in the PEIR. In general, those regional projects that will undergo separate CEQA review from the PEIR have independent utility from the overall WSIP and have no effects on regional system operations or capacity. The PEIR will consider these projects to the extent that they contribute to cumulative effects associated with the WSIP actions and projects. (These projects are identified below in Section 2.6, Table 4.)

1.3 Public Scoping Meetings

The San Francisco Planning Department is holding five **PUBLIC SCOPING MEETINGS**, at the following locations, dates, and times:

- SONORA – Wednesday, October 5, 2005, 7:00 to 9:00 PM
  Sonora Opera House, 250 S. Washington Street, Sonora, CA
- MODESTO – Thursday, October 6, 2005, 7:00 to 9:00 PM
  Thomas Downey High School Cafeteria, 1000 Coffee Road, Modesto, CA
- FREMONT – Tuesday, October 11, 2005, 6:00 to 8:00 PM
  Fremont Main Library, Fukaya Room, 2400 Stevenson Boulevard, Fremont, CA
- PALO ALTO – Tuesday, October 18, 2005, 7:00 to 9:00 PM
  Palo Alto Arts Center, 1313 Newell Road, Palo Alto, CA
- SAN FRANCISCO – Wednesday, October 19, 2005, 7:00 to 9:00 PM
  Tenderloin Community School, 627 Turk Street (at Van Ness), San Francisco, CA

The purpose of these meetings is to assist the San Francisco Planning Department in reviewing the proposed scope and content of the programmatic environmental impact analysis, summarized in this NOP, and the information to be contained in the PEIR for the WSIP. The public will have the opportunity to comment and offer testimony for consideration. Written comment will also be accepted at the meetings and by the San Francisco Planning Department until the close of business on **October 24, 2005.**

2.0 Program Description

2.1 Location and Service Area

The SFPUC regional water system consists of a complex network of facilities covering a geographic range of about 160 miles, from the Sierra Nevada on the east to San Francisco on the west. The regional water system crosses seven counties—Tuolumne, Stanislaus, San Joaquin, Alameda, Santa Clara, San Mateo, and San Francisco—as shown in Figure 1, above.

The SFPUC provides water delivery services to retail and wholesale customers primarily in San Francisco, San Mateo, Santa Clara, and Alameda Counties, as shown in **Figure 2**. The SFPUC serves about one-third of its water supplies directly to retail customers in San Francisco, and about two-thirds of its water supplies to 28 wholesale customers by contractual agreement. The 28 wholesale customers consist of 26 cities and water districts and 2 private utilities in San Mateo, Santa Clara, and Alameda Counties (as listed in Figure 2), which are represented by the Bay Area Water Supply and Conservation Agency (BAWSCA); some of these customers have other sources of water in addition to what they receive from the SFPUC regional system. The SFPUC also provides service to some isolated regional retail customers along the water system, including customers in Tuolumne County.

2.2 Existing Water Supply System

Water Supply

The regional water system currently delivers an average of about 265 million gallons per day (mgd) to about 2.4 million people. The major source of water for the regional system is the upper Tuolumne River Watershed in the Sierra Nevada, which provides about 85 percent of the total water supply. The remaining 15 percent of the water supply is provided by local creeks and runoff in the Alameda Watershed, which is generally located in Sunol Valley, and the Peninsula Watershed on the San Francisco Peninsula (referred to collectively as the "local" watersheds). In the Alameda Watershed, the creeks feeding the local reservoirs include Alameda, Arroyo Hondo, Calaveras, and San Antonio Creeks; on the Peninsula, San Mateo, Pilarcitos, and San Andreas Creeks are the major local water sources.

Water Quality

The SFPUC regional water system delivers extremely high-quality water. The majority of the water originates in the upper Tuolumne River Watershed high in the Sierra Nevada, remote from human development and pollution. This pristine water, referred to as Hetch Hetchy water, is protected in pipes and tunnels as it is conveyed to the Bay Area, requiring only primary disinfection and pH adjustment to control corrosion in the pipelines.

The U.S. Environmental Protection Agency and the California Department of Health Services have approved the use of this drinking water source without requiring filtration at a treatment plant. However, local water from the Alameda and Peninsula Watersheds does require filtration to meet drinking water quality requirements. The filtered and treated water from the local watersheds is blended with Hetch Hetchy water, and most customers receive water from a blended source. System water quality, including

SFPUC Water Service Area

both raw water and treated water, is continuously monitored and tested to assure that water delivered to customers meets or exceeds federal and state drinking water/public health requirements.

Major Regional Facilities

The SFPUC regional water system includes over 280 miles of pipelines, over 60 miles of tunnels, 11 reservoirs, 5 pump stations, and 2 water treatment plants. Major facilities in the water system generally fall into three categories based on their function: storage, transmission, and treatment facilities. **Table 1** lists the major facilities in the regional water system by their function as well as by their geographic sub-region. From east to west, the sub-regions are: Hetch Hetchy sub-region, San Joaquin sub-region, Sunol Valley sub-region, Bay Division sub-region, Peninsula sub-region, and San Francisco sub-region.

System Operations

The regional water system is basically a linear system transporting water from the Sierra Nevada to the Bay Area. The water system starts with the Hetch Hetchy Reservoir and O'Shaughnessy Dam, located on the main stem of the Tuolumne River in Yosemite National Park. From the Hetch Hetchy Reservoir, water flows west through a series of tunnels and hydropower facilities in the Sierra foothills and then to the San Joaquin Valley. Water is conveyed 47 miles in three San Joaquin Pipelines across the San Joaquin Valley and is disinfected at the Tesla Disinfection Facility near Tracy. The water is then transported 25 miles through the Coast Range Tunnel to the three Alameda Siphons in the Sunol Valley, where it is blended with treated sources of local water in the Alameda Watershed.

In the Alameda Watershed, local water from creeks and runoff is captured and stored in the Calaveras and San Antonio Reservoirs. San Antonio Reservoir is also used to store water from the Hetch Hetchy system. Water from the Calaveras and San Antonio Reservoirs is filtered and chloraminated at the Sunol Valley Water Treatment Plant (WTP) before it is blended with Hetch Hetchy water at the Alameda Siphons. The Alameda Siphons carry Hetch Hetchy water, blended with treated Alameda Watershed water, about one-half mile across the Sunol Valley to the Irvington Tunnel. Water flows about 3.5 miles through the Irvington Tunnel to the city of Fremont in the East Bay.

From the west end of the Irvington Tunnel in Fremont, the regional water supply is distributed through four Bay Division Pipelines, two of which cross San Francisco Bay and two of which go around the South Bay; the four pipelines then meet in Redwood City on the Peninsula at the Pulgas Tunnel. Up to this point, the water from Hetch Hetchy Reservoir flows entirely by gravity for over 120 miles. Part of the regional water supply from the Pulgas Tunnel continues to flow by gravity north up the Peninsula, ending at University Mound Reservoir in San Francisco. The remaining water from the Pulgas Tunnel flows into Crystal Springs Reservoir and blends with local water sources on the Peninsula Watershed. Water from Crystal Springs Reservoir is pumped to the adjacent San Andreas Reservoir, which is then pumped to the Harry Tracy WTP where it is filtered and disinfected. Treated water from Harry Tracy WTP is then piped to the Sunset Reservoir in San Francisco. The regional water is distributed to wholesale and a few retail customers through turnouts all along the system.

System operations and the amount of water delivered to customers vary throughout the year based on seasonal demand and the availability of water. The water available to deliver to customers is affected by

numerous factors, including meteorological and hydrologic conditions; the capacity and operating condition of physical facilities and infrastructure; and institutional parameters that regulate and allocate the distribution of water from the various sources. The system is highly dependent on storage, both in the Sierra and locally in the Bay Area, to be able to serve water under a wide variety of meteorological/ hydrologic and operating conditions.

2.3 Need for Program

Planning for the existing water system began over a century ago, and the basic network of major facilities in the regional system was built from the late 1800s through the 1930s. Expansion and improvements of the major facilities continued through the 1970s. Although the population within the SFPUC service area has steadily grown, ongoing repairs, maintenance, and upgrades have not kept pace with the overall system needs to meet increasing water demand from customers. Aging facilities within the system, some of which made use of now outdated construction methods and materials, are currently in need of major repair, rehabilitation, upgrade, or replacement, and it has become difficult to balance the need for long-term maintenance and upgrades with the day-to-day operational demands of the system. Exacerbating the need for long-term maintenance and upgrade is the fact that the regional system crosses five active earthquake faults. Thus, portions of the existing system are vulnerable to extensive damage from a major earthquake and are at risk of interruption or failure during normal operations. In addition, the California Division of Safety of Dams has imposed operating restrictions on Calaveras and Crystal Springs Dams due to seismic concerns, reducing the local storage capacity and impairing normal system operations; this storage capacity needs to be restored. Existing and future water quality regulations also require further facility modifications as well as ongoing watershed management actions. The SFPUC has also determined that the current regional system cannot provide adequate reliable water delivery to its existing customers during a prolonged drought or meet expected increases in customer water purchases through the planning year of 2030.

The SFPUC began planning for major system improvements over 10 years ago, and public awareness of the need for major capital improvements became evident in 2002 with the passage of three related legislative actions. Propositions A and E, passed in November 2002 by San Francisco voters, approved financing for San Francisco’s portion of the multi-billion-dollar water system improvements. Also approved in 2002, Assembly Bill No. 1823 (AB 1823), the Wholesale Regional Water System Security and Reliability Act, requires the City and County of San Francisco to adopt a capital improvement program designed to restore and improve the regional water system and to review and update the program as necessary. The WSIP addresses these needs.

2.4 Program Goals And Objectives

The WSIP is designed to further the SFPUC’s overall mission as a water service agency, which is to serve San Francisco and its Bay Area customers with reliable, high-quality, and affordable water while maximizing the benefits from power operations and responsibly managing the resources entrusted to its care. The SFPUC based the goals and system performance objectives on two fundamental principles: maintaining a clean, unfiltered water source from the Hetch Hetchy system, and maintaining a gravity-driven system.

The overall goals of the WSIP for the regional water system are to:

- Maintain high-quality water
- Reduce vulnerability to earthquakes
- Increase delivery reliability
- Meet customer water supply needs
- Enhance sustainability
- Achieve a cost-effective, fully operational system

To further these program goals, the WSIP includes objectives that address system performance. **Table 2** presents these objectives as they relate to the WSIP goals. The system performance objectives describe and, in many cases, more specifically quantify what the regional water system is to achieve, and thereby guide the water supply actions, facility improvements, and maintenance requirements included in the WSIP. Although Table 2 lists certain sustainability objectives for the WSIP, enhancing sustainability is part of the SFPUC's ongoing watershed management and operational efforts and is not specifically or exclusively an element of the WSIP.

To meet the SFPUC's system goals and service performance objectives, the SFPUC would undertake a series of actions and projects under the WSIP. The following sections describe the proposed changes in system operations and level of service, including proposed water supply options, as well as the proposed facility projects to be implemented under this program.

2.5 Proposed System Operations and Levels of Service

As described above, the regional water system operations are affected by numerous factors, including meteorological and hydrologic conditions; physical facilities and infrastructure; and institutional parameters. The WSIP addresses the condition of the physical facilities and infrastructure while planning for and taking into account both the meteorological/hydrologic conditions and institutional parameters. Under the WSIP, the regional water system would continue to comply with the conditions of all applicable institutional and planning requirements, including:

- Complying with all water quality and public safety regulations
- Maximizing use of water from local watersheds
- Assigning a higher priority to water delivery over hydropower generation
- Meeting all downstream flow requirements

Table 3 summarizes the proposed changes in levels of service with implementation of the WSIP compared to existing conditions.

Water Quality

With implementation of the WSIP, the regional system would continue to meet all local, state, and federal drinking water quality requirements, but would also comply with anticipated future regulations. Changes to system operations are being proposed in order to comply with the proposed Long Term-2 Enhanced Surface Water Treatment Rule and provide secondary disinfection for the Hetch Hetchy water. Projects are proposed to upgrade both regional treatment plants. In addition, to support the objective of maintaining the filtration exemption status for Hetch Hetchy water, ongoing system operations would

TABLE 2

WSIP GOALS AND OBJECTIVES

Program Goal	System Performance Objective
Water Quality – *maintain high water quality*	• Design improvements to meet current and foreseeable future federal and state water quality requirements. • Provide clean, unfiltered water originating from Hetch Hetchy Reservoir and filtered water from local watersheds. • Continue to implement watershed protection measures.
Seismic Reliability – *reduce vulnerability to earthquakes*	• Design improvements to meet current seismic standards. • Deliver basic service to the three regions in the service area (East/ South Bay, Peninsula, and San Francisco) within 24 hours after a major earthquake. Basic service is defined as average winter-month usage, and the performance objective for the regional system is 215 mgd. The performance objective is to provide delivery to at least 70 percent of the turnouts in each region, with 96, 37, and 82 mgd delivered to the East/South Bay, Peninsula, and San Francisco, respectively. • Restore facilities to meet average-day demand within 30 days after a major earthquake.
Delivery Reliability – *increase delivery reliability and improve ability to maintain the system*	• Provide operational flexibility to allow planned maintenance shutdown of individual facilities without interrupting customer service. • Provide operational flexibility to minimize the risk of service interruption due to unplanned facility upsets or outages. • Provide operational flexibility and system capacity to replenish local reservoirs as needed. • Meet the estimated average annual demand of 300 mgd for 2030 under the conditions of one planned shutdown of a major facility for maintenance concurrent with one unplanned facility outage due to a natural disaster, emergency, or facility failure/upset.
Water Supply – *meet customer water needs in nondrought and drought periods*	• Meet average annual water purchase requirements of 300 mgd from retail and wholesale customers during nondrought years for system demands through 2030. • Meet dry-year delivery needs through 2030 while limiting rationing to a maximum 20 percent systemwide reduction in water service during extended droughts. • Diversify water supply options during nondrought and drought periods. • Improve use of new water sources and drought management, including groundwater, recycled water, conservation, and transfers.
Sustainability – *enhance sustainability in all system activities*	• Manage natural resources and physical systems to protect watershed ecosystems. • Meet, at a minimum, all current and anticipated legal requirements for protection of fish and wildlife habitat. • Manage natural resources and physical systems to protect public health and safety.
Cost-effectiveness – *achieve a cost-effective, fully operational system*	• Ensure cost-effective use of funds. • Maintain gravity-driven system. • Implement regular inspection and maintenance program for all facilities.

TABLE 3

EXISTING AND PROPOSED REGIONAL SYSTEM LEVELS OF SERVICE [a]

Operating Parameter	Existing Level of Service	Proposed Level of Service with WSIP (2030)
Water Quality	Meet all local, state, and federal water quality requirements in 2005	Meet all local, state, and federal water quality requirements in 2030
Seismic Response After Major Earthquake	Not defined	Provide basic service [b] of 215 mgd within 24 hours; average-day service of 300 mgd within 30 days
Average Annual Delivery	265 mgd	300 mgd [c]
Regional System Firm Yield [d]	223 mgd	256 mgd
Drought-Year Rationing	No maximum limit to rationing	Up to 20 percent systemwide rationing

[a] Level of service flow rates are defined on a systemwide basis and are not specific to any customer turnout (i.e., water diversion point).

[b] Basic service is defined as winter month demand (215 mgd).

[c] Includes 10 mgd from conservation, recycled water and groundwater supply programs.

[d] System firm yield is defined as: the maximum annual water delivery that can be sustained by the regional water system during an extended drought. The SFPUC uses an 8.5-year design drought for planning purposes. Currently, due to recent operating restrictions imposed by the California Division of Safety of Dams on the Calaveras Dam, the system firm yield is reduced from its normal system firm yield of 223 mgd to about 219 mgd.

include continued implementation of source water protection and systemwide watershed management and protection.

Delivery Reliability

The WSIP goal for water delivery reliability is to increase the reliability of the regional system to meet customer demand under a range of operating conditions. While current system operating strategies would generally remain unchanged, implementation of the WSIP would rehabilitate and upgrade existing facilities as well as provide a wider range of operational flexibility, thereby increasing the reliability of the system to deliver water to all customers.

The WSIP includes an improved maintenance program to increase day-to-day reliability that establishes a schedule and allows for the planned shutdown of facilities for inspection and maintenance while continuing to meet customer demands. Currently, some critical facilities cannot be taken out of service for inspection and maintenance, but the WSIP would provide adequate redundancy of critical facilities to enable inspection and maintenance on a regular schedule. Redundant facilities would also increase the operational flexibility and thus the reliability of water service to customers in the event of an unplanned facility failure or system upset, natural disaster, or other emergency situation. As summarized in Table 2, the SFPUC has set performance objectives to maintain water delivery services during planned facility maintenance activities and unplanned outages of key facilities.

The proposed system upgrades would optimize water storage to provide Bay Area customers with a local supply in the event of an emergency. At present, depending on hydrologic conditions and the transmission capacity of pipelines, replenishment of local reservoirs can take more than one year to complete. The WSIP includes an increase in the transmission capacity of pipelines such that the Alameda and Peninsula Reservoirs can be replenished while continuing to meet customer demands. Implementation of the WSIP would increase the SFPUC's ability to replenish local reservoirs more quickly, which is required both during normal and wet years after an unplanned outage that requires significant drawdown of the local reservoirs to keep water flowing to customers (see Seismic Reliability, below).

Seismic Reliability

To improve seismic reliability for the regional system, critical facilities would be upgraded to meet current seismic standards, thereby improving their ability to withstand seismic damage. In addition, the increased level of operational flexibility would improve the ability to respond and restore service following an earthquake.

In addition, to increase seismic reliability for the system (as described above for water delivery reliability), water storage in the Bay Area and the ability to replenish depleted water storage would be improved under the WSIP so that water service could be restored more rapidly and reliably following a seismic event.

Water Supply

The SFPUC's chief service objectives for water supply are (1) to fully meet customer purchase requests in nondrought years through the planning year 2030, and (2) to provide drought-year delivery with a maximum systemwide cutback of 20 percent in any one year of a drought. The SFPUC, in conjunction with its wholesale customers, has conducted extensive studies to determine water demand projections, conservation and recycled water potential, and water purchase estimates from the regional system. The current estimated total water demand within the entire SFPUC service area is 374 mgd. Of this current total demand, about 265 mgd is purchased annually from the SFPUC. SFPUC customers meet the balance of their supply needs with supplies from other sources. To develop their 2030 purchase requests to the SFPUC, customers have considered conservation and recycled water potential as well as other supply source options available to them. The total projected 2030 water demand within the service area is 417 mgd while the 2030 customer purchase requests to the SFPUC total 300 mgd.[3] The remaining 117 mgd of the 417 mgd total 2030 demand would be met through the other customer sources, primarily water purchases from other agencies, water recycling and conservation.

The 2030 customer purchase request of 300 mgd from the SFPUC is 35 mgd more than the current 265 mgd average annual delivery from the regional system. The SFPUC's proposed water supply option meets this 2030 request by increasing, on average, the SFPUC's annual diversion from the Tuolumne River by 25 mgd and implementing additional conservation, water recycling, and groundwater supply programs to achieve the other 10 mgd needed. SFPUC studies indicate that the SFPUC's existing water sources (i.e., local watersheds and the Tuolumne River) are sufficient to meet current and future water purchases in most years (assuming restored storage capacity in Bay Area reservoirs). Although the SFPUC can meet projected 2030 water purchases of 300 mgd from local supplies and Tuolumne River diversions in most years, those supplies alone have not allowed for full water deliveries during past droughts and cannot be relied upon alone in the future for water deliveries during potential future droughts.

3 San Francisco Public Utilities Commission, *2030 Purchase Estimates,* Technical Memorandum, December 2004.

With respect to drought-year supply, the system firm yield is defined as the maximum annual water delivery that can be sustained during an extended drought; the SFPUC uses an 8.5-year design drought for planning purposes. The current firm yield of the system is 223 mgd.[4] By 2030, with customer purchase requests of 300 mgd and assuming 10 mgd of this request is met by a combination of water recycling, conservation and groundwater supply programs as proposed, the system firm yield is estimated to be 256 mgd. The equivalent of an additional 33 mgd of firm yield is required to provide adequate water delivery in drought years by 2030. The SFPUC proposes to meet this 2030 system firm yield need with a combination of water transfers, groundwater conjunctive-use programs and rationing.

To address existing and future water delivery needs for customers under both average annual and drought conditions, the SFPUC has identified the following proposed water supply option as well as alternatives to be evaluated in the PEIR in comparison to the proposed option.

Proposed Water Supply Option

The SFPUC proposed water supply option to meet the projected 35 mgd increase in average annual delivery through 2030 includes increased use of Tuolumne River water coupled with increased conservation, water recycling and groundwater supply programs. Under this proposed option, the SFPUC would implement additional conservation, water recycling and groundwater supply programs to achieve the equivalent of 10 mgd of supply every year (in all year types: nondrought and drought). In nondrought years, the SFPUC would meet the remaining increase in average annual demand through 2030 (25 mgd) with increased use of Tuolumne River water under its existing water rights.

In drought years, the SFPUC would implement a multistep drought response program to:

- Acquire up to 25 mgd[5] of supplemental dry-year Tuolumne River water through water transfer agreements with Modesto Irrigation District and/or Turlock Irrigation District
- Implement a groundwater conjunctive-use program in the Westside Basin, in San Mateo County, to store water through in-lieu recharge in nondrought years and provide approximately 6 mgd[5] of water in a drought year
- Implement up to 20 percent systemwide rationing in any year of a drought

The facilities and facility improvements required to implement this water supply option are described in greater detail in the following section. Key regional system facility improvements needed include: increasing SFPUC regional system transmission capacity and redundancy in San Joaquin Pipelines and Bay Division Pipelines; restoring full storage capacity in the existing Crystal Springs Reservoir and Calaveras Reservoir; and developing additional wells to implement the regional groundwater conjunctive-use program. Additional facility improvements, described in the following section, are also needed to

---

4 Currently, due to recent operating restrictions imposed by the California Division of Safety of Dams on the Calaveras Dam, the system firm yield is reduced from its normal system firm yield of 223 mgd to about 219 mgd.

5 The contribution to system firm yield from individual projects represents the system firm yield of the projects when evaluated independently by the simulation model. Restoration of Crystal Springs Reservoir storage capacity accounts for 1 mgd. When the projects (District transfers, Westside Basin and Crystal Springs Reservoir restoration) are combined and evaluated as one scenario in modeling, the system firm yield is slightly higher at 33 mgd. The small difference in combined system yield is due to changes in net evaporation over the design drought sequence.

meet the water quality, seismic reliability and delivery reliability performance objectives the SFPUC has established for the regional system in nondrought and drought years.

Other Supply Options

At the SFPUC's request the PEIR will provide a programmatic analysis and comparative evaluation of three other water supply options: (1) increased Tuolumne River diversions without additional recycling, conservation, and groundwater supply programs; (2) additional non-Tuolumne River surface water supplies that may include Delta water transfers and desalination, as well as recycling, conservation, and groundwater supply programs, but no additional Tuolumne River diversions; and (3) a combination of aggressive conservation / water recycling and naturally renewable groundwater supply, with no additional Tuolumne River diversions and no acquisition or use of other additional surface water supplies. Option 1 is a variation of the proposed water supply option described above and has similar facility requirements. Options 2 and 3 would involve repair and improvement of the SFPUC regional system as well as additional facility projects, such as additional transmission pipelines, additional storage facilities, new and/or modified treatment facilities (for example, desalination plant(s), additional recycled water treatment capacity and/or new plants, modifications at SFPUC water treatment plants in order to treat other supply sources), new wells, and additional distribution system pipelines. The feasibility of Options 2 and 3 is currently under study. The PEIR will investigate and compare the nature and magnitude of environmental impacts associated with these water supply options to the SFPUC's proposed water supply option.

At the request of the SFPUC, the PEIR will also provide a programmatic analysis and comparative evaluation of two other drought rationing scenarios: a maximum reduction of 10 percent and a maximum reduction of 30 percent of the 2030 customer purchase requests. These two rationing scenarios will be reviewed to see what effect they might have on the proposed WSIP facility projects. It is expected that all of the proposed WSIP facility projects would still be needed under these two rationing scenarios, but that the size requirements of certain facilities could be affected. In general, it is expected that the 10 percent maximum systemwide rationing scenario would require more supplemental dry-year water, more storage capacity, and possibly more transmission capacity than the SFPUC's proposed option (which includes a maximum of 20 percent systemwide rationing). By contrast, the maximum 30 percent systemwide rationing scenario is expected to require less supplemental dry-year supply than the proposed option. For this scenario, storage and transmission capacity sizing is expected to remain the same as described for the proposed water supply option in order to meet other regional system goals for day-to-day delivery reliability and seismic reliability as well as drought reliability. The SFPUC will confirm the appropriate facilities and sizing for each of these scenarios and this information will be presented in the PEIR.

2.6 WSIP Facility Improvement Projects

To achieve the system performance objectives of the WSIP, the SFPUC has proposed projects to repair, improve and, in some cases, expand the physical facilities in the regional system. **Table 4** lists and briefly describes the individual projects that have been identified in the WSIP, and **Figure 3** shows the locations of these projects. Project descriptions in Table 4 present information pertinent only to that individual facility as an isolated project and do not include how each project relates to the overall system in terms of operations and capacity; that information will be provided in the PEIR.

TABLE 4

SUMMARY OF WSIP FACILITY IMPROVEMENT PROJECTS

No.	Project Title	Type of Facility [a]	CEQA Review Approach [b]	Project Description
San Joaquin Sub-region				
SJ-1	Hetch Hetchy Advanced Disinfection	Treat	PEIR, possible separate CEQA	This project would construct a facility for secondary disinfection for the Hetch Hetchy water supply to comply with the proposed federal drinking water regulations contained in the Long Term-2 Enhanced Surface Water Treatment Rule to remove target organisms such as cryptosporidium.
SJ-2	Lawrence Livermore Filtration	Treat	PEIR	This project would construct treatment upgrades for potable water that the SFPUC provides to the Lawrence Livermore Laboratory. The project would install package membrane technology to ensure that this customer receives consistently high-quality water and would also meet the proposed federal drinking water regulations contained in the Long Term-2 Enhanced Surface Water Treatment Rule.
SJ-3	San Joaquin Pipeline System	Trans	PEIR	This project includes an alternative to construct a fourth 47-mile-long pipeline across the San Joaquin Valley adjacent to the existing three San Joaquin Pipelines and construct two new crossover facilities between all the pipelines. This project is designed to provide redundant system hydraulic capacity sufficient to allow long-term repairs on the existing pipelines while maintaining water supply service to the Bay Area; however, it will also increase the transmission capacity of the San Joaquin Pipelines.
SJ-4	Tesla Portal Disinfection Facility	Treat	Separate CEQA	This project would rehabilitate and upgrade the system's existing primary disinfection for the Hetch Hetchy supply to meet current seismic, safety/fire, and building code standards. The project would replace the existing facilities at the Tesla Portal.
Sunol Valley Sub-region				
SV-1	(project moved)			The project initially labeled as SV-1, Alameda Creek Fishery Enhancement, has been incorporated into SV-2, Calaveras Dam Replacement Project.
SV-2	Calaveras Dam Replacement and Alameda Creek Fishery Enhancement	Storage	PEIR	This project would replace the existing dam at the Calaveras Reservoir to meet seismic safety requirements and would be located just downstream from the existing site. Currently, the capacity of Calaveras Reservoir is restricted to 37,800 acre-feet by the California Department of Water Resources, Division of Safety of Dams due to potential seismic failure of the dam. The proposed dam would be designed to provide a reservoir with the same storage capacity as Calaveras Reservoir was originally designed to accommodate (96,850 acre-feet) to withstand the Maximum Credible Earthquake originating on the Calaveras fault, as well as to withstand the Probable Maximum Flood. The replacement dam would include a new intake tower. Upgrades to the Calaveras Pipeline, San Antonio Pipeline, San Antonio Pump Station, and San Antonio Cone Valve are being considered to provide reliability of water delivery in the event of interruption or outage of Hetch Hetchy water. As part of this project, Calaveras Reservoir would be operated to release up to 6,300 afy (5.5 mgd) of water to Alameda Creek for fish flow enhancement. New facilities would be installed downstream of the dam to recapture the released water and return it back to the regional system for use.
SV-3	Additional 40 mgd Treated Water Supply	Treat	PEIR	This project would construct new or additional water treatment facilities to provide an additional 40 mgd of treatment capacity at either the Sunol Valley (preferred location) or the Harry Tracy WTP.

TABLE 4

SUMMARY OF WSIP FACILITY IMPROVEMENT PROJECTS

No.	Project Title	Type of Facility [a]	CEQA Review Approach [b]	Project Description
SV-4	Irvington Tunnel / Alameda Siphons	Trans	PEIR	Irvington Tunnel – A second tunnel would be constructed to convey water from the Sunol Valley to Fremont in the East Bay. The second tunnel would be a redundant water transmission facility to the existing Irvington Tunnel. Alameda Siphons – A fourth Alameda Siphon would be constructed across the Sunol Valley. The fourth Alameda Siphon would be the seismic backbone and a redundant pipeline to the existing three Alameda Siphons.
SV-5	San Antonio Pump Station Upgrade	Trans	PEIR	This project would upgrade and rehabilitate facilities at the San Antonio Pump Station, which pumps water from San Antonio Reservoir to the Sunol Valley WTP and pumps Hetch Hetchy water to the Sunol Valley WTP, San Antonio Reservoir, or San Antonio Creek. This project provides seismic retrofit of structural deficiencies in the facility, replacement of three electric pumps, backup power for those three pumps, and an electrical substation. This project would allow the facility to sustain existing pumping capacity of 160mgd.
SV-6	Sunol Valley WTP – New Treated Water Reservoir	Treat	PEIR, possible separate CEQA	This project would construct a new 22.5-million-gallon storage reservoir for treated water at the Sunol Valley WTP plus miscellaneous pumping appurtenances to increase treatment efficiency of the WTP during periods of peak demand. The proposed project site is just north of the Sunol Valley WTP.
SV-7	Pipeline Repair Plan and Readiness Improvements	Trans	Separate CEQA	This project consists of developing a plan and purchasing materials for emergency repair and operation of the regional pipelines following an earthquake.
SV-8	Standby Power Facilities (various locations)	Other	Separate CEQA	This project would provide for standby backup power at various facilities to ensure continued operation during power outages. Project locations include the San Pedro and Capuchino Valve Lots, Millbrae Facility, San Antonio and Calaveras Reservoirs, Alameda West Portal, and Harry Tracy WTP.
Bay Division Sub-region				
BD-1	Bay Division Pipeline Hydraulic Capacity Upgrade	Trans	PEIR	This project would construct a new Bay Division Pipeline from Fremont to Redwood City, consisting of 16 miles of pipeline and 5 miles of tunnel running under San Francisco Bay between Newark and East Palo Alto. The new facility would replace the deteriorated existing submarine sections of Bay Division Pipelines 1 & 2. With the pipeline hydraulic upgrade and decommissioning of Bay Division Pipelines 1 & 2 sections, the transmission capacity of the pipeline system would increase.
BD-2	Bay Division Pipelines 3 & 4 Crossovers	Trans	PEIR	This project would construct three additional crossover facilities along Bay Division Pipelines 3 & 4 to provide operational flexibility for maintenance or during emergencies.
BD-3	Slipline Bay Division Pipeline 4 PCCP Sections	Trans	PEIR	This project would rehabilitate sections of the Bay Division Pipeline 4 where vulnerable prestressed concrete cylinder pipe (PCCP) currently exists.
BD-4	Seismic Upgrade of Bay Division Pipelines at Hayward Fault	Trans	Separate CEQA	This project would construct shutoff valves in underground vaults at two locations along Bay Division Pipelines 3 & 4 on either side where they cross the trace of the Hayward fault and upgrade the pipelines between the new shutoff valves. The project would not affect the transmission capacity of the pipelines.
BD-5	SFPUC/EBMUD Intertie	Trans	Separate CEQA	This project will provide a connection between the SFPUC and East Bay Municipal Utility District (EBMUD) water systems such that 30 mgd can be transferred in either direction in the event of an emergency. CEQA review on this project is complete and the project is currently under construction.

TABLE 4

SUMMARY OF WSIP FACILITY IMPROVEMENT PROJECTS

No.	Project Title	Type of Facility [a]	CEQA Review Approach [b]	Project Description
BD-6	Installation of SCADA System – Phase II	Other	Separate CEQA	The Supervisory Control and Data Acquisition (SCADA) project would install monitoring and control equipment at approximately 50 sites to allow collection of water quality and flow data throughout the regional system.
Peninsula Sub-region				
PN-1	Adit Leak Repair, Lower Crystal Springs & Calaveras Reservoirs	Trans	Separate CEQA	This project would repair leaking adits (outlet structures) used to control withdrawal of water from Lower Crystal Springs and Calaveras Reservoirs. The project includes Lower Crystal Springs Outlet Tower No. 1 and Calaveras Outlet Tower.
PN-2	Baden and San Pedro Valve Lots Improvements	Trans	PEIR	This project would upgrade valves, vaults, and piping at the Baden Valve Lot and the San Pedro Valve Lot to meet current seismic standards. The project would include a new pressure-reducing valve to allow transfer of water between high- and low-pressure zones, facilitating backfeed of water from Harry Tracy WTP to Peninsula customers to the south in an emergency.
PN-3	Capuchino Valve Lot Capacity Improvements	Trans	PEIR	This project would seismically upgrade the existing vault and relocate isolation valves to improve reliability of the Capuchino Valve Lot, which allows transfer of water from the high-pressure regional system to low-pressure zones in San Francisco.
PN-4	Cross Connection Controls (various locations)	Trans	Separate CEQA	This project would upgrade the existing valves and piping at 291 locations to eliminate and prevent cross connections and backflow from unapproved sources into the water system in compliance with California water quality regulations.
PN-5	New Crystal Springs Bypass Tunnel	Trans	PEIR, possible separate CEQA	This project would construct a 4,200-foot-long tunnel to replace an existing pipeline that is vulnerable to seismic and landslide hazards. Although the new tunnel would be a replacement facility, the existing pipeline would remain in place and be kept in service as a redundant facility to allow tunnel maintenance.
PN-6	Crystal Springs / San Andreas Transmission Upgrade	Trans	PEIR	This project would consist of hydraulic and seismic upgrades of facilities that convey water from Crystal Springs Reservoir to the Harry Tracy WTP, including the Crystal Springs Outlet facilities, Crystal Springs Pump Station, Crystal Springs–San Andreas Pipeline, and the San Andreas Outlet facilities. The project includes pipeline repair and replacement, a chemical system upgrade, and general structural repairs. This project would increase the transmission capacity of raw water from Crystal Springs Reservoir to San Andreas Reservoir for treatment at the Harry Tracy WTP to sustain delivery to Peninsula customers.
PN-7	Harry Tracy WTP Short-Term Improvements	Treat	PEIR, possible separate CEQA	This project would replace and upgrade the filtration system at the Harry Tracy WTP to increase the reliability and efficiency of the treatment process to deal with challenging raw water conditions. The project would improve the WTP's filtration and coagulation/flocculation process. With these improvements, the plant would reliably maintain its current sustainable capacity of 120 mgd for 60 days.
PN-8	Harry Tracy WTP Long-Term Improvements	Treat	PEIR	This project would be a seismic retrofit and rehabilitation of the existing building and facility, including raw water pumping and transmission improvements, and hydraulic and piping upgrades. The project would increase the sustained treatment capacity of the plant from 120 mgd to 140 mgd, sustainable for 60 days.
PN-9	Lower Crystal Springs Dam Improvements	Storage	PEIR	This project would consist of major repairs and improvements to Lower Crystal Springs Dam to provide adequate protection from the Probable Maximum Flood as well as the Maximum Credible Earthquake. Currently, California Division of Safety of Dams has placed operational restrictions on the dam, and the capacity of the reservoir is limited to 58,400 acre-feet. The project would restore the historic reservoir capacity of 69,300 acre-feet.

TABLE 4

SUMMARY OF WSIP FACILITY IMPROVEMENT PROJECTS

No.	Project Title	Type of Facility [a]	CEQA Review Approach [b]	Project Description
PN-10	Pulgas Balancing Reservoir Rehabilitation	Trans	PEIR	This project would install new inlet/outlet piping to improve mixing in the reservoir, replace the eroding Pulgas Channel to accommodate current maximum flows of 250 mgd, and replace the reservoir roof to meet current seismic standards.
San Francisco Regional Projects				
SF-1	Crystal Springs Pipeline 2 Replacement	Trans	Separate CEQA	This project would repair and replace aging and seismically vulnerable sections of the existing 19-mile-long Crystal Springs Pipeline 2. Transmission capacity of the pipeline would not change.
SF-2	San Andreas Pipeline 3 Installation	Trans	PEIR	This project would construct a new 3.9-mile pipeline extension between Daly City and San Francisco to replace the Baden-Merced Pipeline, which is beyond repair. The project would provide seismic reliability and system redundancy for Peninsula and San Francisco customers.
SF-3	Sunset Reservoir – North Basin	Storage	Separate CEQA	This project would involve seismic upgrades and rehabilitation of the existing reservoir, including seismically strengthening the reservoir roof, columns, and beams and stabilizing the earth embankment around the reservoir. There would be no change in reservoir capacity.
SF-4	University Mound Reservoir – North Basin	Storage	Separate CEQA	This project would involve seismic upgrades and rehabilitation of the existing reservoir, including seismically strengthening the reservoir roof, columns, and beams; upgrades to valves, gates, and drainage control; and miscellaneous roadway and site improvements. There would be no change in reservoir capacity.
SF-5	Groundwater Projects	Other	PEIR	This project includes two phases: Local Groundwater Projects and a Regional Groundwater Banking Program. Local Groundwater Projects would include development of about 2 mgd of new local groundwater for injecting and blending with water in the potable water system in San Francisco. The regional banking program would develop about 6 mgd of potable groundwater in San Mateo County as part of a regional conjunctive-use project. In nondrought years under this project, the SFPUC would provide regional system water to these customers to substitute groundwater currently used for municipal purposes, thereby allowing the groundwater basin to recharge naturally; in drought years, the groundwater would be available for local use to supplement the regional system water.
SF-6	Recycled Water Projects	Other	PEIR	This project includes local and regional recycled water projects. The local project would provide about 4.5 mgd of recycled water primarily for irrigation purposes on the west side and the Marina sections of San Francisco; it would include construction of a new recycled water treatment facility and distribution system within parts of San Francisco. The regional projects include SFPUC's partnering with other jurisdictions to develop and implement recycled water, primarily for irrigation uses.

See Figure 3 for the approximate locations of projects.

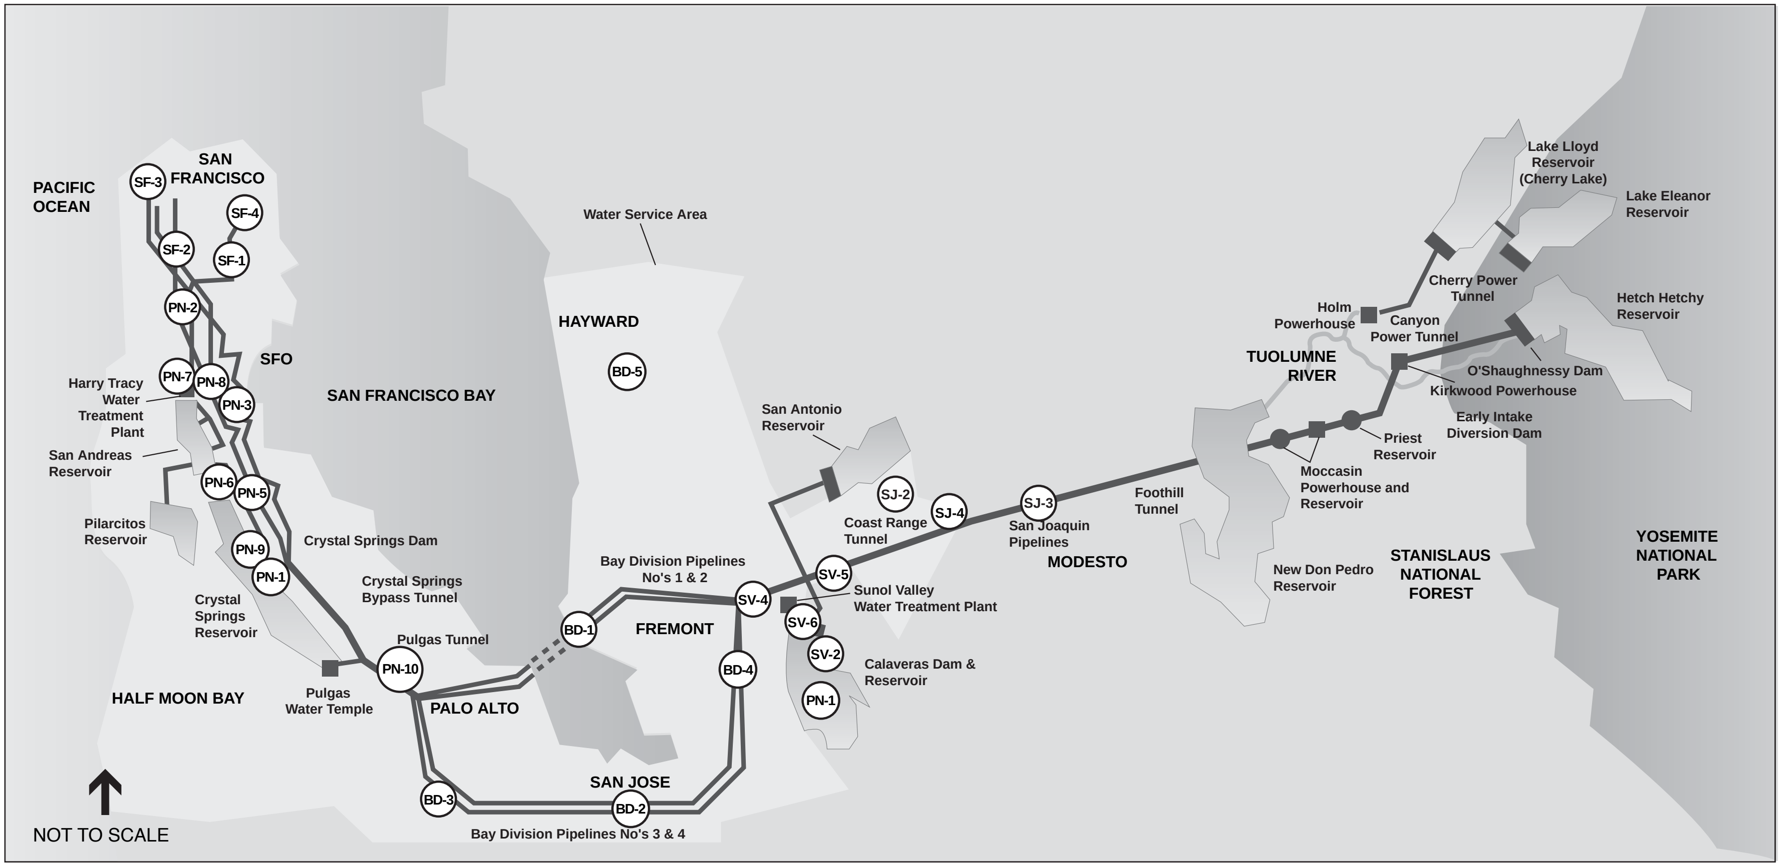
a. Stor = Storage Facility; Trans = Transmission Facility; Treat = Treatment Facility; Other = other types of facilities.

b. This column indicates the status of CEQA analysis for each project.

PEIR = Project to be included in the PEIR impact analysis and alternatives consideration and may undergo or is undergoing additional project-level CEQA analysis as required.

Separate CEQA = Project has undergone or is undergoing separate environmental review independent of the PEIR; however, the project will be considered in the PEIR cumulative effects analyses as relevant.

PEIR, possible separate CEQA = Project to be included in the PEIR impact analysis and alternatives consideration, but may be considered for separate CEQA review and documentation outside of and in advance of the PEIR.



NOTE: Projects SJ-1, SV-3, SV-7, SV-8, BD-6, PN-4, SF-5 and SF-6 not shown because either location not known or project would involve multiple locations. See Table 4 for names and descriptions of projects.

SFPUC Water System Improvement Program . 203287

Figure 3
Location of WSIP Facility Improvement Projects

The projects identified in Table 4 are required to achieve the system performance objectives established by the SFPUC for the regional system and also to support implementation of the proposed water supply option described above. While most of these projects would be needed regardless of which water supply option is ultimately selected, the PEIR will identify particular projects that are not needed for one or more of the water supply alternatives and will identify other projects that may be required to implement a water supply alternative, such as a desalination facility and related transmission/treatment systems.

Table 4 also indicates which WSIP projects will be addressed in the PEIR at a programmatic level of detail and which have undergone or are undergoing separate CEQA review (these latter projects will be considered in the PEIR cumulative analysis as appropriate). The San Francisco Planning Department may also determine that other projects will undergo CEQA review separately and concurrently with the PEIR.

2.7 Implementation Actions

The actions associated with implementation of the WSIP include:

- Ongoing source water protection and systemwide watershed management
- Improved, on-going maintenance
- Drought management planning
- Various actions to secure supplemental water supply to meet 2030 purchase requests and 2030 system firm yield. Actions could include transfer agreements, groundwater conjunctive-use agreements, implementation of water recycling and conservation programs; and possibly additional wells, distribution system connections, and transmission/treatment capacity enhancements
- Construction and operation of WSIP facilities listed in Table 4
- Agreements with SFPUC customers as needed

As the SFPUC continues to develop the projects within the WSIP, it will identify in greater detail the specific implementation actions required for each project and action within the program.

2.8 Schedule

The WSIP includes a preliminary schedule indicating the planning, environmental review, design, and construction phases for all of the regional projects identified in the program. The schedule was developed to assure water delivery service is maintained consistently throughout construction of the numerous projects. The schedule indicates that construction of most projects would be underway by 2008 to 2009 and completed by 2012 to 2013. All projects in the WSIP would be completed by 2017. Acquisition of supplemental water supplies during droughts would be implemented as needed to match water delivery needs of the systemwide customers.

3.0 Environmental Analysis

3.1 Program EIR Level Of Analysis

According to the CEQA Guidelines, Section 15168, a program EIR is one type of environmental review document that may be used to evaluate a plan or program that has multiple components (projects and actions) or to address a series of actions that are related:

- Geographically,
- As logical parts in the chain of contemplated actions,
- In connection with the issuance of rules, regulations, plans, or other general criteria to govern the conduct of a continuing program, or
- As individual activities carried out under the same authorizing statutory or regulatory authority and having generally similar environmental effects that can be mitigated in similar ways.

The PEIR on the proposed WSIP can provide a foundation for any necessary future environmental review of the specific regional system facility projects within the program and, as provided by CEQA, can help simplify the task of preparing any necessary focused environmental documents on projects included in the program. A program EIR can provide the following additional advantages.

- Provide for a more exhaustive consideration of effects and alternatives than would be practical in an EIR on an individual action
- Ensure consideration of cumulative impacts that might not be evident in a case-by-case or project-by-project analysis
- Avoid duplicative consideration of basic policy issues
- Allow the lead agency to consider broad policy alternatives and programwide mitigation measures early in the process when the agency has greater flexibility to deal with basic problems or cumulative impacts
- Allow a reduction in paperwork

A program EIR may be prepared on a plan or program before the details of each and every project within the long-term plan have been developed, as is true for the PEIR on the WSIP. While the SFPUC is aggressively developing the design, construction and operation details of the regional system projects, these project details will not be the focus of the PEIR. The PEIR on the proposed WSIP regional system improvements will be used as a first-tier environmental document; the analysis will focus on the environmental effects of implementing the overall WSIP as a plan to improve and expand the ability of the regional water system to deliver water to the service area. The chief first-tier environmental issues to be evaluated in the PEIR include:

- The overall effects of upgrading and expanding the regional system to meet the water quality and reliability goals proposed for the system
- The effects of providing additional water supply to meet increasing purchase requests within the service area, specifically the effect of increasing average annual water supply to the service area over the next 25 years
- The effects of using the various proposed sources of water to meet the increasing water delivery needs in nondrought and drought periods

The PEIR will evaluate the overall cumulative effects of implementing the various WSIP actions and facility projects in broad terms to identify the major environmental effects and to determine if there are program mitigations and/or program alternatives that should be evaluated at this time. As described in Section 1.2 – Environmental Review Process, the PEIR will not evaluate in detail all the site-specific environmental impacts of constructing and operating each of the many projects proposed as part of the WSIP to rehabilitate, upgrade, and expand the regional system. As required by CEQA, project-level

CEQA review will be conducted for individual projects to address these detailed, site-specific environmental impact issues.

3.2 Environmental Issues to Be Addressed In The PEIR

Following is an overview of the environmental issues that the PEIR will address for the various WSIP actions and projects in association with the proposed water supply option. The PEIR will examine the potentially significant environmental effects in each of the environmental issue areas outlined below, identify mitigation measures, and evaluate whether such measures can reduce impacts to a less-than-significant level.

Surface Water Resources – Hydrology and Water Quality

The WSIP could affect surface water resources in a variety of ways. Changes in the timing and/or amount of supply, diversion and storage could affect Tuolumne River and/or Alameda Creek. Construction activities could cause short-term, temporary effects on local streams and drainages. Potential effects to be evaluated include:

- Changes in surface water flows and resulting adverse effects on beneficial uses (including instream uses such as aquatic habitat and fisheries, and recreation and consumptive uses)
- Changes in surface water quality from program operation or construction activities
- Alteration of existing drainage patterns
- Exposure of people to and/or increasing risk of flooding, seiche, or tsunami hazards

Groundwater Resources – Geohydrology and Water Quality

As part of the WSIP, the SFPUC is proposing greater use of groundwater resources in San Mateo and San Francisco Counties as part of the dry-year supply program. In addition, construction and/or operation of the WSIP facility projects could affect local groundwater resources. Potential effects to be evaluated include:

- Changes in groundwater levels, recharge rates, and/or storage
- Changes in groundwater flow or quality
- Indirect effects (e.g., effects on other beneficial uses of the groundwater, risk of land subsidence)

Fisheries and Aquatic Resources

Fisheries and aquatic resources could be affected indirectly due to changes in river flows or water quality, or directly due to construction activities in or near rivers, streams, and drainages. The PEIR will review the potential for fishery and aquatic resource effects on the Tuolumne River system, Alameda Creek, and within the system reservoirs due to changes in water supply operations as well as, in general, changes in local streams and drainages as a result of facility construction activities. Potential effects to be evaluated include:

- Changes in the extent of habitat or habitat quality
- Changes in a fish population that cause it to drop below self-sustaining levels

- Effects on special-status species
- Interference with the movement of any native or migratory fish species

Terrestrial Vegetation and Wildlife

Construction of the proposed regional system projects could have "footprint" impacts resulting in the loss of habitat at new facilities sites as well as cause construction disturbance to terrestrial habitats and wildlife as a result of short-term effects such noise, vibration, dust, and erosion. Potential effects to be evaluated include:

- Changes in the extent of habitat or habitat quality for terrestrial plants and wildlife
- Effects on special-status species
- Effects of species populations and the ability to maintain self-sustaining levels
- Interference with wildlife species movement corridors or migration

Geology, Soils, and Seismicity

One of the chief goals of the WSIP is to reduce the vulnerability of the system to severe damage during an earthquake and to improve the repair and response time to restore water delivery after an earthquake. The PEIR will describe the WSIP's effect on the water system's vulnerability and response to earthquake damage. In addition, construction of the regional facility projects could result in site-specific impacts to or from local geology and soils conditions. The PEIR will provide a general review of these types of project-specific impacts. Potential effects to be evaluated include:

- Seismic hazards to the water system and/or increased exposure of people and structures to seismic hazards
- Increased exposure of people or structures to geologic hazards (such as liquefaction, poor soil conditions, or unstable slopes)
- Erosion potential

Cultural Resources

The regional facility projects would repair, modify, demolish, and add facilities to the regional system. Construction of these projects could affect the historical significance of components of the water system and/or affect other historic or cultural resources in the vicinity of the system. Potential effects to be evaluated include:

- Effects on archaeological resources
- Effects on historic/architectural resources, including the regional water system
- Effects on Indian Trust assets and Native American resources

Land Use, Plans, and Policies

Construction of the proposed regional system projects could have "footprint" impacts that would affect existing or planned land uses along the regional system. While most of the proposed facility improvements or additions would occur within existing facility sites and rights-of-way for regional system facilities, some projects would involve construction activities at previously undisturbed areas and/or areas outside of the SFPUC's existing rights-of-way. In addition, construction or operation impacts could affect adjacent land uses. Also, WSIP projects could require removal of land uses including, in some cases, structures that have encroached onto SFPUC lands and rights-of-way such as gardens, fences, and sheds, and in one potential case, a house. While these are not permitted land uses, the PEIR will review potential environmental effects of removing or relocating such encroachments. For some projects, site-specific facility construction and operation impacts will be evaluated in detail in subsequent environmental documents; however, the PEIR will provide an overview of the potential land use impacts associated with implementation of these proposed facility projects. In addition, the PEIR will review appropriate local, regional, state, and federal plans and policies within the overall study area and evaluate their relationship to the WSIP and the SFPUC's jurisdiction as a public utility. Potential effects to be evaluated include:

- Substantial conflict with established local, regional, state, or federal plans, policies, and/or guidelines
- Disruption of an established community
- Inconsistency or incompatibility with existing or planned land uses at or adjacent to proposed regional facility sites
- Short-term construction disruption effects on neighboring land uses
- Operations effects on adjacent land uses

Recreation

Proposed program changes in water delivery operations (i.e., the level and timing of diversion from the Tuolumne River) or changes in reservoir storage could affect water-based recreation. In addition, construction of the proposed regional system projects could have "footprint" impacts that might conflict with or affect existing or planned recreation land uses. Also, construction could cause temporary disruption of these uses due to noise, dust, or access restrictions. The PEIR will evaluate the effects of the proposed water supply options and operations on water-based recreation, such as boating, rafting, or fishing, associated with the regional water system or downstream water resources. For some projects, site-specific facility construction and operation impacts will be evaluated in detail in subsequent environmental documents; however, the PEIR will provide an overview of the potential effects of the facility projects on land-based recreation. Potential effects to be evaluated include:

- Effects on water-based recreation facilities in the regional water system as well as any downstream water resources affected by SFPUC operations
- Effects on land-based recreation facilities and activities due to the siting or operations of proposed facilities or construction activities (e.g., short-term effects due to noise, dust, access restrictions)

Agricultural Resources

Siting of new or modified regional system facilities, primarily in the San Joaquin, Livermore and Sunol Valleys, could affect agricultural lands by removing agricultural soils from production. In addition, construction activities could cause short-term impacts to agricultural activities. Operation of proposed regional system facilities is not expected to result in ongoing impacts to neighboring agricultural activities. For some projects, site-specific facility construction and operation impacts will be evaluated in detail in subsequent environmental documents; however, the PEIR will provide a program-level review of the potential effects of the facility projects on agricultural soils and farming activities. Potential effects to be evaluated include:

- Loss of prime farmland
- Impacts or conflicts with existing or planned agricultural activities

Traffic, Transportation, and Circulation

Effects on traffic, transportation, and circulation resulting from the WSIP would largely be associated with facility construction activities and, as such, would be temporary and short term. However, some of the proposed regional system projects could have "footprint" impacts that would affect existing or planned traffic corridors or transportation facilities. For some projects, site-specific facility construction and operation impacts will be evaluated in detail in subsequent environmental documents; however, the PEIR will provide an overview of the potential effects of the facility projects on traffic, transportation, and circulation, including cumulative effects. Potential effects to be evaluated include:

- Effects on the regional transportation network or facilities
- Effects of adding new vehicle trips and contributing to increased traffic congestion during construction and/or operation of proposed facilities
- Effects on traffic safety

Air Quality

Effects on air quality from implementation of the WSIP regional system improvements would largely be associated with facility construction activities and, as such, would be temporary and short term. However, the PEIR will also evaluate potential changes in system operation that could result in long-term air quality effects. For some projects, site-specific facility construction and operation impacts will be evaluated in detail in subsequent environmental documents; however, the PEIR will provide an overview of the potential effects of the facility projects on air quality. Potential effects to be evaluated include:

- Effects of construction emissions, particularly dust
- Effects of system operations
- Consistency with regional air quality plans

Noise and Vibration

Noise and vibration effects from implementation of the WSIP regional system improvements would largely be associated with facility construction activities and, as such, would be temporary and short term. However, the PEIR will also evaluate potential changes in system operation that could result in long-term noise effects affecting adjacent land uses. For some projects, site-specific facility construction and operation impacts will be evaluated in detail in subsequent environmental documents; however, the PEIR will provide an overview of the potential noise effects of the facility projects. Potential effects to be evaluated include:

- Effects of construction noise and vibration
- Effects of operations on noise levels

Public Services, Utilities, and Energy

The PEIR will review the potential effects of the WSIP on utilities, public services, and energy resulting from both construction and operation of the improved and expanded regional system. While the regional water system is operated with water delivery as a higher priority than hydropower generation, the SFPUC system provides energy through its hydropower generation facilities to parts of San Francisco, the Modesto and Turlock Irrigation Districts, and other customers. The WSIP has been developed to focus on the water system infrastructure without affecting hydropower facilities   The PEIR will describe the relationship of the WSIP with the hydropower facilities during construction and operation of the WSIP. In addition, some of the WSIP projects, such as the Advanced Disinfection Project, could require substantial increases in the current energy demands of the regional system. For some projects, site-specific facility construction and operation impacts will be evaluated in detail in subsequent environmental documents; however, the PEIR will provide an overview of the potential effects of the facility projects on public utilities and services. Potential effects to be evaluated include:

- Effects on SFPUC hydropower generation and associated effects on power service provided to customers
- Systemwide increases in energy demands and potential need for expansion of power facilities
- Disruption of services (such as water or power) during construction
- Effects on other utilities (such as the need for relocation)

Hazards and Public Safety

The PEIR will review the hazardous materials proposed for use in operation of the system and evaluate potential changes over current operations. Some of the potential hazards are associated only with construction activities for the facility projects. For some projects, site-specific facility construction and operation impacts will be evaluated in detail in subsequent environmental documents; however, the PEIR will provide an overview of the facility projects with respect to hazards and public safety. Potential effects to be evaluated include:

- Potential to encounter hazardous materials or waste during construction or potential to release hazardous materials during construction
- Potential for accidental release of chemicals during facility operations or changes with respect to the risk of upset

Visual Quality

Effects on visual quality associated with implementation of the WSIP regional system projects would primarily result due to the siting of new or modified facilities. The PEIR will provide a program-level review of the potential visual resource impacts that could result from the proposed facilities projects. For some projects, site-specific facility construction and operation impacts will be evaluated in detail in subsequent environmental documents; however, the PEIR will provide an overview of the potential visual effects of the facility projects. Potential effects to be evaluated include:

- Degradation or obstruction of scenic views and designated scenic resources

Socioeconomics

The PEIR will review existing information about the potential socioeconomic effects of drought rationing, general conservation, and water supply costs and outline the potential socioeconomic effects of the WSIP on the customers within the regional system service area that could, in turn, result in physical environmental effects, such as changes in land use patterns and/or densities. The PEIR will summarize existing, available literature about the potential socioeconomic effects associated with drought rationing at different levels, and associated with varying costs of water supply options. If available, the PEIR will discuss the socioeconomic effects in the Bay Area and within the SFPUC service area of the most recent 1987 – 1992 drought.

Growth-Inducement Potential and Secondary Effects of Growth

The PEIR will evaluate the WSIP service goal to meet the future purchase requests of the SFPUC's customers within the existing service area through 2030. There is no proposal to expand the service area, but the SFPUC does propose to increase water supply to meet the needs of planned growth within its current service area. CEQA requires a discussion of a project's potential to remove an obstacle to growth, and an evaluation of the potential indirect environmental impacts, or secondary effects, of that growth. The PEIR evaluation will address the following:

- Relationship of the 2030 customer purchase requests for water supply to the planned growth and land uses reflected in currently adopted local land use plans (i.e., General Plans)
- Regional growth projections for the service area from the Association of Bay Area Governments and the California Department of Finance
- Secondary effects of growth projected within the service area, including effects on land uses, biological resources, traffic and transportation, air quality, noise, water quality, public services, and water resources

Cumulative Effects

The PEIR will evaluate the overall cumulative effects of implementing the WSIP, including implementation of all of the regional system projects. The analysis will also consider the cumulative effects of implementing the WSIP in conjunction with past, present, and reasonably foreseeable projects sponsored by the SFPUC and others in the vicinity of the regional system facilities.

3.3 Alternatives

CEQA requires that an EIR evaluate a reasonable range of feasible alternatives to the project, or to the location of the project, that would attain most of the basic project objectives, but that could avoid or substantially lessen any of the significant effects of the project, so that the merits of each alternative are compared to those of the proposed program. The PEIR alternatives analysis will identify the potentially significant impacts of the proposed WSIP regional system actions and facility projects. The findings of the PEIR impact analysis will guide the refinement of an appropriate range of alternatives to be evaluated in the PEIR to avoid or substantially lessen identified impacts.

As requested by the SFPUC, the PEIR will present a comparative evaluation of alternative water supply options for normal and dry-year conditions, including increased Tuolumne River diversion and non-Tuolumne River supply sources, such as Delta water transfers and desalination, as well as aggressive conservation and water recycling with no additional, supplemental surface water supplies. The SFPUC is continuing to assess these alternatives to determine their feasibility. The PEIR will identify other water supply options if appropriate. At a program level of detail, the PEIR will focus the alternatives analysis on different water supply source options and quantities as well as system operations and modifications that could reduce or avoid significant impacts associated with the proposed program.

With respect to facility alternatives, the PEIR will identify whether there are significant impacts associated generally with the proposed sites for the regional facilities and, if so, will identify site location alternatives to be considered to avoid or reduce such impacts. The SFPUC has or is completing an evaluation of a range of alternative sites and designs for major regional facility projects in the WSIP. The PEIR will review those project alternatives studies. For projects requiring site-specific EIRs, detailed evaluation of proposed and alternative sites and designs will occur in those subsequent environmental review documents, but the PEIR will provide a program-level review of facility site alternatives.

The PEIR will also include a discussion of impacts associated with the No Program Alternative. The No Program alternative will compare the potential impacts of the WSIP with the impacts that would be expected to occur in the event that the WSIP is not implemented.

1.0 Introduction and Background

1.1 Introduction

The San Francisco Planning Department is the lead agency for implementation of California Environmental Quality Act (CEQA) requirements for all projects sponsored by the City and County of San Francisco or conducted within San Francisco. The San Francisco Planning Department is preparing a Draft Program Environmental Impact Report (PEIR) on the San Francisco Public Utilities Commission's (SFPUC's) proposed Water System Improvement Program (WSIP, or program). The Draft PEIR, which will assess the potential impacts of the WSIP on the physical environment of the program area, is being prepared in accordance with CEQA. CEQA requires the preparation of an EIR when a proposed project (in this case, a proposed program) could significantly affect the physical environment.

As part of the Draft PEIR process, the San Francisco Planning Department conducted a public scoping effort in September and October 2005, soliciting comments from agencies and the public to help determine the scope of the Draft PEIR. This report describes the scoping process and summarizes the public and regulatory agencies' comments received during scoping.

1.2 Notice of Preparation

As the first step in the CEQA process, the San Francisco Planning Department published a Notice of Preparation (NOP) on September 6, 2005 announcing the anticipated preparation of the Draft PEIR on the WSIP. The NOP summarized the goals, objectives, and elements of the proposed WSIP, and presented the San Francisco Planning Department's determination that the proposed WSIP may have a significant effect on the environment. The NOP also described the requirement for preparation of an environmental impact report (EIR) on the WSIP under CEQA. The San Francisco Planning Department determined that a Program EIR is the appropriate environmental document for the proposed WSIP. The NOP also described the scoping process and included information on the public scoping meetings. The scoping process, notification procedures, and outcome of the scoping meetings are described below, following a brief description of the WSIP.

1.3 Water System Improvement Program

The proposed WSIP is designed to increase the reliability of the regional water system, which currently provides drinking water to 2.4 million people in San Francisco, San Mateo, Santa Clara, Alameda, and Tuolumne Counties. The program would implement the service goals and system performance objectives established by the SFPUC for the regional water system in the specific areas of water quality, seismic reliability, delivery reliability, and water supply, through the year 2030. The $4.3 billion WSIP includes numerous improvement projects located throughout the regional system to meet the system performance goals and objectives; these project include repairs, upgrades, and, in some cases, expansion of system facilities.

The WSIP as presented in the NOP is based on a draft description issued by the SFPUC in February 2005. The SFPUC has continued to develop and refine the WSIP, issuing revised descriptions of various WSIP elements in October and November 2005 and January 2006. The revised WSIP maintains the same overall program, service goals, and system performance objectives as described in the NOP, and changes are limited to modifications and clarification to individual improvement projects, schedules, and costs. Therefore, although the program refinements were developed subsequent to the publication of the NOP and the scoping process, they likely will not affect the environmental analysis and scope of the Draft PEIR.

2.0 Purpose of the Scoping Process

The purpose of scoping is to solicit input from the public and agencies on the appropriate scope, focus, and content of the Draft PEIR. The San Francisco Planning Department will consider all of the input received during the scoping process in the preparation of the Draft PEIR.

The Draft PEIR will describe the existing environmental conditions of the area that could be affected by the proposed program and evaluate the potential effects of the WSIP in accordance with CEQA. The comments provided by the public and agencies during scoping will help the San Francisco Planning Department identify pertinent issues, methods of analyses, and level of detail that should be addressed in the Draft PEIR. The scoping comments will also provide the basis for developing a reasonable range of feasible alternatives that will be evaluated in the Draft PEIR.

The scoping comments will augment the information developed by the EIR team, which includes specialists in each of the environmental subject areas covered in the EIR. This combined input will result in an EIR scope of work that is both comprehensive and responsive to issues raised by the public and regulatory agencies, and that meets CEQA requirements. The Draft PEIR is scheduled to be available for public comment in 2006.

In addition to facilitating public and regulatory agency input on the scope and focus of the Draft PEIR, scoping allows the San Francisco Planning Department to explain the EIR process to the public and to identify additional opportunities for public comment and public involvement during the EIR process. CEQA requires that the public be informed about the significant environmental effects of a proposed project or program, and the ways in which those environmental effects can be avoided or reduced, before the project or program is approved.

3.0 Notification of Scoping

The scoping period began on September 6, 2005 with the issuance of the NOP. Scoping meetings were conducted on October 5, 6, 11, 18, and 19, 2005, and written comments were accepted through October 24, 2005. Agencies and the public were notified in advance about the availability of the NOP and the scoping meeting dates and locations, and were provided with details on the comment process. The following methods of notification were used:

- **Mailing List**. A mailing list was compiled, including approximately 1,400 contacts for affected federal, state, regional, and local agencies; federal, state, regional, and local elected officials; regional and local interest groups; member agencies of the Bay Area Water Supply and Conservation Agency (BAWSCA); other potentially affected water and irrigation districts; SFPUC Community Advisory Committee members; information repositories; media contacts; and individuals who attended the SFPUC informational meetings in May 2005. The May 2005 PEIR Informational Meeting Summary can be found on the PEIR section of the www.sfwater.org website under "Meetings."
- **NOP and NOP Notice of Availability**. On September 6, 2005, copies of the NOP were distributed via certified mail to 21 affected agencies, and 25 copies were delivered to the State Clearinghouse. Copies of the NOP were also sent via first-class mail to 272 additional organizations and individuals. In addition, a notice of availability of the NOP was distributed via first-class mail to the entire mailing list. (See Appendix A for copies of the NOP and NOP Notice of Availability.)
- **Meeting Notification**. Notice of the scoping meetings was provided to individuals and the general public through the following means (see Appendix B for copies of these materials):
  - **Six-week notice to stakeholders**. The SFPUC emailed advance notice of the meetings to individuals who had requested early notification.
  - **Two-week notice to entire mailing list**. Notifications of the scoping meetings—including information on the WSIP PEIR and the scoping process, and instructions on how to obtain a copy of the NOP and provide public comment—were mailed to the entire 1,400-contact mailing list two weeks prior to the first scoping meeting. The notice included contact information for Spanish and Chinese speakers.
  - **Legal notices**. Notices of the scoping meetings and information on how to obtain a copy of the NOP and provide public comment were placed in the legal classified section of the *Sonora Union Democrat* (9/28/05), *Modesto Bee* (9/29/05), *Fremont Argus* (9/30/05), *San Mateo Times* (10/7/05), and *San Francisco Chronicle* (10/10/05).
  - **Display ads**. Display ads with information about the scoping meetings and information on how to obtain a copy of the NOP and provide public comment were placed in the *Sonora Union Democrat* (9/30/05), *Modesto Bee* (10/1/05), *Fremont Argus* (10/1/05), *San Francisco Examiner* (10/8/05), and *San Mateo Times* (10/8/05).
  - **Community newspapers**. The SFPUC provided text about the scoping meetings to the Clerk of the Board of Supervisors in San Francisco for placement in selected San Francisco community newspapers in September and October 2005.
  - **Website**. A WSIP PEIR webpage was developed and uploaded to the SFPUC's website. Information about the WSIP, the environmental review process, the availability of the NOP, the scoping process, and how to provide public comment was provided in English, Chinese, and Spanish. The website also included the dates and locations of the scoping meetings.

– **Locations to obtain a copy of the NOP**. The NOP notice of availability and full NOP were posted to the project website (www.sfwater.org), as well as the San Francisco Planning Department's website (www.sfgov.org/site/planning). A printed copy of the NOP was also provided to anyone who requested it from the SFPUC or the San Francisco Planning Department.

Table 1 presents an itemized list of mailings.

TABLE 1
NUMBER OF RECIPIENTS ON MAILING LIST FOR NOP AND NOTICE OF SCOPING MEETINGS

Category	Number of NOP Recipients	Number of NOP Notice of Availability Recipients
Federal Agencies/Elected Officials	16	25
State and Regional Agencies/Elected Officials	72	30
Local Agencies/Elected Officials	16	630
Water Agencies/Irrigation Districts	84	25
Special Interest and Environmental Groups	44	120
Businesses or other Organizations	4	95
Media, Libraries, and Individuals	57	182
TOTAL	**293**	**1,107**

4.0 Scoping Meetings

The San Francisco Planning Department held public scoping meetings at five locations along or near the SFPUC's regional water system during October 2005, approximately one month after publication of the NOP, to solicit input from the public on potential impacts of the WSIP, the significance of impacts, the appropriate scope of the EIR, mitigation measures, and potential alternatives to the WSIP. The locations and dates of the meetings, and approximate number of attendees, are listed below.

- Sonora (93 attendees) – Wednesday, October 5, 2005
  Sonora Opera House, 250 S. Washington Street, Sonora, CA
- Modesto (33 attendees) – Thursday, October 6, 2005
  Thomas Downey High School Cafeteria, 1000 Coffee Road, Modesto, CA
- Fremont (62 attendees) – Tuesday, October 11, 2005
  Fremont Main Library, Fukaya Room, 2400 Stevenson Boulevard, Fremont, CA
- Palo Alto (36 attendees) – Tuesday, October 18, 2005
  Palo Alto Arts Center, 1313 Newell Road, Palo Alto, CA
- San Francisco (37 attendees) – Wednesday, October 19, 2005
  Tenderloin Community School, 627 Turk Street, San Francisco, CA

The total attendance for the five scoping meetings was 260 (based on the meeting sign-in sheets), representing a range of interested parties from the Tuolumne River Trust, Sierra Club, whitewater rafting groups, the Bay Area Water Supply and Conservation Agency, local governments, and the

League of Women Voters. A total of 80 participants provided oral comments at the five meetings, and local media attended each meeting. All five scoping meetings were recorded by certified court reporters who provided verbatim written transcripts of the proceedings. The transcripts can be found under Appendix D of this report.

Each meeting included presentations on the environmental review process and the proposed WSIP, followed by a formal public comment period. Attendees interested in presenting verbal comments submitted speaker cards and were allotted three minutes to speak. At all the meetings, there was sufficient time for all interested parties to speak. The meetings concluded with closing remarks. Following the formal meetings, attendees were invited to review project display boards and ask questions of the project team. (See Appendix C for copies of the scoping meeting presentation, handouts, display boards, comment/speaker cards, and sign-in sheets.)

The San Francisco Planning Department also held a scoping meeting for resource agencies on Thursday, November 3 in San Francisco. Representatives from the following agencies attended: U.S. Army Corps of Engineers, San Francisco Bay Regional Water Quality Control Board, California Department of Fish and Game, and the United States Fish and Wildlife Service. Representatives from the U.S. Environmental Protection Agency and National Marine Fisheries Service were invited but were unable to attend. A summary of this meeting can be found in Appendix D.

5.0 Overview of Comments Received

Agencies and members of the public utilized several different methods of providing input: verbal comments during the meetings, written comments submitted during the meetings or sent via U.S. mail, email or fax, and voice mail messages left at the San Francisco Planning Department. Tables 2 and 3 summarize the number of comments submitted via each method, and describe the commenters.

TABLE 2
TOTAL NUMBER OF COMMENTS RECEIVED

Category of Commenter	Number	Description
Written Comments		
Comment Letters	104	This includes 5 distinct form letters counted once each, but submitted multiple times, representing approximately 3,275 individuals or organizations.
Verbal Comments		
Speakers at scoping meetings	75	Two people spoke at multiple meetings
Speakers at resource agency meeting	4	
Voicemail messages left at SF Planning Department[a]	187	

[a] Received as of November 2, 2005.

Verbal comments were made by representatives from government agencies, water agencies, environmental interests, commercial interests, and private citizens. Seventy-five people spoke at the five scoping meetings, including two individuals representing Tuolumne River Trust and Friends of Lake Merced who spoke at multiple meetings. Four representatives from federal and state agencies spoke at the resource agency meeting. Written comments were submitted by federal agencies, state agencies, local agencies, special interests and environmental groups, business groups, and individuals.

Multiple copies of form letters were submitted by the following special interest and environmental groups:

- Working Assets (approximately 2,950 copies)
- Tuolumne River Trust (204 copies)
- Various environmental organizations (more than 100 copies)

TABLE 3
DESCRIPTION OF COMMENTERS

Category of Commenter	Number	Description
Written Comments		
Federal Agencies	1	U.S. Department of the Interior
State Agencies	6	State Water Resources Control Board, Central Valley Regional Water Quality Control Board, California Department of Parks and Recreation, California State Lands Commission, California Department of Health Services, California Department of Transportation (Caltrans)
Local Agencies	23	Representing cities, counties, park districts, water districts, sanitation districts, air districts, fire commission
Special Interest Groups	14	Representing Alameda Creek Alliance, Restore Hetch Hetchy, Tuolumne River Trust, Friends of Lake Merced, Environmental Defense, Audubon Society, Sierra Club, Clean Water Action, and others
Businesses	6	Representing rafting companies, manufacturing business, chamber of commerce
Individuals	45	Representing individuals in San Francisco, San Mateo, Santa Clara, Alameda, San Joaquin, Stanislaus, and Tuolumne Counties, and other areas
Verbal Comments from Public and Resource Agency Scoping Meetings		
Federal Agencies	2	U.S. Army Corps of Engineers, U.S. Fish and Wildlife Service
State Agencies	2	San Francisco Bay Regional Water Quality Control Board, California Department of Fish and Game
Local Agencies	7	Representing cities, water districts, county fire commissioners, county boards of supervisors
Special Interest Groups	37	(same as written comments, above)
Businesses	4	Representing rafting companies
Individuals	18	Representing individuals in San Francisco, San Mateo, Santa Clara, Alameda, San Joaquin, Stanislaus, and Tuolumne Counties

In this summary report, verbal and written comments are divided into two broad categories: 1) CEQA, which includes comments on environmental issues or on potential alternatives to be considered in the PEIR; and 2) WSIP, which includes comments on the program and objectives, specific projects within the program, and SFPUC system operations. Tables 4 through 6 show the approximate number of comments in each subject area, with most letters and speakers providing comments in multiple subject areas.

TABLE 4
APPROXIMATE NUMBER OF COMMENTS BY CEQA SUBJECT AREA

Type of Comment	Written	Verbal at Scoping Meetings
Agricultural Resources	4	2
Air Quality	5	0
Biological Resources – Aquatic	20	10
Biological Resources – Terrestrial	15	10
Cultural Resources	1	1
Geology, Soils, and Seismicity	2	0
Groundwater Resources	10	2
Hazards and Public Safety	2	0
Land Use, Plans, and Policies	15	0
Noise and Vibration	5	0
Public Services and Utilities	10	1
Recreation	15	10
Socioeconomics	20	10
Surface Water Resources / Water Quality	45	15
Traffic, Transportation, and Circulation	10	0
Visual Quality	5	0
Growth-Inducement	10	10
Cumulative Effects	10	5
CEQA Alternatives	145	80
CEQA Process	10	5

TABLE 5
APPROXIMATE NUMBER OF COMMENTS RELATED TO ALTERNATIVES

Recommended Alternative	Number of Written Comments	Number of Verbal Comments at Scoping Meetings	Number of Phone Comments
Conservation and Recycling	75	40	1
Desalination	10	5	
Delta and Other Water Transfers	5	1	
Restore Hetch Hetchy	15	10	1
Other	50	20	

TABLE 6

6.0 Summary of Comments by Subject Area

This section summarizes the issues raised in both verbal and written comments during the scoping period. The comment summaries are presented in two categories: CEQA and WSIP. The issues and topics listed below are not inclusive of all comments received, but rather present a summary of the sentiments expressed by the commenters. The numbers in parenthesis following each comment summary refers to the specific comment letter or verbal commenter, which are listed in Tables 7 and 8 at the end of this section and may be used to cross-reference the source of the comments. (Appendix D also contains the index of commenters as well as all of the commenter correspondence and copies of the scoping meeting transcripts.)

6.1 CEQA Comments

6.1.1 Environmental Review Process

Comments on the CEQA/environmental review process included:

- Role of the National Environmental Policy Act (NEPA) in the PEIR review (Letters 93, 94; Verbal 55)
- Request for additional scoping meetings and extension of comment period (Letters 90, 136; Verbal 11)
- Coordination and interaction of the PEIR process with the SFPUC's ongoing changes in the WSIP (Letter 62; Verbal 3, 63, 67)
- Standards of significance used in EIR analysis (Letter 94)

6.1.2 EIR Issue Areas

Agricultural Resources

Comments on agricultural resources primarily related to reduced Tuolumne River water available for irrigation in the Central Valley (Letters 13, 35, 62; Verbal 27) and use of water conservation in agriculture (Letter 82).

Air Quality

Comments on air quality included:

- Effects of construction emissions, particularly dust (Letters 89, 136)
- Effects of system operations, including air pollution from increased energy use (Letters 60, 89)
- Consistency with air quality regulations and regional air quality plans (Letter 89)

Biological Resources

Comments related to biological resources are divided into two main categories: fishery/aquatic resources and terrestrial vegetation/wildlife.

Comments on fishery and aquatic resources related primarily to potential changes in the extent or quality of fish habitat, changes in fish populations, and effects on special-status fish species due to proposed increases in water diversions and changes in stream flow. Comments included suggestions for habitat protection and enhancement, species recovery, survey methods, and ecological benchmarks (Letters 2, 6, 12, 13, 14, 43, 48, 49, 51, 62, 65, 72, 76, 84, 87, 94, 95, 136; Verbal 7, 28, 44, 47, 49, 72, 73).

Some of the fishery-related comments specifically involve the following water bodies:

- Alameda Creek (Letters 2, 6, 14, 62)
- Tuolumne River to its confluence with San Joaquin River (Letters 43, 62, 72, 87, 94, 95)
- San Joaquin River and Delta, and San Francisco Bay (Letters 49, 51, 94)
- Calaveras Reservoir (Letters 6, 48, 62)
- Pilarcitos Creek (Letter 95)

Comments on terrestrial vegetation and wildlife issues were associated both with impacts from construction and operation of facility improvement projects and with diversion of water from natural water bodies. Specific habitats of concern included riparian, wetland, and vernal pool. Comments included suggestions for habitat protection, restoration and enhancement, watershed management, wildlife and habitat surveys, and potential for altering SFPUC water supply operations. The comments included:

- Changes in the extent of habitat or habitat quality for terrestrial plants and wildlife within the Alameda Watershed, Peninsula Watershed (includes Pilarcitos Creek and reservoir), Tuolumne River watershed, San Francisco Bay, and the Delta (Letters 2, 6, 12, 44, 49, 65, 72, 84, 87, 94, 95, 136; Verbal 7, 16, 28, 44, 47, 65, 72, 73; Resource Agency Meeting Summary)
- Effects on special-status species (Letter 17; Verbal 43; Resource Agency Meeting Summary)
- Loss of mature trees (Letter 71)

Cultural Resources

Comments on cultural resources pertained to Native American and cultural resources buried under water at Hetch Hetchy Reservoir, and the potential to encounter cultural resources during system construction and expansion (Letter 62; Verbal 11).

Geology, Soils, and Seismicity

Comments on geologic issues included the potential for seismic hazards to the water system and/or increased exposure of people and structures to seismic hazards (Letters 47, 62).

Groundwater Resources

Comments on groundwater resource issues and conjunctive use programs included:

- Potential changes in groundwater levels, flows, quality recharge rates, and storage in Tuolumne, Stanislaus, Alameda, Santa Clara, and San Mateo Counties, and in particular the Westside Basin (Letters 52, 58, 62, 93, 94, 95, 141; Verbal 53)
- Indirect effects associated with increased use of groundwater resources, including saltwater intrusion, dewatering impacts, and groundwater infiltration into the water system (Letters 10, 20, 71, 137, 141)

Hazards & Public Safety

Comments were raised about the potential to encounter hazardous materials or waste during construction, the potential to release hazardous materials during construction, or the potential to release hazardous materials in the event of a system failure (Letters 38, 71).

Land Use, Plans, and Policies

Comments on land use issues included:

- Potential for conflict with established local, regional, state, or federal plans, policies, and/or guidelines, including plans related to Yosemite National Park, Stanislaus National Forest, Tuolumne River, San Joaquin River, Golden Gate National Recreation Area, and San Bruno Mountain (Letters 12, 17, 19, 53, 84, 87, 93)
- Compatibility of WSIP with existing or planned land uses at or adjacent to proposed regional facility sites (Letters 14, 84, 136)

Noise and Vibration

Comments on noise or vibration issues included potential effects of construction noise and vibration on adjacent facilities and land uses (Letters 14, 28, 58, 71, 136).

Public Services, Utilities, and Energy

Comments on public services, utilities, or energy included:

- Potential for increases in energy demands, need for expansion of power facilities, effects on SFPUC hydropower generation, and associated effects on power service provided to customers (Letters 60, 68)
- Potential for disruption of services such as water, power, or fire protection during construction, and potential need for relocation of utilities (Letters 14, 39, 64, 93, 97, 137; Verbal 40)

Recreation

Comments on recreational issues included:

- Potential effects on water-based recreational activities on water bodies within and downstream of the regional system, including whitewater rafting on the Upper Tuolumne River and Cherry Creek, boating on the Lower Tuolumne River, and boating/rafting and fishing at various locations (Letters 12, 13, 32, 49, 55, 62, 65, 68, 69, 72, 77, 78, 87, 92, 94, 136; Verbal 6, 7, 28, 44, 72, 73)
- Potential effects on land-based recreation facilities and activities (such as hiking, birding, or camping) in Yosemite and East Bay parks, due to the siting, construction, or operation of proposed facilities, or due to overall program implementation (Letters 14, 17, 54, 60, 62, 77, 136; Verbal 73)

Socioeconomics

Comments on socioeconomic issues included:

- Direct and indirect impacts of WSIP rationing scenarios (Letters 69 and 91)
- Economic impacts of WSIP and increased water diversions from the Tuolumne River to Tuolumne and Stanislaus Counties (Letters 5, 13, 15, 18, 40, 41, 42, 44, 51, 54, 73, 93, 94, 96, 136; Verbal 11, 12, 33)
- Economics of conservation (Letters 49, 95)
- Economics of increased fees (Letter 38; Verbal 37)
- Economic benefits of WSIP (Letter 46)
- Potential for environmental justice issues (Letters 38, 55; Verbal 68)

Surface Water Resources and Water Quality

Comments on surface water resources and water quality included:

- Potential changes in surface water flows and resulting effects on beneficial uses due to proposed increases in diversions (Letters 5, 6, 8, 33, 41, 44, 49, 51, 55, 62, 65, 67, 68, 72, 79, 84, 87, 93, 94, 95, 133, 163; Verbal 10, 13, 16, 32, 33, 55, 66, 67, 72; Resource Agency Meeting Summary). Comments included suggestions for methods of analysis, requests to restore stream flows to affected watersheds, and recommendations for program-level mitigations to enhance stream flows and restore wildlife habitat on the lands and rivers affected by San Francisco's water system. Specific concerns were raised about the following water bodies:

(1) Alameda Creek and watershed (Letters 6, 62; Resource Agency Meeting Summary)

(2) Tuolumne River to its confluence with San Joaquin River, including water transfers affecting the Tuolumne River (Letters 49, 62, 65, 67, 72, 84, 94, 95; Resource Agency Meeting Summary)

(3) Cherry Creek (Letter 62)

(4) Pilarcitos Creek and watershed (Letters 6, 8, 95)

(5) Lake Merced (Letter 72)

(6) Stanislaus River watershed (Letter 93)

(7) San Joaquin River and Delta, and San Francisco Bay (Letters 62, 94)

- Changes in storage in Hetch Hetchy, Calaveras, and Don Pedro Reservoirs (Letter 62)
- Changes in surface water quality, specifically the parameters of temperature, dissolved oxygen, and turbidity, due to WSIP operation or construction activities and associated impacts on habitat, fish, and wildlife. Specific concerns were raised about the following water bodies:

(1) Alameda Watershed (Letters 14, 62)

(2) San Francisquito Creek (Verbal 45)

(3) San Francisco Bay (Letters 13, 60, 72; Verbal 60)

(4) Impact on Delta water quality from Tuolumne diversion (Letters 13, 67, 72, 136; Verbal 7, 28, 44, 73)

(5) Calaveras Reservoir (Letter 62)

(6) San Joaquin River (Letter 62; Verbal 34)

- Alteration of existing drainage patterns and related stormwater management and water quality concerns due to WSIP construction and operation, including changes in point and nonpoint discharges to San Francisco Bay (Letters 10, 14, 60, 71, 138)
- Exposure of people to, and/or increased risk of, flooding, seiche, or tsunami hazards, including tidal flooding (Letters 38, 71; Verbal 45)
- Exposure to flooding below Calaveras, Hetch Hetchy, and Don Pedro Reservoirs (Letter 62)
- Changes in stream/fluvial geomorphology (Letter 72; Resource Agency Meeting Summary)
- Impacts of global warming (Letters 9, 60, 93; Verbal 5, 15, 35)

Traffic, Transportation, and Circulation

Comments on transportation issues included:

- Effects on the regional transportation network or facilities (Letters 14, 71, 135, 136)
- Effects of adding new vehicle trips and contributing to increased traffic congestion during construction and/or operation of proposed facilities, potentially affecting emergency access and causing roadway wear and tear (Letters 28, 58, 71)

Visual Quality

Comments on visual quality included the potential degradation or obstruction of scenic views and designated scenic resources, including impacts on parks, open space, river corridors, and local communities along the regional system (Letters 12, 13, 14, 53, 71).

6.1.3 Other EIR Topics

Growth Inducement

Comments on growth inducement primarily consisted of the relationship between the 2030 customer purchase requests for water supply associated with the WSIP and the planned growth and land uses reflected in currently adopted local land use plans. The comments indicated concern over the dispersal of planned growth beyond San Francisco and the wholesale customers' service area. Concern was also expressed about secondary effects of growth projected within the service area, including effects on land uses, biological resources, traffic and transportation, air quality, noise, water quality, public services, and water resources. In addition, commenters recommended strategies for analyzing growth and for reducing growth-related impacts (Letters 1, 55, 60, 62, 91, 94, 136; Verbal 2, 11, 21, 23, 31, 37, 45, 68, 70).

Cumulative Effects

Comments on the overall cumulative effect of implementing the proposed WSIP were associated with the potential for combined effects of the WSIP and other projects in the vicinity of the regional water system. They also included comments on the combined effects of implementing all the improvement projects in the WSIP. Comments involved the extent of geographic coverage for the cumulative impact analysis, jurisdictions with other projects that could contribute to cumulative effects, and types of analyses to be conducted. Comments also referred to the cumulative impacts of recycling and groundwater and of water conservation, both of which should be addressed in the PEIR (Letters 4, 28, 53, 60, 62, 63, 93, 94; Verbal 12, 31, 37, 64, 71).

Alternatives

Comments on alternatives to be analyzed in the PEIR received during the scoping period included:

- No Program alternative (Letters 91, 94)
- Water Supply alternatives —
  - Desalination (Letters 1, 11, 20, 21, 32, 55, 60, 80, 81, 84, 93, 135; Verbal 20, 52, 54)
  - Increased recycled water and/or conservation on regional and local levels (Letters 1, 2, 3, 4, 5, 6, 8, 11, 12, 13, 20, 21, 23, 25, 27, 30, 31, 33, 35, 37, 38, 40, 41, 42, 43, 44, 45, 48, 50, 51, 52, 55, 57, 59, 60, 62, 65, 68, 70, 72, 75, 76, 78, 81, 82, 84, 85, 90, 91, 93, 94, 95, 96, 135, 136, 142, 143; Verbal 1, 7, 9, 14, 16, 18, 19, 20, 21, 27, 28, 29, 30, 32, 36, 41, 44, 47, 49, 52, 53, 58, 64, 65, 66, 69, 70, 71, 72, 73, 74)

- Water transfers from surface waters other than the Tuolumne River, including Delta water (Letters 1, 67, 68, 84, 136; Verbal 33)
- Stormwater (Letter 26; Verbal 22)
- Groundwater (Letters 38, 62, 68)
- Alternative with different combinations of water sources (Letter 94)

- Operational alternatives —
  - Restore Hetch Hetchy Valley and remove O'Shaughnessy Dam (Letters 5, 54, 55, 62, 68, 72; Verbal 3, 12, 26, 61, 62, 65, 68, 76, 77)
  - Keep Hetch Hetchy dam (Letter 23)
  - Filtration alternative for Hetch Hetchy water (Letters 55, 60, 62, 68, 72, 83, 93, 95,133, 137)
  - Repair leaky pipes alternative (Letters 31, 84)
  - Alternatives that allow increased releases to surface streams (i.e., alternatives that reduce diversions), including releases to the Tuolumne River (Letters 55, 73, 94, 96, 142), increases in rafting flows above existing levels (Letter 55), and releases to Pilarcitos Creek (Letter 95; Verbal 58)
- Alternative program objectives —
  - Alternative that meets only seismic and water quality objectives (Letter 94)
  - Alternative that meets sustainability objective (Letter 94)
  - Alternative that does not fully meet 2030 purchase request (Letters 62, 94, 95)
  - Alternative rationing objective/scenarios (Letters 58, 69, 91)
  - Alternative that meets program goals and objectives, but without maintaining a gravity-driven system (Letter 95)
- Alternative storage —
  - Expansion of downstream and off-stream storage (Letters 68, 95)
  - New Melones Reservoir (Letter 68)
  - Groundwater banking in Central Valley/conjunctive use (Letters 62, 68)
  - Increased storage at Calaveras Reservoir (Letters 54, 62, 91, 94)
  - Use of water stored in other Sierra reservoirs, such as Cherry, Eleanor, or Don Pedro Reservoirs (Letter 54)
- Conveyance alternatives (Letters 68, 95)
  - Intertie between the SFPUC system and the Santa Clara Valley Water District (Letter 61)
  - Pump station at Tesla Portal (Letter 62)
  - Pump station downstream from Holm Powerhouse to pump from Cherry Creek, and large intertie to Cherry Creek (Letter 62)
  - Don Pedro Reservoir to San Joaquin Pipelines (Letter 68)

  - Cherry Reservoir to Mountain Tunnel (Letter 68)
  - South Bay Aqueduct to San Antonio Reservoir (Letter 68)
  - California Aqueduct/Delta Mendota Canal to Hetch Hetchy system (Letter 68)
  - Alternative without San Joaquin Pipeline No. 4 (Letter 73, 94, 96, 142)
  - Alternative that analyzes the maximum conveyance capacity (Letter 95)
- Alternatives with additional facilities projects to meet various objectives (Letter 62)

6.2 WSIP Comments

6.2.1 SFPUC Regional System

Comments on the facilities and operations of the existing SFPUC regional water system included:

- Existing water and hydropower system operations (Letters 6, 8, 55, 62, 93, 133)
- Rafting flows, including releases, timing and volume, and seasons (Letters 55, 62, 92)
- Raker Act and Tuolumne River water rights (Letters 9, 11, 34, 35, 37, 52, 55, 62, 90, 93, 94, 133, 137); other water rights (Letter 58)
- Filtration avoidance, status and stipulations of waiver for Hetch Hetchy water system, and public health/water quality considerations of filtration avoidance (Letters 55, 60, 62, 68, 72, 83, 93, 95,133, 137; Resource Agency Meeting Summary)
- Existing drinking water and water quality regulations, including use of chloramines for disinfection and effect of chloramines on pipe materials. Specific regulations include California Safe Drinking Water Act and Disinfectants and Disinfection By-Product Rule (Letters 52, 56, 60; Verbal 46, 60)
- Operations and status of existing facilities, including San Joaquin pipeline system, Alameda Diversion Dam, releases from Calaveras Reservoir, Sunol Valley Water Treatment Plant, Sunol area water system, Mountain Tunnel, and Groveland facilities (Letters 2, 62, 93, 95, 97, 137)

6.2.2 Program Description

Assumptions

Comments requesting clarification or corrections to assumptions used in WSIP development included:

- Water demand/purchase request assumptions, including comparison with assumptions used for long-term water supply, use of Master Water Sales Contract, consideration of elasticity of demand, and clarification on conservation assumptions (Letters 55, 60, 62, 66, 139)
- Corrections to water demand assumptions (Letters 16, 57)
- Design drought compared to historical hydrology (Letters 62, 133)

Goals and Objectives

- WSIP goals and performance objectives, including clarification on the basis for the goals and objectives, and consistency with SFPUC goals in other documents (Letters 60, 62, 91, 141)
- Add program goal, level of service, and specific components to address sustainability, stewardship, and environmental enhancement (Letters 2, 6, 8, 13, 40, 41, 50, 51, 60, 62, 76, 78, 81, 94; Verbal 63, 69)
- Add program goal for redundancy (Letter 91)
- Basis for 20 percent rationing objective (Letters 57, 91, 139)

Program Elements

- Relationship of program elements, improvement projects, and operational assumptions to goals and clarification on how goals will be met (Letter 91, 94, 141)
- Requests for modeling results (Letters 91, 133)
- Ability of the WSIP to meet the goals and levels of service (Letter 91)
- More information on 10 million gallons per day (mgd) of additional conservation, water recycling, and groundwater supply programs (Letter 91)
- More information on proposed conservation as part of WSIP (Letters 55, 62, 91)
- More information on proposed drought response program, and how proposed drought rationing would be shared among SFPUC customers; more information on how rationing scenario relates to transmission capacity (Letter 91)
- Relationship between water delivery and hydropower generation with proposed program operations (Letter 91)
- Confirm with Modesto and Turlock Irrigation Districts regarding water transfers from those systems as a project element (Letter 133)

Facilities Improvement Projects

Comments on specific facility improvement projects in the WSIP included:

- San Joaquin Pipeline No. 4 (Letters 11, 12, 13, 15, 21, 41, 43, 44, 60, 67, 72, 78, 76, 84,90, 96; Verbal 33)
- Calaveras Dam Replacement (Letters 6, 8,14, 62, 95)
- Alameda Creek Fisheries Enhancement (Letters 2, 6, 95)
- Additional 40 mgd Treated Water Supply (Letter 6)
- Irvington Tunnel/Alameda Siphon (Letter 62)
- Hetch Hetchy Advanced Disinfection (Letters 56, 62)
- Bay Division Pipeline (Letters 62, 71; Verbal 42)
- Slipline Bay Division Pipeline No. 4 (Letters 71, 141)
- East Bay Municipal Utility District-SFPUC Hayward Intertie (Letter 62)
- Bay Division Pipeline Nos. 3 and 4 crossovers (Letter 62)
- Recycled water projects (Letters 58, 62)
- Tesla Portal Disinfection (Letter 56)

- Sunol Valley and Harry Tracy Water Treatment Plant projects (Letter 56, 58)
- Cross connection controls (Letter 56)
- Groundwater project (Letter 58)
- Capuchino Valve Lot (Letter 58)

Agency Coordination/Permits and Approvals

Comments included requests for continued coordination and consultation with agencies and other jurisdictions involved (Letters 14, 17, 39, 53, 58, 61, 63, 64, 66, 67, 69, 71, 89, 91, 93, 133, 137, 138, 139, 141; Resource Agency Meeting Summary). In addition, the Turlock Irrigation District indicated that the Modesto and Turlock Irrigation Districts should be consulted to confirm proposed water transfers as a project element (Letter 133).

Comments on regulatory compliance and permitting issues were received from governmental agencies as well as members of the public. Comments cited rules and regulations to which the WSIP (or some aspect of it) may be subject (Letters 6, 9, 10, 19, 37, 53, 56, 60, 62, 89, 91, 93, 95, 133, 135; Resource Agency Meeting Summary). Regulations, rules, and agreements cited (other than those related to CEQA and NEPA) included:

- Agreement between SFPUC and Golden Gate National Recreation Area
- Pre-1914 appropriative water right/Raker Act
- National Pollutant Discharge Elimination System permit process
- Clean Water Act, Sections 303 (d), 401,404
- Public Resources Code, Section 6327
- Wholesale Regional Water System Security and Reliability Act (AB 1823)
- California Safe Drinking Water Act
- Porter-Cologne Water Quality Control Act, including the Basin Plan
- Encroachment permit from Caltrans
- San Joaquin Valley Air District Air Quality Rules and Regulations
- Agreement between San Francisco and Modesto and Turlock Irrigation Districts regarding the Don Pedro Project and Federal Energy Regulatory Commission (FERC)-order fish flows
- State Water Code Section 73503(b)
- Stage 2 Disinfectant and Disinfection By-Product Rule
- Tuolumne County Ordinance Code 13.20 pertaining to groundwater
- Special Drainage Area 7-1 Drainage Fees
- California Fish and Game Code 5937
- AB 2717 pertaining to statewide Landscape Task Force
- San Joaquin River Agreement, including the Vernalis Adaptive Management Plan
- Wild and Scenic Rivers Act

Schedule

Comments on the WSIP schedule related primarily to scheduling priorities (Letters 1, 15, 38, 56, 64, 68).

Appendix B
WSIP Initial Study Checklist

APPENDIX B

SFPUC Water System Improvement Program Initial Study Checklist – File No. 2005.0159E

A. Project Description

See Chapter 3 of this PEIR for Background and Description of the proposed Water System Improvement Program (WSIP or proposed program).

B. Project Setting

See Chapters 2 and 3 for description of the existing regional water system and regional location of proposed program.

C. Compatibility with Existing Zoning and Plans

	Applicable	*Not Applicable*
Discuss any variances, special authorizations, or changes proposed to the Planning Code or Zoning Map, if applicable.	☐	☒
Discuss any conflicts with any adopted plans and goals of the City or Region, if applicable.	☒	☐
Discuss any approvals and/or permits from City departments other than the Planning Department or the Department of Building Inspection, or from Regional, State, or Federal Agencies.	☒	☐

The program does not propose any variances, special authorizations or changes to the Planning Code or Zoning Map. See Chapter 4, Section 4.2, Plans and Policies, for discussion of plans and policies applicable to WSIP facility improvement projects. See Chapter 5, Section 5.2, Plans and Policies, for discussion of plans and policies applicable to WSIP water supply and system operations. See Chapter 3, Section 3.12, Required Actions and Approvals, for discussion of approvals applicable to the proposed program.

D. Summary of Environmental Effects

The proposed project could potentially affect the environmental factor(s) checked below. The following pages present a more detailed checklist and discussion of each environmental factor.

- ☒ Land Use
- ☒ Aesthetics
- ☒ Population and Housing
- ☒ Cultural Resources
- ☒ Transportation and Circulation
- ☒ Noise
- ☒ Air Quality
- ☐ Wind and Shadow
- ☒ Recreation
- ☒ Utilities and Service Systems
- ☒ Public Services
- ☒ Biological Resources
- ☒ Geology and Soils
- ☒ Hydrology and Water Quality
- ☒ Hazards/Hazardous Materials
- ☒ Mineral/Energy Resources
- ☒ Agricultural Resources
- ☒ Mandatory Findings of Signif.

E. Evaluation of Environmental Effects

Topics:		*Potentially Significant Impact*	*Less Than Significant with Mitigation Incorporated*	*Less Than Significant Impact*	*No Impact*	*Not Applicable*
1.	**LAND USE AND LAND USE PLANNING—Would the project:**					
a)	Physically divide an established community?	☐	☐	☐	☐	☒
b)	Conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to the general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect?	☒	☐	☐	☐	☐
c)	Have any substantial impact on the existing character of the vicinity?	☒	☐	☐	☐	☐

Additional Land Use Significance Criterion Evaluated in the PEIR

- Substantially disrupt or displace existing land uses or land use activities

See Chapter 4, Section 4.2, and Chapter 5, Section 5.2, for discussion of plans and policies, for WSIP facilities and water supply/system operations, respectively. See Chapter 4, Section 4.3, Land Use and Visual, for discussion of impact upon the existing character of the vicinity associated with WSIP facility improvement projects. This issue (criterion c) is not discussed in Chapter 5 because the proposed water supply option and system operations would not affect the existing character of the vicinity. The program would not physically divide established communities; therefore, criterion (a) is not discussed.

Topics:	*Potentially Significant Impact*	*Less Than Significant with Mitigation Incorporated*	*Less Than Significant Impact*	*No Impact*	*Not Applicable*
2. AESTHETICS—Would the project:					
a) Have a substantial adverse effect on a scenic vista?	☒	☐	☐	☐	☐
b) Substantially damage scenic resources, including, but not limited to, trees, rock outcroppings, and other features of the built or natural environment that contribute to a scenic public setting?	☒	☐	☐	☐	☐
c) Substantially degrade the existing visual character or quality of the site and its surroundings?	☐	☐	☒	☐	☐
d) Create a new source of substantial light or glare that would adversely affect day or nighttime views in the area or substantially impact other people or properties?	☐	☒	☐	☐	☐

See Chapter 4, Sections 4.3 and 4.16, Land Use and Visual, for discussion of visual quality effects of the WSIP facility improvement projects. See Chapter 5, Sections 5.3.8, 5.4.7 and 5.5.7, for discussion of visual quality effects of the proposed water supply option and system operations. However, criterion (d) is not discussed in Chapter 5 because the proposed water supply option and system operations would not create a new source of substantial light or glare that would adversely affect views in the area or substantially impact other people or properties.

Topics:	*Potentially Significant Impact*	*Less Than Significant with Mitigation Incorporated*	*Less Than Significant Impact*	*No Impact*	*Not Applicable*
3. POPULATION AND HOUSING—Would the project:					
a) Induce substantial population growth in an area, either directly (for example, by proposing new homes and businesses) or indirectly (for example, through extension of roads or other infrastructure)?	☒	☐	☐	☐	☐
b) Displace substantial numbers of existing housing units or create demand for additional housing, necessitating the construction of replacement housing?	☐	☐	☐	☐	☒
c) Displace substantial numbers of people, necessitating the construction of replacement housing elsewhere?	☐	☐	☐	☐	☒

See Chapter 7, Growth Inducement Potential, for discussion of program effects on population growth, including direct and indirect effects. The program would not displace existing housing units, create demand for additional housing or displace people; therefore, criteria (b) and (c) are not discussed.

Topics:		*Potentially Significant Impact*	*Less Than Significant with Mitigation Incorporated*	*Less Than Significant Impact*	*No Impact*	*Not Applicable*
4.	**CULTURAL RESOURCES— Would the project:**					
a)	Cause a substantial adverse change in the significance of a historical resource as defined in CEQA Guidelines Section 15064.5, including those resources listed in Article 10 or Article 11 of the San Francisco Planning Code?	☒	☐	☐	☐	☐
b)	Cause a substantial adverse change in the significance of a unique archaeological resource pursuant to Section 15064.5?	☐	☒	☐	☐	☐
c)	Directly or indirectly destroy a unique paleontological resource or site or unique geological feature?	☐	☒	☐	☐	☐
d)	Disturb any human remains, including those interred outside of formal cemeteries?	☐	☒	☐	☐	☐

See Chapter 4, Sections 4.7 and 4.16, Cultural Resources, for discussion of cultural resources effects of the WSIP, including effects of the proposed water supply option and system operations. Therefore, this resource area is not discussed in Chapter 5.

Topics:		*Potentially Significant Impact*	*Less Than Significant with Mitigation Incorporated*	*Less Than Significant Impact*	*No Impact*	*Not Applicable*
5.	**TRANSPORTATION AND CIRCULATION— Would the project:**					
a)	Cause an increase in traffic that is substantial in relation to the existing traffic load and capacity of the street system (i.e., result in a substantial increase in either the number of vehicle trips, the volume-to-capacity ratio on roads, or congestion at intersections)?	☐	☒	☐	☐	☐
b)	Exceed, either individually or cumulatively, a level of service standard established by the county congestion management agency for designated roads or highways (unless it is practical to achieve the standard through increased use of alternative transportation modes)?	☐	☐	☐	☐	☒

Topics:		*Potentially Significant Impact*	*Less Than Significant with Mitigation Incorporated*	*Less Than Significant Impact*	*No Impact*	*Not Applicable*
c)	Result in a change in air traffic patterns, including either an increase in traffic levels, an obstruction to flight, or a change in location, that results in substantial safety risks?	☐	☐	☐	☐	☒
d)	Substantially increase hazards due to a design feature (e.g., sharp curves or dangerous intersections) or incompatible uses, or interfere with existing transportation systems (including vehicular, pedestrian, and bicycle networks), causing substantial alterations to circulation patterns or major traffic hazards.	☐	☒	☐	☐	☐
e)	Result in inadequate emergency access?	☐	☒	☐	☐	☐
f)	Result in inadequate parking capacity that could not be accommodated by alternative solutions?	☐	☒	☐	☐	☐
g)	Conflict with adopted policies, plans, or programs supporting alternative transportation (e.g., conflict with policies promoting bus turnouts, bicycle racks, etc.), or cause a substantial increase in transit demand that cannot be accommodated by existing or proposed transit capacity or alternative travel modes?	☒	☐	☐	☐	☐

See Chapter 4, Sections 4.8 and 4.16, Traffic, Transportation, and Circulation, for discussion of traffic effects of WSIP facility improvement projects. The level of service standards established by county congestion management agencies and documented in congestion management plans are intended to regulate long-term traffic impacts due to future development, and do not apply to temporary construction projects; no further consideration of this criterion (b) is required. The program would not have the potential to change air traffic patterns at any airport in the area; therefore, criterion (c) is not discussed.

This resource area is not discussed in Chapter 5 because the proposed water supply option and system operations would not affect traffic, transportation or circulation.

Topics:		*Potentially Significant Impact*	*Less Than Significant with Mitigation Incorporated*	*Less Than Significant Impact*	*No Impact*	*Not Applicable*
6.	**NOISE—Would the project:**					
a)	Expose people to or generate noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies?	☒	☐	☐	☐	☐
b)	Expose people to or generate excessive groundborne vibration or groundborne noise levels?	☒	☐	☐	☐	☐

Topics:	Potentially Significant Impact	Less Than Significant with Mitigation Incorporated	Less Than Significant Impact	No Impact	Not Applicable
c) Create a substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project?	☐	☐	☒	☐	☐
d) Create a substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project?	☒	☐	☐	☐	☐
e) For a project located within an area covered by an airport land use plan (or, where such a plan has not been adopted, within two miles of a public airport or public use airport), expose people residing or working in the project area to excessive noise levels?	☐	☐	☐	☐	☒
f) For a project within the vicinity of a private airstrip, expose people residing or working in the project area to excessive noise levels?	☐	☐	☐	☐	☒
g) Be substantially affected by existing noise levels?	☐	☐	☐	☐	☒

See Chapter 4, Sections 4.10 and 4.16, Noise and Vibration, for discussion of noise and vibration effects of WSIP facility improvement projects. The WSIP facilities are not located within an airport land use plan area, nor in the vicinity of a private airstrip, therefore criterion (e) and (f) are not discussed. The WSIP facilities are not a noise-sensitive use; therefore, criterion (g) is not discussed.

This resource area is not discussed in Chapter 5 because the proposed water supply option and system operations would not affect noise and vibration.

Topics:	Potentially Significant Impact	Less Than Significant with Mitigation Incorporated	Less Than Significant Impact	No Impact	Not Applicable
7. AIR QUALITY Where available, the significance criteria established by the applicable air quality management or air pollution control district may be relied upon to make the following determinations. **Would the project:**					
a) Conflict with or obstruct implementation of the applicable air quality plan?	☐	☐	☒	☐	☐
b) Violate any air quality standard or contribute substantially to an existing or projected air quality violation?	☐	☒	☐	☐	☐
c) Result in a cumulatively considerable net increase of any criteria pollutant for which the project region is in nonattainment under an applicable federal or state ambient air quality standard (including releasing emissions that exceed quantitative thresholds for ozone precursors)?	☒	☐	☐	☐	☐

Topics:		*Potentially Significant Impact*	*Less Than Significant with Mitigation Incorporated*	*Less Than Significant Impact*	*No Impact*	*Not Applicable*
d)	Expose sensitive receptors to substantial pollutant concentrations?	☐	☒	☐	☐	☐
e)	Create objectionable odors affecting a substantial number of people?	☐	☐	☒	☐	☐

Additional Air Quality Significance Criteria Evaluated in the PEIR

- Conflict with the state goal of reducing Greenhouse Gas emissions in California to 1990 levels by 2020, as set forth by the timetable established in AB 32, California Global Warming Solutions Act of 2006

See Chapter 4, Sections 4.9 and 4.16, Air Quality, for discussion of air quality effects of WSIP facility improvement projects. This resource area is not discussed in Chapter 5 because the proposed water supply option and system operations would not affect air quality.

Topics:		*Potentially Significant Impact*	*Less Than Significant with Mitigation Incorporated*	*Less Than Significant Impact*	*No Impact*	*Not Applicable*
8.	**WIND AND SHADOW—Would the project:**					
a)	Alter wind in a manner that substantially affects public areas?	☐	☐	☐	☐	☒
b)	Create new shadow in a manner that substantially affects outdoor recreation facilities or other public areas?	☐	☐	☐	☐	☒

The program would have no effect on wind patterns since proposed facilities would either be located below ground; be located in, adjacent to or replace existing structures; or have a maximum height of 40 feet but not in a location that affects public areas. In addition, the program would not create new shadows in a manner that would affect recreational facilities (discussed separately under Recreation) or other public areas due to the maximum height and location of proposed structures. This resource area is not discussed in either Chapter 4 or 5.

Topics:	*Potentially Significant Impact*	*Less Than Significant with Mitigation Incorporated*	*Less Than Significant Impact*	*No Impact*	*Not Applicable*
9. RECREATION—Would the project:					
a) Increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facilities would occur or be accelerated?	☐	☐	☐	☐	☒
b) Include recreational facilities or require the construction or expansion of recreational facilities that might have an adverse physical effect on the environment?	☐	☐	☐	☐	☒
c) Physically degrade existing recreational resources?	☐	☒	☐	☐	☐

Additional Recreation Significance Criteria Evaluated in the PEIR

- Remove or damage existing recreational resources directly
- Cause environmental impacts (such as air quality or noise effects) that would indirectly result in deterioration in the quality of the recreational experience
- Disrupt access to existing recreation facilities (which would divide a community from some of the established amenities used by its members)

See Chapter 4, Sections 4.12 and 4.16, Recreational Resources, for discussion of effects of WSIP facility improvement projects on recreational resources, and see Chapter 5, Sections 5.3.8, 5.4.7, and 5.5.7 for discussion of effects of the proposed water supply option and system operations on recreational resources. The program would not increase the use of existing neighborhood and regional parks or require the construction/expansion of recreational facilities; therefore, criteria (a) and (b) are not discussed.

Topics:	*Potentially Significant Impact*	*Less Than Significant with Mitigation Incorporated*	*Less Than Significant Impact*	*No Impact*	*Not Applicable*
10. UTILITIES AND SERVICE SYSTEMS—Would the project:					
a) Exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board?	☐	☐	☐	☐	☒
b) Require or result in the construction of new water or wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects?	☐	☒	☐	☐	☐

Topics:	Potentially Significant Impact	Less Than Significant with Mitigation Incorporated	Less Than Significant Impact	No Impact	Not Applicable
c) Require or result in the construction of new storm water drainage facilities or expansion of existing facilities, the construction of which could cause significant environmental effects?	☐	☐	☐	☐	☒
d) Not have sufficient water supply available to serve the project from existing entitlements and resources, or require new or expanded water supply resources or entitlements?	☐	☒	☐	☐	☐
e) Result in a determination by the wastewater treatment provider that would serve the project that it has inadequate capacity to serve the project's projected demand in addition to the provider's existing commitments?	☐	☐	☐	☐	☒
f) Be served by a landfill with insufficient permitted capacity to accommodate the project's solid waste disposal needs?	☐	☒	☐	☐	☐
g) Be out of compliance with federal, state, and local statutes and regulations related to solid waste?	☐	☒	☐	☐	☐

Additional Utilities and Service Systems Significance Criterion Evaluated in the PEIR

- Disrupt operation of or require relocation of regional or local utilities

See Chapter 4, Sections 4.11 and 4.16, Public Services and Utilities, for discussion of effects of WSIP facility improvement projects on services and utilities. This resource area is not discussed in Chapter 5 because the proposed water supply option and system operations would not affect public services and utilities.

The program would result in improvements and possibly expansion of existing water facilities (part of criterion b) as part of the increased system reliability objectives of the WSIP; these impacts are discussed in Chapters 4, 5 and 7 of the PEIR. The existing entitlements are discussed in Chapter 2, Section 2.5.1, Existing Water Rights and Entitlements, and new or expanded water supply resources are described in Chapter 3 as part of the proposed water supply option (criterion d). The effects of the proposed water supply option are discussed in Chapters 5 and 7.

The program would have no effect on wastewater treatment requirements (criterion a) The program would not require construction or expansion of wastewater facilities (other part of criterion b), and any increase in wastewater demand associated with implementation of WSIP is addressed under secondary impacts of growth in Chapter 7 (criterion e). The program would not require construction or expansion of existing storm drainage facilities (criterion c). Therefore, these criteria are not further discussed.

Topics:	*Potentially Significant Impact*	*Less Than Significant with Mitigation Incorporation*	*Less Than Significant Impact*	*No Impact*	*Not Applicable*
11. PUBLIC SERVICES— Would the project:					
a) Result in substantial adverse physical impacts associated with the provision of, or the need for, new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times, or other performance objectives for any public services such as fire protection, police protection, schools, parks, or other services?	☐	☐	☐	☐	☒

The program would not directly affect the need for public services or governmental facilities, including fire protection, police protection, schools, parks or other services. Chapter 7, Section 7.4, addresses potential changing needs for these services and facilities as a result of the indirect or secondary effects of growth. The direct effects of WSIP facility project construction and/or operation on neighboring schools are discussed in Chapter 4, Section 4.3, under Land Use; and effects on parks are discussed in Chapter 4, Section 4.12, Recreational Resources. Otherwise, this resource area is not discussed further in Chapters 4 or 5.

Topics:	*Potentially Significant Impact*	*Less Than Significant with Mitigation Incorporation*	*Less Than Significant Impact*	*No Impact*	*Not Applicable*
12. BIOLOGICAL RESOURCES— Would the project:					
a) Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Game or U.S. Fish and Wildlife Service?	☐	☒	☐	☐	☐
b) Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations or by the California Department of Fish and Game or U.S. Fish and Wildlife Service?	☐	☒	☐	☐	☐
c) Have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means?	☐	☒	☐	☐	☐

Topics:	Potentially Significant Impact	Less Than Significant with Mitigation Incorporation	Less Than Significant Impact	No Impact	Not Applicable
d) Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites?	☐	☒	☐	☐	☐
e) Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance?	☐	☒	☐	☐	☐
f) Conflict with the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, or state habitat conservation plan?	☐	☒	☐	☐	☐

Additional Biological Resources Significance Criterion Evaluated in the PEIR

- Have a substantial adverse effect, either directly or through habitat modification, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations, or by the CDFG, NMFS, or USFWS.
- Conflict with the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, or state habitat conservation plan, including the *Tuolumne Wild and Scenic River Management Plan.*

See Chapter 4, Sections 4.6 and 4.16, Biological Resources, for discussion of effects of WSIP facility improvement projects on biological resources, and see Chapter 5, Sections 5.3.6, 5.3.7, 5.4.5, 5.4.6, 5.5.5, and 5.5.6 for discussion of effects of the proposed water supply option and system operations on fisheries and other biological resources.

Topics:	Potentially Significant Impact	Less Than Significant with Mitigation Incorporated	Less Than Significant Impact	No Impact	Not Applicable
13. GEOLOGY AND SOILS— Would the project:					
a) Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:					
i) Rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault? (Refer to Division of Mines and Geology Special Publication 42.)	☐	☐	☒	☐	☐
ii) Strong seismic ground shaking?	☐	☐	☒	☐	☐

Topics:	Potentially Significant Impact	Less Than Significant with Mitigation Incorporated	Less Than Significant Impact	No Impact	Not Applicable
iii) Seismic-related ground failure, including liquefaction?	☐	☐	☒	☐	☐
iv) Landslides?	☐	☐	☒	☐	☐
b) Result in substantial soil erosion or the loss of topsoil?	☐	☐	☒	☐	☐
c) Be located on a geologic or soil unit that is unstable, or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction, or collapse?	☐	☒	☐	☐	☐
d) Be located on expansive or corrosive soil, creating substantial risks to life or property?	☐	☒	☐	☐	☐
e) Have soils incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems where sewers are not available for the disposal of wastewater?	☐	☐	☐	☐	☒
f) Substantially change the topography or any unique geologic or physical features of the site?	☐	☐	☒	☐	☐

Additional Geology and Soils Significance Criteria Evaluated in the PEIR

- Substantially change the topography such that ecological, hydrologic, or aesthetic functions are adversely affected, or substantially change any unique geologic or physical features of the site or area
- Potentially result in onsite or offsite land subsidence that would cause substantial structural damage, increased flooding, or altered drainage patterns

See Chapter 4, Sections 4.4 and 4.16, Geology, Soils and Seismicity, for discussion of geologic/seismic effects of WSIP facility improvement projects. This resource area is generally not discussed in Chapter 5 because the proposed water supply option and system operations would not affect soils and seismicity; however, geomorphology effects on stream channels are discussed in Chapter 5, Sections 5.3.2, 5.4.2, and 5.5.2. None of the WSIP projects are expected to construct septic tanks or alternative wastewater disposal facilities; therefore, criterion (e) is not discussed.

Topics:	*Potentially Significant Impact*	*Less Than Significant with Mitigation Incorporation*	*Less Than Significant Impact*	*No Impact*	*Not Applicable*
14. HYDROLOGY AND WATER QUALITY—Would the project:					
a) Violate any water quality standards or waste discharge requirements?	☐	☒	☐	☐	☐
b) Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of pre-existing nearby wells would drop to a level that would not support existing land uses or planned uses for which permits have been granted)?	☐	☒	☐	☐	☐
c) Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation on or off the site?	☐	☐	☒	☐	☐
d) Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on or off the site?	☐	☐	☒	☐	☐
e) Create or contribute runoff water which would exceed the capacity of existing or planned stormwater drainage systems or provide substantial additional sources of polluted runoff?	☐	☒	☐	☐	☐
f) Otherwise substantially degrade water quality?	☐	☒	☐	☐	☐
g) Place housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other authoritative flood hazard delineation map?	☐	☐	☐	☐	☒
h) Place within a 100-year flood hazard area structures that would impede or redirect flood flows?	☐	☒	☐	☐	☐
i) Expose people or structures to a significant risk of loss, injury or death involving flooding, including flooding as a result of the failure of a levee or dam?	☐	☐	☐	☐	☒
j) Expose people or structures to a significant risk of loss, injury or death involving inundation by seiche, tsunami, or mudflow?	☐	☐	☐	☐	☒

Additional Hydrology and Water Quality Significance Criteria Evaluated in the PEIR

- Result in substantial adverse changes in operations or substantial decreases in water deliveries for water users, as measured by significant changes in reservoir storage, timing or rate of river flows, or water quality

- Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of the stream or river, in a manner that would result in substantial erosion or siltation or adversely affect the ecological, hydrologic or aesthetic functions of the site or area
- Substantially alter stream flows such that they are outside the range of pre-project (pre-WSIP) conditions and result in adverse hydrologic effects
- Substantially alter stream flows such that they are outside the range of pre-project (pre-WSIP) conditions and result in substantial hydrologic changes
- Substantially impair a water body's ability to support its designated beneficial uses, as specified by the State Water Resources Control Board
- Substantially impair a water body's ability to support beneficial uses designated by the State Water Resources Control Board or Regional Water Quality Control Board
- Violate any water quality standards or otherwise substantially degrade water quality

See Chapter 4, Section 4.5, Hydrology and Water Quality, for discussion of hydrology and water quality effects of WSIP facility improvement projects. See Chapter 5, Sections 5.3 (Tuolumne River System and Downstream Water Bodies), Section 5.4 (Alameda Creek System and Related Resources), Section 5.5 (Peninsula Watershed Resources), and Section 5.6 (Westside Basin Groundwater Resources) for discussion of effects of the proposed water supply option and system operations on hydrology and water quality. The program would not involve the construction of housing; therefore, criterion (g) is not discussed. The program would not expose people to a significant flood risk or inundation by seiche, tsunami, or mudflow; therefore, criterion (i) and (j) are not discussed.

Topics:		*Potentially Significant Impact*	*Less Than Significant with Mitigation Incorporated*	*Less Than Significant Impact*	*No Impact*	*Not Applicable*
15.	**HAZARDS AND HAZARDOUS MATERIALS Would the project:**					
a)	Create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials?	☐	☐	☒	☐	☐
b)	Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment?	☐	☒	☐	☐	☐
c)	Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within 1/4 mile of an existing or proposed school?	☐	☐	☒	☐	☐

Topics:		*Potentially Significant Impact*	*Less Than Significant with Mitigation Incorporated*	*Less Than Significant Impact*	*No Impact*	*Not Applicable*
d)	Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would create a significant hazard to the public or the environment?	☐	☒	☐	☐	☐
e)	For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, result in a safety hazard for people residing or working in the project area?	☐	☐	☐	☐	☒
f)	For a project within the vicinity of a private airstrip, result in a safety hazard for people residing or working in the project area?	☐	☐	☐	☐	☒
g)	Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan?	☐	☒	☐	☐	☐
h)	Expose people or structures to a significant risk of loss, injury or death involving fires?	☐	☐	☒	☐	☐

See Chapter 4, Sections 4.14 and 4.16, Hazards, for discussion of hazards effects of WSIP facility improvement projects. This resource area is not discussed in Chapter 5 because the proposed water supply option and system operations would not involve use or exposure to hazards. The program would not be located within an airport land use plan or within the vicinity of a private airstrip; therefore, criteria (e) and (f) are not discussed. Section 4.8, Traffic, Transportation, and Circulation discusses access for emergency response vehicles with respect to emergency response plans or emergency evacuation plans (criterion g).

Topics:		*Potentially Significant Impact*	*Less Than Significant with Mitigation Incorporated*	*Less Than Significant Impact*	*No Impact*	*Not Applicable*
16.	**MINERAL AND ENERGY RESOURCES—Would the project:**					
a)	Result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state?	☐	☐	☐	☐	☒
b)	Result in the loss of availability of a locally-important mineral resource recovery site delineated on a local general plan, specific plan or other land use plan?	☐	☐	☐	☐	☒
c)	Encourage activities that result in the use of large amounts of fuel, water, or energy, or use these in a wasteful manner?	☐	☒	☐	☐	☐

Additional Mineral and Energy Significance Criteria Evaluated in the PEIR

- Reduce the production of renewable energy

See Chapter 4, Sections 4.15 and 4.16, Energy Resources, and Chapter 5, Section 5.3.9, for discussion of energy effects of the WSIP. Mineral resources in the WSIP area consist primarily of fuel resources and industrial minerals (e.g., aggregate, sand and gravel, and clay). Although access to these resources could be lost due to the conversion of lands underlain by these resources to other uses, conversion of land within close proximity to the resources, or due to changes in land ownership (e.g., non-renewal of a lease where active mining is occurring), none of the WSIP projects would result in a loss of mineral resources or make them inaccessible. Furthermore, construction of pipelines and other public engineering projects is excluded from Surface Mining and Reclamation Act regulation. Therefore, impacts related to the loss of mineral resources would be not applicable to WSIP projects and are not discussed further in Chapters 4 or 5.

Topics:	*Potentially Significant Impact*	*Less Than Significant with Mitigation Incorporated*	*Less Than Significant Impact*	*No Impact*	*Not Applicable*
17. AGRICULTURE RESOURCES In determining whether impacts to agricultural resources are significant environmental effects, lead agencies may refer to the California Agricultural Land Evaluation and Site Assessment Model (1997) prepared by the California Department of Conservation as an optional model to use in assessing impacts on agriculture and farmland. **Would the project:**					
a) Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance, as shown on the maps prepared pursuant to the Farmland Mapping and Monitoring Program of the California Department of Conservation, to non-agricultural use?	☐	☒	☐	☐	☐
b) Conflict with existing zoning for agricultural use, or a Williamson Act contract?	☐	☒	☐	☐	☐
c) Involve other changes in the existing environment which, due to their location or nature, could result in conversion of Farmland of Statewide Importance, to non-agricultural use?	☐	☒	☐	☐	☐

See Chapter 4, Sections 4.13 and 4.16, Agricultural Resources, for discussion of the effects of the WSIP facility improvement projects on agricultural resources. This resource area is not discussed in Chapter 5 because the proposed water supply option and system operations would not directly affect agricultural resources, although the program effects on water supplies for agricultural use are discussed in Chapter 5.

Topics:	*Potentially Significant Impact*	*Less Than Significant with Mitigation Incorporation*	*Less Than Significant Impact*	*No Impact*	*Not Applicable*
18. MANDATORY FINDINGS OF SIGNIFICANCE—Would the project:					
a) Have the potential to degrade the quality of the environment, substantially reduce the habitat of a fish or wildlife species, cause a fish or wildlife population to drop below self-sustaining levels, threaten to eliminate a plant or animal community, or substantially reduce the number or restrict the range of an endangered, rare or threatened species.	☒	☐	☐	☐	☐
b) Have impacts that would be individually limited, but cumulatively considerable? (“Cumulatively considerable” means that the incremental effects of a project are significant when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects.)	☒	☐	☐	☐	☐
c) Have environmental effects that would cause substantial adverse effects on human beings, either directly or indirectly?	☒	☐	☐	☐	☐

See Chapters 4, 5, 6, and 7 for complete discussion of effects of WSIP on the physical environment.

F. Mitigation Measures and Improvement Measures

See Chapter 6 for description of mitigation measures. No improvement measures are recommended for the WSIP.

Appendix C
WSIP Facility Improvement Project Information

APPENDIX C
WSIP Facility Improvement Project Information

TABLE C.1
SFPUC WSIP PROJECT INFORMATION – DESCRIPTION OF PROJECT FACILITIES[1]

Project Number	Project Name	Description	PHYSICAL STRUCTURES											PHYSICAL REQUIREMENTS			
			Pipeline (miles)	Tunnel (miles)	Storage/ Basin (square feet)	Treatment (square feet)	Vaults/ Valve Houses	Pump Station	Other Facilities	Number of Structures	Maximum Height (feet)	Maximum Depth (feet)	Additional Sites for Borrow or Disposal?	Existing Land Use	Land Acquisition Required?	Temporary Staging Areas	Power Available?
SJ-1	Advanced Disinfection	This project would provide for the planning, design and construction of a new advanced disinfection facility for the Hetch Hetchy water supply to comply with the new federal drinking water regulatory requirements contained in the Long Term-2 Enhanced Surface Water Treatment Rule. This regulation is designed to provide treatment for the parasite *Cryptosporidium*. The project is in the planning phase and the SFPUC is evaluating applicable technologies and possible locations to identify the most technologically sound and cost-effective alternative. In addition, the project includes planning and conceptual engineering for providing advanced disinfection facilities at the Sunol Valley and Harry Tracy WTPs. This project may be combined with the Tesla Portal Disinfection project (SJ-5) along with portal modifications and the need for project SJ-2 may be affected by the location and technology selected for this project.	0.2	0	0	20,000	4	0	None	1	35'	20'	No	At Tesla Portal, a caretaker's residence, two valve houses, & chlorination facility	No, except land possibly needed for associated power requirements	On-site	Yes, but potentially need additional power from Hetch Hetchy
SJ-2	Lawrence Livermore Supply Improvements	This project includes design and construction of treatment upgrades for the water supplied to the Lawrence Livermore Laboratory. The project would construct water treatment facilities from the Thomas Shaft of the Coast Range Tunnel. An advanced disinfection facility planned at an upstream location (SJ-1) could affect project design.	0	0	0	TBD	TBD	TBD	TBD	TBD	TBD	TBD	TBD	Undeveloped	No	TBD	Yes
SJ-3	San Joaquin Pipeline System	The preferred project would generally be located within the existing San Joaquin Pipeline (SJPL) right-of-way and would include: • Construction of a new 6.4 mile long, 86" diameter fourth SJPL parallel to the existing three pipelines at the east end of the pipelines, starting at Oakdale Portal, and associated portal modifications; • Construction of two additional crossover facilities between the San Joaquin Pipelines within the existing right-of-way, both located in Stanislaus County with one about 20 miles east of Modesto and the other about 15 miles west of Modesto and improvements at the existing Roselle Crossover; • Construction of a new 10-mile long, 86-inch diameter fourth SJPL parallel to the existing three pipelines at the west end of the pipelines ending at Tesla Portal. This project would provide additional facilities to upgrade the hydraulic capacity of the SJPL system to 314 mgd (and a 271 mgd average during system maintenance when a pipeline segment must be taken out of service) and provide redundancy for pre-stressed concrete cylinder pipe for reliability. Note: While the current preferred alternative would construct 16 miles of pipeline facilities, depending on the results of the conditions assessment of the existing pipelines, as much as 22 miles of pipeline facilities could be constructed.	16.4	TBD where required for pipeline under-pass of roads, other utilities or environ-mentally sensitive areas	0	0	2	0	New valve houses and improvements at Oakdale Portal and Tesla Portal; two new crossover facilities.	NA	12' deep for 90" pipe assumes max 4' cover (may need to be revised)	Trench: 11' wide, 12' deep (assumes maximum 4' cover over 86" pipe	Clean spoils may be stockpiled on ROW (so as not to block irrigation) and adjacent property owners may be allowed to move spoils to adjacent agricultural land if they so desire and it is agreeable to City.	Agriculture and golf course uses within SFPUC ROW; residential uses adjacent to SFPUC ROW.	No, except land possibly needed for associated power requirements and temporary construction easements.	Additional ROW might be needed temporarily for staging.	TBD (depends on location of 2 proposed crossover facilities)

TABLE C.1 (Continued)
SFPUC WSIP PROJECT INFORMATION – DESCRIPTION OF PROJECT FACILITIES[1]

Project Number	Project Name	Description	PHYSICAL STRUCTURES											PHYSICAL REQUIREMENTS			
			Pipeline (miles)	Tunnel (miles)	Storage/ Basin (square feet)	Treatment (square feet)	Vaults/ Valve Houses	Pump Station	Other Facilities	Number of Structures	Maximum Height (feet)	Maximum Depth (feet)	Additional Sites for Borrow or Disposal)	Existing Land Use	Land Acquisition Required?	Temporary Staging Areas	Power Available?
SJ-4	Rehabilitation of Existing San Joaquin Pipelines	Reconditioning/rehabilitation of the existing SJPL pipelines. There are three existing pipelines, each 47.7 miles long, extending from Oakdale Portal to Tesla Portal: • SJPL-1, riveted steel pipe 56- to 72-inch internal diameter; • SJPL-2, reinforced concrete pipe and welded steel pipe, 61- to 62-inch internal diameter; • SJPL-3, pre-stressed concrete cylinder pipe and welded steel pipe, 78-inch internal diameter.	47.7 miles long each	0	0	0	SJPL – 2 Throttling Stations 1 and 2 Roselle Crossover San Joaquin River Valve House	0	None	0	NA	NA	No	Pipelines (within existing SJPL right-of-way) and routed through: open grasslands (sometimes used for grazing), City of Modesto, orchards, Tracy Golf Course. Conditions assessment and reconditioning activities could also affect public recreation areas in Modesto (linear parks with walking and bike paths).	No	No	No
SJ-5	Tesla Portal Disinfection Station	This project includes the planning, design, and construction of new disinfection facilities for the Hetch Hetchy water supply. The project would replace and upgrade the existing disinfection facilities at the Tesla Portal Disinfection Facility to meet current seismic, safety/fire, and building code standards. The preferred project would include construction of: • New control building and storage room; • Pump houses; • Chemical storage tanks and feed equipment and sampling systems; • Emergency generator, including primary and standby power supplies; • Access road. It should be noted that the design and location of the Advanced Disinfection project (SJ-1), would affect the design and location of this project.	0	0	0	6,000	0	0	Administration building (control room and offices) and pump houses (low horsepower pumps for domestic water and fire safety).	1	30'	15'	TBD	A caretaker's residence, two valve houses, and chlorination facility.	No except land possibly needed for associated power requirements	Yes	Yes
		Sub-totals	**64+**	**0**	**0**	**26,000**	**6+**	**0**		**2**	**30 to 35'**	**11 to 20'**					
SV-1	Alameda Creek Fishery Enhancement	This project would recapture the water released as part of the Calaveras Dam project (SV-2) and return it back to the regional system for use. A number of structural and non-structural recovery alternatives are under consideration including: a water recapture facility downstream of the Sunol Valley WTP, conjunctive groundwater use, horizontal collector wells, or other groundwater recovery systems yet to be defined. Other alternative designs for this project could be developed. If a structural alternative involving construction of a recapture facility is selected, the recapture facility would be located at the downstream end of the reach of Alameda Creek between the lower Sunol Valley and the confluence with Arroyo de la Laguna. As an alternative to the recapture facility, the SFPUC may coordinate with other water agencies to develop and implement other means of recapturing fishery enhancement flows consistent with the 1997 CDFG MOU.	TBD	0	0	0	0	TBD	Number of pumps depends on the alternative, ranging from 1 pump station to multiple pumps required.	TBD	TBD	TBD	TBD	Alternatives would be located in or near Alameda Creek downstream of Sunol Valley WTP.	No	TBD	TBD
SV-2	Calaveras Dam Replacement	This project would provide for the planning, design, and construction of a replacement dam at the Calaveras Reservoir to meet seismic safety requirements. The new dam would provide for a reservoir with the same storage capacity as the original reservoir (96,800 acre-feet), but the replacement dam would be designed to accommodate enlargement of the dam in the future. The preferred project would include construction of: • New earth-fill dam;	0	0	62,508,600	0	2	0	1. Zoned Earth-Fill Dam with Open Chute Spillway; 2. Various instrumentation; 3. Calaveras Road Upgrades (TBD).	3 (Dam, Spillway, Inlet Tower)	220' (foundation to dam crest)	NA	7 borrow areas (totaling over 222 acres)	Existing Calaveras Dam	No	Four staging areas: (1) north of the replacement dam; (2) south of the existing dam at Watershed Keeper's residence;	Yes

TABLE C.1 (Continued)
SFPUC WSIP PROJECT INFORMATION – DESCRIPTION OF PROJECT FACILITIES[1]

Temporary Staging Areas	Power Available?
SV-2 (cont.)	Calaveras Dam Replacement	• New intake tower and new outlet valve for water releases for instream flow requirements; • New or rehabilitated outlet works for seismic safety and improved operations and maintenance. • New bypass structure at the Alameda Creek Diversion Dam As part of this project, Calaveras Reservoir would be operated to release up to 6,300 afy (5.5 mgd) of water to Alameda Creek in support of fisheries in compliance with the 1997 CDFG MOU. When flow is available in Alameda Creek, releases would be made through the proposed bypass structure at the Alameda Creek Diversion Dam and would be supplemented as necessary with releases from Calaveras Dam.														(3) dam access road at Calaveras Road; (4) top of the existing dam.	

TABLE C.1 (Continued)
SFPUC WSIP PROJECT INFORMATION – DESCRIPTION OF PROJECT FACILITIES[1]

Project Number	Project Name	Description	PHYSICAL STRUCTURES											PHYSICAL REQUIREMENTS			
			Pipeline (miles)	Tunnel (miles)	Storage/ Basin (square feet)	Treatment (square feet)	Vaults/ Valve Houses	Pump Station	Other Facilities	Number of Structures	Maximum Height (feet)	Maximum Depth (feet)	Additional Sites for Borrow or Disposal)	Existing Land Use	Land Acquisition Required?	Temporary Staging Areas	Power Available?
SV-3	Additional 40-mgd Treated Water Supply	This project would provide for the planning, design, and construction of an additional 40 mgd of treatment capacity at the Sunol Valley WTP. The project would increase the sustainable capacity of the Sunol Valley WTP to 160 mgd. The planning level study will include studies to evaluate treatment operations protocol and an alternative treatment process. The preferred project would include construction of: • New flocculation and sedimentation system; • Upgrade of existing filters or addition of three new filters and a new flow distribution chamber; • New filtered water and backwash piping; • New chemical feed and piping system; • Upgrade of the electrical supply system; • Miscellaneous piping, valves, and mechanical and electrical work; • Approximately 2 miles of 78-inch diameter pipe to connect to the Alameda Siphons or Irvington Tunnel.	1.5 to 2	0	42,000	0	0	0	Misc. piping, valves, chemical feed, electrical supply upgrades, and drainage piping system. Upgrade of electrical supply system (e.g. the Calaveras Substation)	1	10'	TBD	TBD	Undeveloped SFPUC lands immediately adjacent to Sunol WTP facilities	No, but may need easement across private property.	TBD	Yes
SV-4	New Irvington Tunnel	This project would construct a new tunnel parallel to and just south of the existing Irvington Tunnel to convey water from the Hetch Hetchy system and the Sunol Valley WTP to the Bay Area. The new tunnel would be a redundant water transmission facility to the existing Irvington Tunnel. The preferred project would include construction of: • New 18,200-foot long, 10-foot diameter tunnel; • New portal at the east end adjacent to the existing Alameda West Portal in the Sunol Valley with connections to the existing and proposed new siphon; • New portal at the west end adjacent to the existing Irvington Portal in Fremont with connections and to the existing and proposed new pipeline (BD-1); • Valves and equipment to control and monitor flows; • Modifications to the existing Alameda West and Irvington Portals.	0.0	3.4	0	0	9-12 (reinforced concrete vault across fault, Irvington Portal crossover valve vault, etc.)	0	1. New Alameda West Portal 2 and Overflow Shaft. 3. New access road to Irvington Portal and Alameda West Portal. 4. New Irvington Portal 2 and air release pipe. 5. Complete demolition and rebuild of existing Irvington Portal manifold. 6. Valves and equipment to control and monitor flows. 7. Two new permanent bridges across Alameda Creek. (Note: A total of two bridges are necessary to construct and operate both the New Irvington Tunnel and Alameda Siphons Upgrade projects; the determination of when to build the bridges would depend on which project would be constructed first. Since this determination has not been made to date, the bridges are evaluated under both projects.)	0	NA	NA	Up to four spoils disposal areas proposed; spoils transported to one of these areas by conveyor belt.	New east tunnel portal would be about 75 feet north or south of Alameda West Portal. New west tunnel portal would be about 175 feet south of existing Irvington Portal. Lands immediately adjacent to existing portals are undeveloped except for caretaker's home and water facilities at Irvington Portal and water facilities at Alameda West Portal. There is one residence located south of Alameda West Portal and residential uses located west of Irvington Portal.	Some sections of ROW do not have easements or fee ownership. Access to new west portal (south of Irvington Portal) would likely be outside of easement.	Three staging areas: 1. east of Alameda West Portal; 2.northwest of Alameda East Portal (west of Calaveras Rd); 3. west of existing cottage at Irvington Portal (at base of hill, east of homes).	NA
SV-5	SVWTP – Treated Water Reservoirs	This project would provide for the planning, design, and construction of new treated water storage reservoirs at the Sunol Valley WTP (SVWTP) to comply with requirements of the California Department of Health Services. The preferred project would include construction of: • One five-million-gallon chlorine contact basin; • Two 8.75-million gallon storage basins; • New inlet and outlet piping and reservoir drainage system; • Pipe bridge over Alameda Creek; • Chemical (ammonia and chlorine) storage and feed system; • Backup filter wash water supply and filter washwater supply system;	0.3	0	138,200	0	1	0	1. Chemical storage and feed system. 2. Pumping system for filter backwashing and other miscellaneous pumping appurtenances. 3. Backup filter backwash system. 4. Washwater supply system. 5. Reservoir drainage system, controls & instrumentation. 6. Expansion of the existing SVWTP electrical substation. 7. Modification of existing valves. 8. Upgrade of existing dechlorination station and miscellaneous piping.	1	15'	TBD	TBD	Site is within boundary of existing SVWTP. Site is currently used for temporary equipment or supply storage on an as-needed basis. The existing Calaveras Nursery is located to the north and open space is located to the west.	No	Not Specified	The power supply would be through an expansion of the existing SVWTP electrical substation.

TABLE C.1 (Continued)
SFPUC WSIP PROJECT INFORMATION – DESCRIPTION OF PROJECT FACILITIES[1]

			PHYSICAL STRUCTURES											PHYSICAL REQUIREMENTS			
Project Number	Project Name	Description	Pipeline (miles)	Tunnel (miles)	Storage/ Basin (square feet)	Treatment (square feet)	Vaults/ Valve Houses	Pump Station	Other Facilities	Number of Structures	Maximum Height (feet)	Maximum Depth (feet)	Additional Sites for Borrow or Disposal)	Existing Land Use	Land Acquisition Required?	Temporary Staging Areas	Power Available?
SV-5 (cont.)	SVWTP – Treated Water Reservoirs (cont.)	• Instrumentation and controls and miscellaneous pumping appurtenances to integrate the reservoirs into the existing treatment plant; • Expansion of the existing SVWTP electrical substation; • Two 750 kW diesel powered emergency generators.															
SV-6	San Antonio Backup Pipeline	This project would consist of three proposed facilities: 1. San Antonio Backup Pipeline, a new pipeline (size undetermined) from San Antonio Reservoir to San Antonio Pump Station, about 2 miles long; (2) San Antonio Creek Discharge Facilities (improvements allowing for the discharge of Hetch Hetchy water and associated road improvements); and (3) Alameda East Portal Vent Overflow Pipeline and portal modifications.	2.3	0	0	0	2	0	1. New discharge facilities at San Antonio Creek (at end of the new pipeline). 2. New pipeline from the existing overflow outlet near Alameda East Portal, passing adjacent to the San Antonio Pump Station (SAPS), and continuing to the discharge point on Alameda Creek.	NA	NA	No	Undeveloped SFPUC lands	Undeveloped SFPUC lands; pipeline alignment would generally extend between San Antonio Creek and reservoir access road (sometimes extending in the road, across this road, or close to the creek), then cross Calaveras Road, and extend along the west side of this road to SAPS.	TBD	No	NA
		Sub-totals	**4 to 5**	**3+**	**63 million**	**0**	**14 to 17**	**TBD**		**5+**	**10 to 220'**						
BD-1	Bay Division Pipeline Reliability Upgrade	This project would construct a new Bay Division Pipeline No. 5 (BDPL 5) from the Irvington Tunnel Portal in Fremont to the Pulgas Tunnel Portal near Redwood City, consisting of 16 miles of new pipeline and 5 miles of tunnel under San Francisco Bay. Portions of the section of BDPL No. 1 between Edgewood Valve Lot and Pulgas Valve Lot would be removed (approximately 1.4 miles) and existing above ground and submarine sections of BDPL Nos. 1 and 2 over the 5-mile long section from Newark Valve House to Ravenswood Valve House would be decommissioned (decommissioning is not part of this project). The redundancy provided by the project would increase the overall transmission capacity of the Bay Division pipeline system. The preferred project would include construction of: • New welded-steel pipeline, approximately 72 inches in diameter, extending along the 7-mile reach from Irvington Portal to Newark Valve Lot, located within the existing SFPUC ROW of BDPL Nos. 1 and 2; • New "Bay Tunnel" segment of BDPL No. 5, approximately 120 inches in diameter, extending 5 miles from Newark Valve Lot to Ravenswood Valve Lot, crossing under San Francisco Bay and adjacent marshlands. BDPL Nos. 1 and 2 would tie into the tunnel at both ends and would be decommissioned between Newark and Ravenswood Valve Lots; • New welded-steel pipeline, approximately 60 inches in diameter extending along the 9-mile reach from Ravenswood Valve Lot to Pulgas Portal, located within the existing SFPUC ROW of BDPL Nos. 1 and 2; • New facilities at eight valve vault lots along the alignment, containing new concrete vaults and control structures that house electrical control panels, isolation valves, mechanical equipment, and cross-connections between BDPL No. 5 and the existing BDPLs;	16	5	0	0	8 valve facilities, with up to 15 vaults total	0	Isolation valves and piping for connection to new Irvington extension and Pulgas Tunnels. One flow meter at each end of the alignment (2 total). Control buildings for electrical and mechanical equipment at each of the valve lots (8 total). New tunnel shafts at Ravenswood and Newark. Final decision as to which shaft would be the drive shaft and which would be the receiving shaft is still to be determined. For the drive shaft, excavated diameter would be approximately 50 feet with parking for up to 40 construction work vehicles. Staging area would accommodate mucking out materials handling area, on-site power generation (as needed) or a transformer station, ventilation fans and mufflers, water supply, compressed air supply and miscellaneous temporary construction facilities totaling approximately 30,000 s.f. The receiving shaft would require a demobilization area for disassembly & removal of Tunnel Boring Machine, materials handling area, on-site power generation (as needed) or a transformer station, ventilation fans & mufflers, water supply, compressed air supply and miscellaneous temporary construction facilities totaling approximately 11,000 s.f.	8 above ground electrical control buildings at the valve lots	Electrical control buildings would be above ground single story structures (up to 30' high).	The pipeline would be buried. The valve vaults are mostly below ground.	Potential disposal areas include salt ponds near Dumbarton Strait and South Bay Salt Pond Restoration Project.	Pipeline ROW traverses urbanized areas of Fremont, Newark, East Palo Alto, Menlo Park, Redwood City, traversing commercial, residential, school, park uses. The pipeline could affect approximately 16 schools (Cesar Chavez Academy [1,000 ft.], Costano [crossed by ROW] in East Palo Alto; Chadbourne, Durham [1,000 ft.], Fremont [1,500 ft.], Irvington [adjacent], Mission San Jose Junior/Senior High School [1,000 ft.], school near Azeveda Park [500 ft.], Walters Junior High School [750 ft.] in Fremont; Bell Haven [500 ft.] and Flood [500 ft.] in Menlo Park; Bunker [crossed by ROW] in Newark; Fair Oaks [1,500 ft.], Hawes [crossed by ROW], John Gill [crossed by ROW], West Bay Christian Academy [crossed by ROW] in Redwood City) and 11 parks (Azeveda, Fremont, Knoll, and Mission San Jose parks in Fremont; Flood County in Menlo Park; Ash Street and Birch Grove parks in Newark; Edgewood, Fleishman, Hawes, and Red Morton parks in Redwood City). The Newark shaft site has an existing valve house and is surrounded by industrial uses. The Ravenswood shaft site is bordered by BDPL right-of-way to the south, marshland to the east, Cargill Salt Ponds to the north, and University Avenue to the west. Approximately 15 acres of this site is in use for soil remediation, and might eventually be used as a maintenance yard. The Irvington portal vicinity is mostly undeveloped (except for caretaker's home and water facilities) and residential uses are located west of the portal and adjacent to BDPL right-of-way in this vicinity.	Some sections of the ROW do not have easements or fee ownership. The tunnel shaft on the west end of the tunnel can be located on a 40-acre site owned by SFPUC at the Ravenswood valve house. The tunnel shaft on the east end of the tunnel can be located on a 12-acre site owned by SFPUC at the Newark Valve House. The tunnel would require subsurface easement. Some additional easements may be needed for access along the right-of-way. [Note: BD-1 may require an easement at the Hayward Fault Crossing to the north of the SFPUC ROW, depending on the design selected. If the design routes the pipeline to the north of existing fault crossing facilities for BDPLs 1&2, then there would not be room for BDPL 5 within the SFPUC	For the tunnel section, the staging area near the Newark Valve House would require leasing additional land from owners adjacent to the existing pipeline ROW for use as temporary construction staging and stockpiling area. Owners include Leslie Salt Co., FMC Co., Cargill, and SamTrans. Additional staging areas for the pipeline contractors are being investigated.	Yes

TABLE C.1 (Continued)
SFPUC WSIP PROJECT INFORMATION – DESCRIPTION OF PROJECT FACILITIES[1]

Project Number	Project Name	Description	PHYSICAL STRUCTURES											PHYSICAL REQUIREMENTS			
			Pipeline (miles)	Tunnel (miles)	Storage/ Basin (square feet)	Treatment (square feet)	Vaults/ Valve Houses	Pump Station	Other Facilities	Number of Structures	Maximum Height (feet)	Maximum Depth (feet)	Additional Sites for Borrow or Disposal)	Existing Land Use	Land Acquisition Required?	Temporary Staging Areas	Power Available?
BD-1 (cont.)	Bay Division Pipeline Reliability Upgrade (cont.)	• Two flow metering vaults at or near Mission Boulevard (in Fremont) and Pulgas Portal areas; and • New Isolation valves and piping for connecting BDPL No. 5 to Irvington and Pulgas portals.													right-of-way. If required, the easement would be just to the north of the SFPUC right-of-way, and could be up to 2,300 feet long and 5 to 15 feet wide.		
BD-2	BDPL Nos. 3 and 4 Crossovers	This project would construct three additional crossover facilities along Bay Division Pipelines Nos. 3 and 4 (BDPL 3 and 4) to provide operational flexibility for maintenance or during emergencies. The new crossover facilities would reduce the length of pipe to be removed from service, either for maintenance or for emergencies, and would reduce the duration of outages. Each crossover facility would include construction of: • Four mainline valves and one cross-connect valve; • Automatic controlled actuators; • Discharge facilities to enable release of water that meets water quality discharge requirements within discrete pipeline segments to surface waters either for maintenance or emergencies.	0	0	0	0	3 valve vaults	0	Valve vaults would be 3,750 square feet each. Discharge location of drainage outfalls vary depending on site conditions. Piping to connect facility to outfalls. Control buildings for electrical and mechanical equipment at each valve vault (3 total).	3 above ground control buildings	3 to 8'	TBD (mostly under-ground)	TBD	Sites would be located in undeveloped areas on Veterans Administration Medical Center and Gunn High School lands (Barron Creek), Ulistac Natural Area (Guadalupe Creek), and reservoir lands (Bear Gulch).	If permanent drainage outfalls are constructed, an easement or use permit would likely be required. If temporary connections are made, easements/ permits may not be required.	Not specified, but adjacent areas at Bear Gulch and Guadalupe River are undeveloped.	No
BD-3	Seismic Upgrade of BDPLs Nos. 3 and 4 at Hayward Fault	This project would provide for the planning, design and construction of upgraded, seismically-resistant sections of the Bay Division Pipelines Nos. 3 and 4 where they cross the Hayward Fault. The replacement pipelines would be located between the two new crossover/isolation valves that would be built as part of the BDPL Nos. 3 and 4 Crossover/ Isolation Valve at Hayward Fault project (an WSIP project determined to be independent of the PEIR). In addition to the replacement pipelines, a new bypass pipeline between the two new crossover/isolation valve vaults could also be built as part of one of the several alternatives being considered for this project.	3	0	0	0	0-2 (TBD)	0	None	0	NA	Buried pipeline	No	Site spans the I-680/Mission Boulevard freeway interchange. All work would be performed within existing ROW.	No	Within BDPL ROW	TBD
		Sub-totals	**19**	**5**	**0**	**0**	**11 to 20**	**0**		**11**	**Up to 30'**						
PN-1	Baden and San Pedro Valve Lots Improvements	This project would upgrade valve vaults, valves, and piping at the existing Baden and the San Pedro Valve Lots to meet current seismic standards. Work could also be performed at the Pulgas Pump Station and Pulgas Valve Lot as part of transmission reliability. The project would include a new pressure-reducing valve at one of the locations to allow transfer of water between high- and low-pressure zones from the Harry Tracy WTP to the Peninsula under an emergency scenario.	<1	0	0	0	2 at San Pedro; 6 at Baden	2	Install new valves, pressure and flow meters, motor operators, SCADA valve controls, modify valves/pumps/ sump/vent shaft, and either enlarge existing vault or add new vault at Baden and/or San Pedro Valve Lots.	1 new; 11 retrofitted / rebuilt / replaced	Vaults: 1 to 3' above ground	30'	Disposal sites for excavated materials	Majority of work would occur within existing water supply facility sites owned by SFPUC.	No	On-site	Yes, from PG&E service area
PN-2	Crystal Springs/ San Andreas Transmission Upgrade	This project would consist of seismic improvements of facilities that convey water from Crystal Springs Reservoir to the Harry Tracy WTP. This project would increase the transmission capacity of the existing raw water pipeline from Crystal Springs Reservoir to San Andreas Reservoir in order to reliably supply 140 mgd of raw water for treatment at the Harry Tracy WTP. The project would include:	4.5	0.5**	0	Emergency chemical injection systems at CS and SA	32 existing vaults (number of vaults would most likely be reduced) & new vaults	Complete renovation or new pump station based on alternatives analysis	Repair lower culvert linking Upper and Lower Crystal Springs Reservoir; upgrade/repair Crystal Springs Outlet Structure Nos. 1 & 2; upgrade or replace Crystal Springs Pump Station (PS), including increasing capacity to transfer water between	8 existing, 1 or 2 may be completely replaced	Existing PS is 25' and new PS would be no higher; other structures would be below ground.	100' for tunnels; 30' for pipelines; 15' for building foundations; 100' for piles.	TBD	Project involves repair or replacement of existing SFPUC water facilities. If a new parallel pipeline is needed and an alternative alignment is chosen, an easement may be necessary. The most likely alignments would be within the watershed on SFPUC lands.	TBD	Significant staging areas would be required at all work sites. UCSD, CSOS1, CSOS2, CSPS,	Power upgrades at CSPS required. Low voltage and/or solar cells at various locations

TABLE C.1 (Continued)
SFPUC WSIP PROJECT INFORMATION – DESCRIPTION OF PROJECT FACILITIES[1]

Project Number	Project Name	Description	PHYSICAL STRUCTURES											PHYSICAL REQUIREMENTS			
			Pipeline (miles)	Tunnel (miles)	Storage/ Basin (square feet)	Treatment (square feet)	Vaults/ Valve Houses	Pump Station	Other Facilities	Number of Structures	Maximum Height (feet)	Maximum Depth (feet)	Additional Sites for Borrow or Disposal)	Existing Land Use	Land Acquisition Required?	Temporary Staging Areas	Power Available?
PN-2 (cont.)	Crystal Springs/ San Andreas Transmission Upgrade (cont.)	• Repair of the Upper Crystal Springs Dam discharge culverts; • Upgrade and repair of Lower Crystal Springs Dam outlet structures and tunnels conveying water to the Crystal Springs Pump Station; • Replacement or refurbishment of the Crystal Springs Pump Station; • Upgrade and repair of the chemical system and Crystal Springs chlorine emergency feed; • Improvements to the Crystal Springs–San Andreas Pipeline, including replacement of approximately 1,350 feet of 66-inch diameter pipeline, general renewal of the remaining pipeline, and addition of new manholes, blow-off valves, and isolation valves; or construction of a new redundant pipeline along a new alignment; • Seismic and hydraulic upgrade and repair of the San Andreas outlet facilities; • Addition of fish screens on the outlet structures for both Crystal Springs and San Andreas Reservoirs; • Repair of two pipelines that convey raw water from San Andreas Reservoir to the Harry Tracy WTP raw water pump station.					are limited to CSPS and outlets of four tunnels.		reservoirs from 80 to approximately 120 mgd depending on future modeling (maximum rate would be 140 mgd to match HTWTP output); build new power substation (chemical injection equipment is new only minor strengthening of pipe required); renew pipeline sections that are not replaced at San Andreas Reservoir; depending on alternative analysis, a new redundant pipeline may be required; upgrade/repair of San Andreas Outlet Structure Nos. 2 & 3 (significant retrofit of SA 2 Tunnel may be required); repair San Andreas pipelines Nos. 2 & 3; pump station capacity upgrades as required to meet HTWTP raw water supply requirements. **There are four existing tunnels that would require strengthening and/or retrofit.							CSSAPL, SAOS2, SAOS3, HTWTP.	throughout the project.
PN-3	HTWTP Long-Term Improvements	This project would be a seismic retrofit and rehabilitation of the existing building and facility to provide long-term reliability and process improvements. The project would increase the sustained treatment capacity of the plant from 120 to 140 mgd for 60 days. The proposed improvements would include: • Replacement and upgrade of the ozone generation system for primary disinfection; • Replacement or upgrade of the existing sedimentation basins at the same location; • Improvements to sludge handling facilities; • New, redundant pipeline from the treatment works to the finished water storage reservoir; • Raw water pump station improvements; • Upgrade and replacement of electrical and instrumentation components, including improvements to process and plant security facilities.	Possible transmission improvements within the facility property (1-2 miles)	0	2 treated water reservoirs	Project is a treatment facility	TBD (valves and vaults may be required)	1 raw water pump station	Some of the 16 identified structures would require upgrades but would not be determined until completion of PN-7. Mechanical, structural, electrical, and process upgrades are anticipated with known upgrades occurring within existing development footprints. However, structures could be added within the HTWTP property. Improvements include disinfection treatment upgrades, raw water pumping upgrades, replacement/ upgrade of sedimentation basins at same location, sludge facilities, and power and instrumentation upgrades.	TBD	TBD	TBD	TBD	HTWTP site is currently developed with water treatment facilities.	No	Available area within HTWTP property.	Yes
PN-4	Lower Crystal Springs Dam Improvements	This project would consist of major repairs and improvements to Lower Crystal Springs Dam to provide adequate protection of the dam and downstream areas from the probable maximum flood, as defined by the California Division of Safety of Dams (DSOD). DSOD has placed operational restrictions on the dam, and the capacity of the reservoir is limited to 56,800 acre-feet. The project would restore the historical reservoir capacity of 68,000 acre-feet. The project would be coordinated with San Mateo County, which is concurrently planning the replacement of the existing county bridge built above the crest of the dam. Project elements would include:	0	0	0	0	0	0	Raise dam parapet to provide required freeboard during probable maximum flood (PMF), which also could require strengthening abutments; lengthen spillway crest to increase discharge capacity; install new mechanical gates to replace the antiquated stop log system; enlarge the stilling basin to accommodate the PMF discharge. Project cannot be completed until Skyline Blvd (Hwy 35) bridge project is completed by San Mateo County.	TBD	TBD	TBD	TBD	The Lower Crystal Springs Dam is an existing dam and the Lower Crystal Springs Reservoir level is currently restricted by the CA Division of Safety of Dams (DSOD). The inundation zone is currently undeveloped; with implementation of the proposed project, including improvements to the dam and spillway, the reservoir levels would be restored to inundation zone levels that were permissible by DSOD prior to 1983.	No	Adjacent to the Dam's south abutment	Yes

TABLE C.1 (Continued)
SFPUC WSIP PROJECT INFORMATION – DESCRIPTION OF PROJECT FACILITIES[1]

			PHYSICAL STRUCTURES											PHYSICAL REQUIREMENTS			
Project Number	Project Name	Description	Pipeline (miles)	Tunnel (miles)	Storage/ Basin (square feet)	Treatment (square feet)	Vaults/ Valve Houses	Pump Station	Other Facilities	Number of Structures	Maximum Height (feet)	Maximum Depth (feet)	Additional Sites for Borrow or Disposal)	Existing Land Use	Land Acquisition Required?	Temporary Staging Areas	Power Available?
PN-4 (cont.)	Lower Crystal Springs Dam Improvements (cont.)	• Lowering the existing parapet wall on either side of the existing spillway to lengthen the overflow weir (central spillway) from the reservoir; • Raising the remaining parapet walls and adding two new spillway bays, one on each side of the existing central spillway; • Enlarging the spillway stilling basin to accommodated the probable maximum flood; • Installing four gates (with control building) or installing a fixed weir within the spillway to restore the historical storage capacity.															
PN-5	Pulgas Balancing Reservoir Rehabilitation	This project would provide for the planning, design, and construction of improvements to the existing Pulgas Balancing Reservoir and associated facilities. The project would include: • Modifications to the inlet/outlet piping (Phase 1, currently under construction); • Design and construction to rehabilitate and/or expand of the discharge channel to Crystal Springs Reservoir (or to install a parallel channel) (Phase 2); • Geotechnical investigations, design and construction of recommended seismic improvements, including repair/replacement of the reservoir walls, floor and roof (Phase 3); • Restoration of a 6- to 8-acre sediment catchment basin in Laguna Creek to also serve as sustainable habitat for San Francisco garter snake and California red-legged frog, including culvert replacement, sediment removal, revegetation, and protective measures to avoid impact to sensitive species (Phase 4); • Modification of the existing dechlorination process, including modifications to the chemical feed system to enable pH adjustment and dechlorination system to operate reliably (Phase 5).	0	0	0	Project is a treatment facility west of Canada Road	0	0	Five phases: 1. new inlet/outlet piping to ensure optimal mixing in reservoir; 2. rehabilitate/ replace existing Pulgas Channel with an enlarged channel to accommodate estimated maximum flow of 250 mgd; 3. structural rehabilitation and roof replacement; 4. restore the existing sedimentation basin for the enhancement of the habitat as a mitigation project for the existing dechloramination facility; 5. modification of the existing dechlorination process (increase capacity of carbon dioxide, chemical feed systems).	NA	NA	NA	NA	Project would be located within existing Pulgas Balancing Reservoir and existing Pulgas Channel, Laguna Creek Sedimentation Basin area and existing dechloramination facility.	No	Pulgas Reservoir parking area at the entrance (east of Canada Road) would be used for Phase 1 Inlet/Outlet Modifications project	Yes
		Sub-totals	**±7 to 9**	**0.5+**	**2**	**0**	**8+**	**3+**		3+	1 to 25						
SF-1	San Andreas Pipeline No. 3 Installation	This project would replace the out-of-service Baden-Merced Pipeline, which is beyond repair, and would construct a new pipeline extension of the existing San Andreas Pipeline No. 3 from the San Pedro Valve Lot in Daly City to the Merced Manor Reservoir in San Francisco. It would also connect the existing San Andreas Pipeline No. 2 at Sloat Boulevard in San Francisco and install an additional pipeline to serve the water turnouts along San Andreas Pipeline No. 2. The project would provide seismic reliability and system redundancy for Peninsula and San Francisco customers. The project would include: • New 3.8 mile long, 36-inch diameter pipeline; • Approximately 0.27 miles of 36-inch diameter pipeline for three connections between San Andreas Pipelines 2 and 3;	4.17	0	0	0	2	0	1. 4.07 miles of 36-inch and 0.1 mile of 12- to 16-inch diameter steel pipeline; 2. removal and/or slurry fill of the existing Baden Merced pipeline; 3. installation of line valves, vaults, and manholes; 4. installation of cathodic protection systems and monitoring stations, sample taps, air valves, blow offs, and other pipeline appurtenances.	2	8'	2'	NA	This pipeline would extend from San Pedro Valve Lot in Daly City to Merced Manor Reservoir in San Francisco. The entire length of the proposed pipelines would be located in developed, urban areas of San Francisco and Daly City. Most of the pipeline alignment, approximately 3 miles, would be located within existing roadways, parking lots, and other paved areas, with the remainder crossing through open space corridors in Lake Merced Golf & Country Club, San Francisco Golf Club. Adjacent uses include residential, commercial, school, church, and park uses.	The entire length of the proposed pipelines would be located within right-of-ways or easements owned by the City and County of San Francisco or in public roadways.	Additional ROW might be needed temporarily for staging	Yes

TABLE C.1 (Continued)
SFPUC WSIP PROJECT INFORMATION – DESCRIPTION OF PROJECT FACILITIES[1]

Project Number	Project Name	Description	PHYSICAL STRUCTURES											PHYSICAL REQUIREMENTS			
			Pipeline (miles)	Tunnel (miles)	Storage/ Basin (square feet)	Treatment (square feet)	Vaults/ Valve Houses	Pump Station	Other Facilities	Number of Structures	Maximum Height (feet)	Maximum Depth (feet)	Additional Sites for Borrow or Disposal)	Existing Land Use	Land Acquisition Required?	Temporary Staging Areas	Power Available?
SF-1 (cont.)	San Andreas Pipeline No. 3 Installation (cont.)	• Removal of the Baden-Merced Pipeline where the new San Andreas Pipeline No. 3 alignment matches the Baden-Merced alignment. • Less than 0.1 mile of 12- to 16-inch diameter new pipeline for five branch connections to user turnouts (three turnouts to Daly City, two turnouts to SF distribution lines); • Installation of line valves and vaults, manholes, cathodic protection and monitoring stations, sample taps, air valves, blow-offs, and other pipeline appurtenances.															
SF-2	Groundwater Projects – Local	This project includes three groundwater projects: Lake Merced, Local Groundwater, and Regional Groundwater. • The Lake Merced project would address raising the level of Lake Merced in San Francisco using a supplemental source of water, such as treated stormwater, recycled water, groundwater, or SFPUC system water. • The Local Groundwater Projects would include development of 2 mgd of new local groundwater for blending with water in the potable water system in San Francisco. An estimated 4 wells and well stations would be constructed to develop this new local groundwater. This project would also include the use of an additional 2 mgd of groundwater through replacement of existing irrigation wells at the San Francisco Zoo, Golden Gate Park and/or other locations, once recycled water were available for irrigation (to be developed under SF-3). Two existing wells also would be modified to enable emergency supply to local residents in the event of a major earthquake or other disaster. This project also would include the pipelines, water treatment equipment and controls needed to add the groundwater to the municipal supply. The additional water supply developed under this project would be used during both nondrought and drought years.	3.5	0	0	500	0	0	Install new wells, well stations and associated pipelines, water treatment and controls at Lake Merced Pump Station, South Sunset Playground, West Sunset Playground, and Golden Gate Park (or alternate location at Central Pump Station or Francis Scott Key Annex). Modify wells at SF Zoo and North Lake (Golden Gate Park) for emergency supply. Replace wells at the Zoo, Pine Lake (Stern Grove), Golden Gate Park and/or other locations (TBD); about 2,500 sq. ft. per site. Projects completed in 2005 and 2006: Initial phases of the Lake Merced project were completed in 2005 (upgrades to allow dechlorinated water to be discharged to Lake Merced and installation of a flow meter and water level meter). Local Groundwater Projects currently underway or completed in 2006 include the following: (1) construction of emergency well upgrades at SF Zoo Well No. 5; (2) construction and testing of test well at South Sunset Playground; and (3) emergency well upgrades in Golden Gate Park (North Lake); (4) earth embankment stabilization for seismic safety at Sunset Reservoir per State Division of Safety of Dams requirements. Sunset Reservoir seismic and general upgrades would resume in early 2007 to provide general facility rehabilitation and upgrade consisting of crack repairs, sealing of the reservoir roof, replacement of expansion joints and cover plates, improved reservoir access, drainage repairs, and miscellaneous roadway and site improvements. Valve and gate upgrades are also included.	6	16'	3'	NA	Varies: SFPUC Lake Merced Pump Station; South Sunset Playground: playground; West Sunset Playground: playground; Francis Scott Key Annex: school's parking lot. Golden Gate Park locations; SF Zoo: zoo; Pine Lake: Stern Grove; Central Pump Station.	Not for well sites located on City property. May be required for sites located on SFUSD property at Francis Scott Key Annex.	It is possible that additional staging, laydown or stockpile areas may be needed that are outside existing identified well locations.	Yes

TABLE C.1 (Continued)
SFPUC WSIP PROJECT INFORMATION – DESCRIPTION OF PROJECT FACILITIES[1]

Project Number	Project Name	Description	PHYSICAL STRUCTURES										PHYSICAL REQUIREMENTS			
			Pipeline (miles)	Tunnel (miles)	Storage/ Basin (square feet)	Treatment (square feet)	Vaults/ Valve Houses	Pump Station	Other Facilities	Number of Structures	Maximum Height (feet)	Maximum Depth (feet)	Additional Sites for Borrow or Disposal)	Existing Land Use	Land Acquisition Required?	Temporary Staging Areas	Power Available?
SF-2 (cont.)	Groundwater Projects – Regional	As part of the regional conjunctive-use project, the SFPUC would construct about 10 new groundwater production wells in San Mateo County to develop about 6 mgd of potable groundwater as part of a regional conjunctive-use project for uses as a supplemental drought-year supply. In non-drought years under this project, the SFPUC would provide potable water from the regional system to customers in Daly City, San Bruno and South San Francisco to substitute for groundwater currently used for municipal purposes, thereby reducing	0.5	0	0	0	0	0	Up to 10 new wells and well stations in San Mateo County, Daly City, San Bruno, South San Francisco and Colma. Wells are estimated to be 600 feet deep.	10	16'	3'	NA	Specific well station sites not yet identified	Locations not determined in San Mateo County	It is possible that additional staging, laydown or stockpile areas may be needed that are outside existing identified well locations.	TBD
SF-3	Recycled Water Projects	This project includes recycled water projects in San Francisco and other locations. Projects include Westside Baseline and Harding Park/Lake Merced. This project would provide treatment, storage, and distribution facilities for about 4 mgd of recycled water to users on the west side of San Francisco. Primary users would include Golden Gate Park, Lincoln Park, Lincoln Park Golf Course, Harding Park Golf Course, San Francisco Zoo, Sunset Boulevard medians, and San Francisco State University. As described under Groundwater Projects (SF-2), the SFPUC is also investigating appropriate sources of supply for increasing and maintaining Lake Merced lake levels, including recycled water that has undergone advanced treatment. • The Westside Baseline project would include a recycled water treatment facility at or near the Oceanside Water Pollution Control Plant (SF Zoo overflow parking lot) or locations in or near Golden Gate Park, about 8 miles of distribution pipelines, new storage at the recycled water treatment plant site, use of existing storage facilities in Golden Gate Park, and additional storage/pumping – possibly in the Lincoln Park area and other locations (TBD). The project would provide about 2.8 mgd of recycled water (average annual demand) primarily to Golden Gate Park, Lincoln Park, Lincoln Park Golf Course, San Francisco Zoo, Sunset Boulevard medians, and San Francisco State University.	20	0	TBD	Approximately 50,000	0	1 or 2	Utilize existing Golden Gate Park (2 mg) Reservoir. Additional storage in the Lincoln Park area. Other potential small booster pumping station(s) have not been identified.	1 to 4	40'	Not Specified	Not Specified	OWPCP has limited space in an existing room that houses odor control scrubbers; the Zoo overflow parking lot is unpaved and in use by the zoo; the Richmond-Sunset site is currently used for construction spoils storage; the McQueen site is currently being used by Rec & Park as their Urban Forestry Center. Golden Gate Park storage tank (existing facility), Lincoln Park (golf course).	Treatment: City-owned property, Dept. of Rec & Parks, Zoological Society has a 30 year lease. Storage: Golden Gate Park (existing 2 mg reservoir); another may be required in the Lincoln Park area, which is owned/operated by the City's Dept. of Rec & Parks.	Not Specified	No
		• The Harding Park/Lake Merced project would probably include advanced recycled water treatment potentially co-located with the tertiary facility, but could also consist of a satellite treatment facility; about 1.3 miles of distribution pipelines, and storage at the recycled water treatment plant. The project would provide about 1.3 mgd of highly treated recycled water for restoration of the Lake Merced levels, and possibly for irrigation of the Harding Park/Fleming Golf Course. The advanced treatment process may be required for use in Lake Merced, and could include nutrient removal to prevent eutrophication of Lake Merced.															
		Sub-totals	**28+**	**0**	**0**	**±50,500**	**2**	**1 or 2**		**19 to 22**	**8 to 40**	**3+**					

NOTES: afy = acre-feet per year; mgd = million gallons per day; NA = Not applicable; SCADA = Supervisory Control and Data Acquisition; sq. ft. = square feet; TBD = To be determined as project designs are developed and as part of separate, project-level CEQA review

TABLE C.2
SFPUC WSIP PROJECT INFORMATION – PROJECT FACILITIES OPERATIONS[1]

Project Number	Project Name	Operational Changes	Change in chemical use?	New Lighting?	Change in Number of Employees	Any New Pumps?	Change in Truck Deliveries?	Permanent Change in Drainage/ Discharges?	Change in Power Demand	Emergency Generator/ Standby Power Required?
SJ-1	Advanced Disinfection	TBD (may require increased manpower).	Possible addition of new treatment chemicals (hydrofluorosilicic acid, and sulfuric acid or carbon dioxide). Potential use of new chemical for cleaning of UV lamps. Propane or diesel for standby power generator.	Likely, lighting at existing facilities	Operations Rep reports to site once/day for 2-4 hours.	TBD	Yes, approximately 1-2 additional deliveries per week per new chemical. Would use existing route: I-580, Chrisman Road, Vernalis Road, Existing Access Road	No new discharges	Yes, power to be provided to new facility.	Yes, standby generator of 750-2500 KVA would be needed.
SJ-2	Lawrence Livermore Supply Improvements	This is unmanned facility monitored by SCADA 24/7.	TBD	TBD	Operations Rep reports to site once/day for 2-4 hours.	TBD	I-580, Corral Hollow Road, Dirt Access Road	TBD	Yes	TBD
SJ-3	San Joaquin Pipeline System	Increased manpower during flow rate changes.	Propane or diesel for standby power generator.	Lighting at new facilities	Operations Rep reports during flow rate changes (8 days per year times two employees).	No	No	TBD	Yes, power to be provided for automation and operation of crossovers and valves at Oakdale and Tesla.	TBD
SJ-4	Rehabilitation of Existing San Joaquin Pipelines	None, reconditioning work would be conducted during the planned maintenance period (November through March).	No	No	TBD	No	No	No	No	No
SJ-5	Tesla Portal Disinfection Station	This is unmanned facility monitored by SCADA 24/7.	Possible addition of new treatment chemicals (hydrofluorosilicic acid, and sulfuric acid or carbon dioxide). Propane or diesel for standby power generator.	Likely, lighting at existing facilities	Operations Rep reports to site once/day for 2-4 hours.	TBD	Yes, approximately 1-2 additional deliveries per week per new chemical. Would use existing route: I-580, Chrisman Road, Vernalis Road, Existing Access Road	No new discharges	Yes, power to be provided to new facility.	Yes

TABLE C.2 (Continued)
SFPUC WSIP PROJECT INFORMATION – PROJECT FACILITIES OPERATIONS[1]

Project Number	Project Name	Operational Changes	Change in chemical use?	New Lighting?	Change in Number of Employees	Any New Pumps?	Change in Truck Deliveries?	Permanent Change in Drainage/ Discharges?	Change in Power Demand	Emergency Generator/ Standby Power Required?
SV-1	Alameda Creek Fishery Enhancement	TBD, depending on alternative selected.	No	No	No	TBD	No	TBD	TBD	No
SV-2	Calaveras Dam Replacement	Increased maintenance; Calaveras Reservoir would be operated to release up to 6,300 afy (5.5 mgd) of water to Alameda Creek for fish flow enhancement. Instrumentation calibrated at least annually or at manufacturer-recommended intervals; all valves cleaned every 6 months; packing or seals should be checked for undue leakage every 6 months.	No	No	No, O&M activities are required for existing dam and would be the same for new dam.	No	No	Dam will not reduce historic discharges since storage would be restored to DSOD-approved levels. The 1997 MOU with California Dept. of Fish & Game requires releases of up to 6,300 AF/year. It is expected a new MOU will be negotiated during the permitting phase.	Negligible.	No
SV-3	Additional 40-mgd Treated Water Supply	25% increase in maintenance activities.	Increased use of treatment chemicals.	400W metal halide cobra lighting fixtures mounted on 30' poles to provide general illumination.	No, same as existing (3 staff per shift, 3 shifts per day).	No, except possibly small pumps for chemical feed.	25% increase in chemical deliveries.	Drainage piping system is proposed to direct surface flows.	Likely increased need for power, but limited since it would be a largely gravity-driven operation.	No, but standby power for SVWTP would likely provide power for project as well.
SV-4	New Irvington Tunnel	NA	NA	NA	NA	NA	NA	NA	NA	NA
SV-5	SVWTP - Treated Water Reservoirs	No	Increased use of sodium hypochlorite and ammonia. Diesel for standby power facilities.	400W metal halide cobra lighting fixtures mounted on 30' poles to provide general illumination; about 11 light standards.	No, same as existing (3 shifts/day).	Yes for filter backwashing, chemical feed, etc.	Additional chemical deliveries of sodium hypochlorite and ammonia.	Possible maintenance discharges.	Yes, power would be provided through an expansion of the existing SVWTP electrical substation.	Yes
SV-6	San Antonio Backup Pipeline	Second pipeline would allow discharge of dechlorinated water to San Antonio	No	No	No	No	No	Improved discharge of Hetch Hetchy water, minimizing environmental impacts.	No	No

TABLE C.2 (Continued)
SFPUC WSIP PROJECT INFORMATION – PROJECT FACILITIES OPERATIONS[1]

Project Number	Project Name	Operational Changes	Change in chemical use?	New Lighting?	Change in Number of Employees	Any New Pumps?	Change in Truck Deliveries?	Permanent Change in Drainage/ Discharges?	Change in Power Demand	Emergency Generator/ Standby Power Required?
SV-6 (cont.)	San Antonio Backup Pipeline (cont.)	Creek during emergency outages. Pipeline would serve as a water supply alternative if existing SAPL is out of service due to maintenance or emergency reasons.								
BD-1	Bay Division Pipeline Reliability Upgrade	Would increase system capacity to meet 2030 demands, improve drought delivery through increased replenishment of Peninsula reservoirs, and allow more frequent maintenance of aged existing BDPLs than is now possible. Following construction of the project, the above ground and submarine sections of BDPL Nos. 1 and 2 from Newark Valve House to Ravenswood Valve House would be decommissioned (decommissioning not part of this project). BDPL No. 1 last reach between Edgewood Valve Lot and Pulgas Valve Lot would be removed.	Propane or batteries for standby power generators.	Yes	NA	Yes	NA	Yes, new treated water discharge to San Francisco Bay would be located at Ravenswood Valve Lot for draining the Bay Tunnel. Draining the Bay Tunnel for maintenance is expected to occur once every 20 years. Additional discharge points would be added to the pipeline reach between Edgewood Road and Pulgas Tunnel.	Yes	Yes

TABLE C.2 (Continued)
SFPUC WSIP PROJECT INFORMATION – PROJECT FACILITIES OPERATIONS[1]

Project Number	Project Name	Operational Changes	Change in chemical use?	New Lighting?	Change in Number of Employees	Any New Pumps?	Change in Truck Deliveries?	Permanent Change in Drainage/ Discharges?	Change in Power Demand	Emergency Generator/ Standby Power Required?
BD-2	BDPL Nos 3 & 4 Crossovers	Reduces the length of pipe out of service at any one time, reduces impact of maintenance or unplanned outages of BDPLs 3 or 4 on system flows. Could allow more frequent maintenance than is now possible.	Propane or diesel for standby power generator.	Yes	No	Yes	No	Yes, treated water would be discharged to creeks for maintenance (every 5 to 10 years, or in an emergency).	Yes	Yes
BD-3	Seismic Upgrade Of BDPLs Nos. 3 and 4 at Hayward Fault	Improves seismic resistance of BDPLs 3&4 across the Hayward Fault.	No	No	No	No	No	No	No	No
PN-1	Baden and San Pedro Valve Lots Improvements	Operation of new PRV at Baden Valve Lot would occur during emergencies only but would be run for maintenance purposes approximately 2 times per year.	Propane for standby power generator.	No	No	No	No	No	No	Baden has two existing standby backup generators and a 10,000-gallon diesel tank on site. New standby generator is required.
PN-2	Crystal Springs/ San Andreas Transmission Upgrade	Increased operations and maintenance due to increased pumping/ transmission capacity.	No	TBD	No	Yes, pump station capacity upgrades.	No	TBD	Yes	No new sources
PN-3	HTWTP Long-Term Improvements	Potential increase in operations and maintenance due to increased sustainable treatment capacity.	Yes, potential increased use of treatment chemicals.	TBD	Increased staffing	Yes, raw water pump station upgrades.	Increased chemical deliveries.	TBD	Yes	TBD
PN-4	Lower Crystal Springs Dam Improvements	Yes, historic storage capacity restored.	No	No	No	No	No	Improvement would allow restoration of historic storage capacity and would continue to allow safe passage of PMF to San Mateo Creek.	No	TBD

SFPUC WSIP PROJECT INFORMATION – PROJECT FACILITIES OPERATIONS[1]

Project Number	Project Name	Operational Changes	Change in chemical use?	New Lighting?	Change in Number of Employees	Any New Pumps?	Change in Truck Deliveries?	Permanent Change in Drainage/ Discharges?	Change in Power Demand	Emergency Generator/ Standby Power Required?
PN-5	Pulgas Balancing Reservoir Rehabilitation	No	No	No	No	No	No	TBD	No	No
SF-1	San Andreas Pipeline No. 3 Installation	No	No	No	No	No	No	No	Yes	No
SF-2	Groundwater Projects - Local	Increased chlorination or chloramination supplies, operation inspections, lubrication, calibration of monitoring equipment.	Increased chlorination or chloramination supplies. Diesel for standby power facilities.	Possible security lighting	1 person, 1 hour every day or two on average	Yes	Increased chemical deliveries.	SFPUC system water, treated stormwater, or recycled water would be added to Lake Merced to augment lake levels.	Yes	Yes, emergency generator or capability to be operated with portable emergency generator.
SF-2	Groundwater Projects – Regional	Increased chlorination or chloramination supplies during drought years only, operation inspections, lubrication, calibration of monitoring equipment.	Increased chlorination or chloramination supplies during drought years only. Diesel for standby power facilities.	Possible security lighting	1 person, 1 hour every day or two on average	Yes	Increased chemical deliveries during drought years.	No	Yes, during drought years and periodic testing.	Yes, emergency generator or capability to be operated with portable emergency generator.
SF-3	Recycled Water Projects	Increased deliveries & maintenance	Increased use of treatment chemicals. Diesel for standby power facilities.	Yes	Up to 6	Yes	Increased chemical deliveries.	Yes (reduced wastewater discharges)	Yes	Yes

[1] Project information presented in this table is preliminary and subject to change as project designs are developed.

TABLE C.3
SFPUC WSIP PROJECT INFORMATION – PROJECT FACILITY LOCATIONS[1]

Project Number	Project Name	Preferred Location	Affected Counties	Affected Cities	Major Access Roads	Nearby Waterways	Alternative Locations
SJ-1	Advanced Disinfection	Tesla Portal	San Joaquin	None	I-580, Chrisman Rd, Vernalis Road, Existing Access Road	A small vegetated swale on-site	None
SJ-2	Lawrence Livermore Supply Improvements	Thomas Shaft, which is off Corral Hollow Road.	San Joaquin	None	I-580, Corral Hollow Rd, dirt access road	Adjacent to drainage swale (determined to be wetlands by Corps) at Thomas Shaft site.	None
SJ-3	San Joaquin Pipeline System	6.4-mile new pipeline starting at Oakdale Portal; two crossovers, one about 20 miles east of Modesto and the other about 15 miles west of Modesto; 10-mile fourth pipeline at west end of pipelines, ending at Tesla Portal.	San Joaquin, Stanislaus, and Tuolumne	None	Access is available, however, in some areas, access would need to be negotiated with the local landowners.	Crosses Delta Mendota Aqueduct and California Aqueduct Alt 5 (16.3 miles on western end crosses San Joaquin River)	Alt 1 & 2: Full length pipelines from Oakdale Portal to Tesla Portal within existing ROW. Alt. 3: New 60-inch pipeline from Oakdale Portal to Tesla Portal with 8,000-horsepower pump station. Alt 4: described as preferred location; Alt. 5: New 16.3 mile pipeline ending at Tesla Portal, two crossovers, replacement of 6.4 miles of PCCP. All alternatives would include upgrade of existing Roselle crossover station.
SJ-4	Rehabilitation of Existing San Joaquin Pipelines	Across Central Valley from Oakdale Portal to Tesla Portal	San Joaquin, Stanislaus, and Tuolumne	Riverbank, Modesto	SFPUC has access rights to the SJPL right-of-way	Existing pipelines cross under the San Joaquin River, Delta Mendota Aqueduct, and California Aqueduct	None
SJ-5	Tesla Portal Disinfection Station	Tesla Portal	San Joaquin	None	I-580, Chrisman Rd, Vernalis Rd, Existing Access Rd	A small vegetated swale on-site	None
SV-1	Alameda Creek Fishery Enhancement	Alameda Creek in Alameda County.	Alameda	None	Calaveras Road	Alameda Creek	Structural and non-structural recovery alternatives under consideration and other alternative designs for this project could be developed.
SV-2	Calaveras Dam Replacement	Immediately downstream of Calaveras Dam.	Alameda and Santa Clara	None	I-680, Highway 84, Calaveras Rd	Calaveras, Arroyo Hondo, Alameda, San Antonio Creeks	None
SV-3	Additional 40-mgd Treated Water Supply	Sunol Valley Water Treatment Plant (SVWTP)	Alameda	None	I-680, Calaveras Rd	Alameda Creek	Sunol Valley

TABLE C.3 (Continued)
SFPUC WSIP PROJECT INFORMATION – PROJECT FACILITY LOCATIONS[1]

Project Number	Project Name	Preferred Location	Affected Counties	Affected Cities	Major Access Roads	Nearby Waterways	Alternative Locations
SV-4	New Irvington Tunnel	New east tunnel portal would be about 75 feet south of Alameda West Portal. New west tunnel portal would be about 175 feet south of existing Irvington Portal.	Alameda	Fremont	I-680, Calaveras Rd	Alameda Creek, Mission Creek (tunnel-no impact), Pirate Creek (tunnel-no impact), unnamed (0.25 mi. west of Mission Blvd, Fremont), and unnamed seasonal drainage (ROW crossing at Calaveras Road).	New 120-inch diameter pipe from Alameda East Portal to a new tunnel portal near SVWTP. From the portal, a new 132-inch diameter tunnel would extend west and terminate in Fremont. Also considering alternate locations for the new Alameda West and Irvington Portals, within a few hundred feet of the existing and proposed portals (similar tunnel location).
SV-5	SVWTP –Treated Water Reservoirs	Site is within boundary of existing SVWTP.	Alameda	None	I-680, Calaveras Rd	Alameda Creek	None
SV-6	San Antonio Backup Pipeline	Pipeline would extend between San Antonio Reservoir and San Antonio Pump Station.	Alameda	None	I-680, Highway 84, Calaveras Rd	Calaveras, Arroyo Hondo, Alameda, San Antonio Creeks	None
BD-1	Bay Division Pipeline Reliability Upgrade	The new pipeline would be located within the existing easement for the BDPL Nos. 1 and 2, which extends approximately 21 miles from Irvington Tunnel Portal in Fremont to Pulgas Tunnel Portal near Redwood City. The 5-mile long tunnel portion extends from Newark to East Palo Alto, running beneath San Francisco Bay and surrounding marshlands. A sub-surface easement would be required for this portion.	Alameda and San Mateo	Newark, Fremont, East Palo Alto, Menlo Park, Redwood City	There are many regional and local roads that traverse the pipeline alignment including the I-680, I-880, and Highway 101 freeways; Highway 84, Edgewood Road on the Peninsula; Mission Boulevard (2 crossings; Highway 238), Washington Boulevard, Paseo Padre Parkway, Durham Road, Grimmer Boulevard, Warren Avenue, Dixon Road, and Scott Creek Road in Fremont.	Crosses San Francisco Bay, Newark/Unnamed Sloughs, and could affect the following creeks: Agua Caliente (Fremont), Cordilleras Creek (Redwood City), Mission Creek (Fremont), Ojo de Agua Creek (Redwood City), six unnamed creeks (at Alameda de las Pulgas in Redwood City, Boone Drive in Fremont, Highway 84 in Redwood City, Marsh Drive in Menlo Park, Moores Avenue in Newark, N. of Farwell Drive in Fremont), and an unnamed drainage at Marsh Road in Newark.	Alternative locations may include a southern or northern alignment adjacent to BDPL Nos. 3 and 4.

TABLE C.3 (Continued)
SFPUC WSIP PROJECT INFORMATION – PROJECT FACILITY LOCATIONS[1]

Project Number	Project Name	Preferred Location	Affected Counties	Affected Cities	Major Access Roads	Nearby Waterways	Alternative Locations
BD-2	BDPL Nos. 3 and 4 Crossovers	Preferred locations and sites include: (1) Guadalupe River – Site B; (2) Barron Creek – Site C; and (3) Bear Gulch Reservoir – Site C.	Santa Clara and San Mateo	San Jose, Santa Clara, Palo Alto, and Atherton	Not Specified	Barron Creek (Santa Clara County, City of Palo Alto), Bear Gulch Reservoir (San Mateo County, Town of Atherton), Guadalupe Creek (Santa Clara County, cities of San Jose and Santa Clara).	Could be located in the vicinity of the following creeks: Adobe Creek (Santa Clara County, cities of Los Altos and Palo Alto), Calabazas Creek (Santa Clara County, cities of Santa Clara and Sunnyvale), Coyote Creek (Santa Clara County, cities of Milpitas and San Jose), Hamlin Court (Santa Clara County, City of Sunnyvale), Matadero Creek (Santa Clara County, City of Palo Alto), Ojo de Agua Creek (San Mateo County, City of Redwood City), Permanente Creek (Santa Clara County, City of Woodside), Redwood Creek (San Mateo Creek, City of Woodside), Saratoga Creek (Santa Clara County, City of Santa Clara), and Stevens Creek (Santa Clara County, City of Mountain View).
BD-3	Seismic Upgrade of BDPL Nos. 3 and 4 at Hayward Fault	Spans the I-680/Mission Boulevard interchange between Tissiack Place, Cayuga Place, and Indian Hills Road on the north side and Crawford Street on the south side	Alameda	Fremont	I-680 and Mission Blvd	Aqua Fria Creek	None
PN-1	Baden and San Pedro Valve Lots Improvements	Baden: W. Orange Ave at El Camino Real in South San Francisco; San Pedro: San Pedro Road and Junipero Serra Boulevard in Daly City; Pulgas Pump Station: Cañada Road between Highway 92 and Edgewood Road. Pulgas Valve Lot: Edgewood Road near I-280.	San Mateo	Baden: South San Francisco; San Pedro: Daly City	Baden: El Camino Real (Highway 82), West Orange Ave in South San Francisco; San Pedro: I-280, Junipero Serra Blvd, San Pedro Rd in Daly City. Pulgas Pump Station off of Canada Road. Pulgas Valve Lot off of Edgewood Road.	Baden Valve Lot: Colma Creek (South San Francisco); Pulgas Pump Station: San Andreas Creek, Crystal Springs Reservoir, and unnamed blue-lined tributary to Crystal Springs Reservoir (Unincorporated San Mateo County); Pulgas Valve Lot: Cordilleras Creek (Unincorporated San Mateo County, City of San Carlos).	None

TABLE C.3 (Continued)
SFPUC WSIP PROJECT INFORMATION – PROJECT FACILITY LOCATIONS[1]

Project Number	Project Name	Preferred Location	Affected Counties	Affected Cities	Major Access Roads	Nearby Waterways	Alternative Locations
PN-2	Crystal Springs/San Andreas Transmission Upgrade	Proposed improvements would be located at: the Upper Crystal Springs (C.S.) Dam culverts (under Hwy 92); C.S. Outlet Tower Nos. 1 & 2 and C.S. Pump Station (west of I-280 near Skyline Blvd/Crystal Springs Rd intersection); Crystal Springs-San Andreas (S.A.) Pipeline, S.A. Inlet Structure, S.A. Outlet Towers Nos. 2 & 3 (west of I-280, generally between Millbrae Ave. and Crystal Springs Rd.), HTWTP (east of I-280 and south of Crystal Springs Rd.).	San Mateo	Pump Station Facility near Hillsborough. San Andreas PL traverses San Mateo County adjacent to Hillsborough, Burlingame, and Millbrae. Adits in San Andreas Reservoir adjacent to Millbrae	I-280 freeway, Skyline Blvd (Hwy 35), Crystal Springs Rd, Polhemus Rd, Hwy 92, SFPUC watershed, pump station, and HTWTP access roads.	San Mateo Creek, Upper and Lower Crystal Springs Reservoir, San Andreas Reservoir	NA
PN-3	HTWTP Long-Term Improvements	HTWTP is located south of Crystal Springs Road.	San Mateo	Adjacent to San Bruno and Millbrae	I-280 freeway, Crystal Springs Rd	San Andreas Reservoir	No long-term alternatives developed yet.
PN-4	Lower Crystal Springs Dam Improvements	Dam is located west of I-280 freeway and Skyline Blvd., and south of Crystal Springs Rd.	San Mateo	None	I-280 freeway, Skyline Blvd, Crystal Springs Rd	San Mateo Creek, Lower Crystal Springs Reservoir	NA
PN-5	Pulgas Balancing Reservoir Rehabilitation	Located on the east side of Cañada Road, southeast of the Pulgas Water Temple.	San Mateo	None	I-280 freeway, Cañada Rd	Pulgas Channel, Upper Crystal Springs Reservoir	NA
SF-1	San Andreas Pipeline No. 3 Installation	This pipeline would extend from San Pedro Valve Lot in Daly City (San Pedro Road at Junipero Serra Blvd) to Merced Manor Reservoir in San Francisco (at Ocean Avenue and 22nd Avenue).	San Francisco and San Mateo	San Francisco, Daly City	Highway 280, Junipero Serra Blvd, 19th Avenue, Brotherhood Way, and Ocean Avenue.	None	NA
SF-2	Groundwater Projects – Local	Lake Merced Pump Station, South Sunset Playground (40th/Wawona), West Sunset Playground (41st/Quintara), Golden Gate Park (Lincoln/42nd), or alternative locations, North Lake (north side of North Lake in Golden Gate Park,	San Francisco	San Francisco	Great Highway, 19th Avenue, Sunset Blvd	Lake Merced and Pine Lake are within 1,000 feet of two of the projects	The 1997 SFPUC Groundwater Master Plan EIR evaluated various groundwater production alternatives & recommended a group of projects very similar to those proposed in the WSIP Local Groundwater Project.

TABLE C.3 (Continued)
SFPUC WSIP PROJECT INFORMATION – PROJECT FACILITY LOCATIONS[1]

Project Number	Project Name	Preferred Location	Affected Counties	Affected Cities	Major Access Roads	Nearby Waterways	Alternative Locations
SF-2 (cont.)	Groundwater Projects – Local (cont.)	near 43rd/Fulton intersection), SF Zoo, Central Pump Station, Pine Lake (Stern Grove), other Golden Gate Park locations.					
	Groundwater Projects – Regional	Up to 10 sites within the Westside Groundwater Basin, cities of Daly City and San Bruno and the service area for the California Water Service Company's South San Francisco Service Area (including South San Francisco, Colma and unincorporated areas of northern San Mateo County). Wells could possibly be located in the cities of San Francisco, Burlingame, or Millbrae	San Mateo	Daly City, San Bruno, San Francisco, Burlingame, Millbrae, South San Francisco, Colma and unincorporated areas of northern San Mateo County.	TBD	Colma Creek	Alternative Analysis Report will be conducted in FY 06/07.
SF-3	Recycled Water Projects	Treatment site location is currently TBD; options include the OWPCP, SF Zoo overflow parking lot, the site of the old Richmond-Sunset Treatment Plant, and the site of the old McQueen Plan. Treated water storage will be provided at the treatment site, and also off-site; off-site locations include new storage in Lincoln Park (golf course), and the conversion of existing storage in Golden Gate Park Pipeline alignments within City streets.	San Francisco	San Francisco	Sloat Blvd, Highway 1, Great Highway	Pacific Ocean, lakes in Golden Gate Park, Lake Merced	Treatment: Previous location of the Richmond-Sunset Treatment Plant (now used as a staging area for Rec & Park) and within Oceanside facility. Storage: not yet identified.

[1] Project information presented in this table is preliminary and subject to change as project designs are developed.

TABLE C.4
SFPUC WSIP PROJECT INFORMATION – PROJECT FACILITY CONSTRUCTION[1]

Project Number	Project Name	Preliminary Construction Schedule	Construction Duration (years)	Construction Area (acres)	Excavation/ Spoils Volume (cubic yards)	Concrete Material (cubic yards)	Demolition Required	Dewatering Required	Temporary Construction Access Routes	Number of Crews	Construction Hours	Construction Rate
SJ-1	Advanced Disinfection	2009-2010	1 to 2	2	TBD	TBD	No	TBD	I-580, Chrisman Rd, Vernalis Rd, Existing Access Rd	TBD	TBD	NA
SJ-2	Lawrence Livermore Supply Improvements	2010-2011	1	TBD	TBD	TBD	No	No	I-580, Corral Hollow Rd, Dirt Access Rd	TBD	TBD	NA
SJ-3	San Joaquin Pipeline System	2011-2014	3	Most construction would occur within existing ROW (100-200 feet wide) with additional 200 feet temporary/ additional ROW possibly needed to the north of the SJPL ROW. Minimum Total Disturbance = 16.4 mi. x 50 feet = 100 acres. Maximum Total Disturbance = 16.4 mi. x 200 feet = 400 ac. (Note that this requirement would range from 140 to 575 acres for alternative 5.) Up to 11 temporary construction staging areas as big as 400 by 700 feet would be required (70 acres).	424,000	TBD	TBD	From San Joaquin River to Highway 33	Construction access available, but would need to be improved and negotiated with local landowners in some locations.	2 to 5 Crews, with maximum of 100 personnel total	TBD	NA
SJ-4	Rehabilitation of Existing San Joaquin Pipelines	2008-2014 The long-range rehabilitation program would not be developed until 2008. Most rehabilitation work would be conducted during the months of November through March. The 1st rehabilitation contract might start as early as 2008.	7 to 8	All work would be within the existing ROW	Rehabilitation spoils quantities cannot be estimated without the conditions assessment and subsequent determination of rehabilitation methods. Conservative estimate would be about 100,000 cubic yards.	None	TBD	Excavations within 4 miles west of the San Joaquin River and 10 miles east of the River most likely would require dewatering	Access to existing ROW exists through ROW agreements. No additional access agreements anticipated	TBD	TBD	NA
SJ-5	Tesla Portal Disinfection Station	2009-2011	1 to 2	2	TBD	TBD	TBD	TBD	I-580, Chrisman Rd, Vernalis Rd, Existing Access Rd	TBD	TBD	NA
	Sub-totals (Rounded)			**±104 to 650**	**±524,000**	**TBD**						
SV-1	Alameda Creek Fishery Enhancement	2011	1	TBD	TBD	TBD	NA	Not Specified	TBD	Not Specified	TBD	NA
SV-2	Calaveras Dam Replacement	2009-2011; flow release after 2011	2 to 3	666 (includes borrow areas)	6,300,000 cy total excavation and 4,000,000 cy spoil	60,000	Yes, existing cofferdam, chemical treatment building and valve vaults, existing spillway, and portions of the outlet tower.	Yes	Calaveras Road	2 to 3 Crews, 25 people/ crew	TBD	NA
SV-3	Additional 40-mgd Treated Water Supply	2010-2013	2 to 3	1.5	100,000	2,000	No	Not Anticipated	Calaveras Rd	Avg. Crew Size: 40 Max. Crew Size: 80	TBD	NA
SV-4	New Irvington Tunnel	2009-2013	3 to 4	120 (additional area for staging could be required)	190,000	TBD	Yes, potential demolition of existing Irvington Portal structure.	Yes	If the spoils are trucked outside of Sunol Valley, project would construct/ improve new access roads between Alameda West Portal and Calaveras Rd, Spoil Area 1 and Calaveras Rd, permanent gravel	Avg. Crew Size: 60 Max. Crew size: 144	TBD	60 to 100 feet per day of tunnel advancement by boring machine drive

TABLE C.4 (Continued)
SFPUC WSIP PROJECT INFORMATION – PROJECT FACILITY CONSTRUCTION[1]

Project Number	Project Name	Preliminary Construction Schedule	Construction Duration (years)	Construction Area (acres)	Excavation/ Spoils Volume (cubic yards)	Concrete Material (cubic yards)	Demolition Required	Dewatering Required	Temporary Construction Access Routes	Number of Crews	Construction Hours	Construction Rate
SV-4 (cont.)	New Irvington Tunnel (cont.)								between existing and new overflow shafts in Sunol Valley, between existing Irvington Portal and Mission Blvd.			
SV-5	SVWTP –Treated Water Reservoirs	2008-2010	2	10.5	300,000	30,900	No	No	Calaveras Rd, Interstate 680	Avg. Crew Size: 40 Max. Crew Size: 80	TBD	NA
SV-6	San Antonio Backup Pipeline	2009-2011	2	TBD	51,000 cy total excavation and 37,000 cy spoil	TBD	No	TBD	Along access road to San Antonio Reservoir	TBD	TBD	TBD
	Sub-totals (Rounded)			**±800**	**±7 million**	**±92,900**						
BD-1	Bay Division Pipeline Reliability Upgrade	2009-2013	4	Construction and staging would occur within the ROW corridor, which varies in width between 40 and 80 feet. Estimated Total Disturbance = 165 to 175 ac. Note that the amount disturbed by the pipeline at any one time would be around 3 acres.	434,000	TBD	Portions of the section of BDPL No. 1 between Edgewood Valve Lot and Pulgas Valve Lot would be removed (approximately 1.4 miles). The above ground and submarine sections of BDPLs 1 and 2 would be decommissioned.	Yes at both tunnel shafts and some reaches of the pipeline.	Both the Newark and Ravenswood Shaft sites would be accessed by existing city streets and there are several alternatives for highway access. The pipeline would be accessed from the numerous local roads and state highways.	Pipeline: A minimum of 5 separate crews; 3 on the pipeline, 2 to 3 for the tunnel, and additional crews at the valve vaults and the street and rail crossings.	TBD	Tunnel: 50 to 80 feet/day for initial liner and 120 feet/day for final liner. Pipeline: 120 to 160 feet per day average, up to 300 feet per day maximum if installing in open fields without obstruction.
	Bay Tunnel Segment	2009-2013	4	3.5 to 9 acres	260,000 to 355,000							
BD-2	BDPL Nos. 3 & 4 Crossovers	2010-2012	2	TBD but minimum 0.4 ac. at each site	43,500	TBD	May have to go through levee at Guadalupe site for outfall.	Discharge of treated water to creeks or exist. storm drains during construction.	Not Specified. Likely routes: Lick Mill Rd (Guadalupe River site), Foothill Expressway-Veterans Administration Medical Center-Gunn High School (Barron Creek), and Reservoir Rd-Alameda de Las Pulgas (Bear Gulch site).	TBD	TBD	TBD
BD-3	Seismic Upgrade of BDPLs Nos. 3 and 4 at Hayward Fault	2010-2012	1 to 2	TBD	Phase B – 55,300	TBD	No	Possible	Construction access to pipeline route would almost always be through the closest roads that intersect the ROW.	TBD	TBD	NA
	Sub-totals (Rounded)			**±170 to 180**	**±800,000 to 900,000**	**TBD**						
PN-1	Baden and San Pedro Valve Lots Improvements	2009-2011	2	Approx. 2 ac.	Baden Valve Lot: 4,000; San Pedro Valve Lot: 700; Pulgas Pump Station: TBD; Pulgas Tunnel Gate Shaft: 270; Pulgas Tunnel Air Shaft: TBD.	TBD	Yes, removal of existing vaults, shed, existing pipeline segment, roof above pump station.	Yes	Baden Valve Lot: El Camino Real (Highway 82), West Orange Ave in South San Francisco; San Pedro Valve Lot: Junipero Serra Blvd and San Pedro Rd in Daly City; Pulgas Pump Station off of Canada Road in San Mateo County; Pulgas Valve Lot off of Edgewood Road in San Mateo County.	TBD	TBD	NA
PN-2	Crystal Springs/ San Andreas Transmission Upgrade	2011-2013	2 to 3	TBD	Not Specified (estimated to be up to 9,000 cy)	TBD	Crystal Springs Pump Station (if not upgraded)	Project has discharge valve that empties into San Mateo Creek; discharge valve would be replaced and/or re-anchored. Outlet structures and the adits within them at both Lower Crystal Springs and San Andreas Reservoirs,	I-280 freeway, Skyline Blvd. (HWY 35), Crystal Springs Road, Polhemus Road, Hwy 92, SFPUC watershed, pump station, and HTWTP access roads	TBD	TBD	NA

TABLE C.4 (Continued)
SFPUC WSIP PROJECT INFORMATION – PROJECT FACILITY CONSTRUCTION[1]

Project Number	Project Name	Preliminary Construction Schedule	Construction Duration (years)	Construction Area (acres)	Excavation/ Spoils Volume (cubic yards)	Concrete Material (cubic yards)	Demolition Required	Dewatering Required	Temporary Construction Access Routes	Number of Crews	Construction Hours	Construction Rate
PN-2 (cont.)	Crystal Springs/ San Andreas Transmission Upgrade (cont.)							are the upstream inlets to the aforementioned valves. There would be structural and mechanical work on these structures to harden them. This may require coffer dams and other dewatering measures.				
PN-3	HTWTP Long-Term Improvements	2011 to 2013	2 to 3	TBD	Not Specified	Not Specified	Not Specified	Not Specified	I-280 freeway, Crystal Springs Road	Not Specified	TBD	NA
PN-4	Lower Crystal Springs Dam Improvements	2010-2011	1	6	21,000	TBD	Yes, modification of spillway, parapet wall, and stilling basin	TBD	I-280 freeway, Skyline Blvd, Crystal Springs Road	TBD	TBD	NA
PN-5	Pulgas Balancing Reservoir Rehabilitation	2010-2013	3	TBD	TBD	TBD	TBD	TBD	I-280 freeway, Cañada Road	TBD	TBD	NA
	Sub-totals (Rounded)			**±8**	**±35,000**	**TBD**						
SF-1	San Andreas Pipeline No. 3 Installation	2009-2010	2	23	44,170	3,200	Yes, removal of certain portions of existing BMPL	Yes	City streets along pipeline alignment.	2 crews, 8 to 10 people/crew	TBD	60 to 200 feet/day
SF-2	Groundwater Projects – Local	2009 to 2012	San Francisco: 3 (intermittent)	0.04/site (0.7 ac. for 18 sites) + pipeline alignments	TBD	TBD	TBD	No	TBD	TBD	TBD	Not Specified
	Groundwater Projects – Regional	2010 to 2014	Regional: 4		TBD	TBD	TBD	No	TBD	TBD	TBD	Not Specified
SF-3	Recycled Water Projects	2010 to 2012	2 yrs for treatment facility; longer for pipelines	5 to 7	47,200	10,800	TBD	Yes	Sloat Blvd, potential Highway 1 entrance. Possible haul routes: Highway 1, Skyline Blvd, Lake Merced Blvd, John Muir Dr, Brotherhood Way, I-280.	2 to 4 crews, 10 to 35 people/crew	TBD	Not Specified
	Sub-totals (Rounded)			**±29 to 31**	**±91,400**	**±14,000**						

[1] Project information presented in this table is preliminary and subject to change as project designs are developed.

TABLE C.5
SFPUC WSIP PROJECT INFORMATION – AFFECTED ROADS/RAILROADS AND CONSTRUCTION TRAFFIC

Project Number	Project Name	Temporary Construction Access Roads	In-Road (parallel to or within ROW)	Freeway Crossing	Major Road Crossings	Minor Road Crossings	Railroad Crossings	Daily Truck Trips	Ave./Max. Worker Daily Trips
SJ-1	Advanced Disinfection	I-580, Chrisman Road, Vernalis Road, Existing Access Road	No	None	No	No	No	TBD	TBD
SJ-2	Lawrence Livermore Supply Improvements	I-580, Corral Hollow Road, Dirt Access Road	No	None	No	No	No	TBD	TBD
SJ-3	San Joaquin Pipeline System	Construction access available, but would need to be negotiated with local landowners in some locations.	Yes	4 Crossings: Hwy 99, I-5, I-580 freeways, Highways 33	21 Crossings: Wilms, Rd., Wamble Rd (twice), River Rd, McCracken Rd, Welty Rd, Koster Rd, Bird Rd, Chrisman Rd, Bernard Rd, W. Vernalis Rd, Fogarty Rd, Emery Rd, Roselle Ave, Blewitt Rd, Koster Rd, The following road crossings would be used as well in addition to the above list if Alt 5 is selected: Blue Gum Ave, Dunn Rd, Gates Rd, Maze Blvd, Pelican Rd, Orchard Rd.	33	2 Crossings	Pipe Delivery: 4 trips/day (ave); haul truck volumes not specified.	
SJ-4	Rehabilitation of Existing San Joaquin Pipelines	None expected	The existing ROW would be used for accessing pipeline sites from nearby local public and private roads.	Existing pipelines cross under I-580 and I-5 freeways. Improvements for these under crossings are not anticipated.	Existing pipelines cross under Rte 33, Rte 132, Rte 99; Rte 108 (McHenry Ave); Standiford Ave near MP 74.8; Prescott Rd near MP 75.1; Sisk Rd near MP 76.2. It is not known at this time if any improvements would be required at these under crossings	The existing pipelines cross under 14 minor roads. It is not known at this time if any of these under crossings would require improvements.	Existing pipelines cross under: Sierra Railroad near MP 57.7; Union Pacific near MP 64; Burlinton Northern Santa Fe near MP 69.3; Union Pacific near MP 73.5; Union Pacific near MP 76.4; Union Pacific near MP 89.5. It is not known at this time if any improvements would be required under crossings.	TBD	TBD
SJ-5	Tesla Portal Disinfection Station	I-580, Chrisman Road, Vernalis Road, Existing Access Road	No	None	No	No	No	15 (average) - 40 (maximum) truck trips/day & up to 4 trips/day	25
SV-1	Alameda Creek Fishery Enhancement	Calaveras Road and possibly Highway 84	No	No	No	No	No	Not Specified	Not Specified
SV-2	Calaveras Dam Replacement	Calaveras Road	TBD	No	No	No	No	88 daily 9 peak hour	240 daily (Up to 400)
SV-3	Additional 40-mgd Treated Water Supply	Calaveras Road	No	No	No	No	No	64 daily 8 peak hour	80 daily
SV-4	New Irvington Tunnel	Construct/improve new access roads between Alameda West Portal and Calaveras Rd, Spoil Area 1 and Calaveras Rd, permanent gravel between existing and new overflow shafts in Sunol Valley, between existing Irvington Portal and Mission Blvd.	No	No	No	No	No	290 daily 36 peak hour	288 daily
SV-5	SVWTP - Treated Water Reservoirs	Calaveras Road	TBD	No	No	No	No	80 daily 10 peak hour	80 daily
SV-6	San Antonio Backup Pipeline	Access road to San Antonio Reservoir and Calaveras Road	San Antonio Reservoir Access Road/Calaveras Road	No	No	Calaveras Road	No	80 daily10 peak hour	80 daily
BD-1	Bay Division Pipeline Reliability Upgrade	Both the Newark and Ravenswood Shaft sites would be accessed by existing city streets and there are several alternatives for highway access. The pipeline would be accessed from the numerous local roads and state highways.	Ivy Drive, Bay Road, Avenue Del Ora, Bennett Road.	Pipeline, 3 crossings: the I-680, I-880, and Highway 101 freeways	20 to 25 major road crossings including: Edgewood Road Woodside Road El Camino Real Middlefield Road Marsh Road Willow Road University Avenue Central Avenue Mowry Avenue	Numerous	7, including 4 active	Pipe Delivery: 8 trips/day (ave); disposal volumes approximately 8 loads per day, 16 one-way trips. Tunnel: If onsite disposal is not available, then 120-160 trips/day to haul muck offsite If concrete rings would be manufactured offsite, then 15 trips/day to transport concrete rings to jobsite.	Pipeline Average: 20 workers per pipe crew, 20 per vault crew, 10 per crossing crew. Tunnel: 25 to 38 workers

TABLE C.5 (Continued)
SFPUC WSIP PROJECT INFORMATION – AFFECTED ROADS/RAILROADS AND CONSTRUCTION TRAFFIC

Project Number	Project Name	Temporary Construction Access Roads	In-Road (parallel to or within ROW)	Freeway Crossing	Major Road Crossings	Minor Road Crossings	Railroad Crossings	Daily Truck Trips	Ave./Max. Worker Daily Trips
BD-1 (cont.)	Bay Division Pipeline Reliability Upgrade (cont.)				Stevenson Blvd. Grimmer Blvd. Fremont Blvd. Paseo Padre Parkway Driscoll Road Mission Blvd.			Should Contractor elect to install an on site concrete batch plant then bulk transport of sand, aggregate, cement would occur periodically throughout the tunnel construction period. For drive and receiving shafts, 9 to 13 truck trips per day, intermittently over several months	
BD-2	BDPL Nos 3 & 4 Crossovers	Not Specified. Likely routes: Lick Mill Rd. (Guadalupe River site), Foothill Expressway-Veterans Administration Medical Center-Gunn High School (Barron Creek), and Reservoir Road-Alameda de Las Pulgas (Bear Gulch site).	No	No	No	No	No	TBD	TBD
BD-3	Seismic Upgrade of BDPLs Nos. 3 and 4 at Hayward Fault	Not specified, but I-680 and Mission Blvd. are adjacent to site.	Yes	I-680 (jack and bore)	I-680 and Mission Blvd.	Not Specified	No	Not Specified	Not Specified
PN-1	Baden and San Pedro Valve Lots Improvements	Baden: El Camino Real (Highway 82), West Orange Avenue in South San Francisco; San Pedro: Junipero Serra Blvd., San Pedro Rd. in Daly City; Pulgas Pump Station off of Canada Road; Pulgas Valve Lot off of Edgewood Road.	No	No	No	No	No	Baden: 2 to 4 peak hour truck trips; San Pedro: 25 peak hour trips; Pulgas Valve Lot and Pulgas Pump Station: 25 peak hour trips	Not Specified
PN-2	Crystal Springs/San Andreas Transmission Upgrade	I-280 freeway, SFPUC watershed and pump station roads	No	I-280 (S.A. Outlet Tower Nos. 2 & 3)	Hwy 92 (Upper C.S. Dam culverts)	No	No	Not Specified	Not Specified

NOTES: ACOE = U.S. Army Corps of Engineers; BAAQMD = Bay Area Air Quality Management District; BCDC = San Francisco Bay Conservation and Development Commission; Caltrans = California Department of Fish and GameTransportation; CDFG = California Department of Fish and Game; CUPA = Certified Unified Program Agency; DHS = California Department of Health Services; DWR = California Department of Water Resources; EC = Early Coordination Requested; (FWCA = Fish and Wildlife Coordination Act); GGNRA = Golden Gate National Recreation Area; MOA = Memorandum of Agreement; NMFS = U.S. National Marine Fisheries Service; (NWP = National Permit for Stream and Wetland Restoration Activities); RWQCB = Regional Water Quality Control Board; SHPO = State Historic Preservation Office; SWPPP = stormwater pollution prevention plan; SWRCB = State Water Resources Control Board; TBD = To Be Determined; TS = Thomas Shaft; USFWS = U.S. Fish and Wildlife Service.

h

a Additional approvals may be identified for WSIP facility projects when separate, project-level CEQA analysis is completed.

b The GGNRA requests consultation during project development and advance notification of meetings and would like to assist in creating mitigations for potential impacts from these projects.

c Section 6327 of the Public Resources Code provides that if a facility is for the "procurement of fresh-water from and construction of drainage facilities into navigable rivers, streams, lakes and bays," and if the applicant obtains a permit from the local reclamation district, State Reclamation Board, the U.S. Army Corps of Engineers, or the Department of Water Resources, then an application shall not be required by the State Lands Commission. Since the proposed program appears to fall within this section, a lease from the Commission would not be required, provided one of the above-listed permits is obtained.

d As part of project-level CEQA review, Caltrans requests that each facility improvement project be reviewed to determine if it encroaches on any state facilities. Any encroachment on Caltrans right-of-way would require an encroachment permit, and CEQA-related environmental studies may be necessary (including studies related to biological resources, cultural resources, and hazardous materials). A qualified professional must conduct these studies to satisfy Caltrans's environmental review policies. Ground-disturbing activities on the site prior to completing and/or approving the required environmental documents could affect Caltrans' ability to issue a permit for the project.

e The USFWS and the Coastal Conservancy are interested in acquiring clean dredge material generated by this project for use in wetland restoration associated with the South Bay Salt Pond Restoration Project, particularly within the Don Edwards San Francisco Bay National Wildlife Refuge (contact Clyde Morris, Manager, 510-792-0222, ext. 25). The USFWS recommends that the SFPUC coordinate with the USFWS's Division of Endangered Species at the Sacramento Fish and Wildlife Office (916-414-6600).

SF-3	Recycled Water Projects				Possible							

NOTE: EC = Early Coordination Requested

f As part of project-level CEQA review, the Alameda County Flood Control and Water Conservation District requests that each facility improvement project that includes pipelines be reviewed to determine if an encroachment permit is required where the pipelines cross the District's channels and creek inverts.

g The ACWD requests that the BD-1 project be coordinated with the ACWD earlier (during project planning and design phases, rather than during the construction phase) to minimize impacts associated with conflicting water facilities and potential impacts on the ACWD's ability to meet customer demands and fire flow requirements. In addition, all Sunol Valley projects (SV-1 through SV-6) will need to take into account potential effects of facility construction on downstream water intakes at ACWD's facilities in the flood control channel. The project-level CEQA review for the SV-2 project will need to consider coordination and notification related to Calaveras Reservoir release protocols that could affect downstream groundwater recharge and the potential for flooding.

h As part of project-level CEQA review, each facility improvement project in the Sunol Valley region should be reviewed to determine if it encroaches on EBRPD property. The EBRPD requests coordination of construction mitigation measures for certain WSIP projects in the Sunol Valley to minimize construction impacts on recreational uses and allow coordination of fire suppression planning and response (including review of traffic control plans). As part of the project-level EIR for SV-2, the EBRPD states that the SFPUC needs to coordinate the timing of water releases from Calaveras Dam to maximize benefits to amphibians and anadromous fish species.

i The City of Fremont requests consultation (regarding the applicability of encroachment permits, and development and review of traffic control plans) during the planning and design phases of the SV-2, BD-1, and BD-3 projects as well as any other WSIP project that could affect the Fremont transportation network.

j As part of the project-level CEQA review, mitigation measures should be developed to establish coordination and notification protocols between the SFPUC and the ACFCWCD regarding Calaveras Reservoir releases that could affect the potential for downstream flooding.

k The USFWS requests that the BD-1 project be coordinated with the Transit District's Dumbarton Rail Project to minimize habitat impacts for both projects.

l The Coastal Conservancy requests that the SFPUC coordinate with the Coastal Conservancy and Association of Bay Area Government's Bay Trail project (regarding completion of the Bay Trail gap through SFPUC lands).

m The City of Menlo Park requests coordination of construction mitigation measures for the BD-1 project to minimize construction impacts (e.g., access and parking) on local residents and businesses, including the Menlo Business Park.

n The City of Palo Alto requests early consultation on the BD-2 project.

o The Coastside CWD requests consultation during development of the adaptive management program for Crystal Springs Reservoir as part of the operations phase of the PN-4 project.

Biological Resources:
Special Status Species
in Alameda and
Peninsula Watersheds

APPENDIX D

Biological Resources: Special Status Species in Alameda and Peninsula Watersheds

TABLE III.E-3
SPECIAL-STATUS ANIMAL SPECIES
POTENTIALLY OCCURRING IN THE ALAMEDA WATERSHED

Common name *Scientific name*	**Listing Status USFWS/ CDFG**	**Habitat Requirements**	**Potential to Occur Within the Watershed**	**Period of Identification**
Invertebrates				
Opler's longhorn moth *Adella oplerella*	FSC/--	Serpentine grasslands	High Potential	Spring
Serpentine phalangid *Calcina serpentinea*	FSC/--	Serpentine rocks and barrens	High Potential	Fall-Winter
Bay checkerspot butterfly *Euphydryas editha bayensis*	FT/--	Serpentine grasslands	Moderate Potential	March-May
Ricksecker's water scavenger beetle *Hydrochara rickseckeri*	FSC/--	Found in freshwater ponds, shallow water of streams marshes and lakes	Moderate Potential	January-July
Curved-foot hygrotus diving beetle *Hygrotus curvipes*	FSC/--	Found in vernal pools and alkali flats	Moderate Potential	January-July
Unsilvered fritillary butterfly *Speyeria adiaste adiaste*	FSC/--	Found in native grasslands with *Viola penduculata* as larval food plant	Moderate Potential	Spring
Callipe silverspot butterfly *Speyeria callippe callippe*	FE/--	Found in native grasslands with *Viola peduculata* as larval food plant	Moderate Potential	Spring
Myrtle silverspot butterfly *Speyeria zerene myrtleae*	FE/--	Found in native grasslands with *Viola peduculata* as larval food plant	Moderate Potential	Spring
Amphibians				
California tiger salamander *Ambystoma californiense*	FC/CSC	Seasonal freshwater ponds with little or no emergent vegetation	High Potential	November-May
California red-legged frog *Rana aurora draytonii*	FT/CSC	Freshwater ponds and slow streams with emergent vegetation for egg attachment	High Potential	April-June
Foothill yellow-legged frog *Rana boylii*	FSC/CSC	Streams with quiet pools absent of predatory fish	High Potential	April-June
Western spadefoot toad *Scaphipus hammondii*	FSC/CSC	Floodplains and grassland pools	High Potential	February-August

TABLE III.E-3 (Continued)
SPECIAL-STATUS ANIMAL SPECIES
POTENTIALLY OCCURRING IN THE ALAMEDA WATERSHED

Common name *Scientific name*	**Listing Status USFWS/ CDFG**	**Habitat Requirements**	**Potential to Occur Within the Watershed**	**Period of Identification**
Reptiles				
Western pond turtle *Clemmys marmaorata*	FSC/CSC	Freshwater ponds and slow streams edged with sandy soils for laying eggs	High Potential	warm days
Southwestern pond turtle *Clemmys marmaorata pallida*	FSC/CSC	Freshwater ponds and slow streams edged with sandy soils for laying eggs	High Potential	warm days
Coastal western whiptail *Cnemidophorus tigris multiscutatus*	FSC/--	Dry open habitats	High Potential	all year
Alameda whipsnake *Masticophis lateralis euryxanthus*	FT/CT	South, southeast and southwest facing slopes of coastal scrub and chaparral	High Potential	warm days
Birds				
Cooper's hawk *Accipiter cooperi*	--/CSC	Nests in riparian growths of deciduous trees and live oaks	High Potential	March-July
Sharp-shinned hawk *Accipiter striatus*	--/CSC	Nests in riparian growths of deciduous trees and live oaks	High Potential	March-July
Western grebe *Aechmophorus occidentalis*	--/*	Quiet lakes with tules or rushes	Moderate Potential	March-May
Tricolored blackbird *Agelaius tricolor*	FSC/CSC	Riparian thickets and emergent vegetation	High Potential	Spring
Golden eagle *Aquila chrysaetos*	BPA/CSC	Nests in large trees, snags, and cliffs, winters on lakes and reservoirs	High Potential	Spring
Great blue heron *Ardea herodias*	--/*	Nests in trees along lakes and estuaries	High Potential	December-July
Short-eared owl *Asio flammeus (nesting)*	--/CSC	Nests in open grasslands	High Potential	March-June
Aleutian Canada goose *Branta canadensis leucopareia*	FT/--	Winters on lakes and inland prairie	High Potential	Winter
Ferruginous hawk *Buteo regalis (wintering)*	FSC/CSC	Winters in flat open grasslands	High Potential	Winter
Northern harrier *Circus cyaneus*	--/CSC	Nests and forages in wet meadows and pastures	High Potential	Year-round

California horned lark *Eremophila alpestris actia*	--/CSC	Open grasslands and irrigated pastures	High Potential	Year-round
Prairie falcon *Falco mexicanus*	--/CSC	Nests in snags and cliffs of arid climates	High Potential	Spring
Bald eagle[a] *Haliaeetus leucocephalus*	FT/CE	Nests and forages on inland lakes, reservoirs, and rivers	High Potential	Winter
Osprey *Pandion haliaetus*	--/CSC	Nests near fresh water lakes and large streams on large snags	Moderate Potential	March-June
American white pelican *Pelecanus erythrorhynchos*	--/CSC	Nests on protected islets near freshwater lakes for protection from predators	Moderate Potential	May-July
Burrowing owl *Speotyto (=Athene) cunicularia (burrow sites)*	FSC/CSC	Nests in mammal burrows in open, sloping grasslands	High Potential	February-June
Mammals				
Pallid bat *Antrozous pallidus*	FSC/CSC	Roosts in caves, old buildings and under bark. Forages in open lowland areas and forms large maternity colonies in spring	Moderate Potential	February-August
Western mastiff bat *Eumops perotis*	FSC/CSC	Open semi-arid to arid habitats roosting on high cliffs and buildings	Moderate Potential	February-August
Small-footed myotis *Myotis ciliolabrum*	FSC/--	Roosts in caves, old buildings and under bark	Moderate Potential	February-August
Fringed myotis *Myotis evotis*	FSC/--	Roosts in caves, old buildings and under bark, forms maternity colony in the spring	Moderate Potential	February-August
Fringed myotis *Myotis thysanodes*	FSC/--	Roosts in caves, old buildings and under bark, forms maternity colony in the spring	Moderate Potential	February-August
Long-legged myotis *Myotis volans*	FSC/--	Roosts in caves, old buildings and under bark; Forms maternity colony in the spring	Moderate Potential	February-August

TABLE III.E-3 (Continued)
SPECIAL-STATUS ANIMAL SPECIES
POTENTIALLY OCCURRING IN THE ALAMEDA WATERSHED

Common name *Scientific name*	**Listing Status USFWS/ CDFG**	**Habitat Requirements**	**Potential to Occur Within the Watershed**	**Period of Identification**
Mammals (cont.)				
Townsend's big-eared bat *Plecotus townsendii*	FSC/CSC	Roosts in caves, old buildings and under bark; Forages in open lowland areas and forms large maternity colonies in spring	Moderate Potential	February-August
American badger *Taxidea taxus*	--/*	Open grasslands with loose, friable soils	Moderate Potential	Year-round
San Joaquin kit fox *Vulpes macrotis mutica*	FE/CT	Annual grasslands or grassy open stages with scattered shrubby vegetation; Need loose-textured sandy soils for burrowing	Moderate Potential	February-October
Mountain Lion *Felis* spp.	--/4800	Rural grasslands and woodlands	High	Year-round

LISTING STATUS CODES:

U.S. Fish and Wildlife Service (USFWS)

FE = Listed as Endangered (in danger of extinction) by the federal government.
FT = Listed as Threatened (likely to become endangered within the foreseeable future) by the federal government.
FPE = Proposed for Listing as Endangered
FPT = Proposed for Listing as Threatened
FC = Candidate to become a *proposed* species.
FSC = Federal Species of Concern. May be endangered or threatened, but not enough biological information has been gathered to support listing at this time.
FC3c = Species removed from listing
BPA = Federal Bald Eagle Protection Act

California Department of Fish and Game (CDFG)

CE = Listed as Endangered by the State of California
CT = Listed as Threatened by the State of California
CR = Listed as Rare by the State of California (plants only)
CSC = California Species of Special Concern
* = Special Animals
3503.5 =Protection for nesting species of Falconiformes (hawks) and Strigiformes (owls)
3511 = A fully protected species as defined by the CDFG
4800 = Mountain lion protection

High Potential = Species expected to occur and meets all habitats as defined in list
Moderate Potential = Habitat only marginally suitable or suitable but not within species geographic range
[a] Federal delisting is currently proposed, pending publication in the *Federal Register*.

TABLE III.E-1
SPECIAL-STATUS PLANT SPECIES
POTENTIALLY OCCURRING IN THE ALAMEDA WATERSHED

Common name ***Scientific name***	**Listing Status USFWS/CDFG/ CNPS**	**Habitat Requirements**	**General Site Occurrence Within the Watershed**	**Flowering Period**
Santa Clara thorn mint *Acanthomintha lanceolata*	--/--/4	Chaparral, shale scree	High Potential Type Habitat-Calaveras[a]	March-June
Balsamroot *Balsamorhiza macrolepis* var. *macrolepis*	--/--/1B	Cismontane woodland, grassland	High Potential Interior slopes near SF Bay	March-June
Oakland star-tulip *Calochortus umbellatus*	--/--/4	Broadleafed upland forests, chaparral, lower montane coniferous forests, grasslands, often on serpentinite	Moderate Potential Mt. Hamilton Range[a]	March-May
Sharsmith's harebell *Campanula sharsmithiae*	FSC/--/1B	Chaparral, ultramafic talus	Moderate Potential Mt. Hamilton Range	May-June
Mt. Hamilton thistle *Cirsium fontinale* var. *campylon*	FSC/--/1B	Ultramafic seeps, sandy streams	High Potential Mt. Hamilton Range[a]	Feb-Oct
Brewer's clarkia *Clarkia breweri*	--/--/ 4	Chaparral, shale talus	High Potential Mt. Hamilton Range[a]	April-May
Santa Clara red ribbons *Clarkia concinna* ssp. *automixa*	FSC/--/1B	Coastal scrub, grassland (ultramafic)	High Potential Alameda County[c]	May-July
Presidio clarkia *Clarkia franciscana*	FE/CE/1B	Coastal scrub, grassland (ultramafic)	Moderate Potential Alameda County[c]	May-July
Serpentine collomia *Collomia diversifolia*	--/--/4	Serpentine seeps, streams	Moderate Potential Red Mountains[a]	May-June
Mt. Hamilton coreopsis *Coreopsis hamiltonii*	FSC/--/1B	Steep, shale talus, woodland	Moderate Potential Mt. Hamilton Range[a]	March-May
Inner Coast Range Larkspur *Delphinium californicum* ssp. *interius*	FSC/--/1B	Dry ravines	High Potential Mt. Hamilton Range[a]	April-June
Western leatherwood *Dirca occidentalis*	--/--/1B	Broadleafed upland forests, closed-cone coniferous forests, chaparral, cismontane woodland, North Coast coniferous forests, riparian forests, riparian woodland; mesic sites	Moderate Potential Alameda, Santa Clara County[c]	Jan-March
Santa Clara Valley dudleya *Dudleya setchellii*	FE/--/1B	Ultramafic grasslands	Moderate Potential Outside of range	May-June

TABLE III.E-1 (Continued)
SPECIAL-STATUS PLANT SPECIES
POTENTIALLY OCCURRING IN THE ALAMEDA WATERSHED

Common name ***Scientific name***	**Listing Status USFWS/CDFG/ CNPS**	**Habitat Requirements**	**General Site Occurrence Within the Watershed**	**Flowering Period**
Tiburon buckwheat *Eriogonum luteolum* var. *caninum*	--/--/3	Chaparral, coastal prairie, grasslands, usually on serpentinite	Moderate Potential Alameda, Santa Clara County[c]	June-Sept
Ben Lomond buckwheat *Eriogonum nudum* var. *decurrens*	--/--/1B	Chaparral, coastal prairie, grasslands, usually on serpentinite	Moderate Potential Alameda, Santa Clara, Santa Cruz County[c]	June-Sept
Jepson's woolly sunflower *Eriophyllum jepsonii*	--/--/4	Coastal scrub	High Potential Alameda, Santa Clara County[c]	April-June
Stinkbells *Fritillaria agrestis*	--/--/4	Valley and foothill grasslands, oak woodlands; on clay flats; sometimes on serpentine	High Potential Alameda, Santa Clara County[c]	March-April
Talus fritillary *Fritillaria falcata*	FSC/--/1B	Chaparral, woodland, on talus	Moderate Potential Alameda, Santa Clara County[c]	March-May
Fragrant fritillary *Fritillaria liliacea*	FSC/--/1B	Coastal scrub, valley and foothill grassland, coastal prairie; on heavy clay soils, often on ultramafic soils	High Potential Alameda, Santa Clara County[c]	Feb-April
Contra Costa goldfields *Lasthenia conjugens*	FE/--/1B	Moist grasslands, vernal pools	Moderate Potential Alameda, Santa Clara County[c]	March-June
Woolly-headed lessingia *Lessingia hololeuca*	--/--/3	Grasslands	Moderate Potential	June-Oct
Arcuate bush mallow *Malacothamnus arcuatus*	--/--/4	Chaparral	Moderate Potential Santa Clara County[c]	April-July
Hall's bush mallow *Malacothamnus hallii*	--/--/4	Chaparral	Moderate Potential Alameda, Santa Clara County[c]	May-Sept
Gairdner's yampah *Perideridia gairdneri*	FSC/--/1B	Broad-leaved Upland forest, chapparral	Moderate Potential Santa Isabella Valley[a]	June-July
Mt. Diablo phacelia *Phacelia phacelioides*	FSC/--/1B	Cismontane woodland, chaparral	High Potential Alameda, Santa Clara County[c]	April-May
Forget-me-not popcorn flower *Plagiobothrys myosotoides*	--/--/4	Chaparral	Moderate Potential Ridge-top in Mt. Hamilton Range[a, c, e]	April-May

TABLE III.E-3
SPECIAL-STATUS ANIMAL SPECIES REPORTED OR POTENTIALLY OCCURRING IN THE PENINSULA WATERSHED

Common name *Scientific name*	**Listing Status USFWS/ CDFG**	**Habitat Requirements**	**Potential for Occurrence Within the Watershed**	**Period of Identification**
Invertebrates				
Opler's longhorn moth *Adella oplerella*	FSC/--	Serpentine bunchgrass grassland	High Potential	Spring
Edgewood blind harvestman *Calcinia minor*	FSC/--	Serpentine rock outcrops and barrens	High Potential	Fall-Winter
Serpentine phalangid *Calcina serpentinea*	FSC/--	Serpentine rocks and barrens	High Potential	Fall-Winter
Monarch butterfly *Danaus plexippus*	--/*	Eucalyptus groves (winter sites)	Moderate Potential	Winter
Bay checkerspot butterfly *Euphydryas editha bayensis*	FT/--	serpentine bunchgrass grassland	High Potential	March-May
Mission blue butterfly *Icaricia icarioides missionensis*	FE/--	Grassland with *Lupinus albifrons*, *L. formosa*, and *L. varicolor*	High Potential	March-June
San Bruno elfin butterfly *Incisalia mossii bayensis*	FE/--	Found in coastal scrub	High Potential	March-April
San Francisco fork-tailed damselfly *Ischnura gemina*	FSC/--	Wetlands with emergent vegetation	High Potential	April-October
San Francisco lacewing *Nothochrysa californica*	FSC/--	Grasslands	Moderate Potential	Spring
Unsilvered fritillary butterfly *Speyeria adiaste adiaste*	FSC/--	Found in native grasslands with *Viola penduculata* as larval food plant	High Potential	Spring
Callipe silverspot butterfly *Speyeria callippe callippe*	FE/--	Found in native grasslands with *Viola peduculata* as larval food plant	High Potential	Spring
Myrtle silverspot butterfly *Speyeria zerene myrtleae*	FE/--	Found in native grasslands with *Viola peduculata* as larval food plant	High Potential	Spring
Amphibians				
California tiger salamander *Ambystoma californiense*	FC/CSC	Seasonal freshwater ponds with little or no emergent vegetation	Moderate Potential	November-May
California red-legged frog *Rana aurora draytonii*	FT/CSC	Freshwater ponds and slow streams with emergent vegetation for egg attachment	High Potential	April-June
Foothill yellow-legged frog *Rana boylii*	FSC/CSC	Streams with quiet pools absent of predatory fish	High Potential	April-June
Western spadefoot toad *Scaphipus hammondii*	FSC/CSC	Floodplains and grassland pools	Moderate Potential	February-August

SPECIAL-STATUS PLANT SPECIES REPORTED OR POTENTIALLY OCCURRING IN THE PENINSULA WATERSHED

Common name *Scientific name*	**Listing Status USFWS/ CDFG/CNPS**	**Habitat Requirements**	**Potential for Occurrence Within the Watershed**	**Flowering Period**
San Mateo thorn-mint *Acanthomintha duttonii*	FE/CE/1B	Grassland and chaparral, on serpentinite	Found in "Triangle" [a,b]	April-June
Coast rock cress *Arabis blepharophylla*	FC3c/--/4	Broadleafed upland forests, coastal prairie, coastal scrub; often in rocky places	Found[b,d]	February-April
San Bruno Mtn. Manzanita *Arctostaphylos imbricata*	FSC/CE/1B	Chaparral, coastal scrub	Found[b,d]	February-May
Montara manzanita *Arctostaphylos montaraensis*	FC/--/1B	Maritime chaparral, coastal scrub	Found[a,b]	January-March
Brewer's calandrinia *Calandrinia breweri*	--/--/4	Burns and disturbed areas in coastal scrub and chaparral	Moderate Potential[c]	March-June
Robust spineflower *Chorizanthe robusta* var. *robusta*	FPE/--/1B	Coastal scrub, coastal dunes, openings in oak woodlands	Moderate Potential[c]	May-September
Fountain thistle *Cirsium fontinale var. fontinale*	FE/CE/1B	Grassland and openings in chaparral, in serpentinite seeps	Found on Pulgas Ridge[b]	June-October
Mountain lady's-slipper *Cypripedium montanum*	FC3c/--/4	Broadleafed upland forests, lower montane coniferous forests	Moderate Potential[c]	March-July
Western leatherwood *Dirca occidentalis*	--/--/1B	Broadleafed upland forests, closed-cone coniferous forests, chaparral, cismontane woodland, North coast coniferous forests, riparian forests, riparian woodland; mesic sites	Found in many communities[e]	January-April
California bottle-brush grass *Elymus californicus*	FC3c/--/4	North coast coniferous forests	Occurs on Cahill Ridge[b,c]	June-August
Marsh horsetail *Equisetum palustre*	--/--/3	Marshes	Moderate Potential[c]	NK
Tiburon buckwheat *Eriogonum luteolum* var. *caninum*	FC3c/--/3	Chaparral, coastal prairie, grasslands, usually on serpentinite	High Potential[c] observed in coastal scrub	June-September
San Mateo woolly sunflower *Eriophyllum latilobum*	FE/CE/1B	Cismontane woodland, on serpentinite, often on roadcuts	Found along Crystal Sps. Rd.[a,b,f]	May-June

Hickman, 1993; The Nature Conservancy, 1990; Corelli, 1991; and Oberlander, 1953). Seven of these species have formal listings as endangered or threatened under the California Endangered Species Act or Federal Endangered Species Act. These species include San Mateo thornmint, fountain thistle, San Mateo woolly sunflower, Marin dwarf flax, white-rayed pentachaeta, San Bruno Mountain manzanita, and Hickman's cinquefoil. All the species have been observed within the Watershed, except Hinkman's cinquefoil, which has a moderate potential to occur.

Appendix E
Growth Inducement Potential and Supporting Information

APPENDIX E

Growth Inducement and Supporting Information

This appendix supplements the information provided in Chapter 7, Growth Inducement Potential and Indirect Effects of Growth, of the WSIP PEIR. In separate subsections it provides information on the following topics:

- E.1 Water Supply Assurances
- E.2 Methodology the SFPUC used to develop 2030 water demand projections and the studies conducted to evaluate potential conservation measures and recycled water projects to help meet future demand, which together provided the basis for the 2030 purchase estimates submitted to the SFPUC.
- E.3 Supplementary information on population, employment, and water demand projections in the SFPUC water service area.
- E.4 Growth trends and policies of a selection of jurisdictions in the service area.
- E.5 Indirect effects of growth and measures identified to mitigate those effects.
- E.6 Project level impacts of growth.

APPENDIX E.1

Water Supply Assurances

Under the terms of the 1984 Settlement Agreement and Master Sales Water Contract (Master Sales Agreement) between the City and County of San Francisco and its suburban water purchasers (the SFPUC wholesale customers) (City and County of San Francisco, et al.,1984), the SFPUC is required to supply up to 184 million gallons per day (mgd) on an annual average basis to the wholesale customers, subject to reductions in the event of a drought, water shortage, earthquake, or other natural disaster, and for rehabilitation and maintenance of the system. In addition, the SFPUC and each of the wholesale customers, except for San Jose and Santa Clara, have negotiated individual supply assurance contracts (individual supply assurances) that cumulatively total 184 mgd. San Jose and Santa Clara do not have supply assurance contracts with the SFPUC.

In most cases, the individual supply assurances specify the amount of water the wholesale customer is entitled to purchase from the SFPUC. The individual supply assurances held by City Hayward and the Estero Municipal Improvement District (MID) are exceptions to this type of contract, as they do not specify a quantified limit on purchases from the SFPUC. A portion of the total 184 mgd (essentially the difference between the subtotal of all the specified individual assurances and 184 mgd, or 28 mgd) is set aside for current usage and growth in consumption by Hayward and Estero MID.[1] If the combined usage by Hayward and Estero exceeds this amount, the Master Sales Agreement provides a method for proportional reduction in the other water customers' supply guarantee (Bay Area Water Users Association [BAWUA], 1993; Bay Area Water Supply and Conservation Association [BAWSCA], 2006). The current individual supply assurance for each wholesale customer is shown in **Table E.1.1**. Table E.1.1 also shows the base year (2001) demand estimate, 2001 purchases, and 2030 purchase estimates for each customer, for comparison purposes. As the table shows, 12 wholesale customers have submitted 2030 purchase estimates that are greater than their existing individual supply assurances, and 11 have submitted purchase estimates that are less than or equal to their existing assurances. Such a comparison does not apply to Estero MID or the City of Hayward, since their individual supply assurances do not specify a limit on SFPUC purchases.

1 A 1993 memorandum from BAWSCA (then BAWUA) to its member agencies regarding allocation of the 184 mgd supply assurance indicated that the combined usage for Hayward and Estero MID at the time was 21.782 mgd and that an additional 6.2 mgd was set aside to allow for growth in Hayward and Estero MID consumption (BAWUA, 1993). The current BAWSCA annual survey (BAWSCA, 2006) shows a combined usage for Hayward and Estero MID in FY2004-2005 of 24.10 mgd and a reserve amount of 3.9 mgd (together equaling the same combined amount allocated for Hayward and Estero MID [28 mgd] in the 1993 memorandum).

TABLE E.1.1
ALLOCATION OF THE 184 MGD SUPPLY ASSURANCE

Customer	Supply Assurances (mgd[a])	Base-Year (2001) Demand Estimate (mgd[a])	Fiscal Year 2001/2002 Purchases from the SFPUC (mgd[a])	2030 Purchase Estimate (mgd[a])
Alameda County Water District	13.76	51.1	11.99	13.76
City of Brisbane	0.46	0.44	0.39	0.89
City of Burlingame	5.23	4.8	4.64	4.70
California Water Service District	35.5

Estero MID[d] and City of Hayward Reserve[h]	3.90			
Subtotal, Estero MID[d] and City of Hayward	28	25	23	34.15 – 34.75
TOTAL	**184**	**366**	**261**	**204 – 209**

NOTE: Numbers may not sum due to rounding.

a mgd = million gallons per day.
b CWS = California Water Service Company.
c CWS-Bear Gulch District includes the base year demand, 2001/2002 purchases, and 2030 purchase estimate for the former Los Trancos County Water District (now part of CWS-Bear Gulch District) as provided in background documents. The Supply Assurance for CWS-Bear Gulch is based on the BAWSCA 2004-2005 annual survey, which no longer lists Los Trancos as a separate entity.
d MID = Municipal Improvement District.
e Portion of north San Jose only.
f Purchase estimate is based on Westborough Water District's 2005 UWMP.
g Base year demand, base year purchases, and 2030 purchase estimate subtotals also include San Jose and Santa Clara, which do not have supply assurance contracts with the SFPUC.
h Because the supply assurance contracts between SFPUC and Estero MID and SFPUC and Hayward do not specify a limit, the current usage of these wholesale customers (as reported in the BAWSCA FY 2004-05 annual survey) is shown as the "supply assurance;" the amount shown as "Estero MID and City of Hayward Reserve" is the difference between the current supply assurance total (184 mgd) and the specified supply assurances (156 mgd) plus current Estero and Hayward usage (24.1).

APPENDIX E.2

Demand Methodology and Purchase Estimates

Water Demand Projections and Purchase Requests

This appendix summarizes the methodology used to develop the water demand projections and the studies undertaken to identify the potential for conservation savings and the use of recycled water within the SFPUC service area, which together provided the basis for the purchase estimates submitted by the water customers to the SFPUC. This summary is based on the following SFPUC technical reports, supplemented by information provided by the SFPUC and BAWSCA staff:

- *SFPUC Wholesale Customer Demand Projections Technical Report* (URS, 2004a) (referred to in this chapter as the wholesale customer demand study)
- *SFPUC 2030 Purchase Estimates Technical Memorandum* (URS, 2004b)
- *SFPUC Wholesale Customer Water Conservation Potential* (URS, 2004c)
- *SFPUC Investigation of Regional Water Supply Option No. 4 Technical Memorandum*, Final (URS, 2006)[1]
- *City and County of San Francisco Retail Water Demands and Conservation Potential* (Hannaford and Hydroconsult, 2004) (referred to in this chapter as the retail customer demand study)
- *SFPUC Wholesale Customer Recycled Water Potential Technical Memorandum* (RMC, 2004)
- *Recycled Water Master Plan for the City and County of San Francisco* (RMC, 2006)[2]

Base-year demand for San Francisco retail customers and the SFPUC's wholesale customers (2000 and 2001, respectively) and projected 2030 demand are shown in **Table E.2.1**. The base-year demand estimate is based on actual consumption data (adjusted for unaccounted-for water) and therefore reflects the implementation of existing conservation programs. The 2030

---

1 This report was not used as a basis for the demand estimates, which were developed in 2004. However, it includes customer specific estimates for 2030 recycled water use not included in the 2004 studies.

2 This is a technical feasibility report that assesses the feasibility of recycled water projects in San Francisco.

TABLE E.2.1
SUMMARY OF BASE-YEAR AND PROJECTED 2030 DEMAND AND PURCHASE ESTIMATES

Customer	Base-Year (2001) Demand Estimate (mgd[a])[b]	Fiscal Year 2001/2002 Purchases from the SFPUC (mgd[a])	Percent of 2001 Demand Met by Purchases from the SFPUC[c]	2030 Projected Demand (with Plumbing Code) (mgd[a])	Projected Change in Demand from 2001 (mgd[a])	Projected Percent Change in Demand from 2001	2030 Purchase Estimates (mgd[a])	Change in Water Purchases from the SFPUC 2001–2030 (mgd[a])	Percent Change in Purchases 2001–2030 (mgd[a])

NOTE: Numbers may not sum due to rounding.

a mgd = million gallons per day.
b Demand estimates shown here include unaccounted-for water, which is the difference between total water produced and total water billed to customers (water consumed). Unaccounted-for water includes fire fighting use, maintenance requirements, system flushing, leaks, and any unauthorized use.
c Based on URS 2004b.
d CWS = California Water Service Company.
e MID = Municipal Improvement District.
f The former Los Trancos County Water District is now part of CWS–Bear Gulch District; information presented here reflects information in background reports (URS, 2004a, 2004b).
g 2030 demand is based on information provided by the City of Palo Alto to the SFPUC (City of Palo Alto, 2005).
h In November 2005, Redwood City informed the SFPUC that it would be purchasing its low range estimate of 11.6 mgd due to anticipated implementation of 1 mgd of recycled water in 2030 (City of Redwood City, 2005). The high-range purchase estimate total published in URS 2004b of 300 mgd remains the SFPUC 2030 purchase estimate for planning purposes to be consistent with the previous and ongoing WSIP studies.
i Portion of north San Jose only.
j Demand and purchase estimates are based on Westborough Water District's 2005 UWMP, as requested by the district in a letter to the SFPUC (Westborough Water District, 2007). Base year demand shown here is based on 2001 total water production presented in the UWMP (which is equal to 2001-02 purchases from the SFPUC).

SOURCES: URS, 2004a; URS, 2004b; URS, 2006, City of Palo Alto, 2005; City of Redwood City, 2005;SFPUC, 2004; Westborough Water District, 2005; Westborough Water District 2007.

projections take into account expected growth in population and employment, the influence of plumbing codes (which include efficiency requirements), and assumptions about rates of water fixture replacement. Thus, the 2030 demand projections already factor in some “passive” water savings due to plumbing code changes as well as the effects of conservation savings accrued prior to the base year. The purchase estimates in Table E.2.1 include the effects of continuing current conservation programs and new future conservation programs that the SFPUC and/or its wholesale customers plan to implement in the future (discussed below), as well as the use of other water sources.

Projections for both retail and wholesale customers were developed using end-use demand models that break down total water use, by water service account, to specific end uses such as toilets, faucets, and irrigation. Projections for the wholesale service area were developed in close consultation with the wholesale customers, which provided critical inputs to the demand model and subsequently submitted statements concurring with the demand projections. Given the central link between the demand forecasts developed for the SFPUC service area and the amount of growth the WSIP could support, this appendix describes in some detail the methodology used to develop the water demand projections and 2030 purchase requests. Additional information on the demand forecast methodology can be found in the above-referenced reports.

Demand Projections

Wholesale Customer Demand

To develop water demand projections for the wholesale customers, the SFPUC undertook a study using an end-use model called the Demand Side Management Least-Cost Planning Decision Support System (DSS) model. The DSS model uses growth in the number of accounts and a complete breakdown of water end uses, by customer billing category, to forecast water demands. This end-use model was selected over other forecasting approaches because it allows a more accurate representation of changing conditions, such as the future effects of plumbing and appliance codes and implementation of additional conservation measures on demand (URS, 2004a).

For the DSS model, water usage is broken down from total water production[3] in the service area to specific water end uses such as toilets, faucets, and irrigation. Natural fixture replacement (i.e., the replacement of fixtures assumed to occur over time due to failure, aging, or remodeling), the effects of plumbing codes, and effects of past conservation programs are factored in. (The effects of continuing existing conservation programs and of additional conservation and water recycling programs on demand were calculated in separate studies and are factored into the final customer purchase estimates shown in Table E.2.1, as discussed in more detail below.)

3 Water produced is the total water consumed (including imported water purchased from others, groundwater, or other sources) plus unaccounted-for water.

Establishing Base-Year Conditions

A key to water demand forecasting is accurately determining existing use. Establishing base-year conditions for the DSS model entailed the following steps: selecting the appropriate base year, developing water use data, and calibrating end uses for that year. The SFPUC selected 2001 as a representative base year because water use data in 2001 showed less influence from the recession than did 2002 data, and because 2001 was a normal year in terms of rainfall. (Complete data were not available for 2003 since the wholesale customer demand study was undertaken that year.)

Development of accurate base-year water use data involved the following steps:

- Determination of the percentage of "unaccounted-for" (unmetered) water in the system. A percentage of every water retailer's water is unaccounted for, resulting from, for example, leakage, pipe flushing, and firefighting. Unaccounted-for water is the difference between total water production and total water consumption (i.e., the difference between total water produced and the amount of water billed to customers), and must be considered in demand projections. The five-year average unaccounted-for water was calculated for each wholesale customer based on data published in customers' UWMPs and the 2002 Bay Area Water Users Association's (BAWUA, now BAWSCA) annual surveys. Estimates of unaccounted-for water in the UWMPs varied between 1 percent and 11 percent, and estimates in the annual surveys varied between 5.5 and 5.7 percent. These estimates of unaccounted-for water are low by national standards (which indicate approximately 15 percent unaccounted-for water within a system), according to an American Water Works Association report cited in the demand study, and are lower than the state average (estimated to be 9.3 percent in a 1982 study of state water agencies prepared for the California Department of Water Resources). Unaccounted-for water in a system is expected to increase as pipes and other infrastructure components age. Therefore, the demand projections assumed a minimum value of 7 percent unaccounted-for water, as a conservative estimate for future demands, unless the wholesale customer's five-year average unaccounted-for water was higher, in which case the higher rate was used. The assumed percentage of unaccounted-for water was added to the total water consumed, obtained from billing data, to arrive at the total water produced (the base year [2001] demand estimate in Table E.2.1).

- Determination of the basic split between indoor and outdoor water use, since outdoor use fluctuates seasonally and future water use will be affected by plumbing codes requiring more water-efficient fixtures.

- The further division of indoor and outdoor water usage into specific end uses, by customer billing category, based on published data of industry standards and data from previous water audits.

- Calibration and verification of residential and employment populations and per-capita water use. Once total water production was broken down into end uses ("disaggregated"), these water usage data were calibrated by performing the reverse: end uses and the average number of persons using them were combined to arrive at total water production. The calibration process requires verification of residential and employment population estimates in the service area and the per-capita and per-employee water use estimates. Census data and customer billing data were used to determine the average number of users per account.

- Reconciliation of service area and census area boundaries. The boundaries of many wholesale customer service areas do not exactly coincide with city or town limits. Therefore, the extent to which service area and census area boundaries conformed needed to be determined and adjustments made where they do not. For example, one water agency may serve all of a city except for a few blocks, which are served (along with other areas) by another agency, or a water agency may serve only a small part of a city. Modelers worked closely with wholesale customers to accurately understand the boundaries. Estimated population and employment projections were verified with wholesale customers and checked through the calibration process.

- Determination of the number of water users per residential account. This involved determining the number of single-family and multifamily buildings in a service area, the number of housing units per multifamily building, and household size. The service area population developed through this process was then checked for reasonableness by comparing it with service area population estimates from the annual survey conducted by BAWSCA.

- Calculation of per-capita water use for residents. This step required determination of total indoor water use for single- and multifamily accounts; usage was divided by average household size to determine per-capita usage.

- Determination of water users per nonresidential account. ABAG employee population figures supplemented by data from the California Department of Finance were used; adjustments were made to account for differences between service area boundaries and those of ABAG jurisdictions.

- Application of fixture models to end uses. Because the efficiency of water fixtures has increased over time, assumptions were required about the model (age) of the fixtures in use. Initial proportions of old, intermediate, and new fixtures were determined based on census age-of-housing data and assumptions about the amount of natural replacement that had occurred prior to the base year.

- Calibration of end uses. The results of the disaggregating and aggregating approaches were then compared and adjusted through a calibration process to match one another.

BAWSCA's annual surveys of wholesale customers since 2001 shows that actual demand for fiscal year (FY) 2001/2002 through FY 2004/2005 has been, for most wholesale customers each year, less than the base-year demand estimate used for the wholesale customer demand projections. As noted above, the SFPUC selected 2001 because it showed less influence from the recession than did 2002 data and was a normal year in terms of rainfall. In addition, as discussed above, the 2001 base year includes adjustments for unaccounted-for water, and therefore is somewhat higher than actual 2001 demand. In FY 2002/2003, total demand was somewhat down from that of the previous year, and only Guadalupe Valley Municipal Improvement District had demand higher than the 2001 base year. Total demand in FY 2003/2004 was greater than that of the two previous years, but slightly less than the 2001 base year. Demand in FY 2004/2005 was lower than that of the previous three years and 8 percent lower than the previous year. According to BAWSCA, the lower-than-normal consumption in FY 2004/2005 reflected expected year-to-year variations and could be explained in part by the combination of higher annual rainfall that year and mild spring temperatures, which extended into late spring and lowered irrigation demand (BAWSCA, 2006).

Forecasting Water Demand

Once the model was calibrated, water demands were forecasted from the base year. The forecasting process entailed the following steps:

- Determination of growth in the number of water accounts and increases in water use in those accounts. Published population and employment projections[4] were used to forecast growth in the number of water accounts. Each customer was asked to select the projections source to be used based on city planning estimates and the most recent general plan, to ensure that the projections were based on land use plans that were relevant to the particular wholesale customer service area. Nineteen of the 30 wholesale customer entities[5] selected ABAG *Projections 2002* as the source of growth rates; others selected BAWSCA's annual surveys,[6] urban water management plans, city planning sources, a service area planning study, a draft general plan,[7] and a water master plan (URS, 2004a). Projections for San Francisco were developed based on information provided by the San Francisco Planning Department.

  Projections 2002 provides forecasts in five year increments only to 2025. Population and employment projections for 2025-2030 were estimated using the 2020-2025 population/employment growth rate, which was applied to the 2025 estimate and carried forward linearly at that rate to 2030.

  To develop yearly projections to 2030 for each source (since none of the selected sources provided yearly projections), the population and employment increase for each five- or ten-year increment was divided evenly and applied yearly throughout the five- or ten-year period (depending on the increment used in the particular projection) to form a linear yearly projection between increments. For each SFPUC customer, the annual demographic projections that were developed through 2030 were used to derive an annual rate of change (annual growth rate) for each of the demographic sources(population and employment).

---

4 Employment projections were not developed for Los Trancos County Water District or Stanford University because Los Trancos only has residential accounts and Stanford University uses other parameters (such as increases in building square footage) to forecast growth in nonresidential accounts. (Since the projection studies were conducted, Los Trancos County Water District was purchased by CWS and is now part of the CWS–Bear Gulch District.)

5 There are 27 wholesale customers, but California Water Service Company (CWS) serves three distinct subgroups—Bear Gulch District, Mid-Peninsula District, and South San Francisco District—which are tracked separately in the SFPUC reports. The former Los Trancos County Water District, which was recently purchased by CWS and is now part of the CWS–Bear Gulch District, is also tracked separately in the SFPUC reports. The 30 wholesale customer entities referenced here include the CWS districts and Los Trancos as distinct entities.

6 This organization was called the Bay Area Water Users Association (BAWUA) at the time the cited annual surveys were conducted.

7 The source of the population and employment projections used as the basis for San Bruno's demand forecasts (the City's draft general plan) has not been adopted and is thus potentially subject to change. Therefore, this analysis compared the projections used with the 2030 population and employment projections for San Bruno in ABAG's *Projections 2003* and *Projections 2005*, and the population projection included in the City's 2003 housing element. (*Projections 2002* was not reviewed for this purpose because it does not provide projections to 2030.) The population projections for 2030 in *Projections 2003* and *Projections 2005* are approximately the same as the projections used for the water demand forecasts (1 percent and 5 percent higher, respectively). Employment projections for 2030 in *Projections 2003* and *Projections 2005* were approximately 8 and 10 percent higher, respectively, than those used for the water demand forecasts. San Bruno's 2003 housing element includes a population projection for 2020 of 46,400, which is about 4 percent lower than the population used in the demand forecast for 2030. Based on these comparisons, the projections used for San Bruno in the demand study are reasonably consistent with the growth estimated by the regional planning agency and the City's 2003 housing element. San Bruno's current general plan, adopted in 1984, does not include applicable projections.

These annual growth rates were then input into the demand model, which applied them to the base-year number of water accounts to forecast the future number of water accounts and ultimately future water demand. In general, population projections were used as the source of growth rates for residential, institutional, and other miscellaneous water accounts and employment projections were applied to commercial and industrial accounts.

To reconcile the ABAG projections with those for wholesale customer service areas, a "blend" of ABAG cities was created (refer to Table 7.1 of PEIR Chapter 7). Projections 2002 was used as the source of employment projections for most of the SFPUC wholesale customers.

Based on *Projections 2002,* which showed relatively constant household sizes in the program area over the forecast period, the wholesale customer demand study assumed the average number of users per account would remain constant for all account categories. Based on this assumption, the rate of growth in demand forecast for each demographic category would be expected to correspond directly to the rate of growth in accounts for the customer-billing category to which the forecast is applied. However, data gathered on new accounts in some billing categories revealed higher water use rates by new accounts than by existing (older) accounts. Research into this disparity confirmed that new accounts in certain categories had higher use rates.[8] Therefore, in cases where some categories showed higher water use by new accounts, a category for new accounts, with water use rates consistent with recent customer billing, was incorporated into the DSS model. In other cases, model mechanics required the creation of new categories to estimate actual projected demand using the account growth method. (For example, a commercial building that was only partially occupied would show lower consumption than it would at full occupancy if not adjusted for the full growth potential.) Customers with new account categories incorporated into their DSS model are shown in **Table E.2.2**. In general, the modelers applied population projections to residential, institutional, and other miscellaneous accounts and applied employment projections to commercial and industrial accounts.

In addition to those described in Table E.2.2, a new commercial account for new/renovated commercial use was created for Daly City. This account was not established because of observed trends in new accounts but in order for the DSS model to accommodate additional planned growth (beyond ABAG employment projections for Daly City) of approximately 0.57 mgd estimated by the City to result from established public policy calling for intensification of mixed uses. The City's estimate of changes in demand expected to result from this is intensification of mixed uses is described in a letter from the Daly City director of water and wastewater resources to BAWSCA (Daly City, 2004). This growth reflecting intensified mixed use is expected to occur by the year 2010 and is documented by a number of project reviews that have gone through public processes in Daly City (Daly City, 2004).

- Determination of the average annual rate of fixture replacement and future plumbing code impacts and incorporation of the effects into the fixture models. Water fixtures are replaced over time due to failure, aging, or remodeling and must be replaced by more efficient models, as required by plumbing codes. Modelers considered the age of housing, income levels, fixture saturation study results, and replacement rate estimates by the California

8 For example, higher use rates were found in areas where redevelopment had replaced paved areas with landscaping. In other cases, higher use was linked to larger lot sizes with larger outdoor areas using irrigation.

TABLE E.2.2
SFPUC WHOLESALE CUSTOMERS WITH DEMAND MODEL CATEGORIES FOR NEW ACCOUNTS[a]

Wholesale Customer	Existing Account Category	Average Water Consumption (gpd/a[b])	New Account Category	Average Water Consumption (gpd/a[b])	Reason for New Category
City of East Palo Alto	Single-Family Residential	314	New Single-Family Residential	340	To represent additional water demand of 0.3 mgd from a new single-family residences in the Ravenswood Business District
	Commercial	1675	New Commercial	5,493	To represent additional water demand of 1.2 mgd from new commercial uses (having an assumed use rate of 5,000 gal /acct/day) in the Ravenswood Business District
Estero MID[c]	Single-Family Residential	320	New Single-Family Residential	450	New homes are assumed to be larger and have a higher outdoor water usage than existing; the per account usage was based on discussion with the wholesale customer. A trend of increasing home prices, based on 1990 and 2000 census information, supports the assumed increase in water usage.
	Commercial/Institutional	2,250	New Commercial/ Institutional	4,000	New commercial users are assumed to be larger and have a higher water usage than existing commercial users. The per account usage was based on discussion with the wholesale customer. Projected new development is expected to consist of large office building complexes.
City of Hayward	Single-Family Residential	275	New Renovated Single-Family Residential	400	Renovation of single family homes is occurring in Hayward where more affordable homes are attracting buyers. Homes are being purchased and remodeled; the remodeled homes have improved landscapes and use a net increase in water (compared to the current average if 275 gpd/a which is lower than most areas of the SFPUC service area). The city expects a 2 percent renovation rate to continue to 2030.
			New High-Use Single-Family Residential	440	To represent 2,200 new higher-use single family homes the City requested be added to the model. These homes have larger lots than existing small-lot homes and are assumed to use 438 gpd/account. At the time the demand modeling was undertaken the City had found that the larger lots being built actually use up to 600 gpd, and estimated the ultimate range for the new homes was 400-600 gpd. Assuming 438 gpd resulted in an overall increase of 0.9 mgd by 2030, which was assumed to be realistic for 2,200 larger homes. This value is slightly higher than the 400 gpd assumed in the City's Water Master Plan and results from the City's field observations showing 600 gpd per new account.
	Commercial/Institutional	1,775	New Commercial / Institutional	8,500	Based on the City's General Plan, which anticipates, and is actively marketing to attract, high technology manufacturing facilities to locate in Hayward. The assumed change for this new industrialization was 400,000 gpd. The new category also includes water for already-approved development of a golf course (170,000 gpd and up to 700,000 in summer, for irrigation), country club (100,000 gpd) and new sports park (45,000 gpd).

TABLE E.2.2 (Continued)
SFPUC WHOLESALE CUSTOMERS WITH DEMAND MODEL CATEGORIES FOR NEW ACCOUNTS[a]

Wholesale Customer	Existing Account Category	Average Water Consumption (gpd/a[b])	New Account Category	Average Water Consumption (gpd/a[b])	Reason for New Category
City of Milpitas	Single-Family Residential	325	New Single-Family Residential	500	All new single family accounts above those existing in 2001 were placed in this category. New homes were assumed to be larger and have higher outdoor water usage. The new single family accounts were assumed to use approximately 50 percent more water than existing accounts (all of which is allocated to outdoor use). Adjustments were based on information provided in the Water Master Plan and conversations with the wholesale customer.
	Commercial	2,164	New Commercial	4,500	All new commercial accounts above those existing in 2001 were placed in this category. These new accounts are assumed to have higher water usage than existing. Assumed to use 4,500 gpd/ acct, based on information in the Water Master Plan and conversations with the wholesale customer.
Purissima Hills Water District	Old Single-Family Residential	716	New/Renovated Single-Family Residential	1,605	The number of old versus new/renovated residential accounts was determined by assuming a 3 percent renovation rate since 1994. This assumption corresponds to a new/renovated water usage of 1,605 gpd/acct in order to reconcile the average water use for all residential accounts with billing data for 2001.
City of Santa Clara	Single-Family Residential	361	New Single-Family Residential	500	A special billing category was added for new single family homes in order to allow higher water usage per account for those future homes at rate provided by the City.

[a] In many of the cases shown here, the new categories were created because the model mechanics required doing so in order to estimate actual projected water demand using the account growth and end-use method. For example, a commercial building that is only 30 percent full has much lower consumption than it would with full occupancy; creation of a new account category provided an adjustment for full growth potential to ensure that consumption for that particular type of account was more accurately forecasted. The average water consumption for the new accounts shown here is not necessarily a reflection of actual use but rather of the adjustments made to more accurately estimate the projected demand using the tools available in the model.
[b] gpd/a = gallons per day per account.
[c] MID = Municipal Improvement District.

SOURCE: URS, 2004a (Appendices B and C).

Urban Water Conservation Council to establish a best estimate of the replacement rates for wholesale customers. The model also incorporated assumptions on the effect of federal legislation regarding high-efficiency clothes washers.

- Incorporation of recycled water use, where appropriate, because the recycled water use represents a demand that would otherwise be served by a potable supply. The cities of Milpitas, Palo Alto, Redwood City, Santa Clara, and Sunnyvale provided information on approved and funded recycled water programs, which was included in base-year and/or future demand projections. Where recycled water information was provided, a new account category for recycled water was added to the wholesale customer's DSS model. Recycled water was assumed to be entirely for outdoor (irrigation) use.

Retail Customer Demand

A separate SFPUC study evaluated retail customer demand (Hannaford and Hydroconsult, 2004). SFPUC retail water customers consist of residents and nonresidential businesses and institutions within the corporate boundaries of San Francisco that receive water from the SFPUC, and several other industrial, governmental, and individual retail customers in the Bay Area and Sierra Nevada foothills (shown in Table 3.1 in Chapter 3, Program Description, of the PEIR). The study evaluated the historical record of San Francisco's retail water demands and projected the future water demands through 2030 based on an estimation of how water uses will change in the future.

The retail customer demand study considered the following factors:

- Historical changes in water use practices that occurred in response to drought-induced water shortages
- Institutional changes, such as the implementation of plumbing fixture retrofit ordinances
- The manner and degree to which the uses of water would change in the future as a result of plumbing code, demographic, and industry changes

In-city customers that receive water hydraulically from the Hetch Hetchy Water and Power system and the SFPUC's Bay Area reservoir system represent more than 90 percent of the SFPUC's retail deliveries. Using an end-use model similar to that employed for the wholesale demand study described above, the retail demand study developed and refined disaggregated water use forecast models for three principal in-city customer categories:

- Nonresidential (representing the commercial, industrial, and service water uses); nonresidential water use was estimated using relationships between employment within San Francisco and employee use of water, segregated by type of business or service enterprise.
- Multifamily residential (representing water use within multiple-family dwellings such as apartments).
- Single-family residential (representing water use within single-family dwellings).

A fourth category (Builders, Contractors, Docks & Shipping) was estimated based on historical water use and maintained constant at the existing level of delivery (based on fiscal years 1997/1998 through 2000/2001) of 0.24 mgd. Unaccounted-for water use, which was based on the historical performance of the SFPUC regional water system, was estimated to be approximately 9 percent of metered water but not less than 7.3 mgd. The year 2000 was used as the base year for the SFPUC retail modeling because this year provided the best available data.

Historical and projected demographic data from the San Francisco Planning Department and ABAG's *Projections 2002* were used in the modeling process to project residential water demand. Data on historical and projected employment figures from the San Francisco Planning Department, the Bureau of the Census, and ABAG were considered in developing the nonresidential demand projections. ABAG's projections (which differed from San Francisco's figures by only 1 percent for 2025) were used because they provided a more comprehensive breakdown by industry type.

Water deliveries to other retail customers, including the U.S. Navy, San Francisco International Airport, and Lawrence Livermore National Laboratory, and nonpotable deliveries to the town of Sunol were assumed to remain constant into the future.[9] Based on a California Department of Water Resources projection for the town of Groveland, the study assumed SFPUC water deliveries to Groveland would also remain constant. The retail demand study also took into account nonpotable water demand within San Francisco that is currently met by groundwater supplies.

As shown in Table E.2.1, retail customer demand is expected to decrease slightly by 2030 to a total demand of 93.4. The net decrease is attributed to an increase in the market penetration of plumbing code changes in the single-family, multifamily, and nonresidential sectors. The total savings due to the plumbing code changes factored into projected retail demand is estimated to be 10.3 mgd by 2030.

Conservation Potential

As discussed above, the end-use demand models factored in water savings that would occur over time (from the base year to 2030) as a result of natural fixture replacement and compliance with plumbing code requirements and effects of past conservation programs. In addition, the SFPUC undertook conservation potential studies in its wholesale and retail service areas to identify conservation potential from feasible conservation measures that could be implemented to partially offset overall growth in water demands. The 2030 purchase estimates (discussed below) factor in projected conservation savings estimated by the individual customers based on these studies.

9 The study does note, however, that the water demand associated with U.S. Navy sites, such as Treasure Island and Hunters Point Naval Shipyard, should be reevaluated as additional information becomes available regarding the future use of these areas.

Wholesale Customer Conservation Potential

The SFPUC, in conjunction with its 30 wholesale customer entities,[10] conducted a comprehensive study to assess potential conservation savings in the wholesale customers' service areas. An initial list of 75 measures was screened qualitatively, considering the following factors:

- Commercial availability of technology/market maturity
- Service area match (i.e., appropriateness of the measure or technology considering such factors as climate, building stock, and lifestyle)
- Customer acceptance/equity
- Relative effectiveness of the measures available

Thirty-two potential conservation measures emerged from this initial screening. The list of 32 measures included (1) rebate and other incentive programs for installing water-saving devices, (2) city/county ordinances requiring the installation of water-saving devices, and (3) educational outreach and award programs that promote water use reductions in businesses and landscaping. (The list of 32 measures is included at the end of this appendix.) The DSS end-use model was used to estimate water savings and evaluate the cost-effectiveness of implementing the 32 measures. Taking into account the cost-benefit analysis and estimated water savings for each measure, as well as service area water characteristics, retail customer behavior patterns, budgetary considerations, and relative ease of implementation, each wholesale customer compiled three packages of conservation measures, referred to as Programs A, B, and C. Water savings resulting from the natural replacement of fixtures under current plumbing codes was assumed to occur with or without any of the three programs. In general, Program A consists of measures that are currently being implemented; Program B consists of the measures in Program A plus additional measures that were considered to be the most readily implemented; and Program C includes the measures in Programs A and B plus all other measures that appeared to be both feasible and cost-effective to implement. Since there was the potential for water savings from some measures to overlap, once the measures for each program were selected, they were modeled together as a program in order to provide the estimated savings for the program as a whole, accounting for the potential overlap between measures. Projected savings under the three programs for the wholesale customer service area are summarized in **Table E.2.3**, and savings projected for each program by customer are shown in **Table E.2.4**. To gauge the effect of plumbing codes and natural fixture replacement, the DSS model also was run without code-required fixture models in place; plumbing code effects on water savings are also shown in Tables E.2.3 and E.2.4.

[10] As previously noted, there are 27 wholesale customers, and the reference to 30 wholesale customer entities considers the three CWS districts and the former Los Trancos County Water District as distinct entities as they are represented in the conservation potential study.

TABLE E.2.3
CONSERVATION EVALUATION RESULTS
FOR SFPUC WHOLESALE AND RETAIL CUSTOMER SERVICE AREAS
(mgd[a])

Conservation Program[b]	2030 Water Savings due to Conservation Programs, Wholesale Service Area	Total Potential Water Savings, Wholesale Service Area	2030 Water Savings due to Conservation Programs, Retail Service Area	Total Potential Savings, Retail Service Area	Total Potential Savings, Wholesale and Retail Service Areas
(Plumbing Code[c])	–	25.4	–	10.3	35.7
Program/Package A	7.7	33.1[d]	0.64	10.9[g]	44.0
Program/Package B	14.5	40.0[e]	3.93	14.2[h]	54.2
Program/Package C	19.6	45.0[f]	4.45	14.8[i]	59.7

a mgd = million gallons per day
b The sets of conservation measures (A, B, and C) in the wholesale and retail conservation studies are referred to as programs and packages, respectively.
c Plumbing code savings represent savings associated with the natural replacement of plumbing fixtures with more efficient fixture models, and are assumed to occur with or without implementation of the conservation programs.
d Includes plumbing code savings plus Program A savings.
e Includes plumbing code savings plus Programs A and B savings.
f Includes plumbing code savings plus Programs A, B, and C savings.
g Includes plumbing code savings plus Package A savings.
h Includes plumbing code savings plus Packages A and B savings.
i Includes plumbing code savings plus Packages A, B, and C savings.

SOURCES: URS, 2004c; Hannaford and Hydroconsult, 2004.

As shown, a total savings of 25.4 mgd in 2030 is expected to be achieved as a result of natural replacement and plumbing code requirements in the wholesale service area; an additional 7.7 mgd would be saved with implementation of Program A; an additional 6.8 mgd would be saved with Program B over the savings achieved by Program A and the plumbing code; and an additional 5.1 mgd would be saved with implementation of Program C over the savings achieved by Programs A and B and the plumbing code. Multiple rounds of feedback from the wholesale customers were conducted, as needed, until the SFPUC and the wholesale customers were satisfied with the model inputs and results. Once agreement was reached, the wholesale customers submitted forms to the SFPUC indicating their concurrence with the demand projections and the range of conservation potential resulting from their Programs A, B, and C (URS, 2004c).

Following completion of the conservation potential study (and related studies described in this appendix), the wholesale customers submitted estimates of projected purchases for the year 2030, which included the customers' specific estimates of conservation savings as well as their other available sources of supply.

The customers' estimates are, for the most part, similar to the projections for Program B, and indicate savings of approximately 13 - 15 mgd (SFPUC, 2004). It should be noted, however, that because many of the wholesale customers meet their water demand through multiple supply sources, the water savings achieved through implementation of the conservation programs would not necessarily represent commensurate water savings for the SFPUC water system (URS, 2004c).

TABLE E.2.4
PROGRAM-SPECIFIC CONSERVATION POTENTIAL
AND CUSTOMER-PROJECTED CONSERVATION SAVINGS
(mgd[a])

SFPUC Customer	Plumbing Code	Program A	Program B	Program C	2030 Projected Conservation Savings[b]

a mgd = million gallons per day.
b Projected conservation savings represent estimates specified by the wholesale customers and the SFPUC (for retail customers) and were considered when making their 2030 purchase estimates (SFPUC,2004, Popp, 2007).
c CWS = California Water Service Company.
d MID = Municipal Improvement District.
e The former Los Trancos County Water District is now part of the CWS–Bear Gulch District. Information presented here reflects information in the wholesale service area conservation study (URS, 2004c).
f Portion of north San Jose only.
g The 2030 demand projection and purchase estimate for Westborough Water District is based on the district's 2005 UWMP, based on a request from the district to the SFPUC (Westborough Water District 2007). The UWMP discusses ongoing and planned future demand management programs but does not quantify conservation savings in relation to its 2030 purchase estimate. The purchase estimate originally submitted by Westborough in 2004 assumed conservation savings of 0.02 mgd.
h The preferred alternative under the WSIP would result in 4 mgd of conservation savings (SFPUC, 2007).

SOURCES: URS, 2004c, URS, 2006; Hannaford and Hydroconsult, 2004; SFPUC, 2004; SFPUC, 2007, Popp, 2007.

Retail Customer Conservation Potential

A similar approach was taken to determine water conservation potential in the SFPUC's retail service area. The SFPUC initially evaluated the water conservation potential of 48 conservation measures, screening these down to 38 measures using the end-use, disaggregated forecast models employed for the demand projections. (The complete list of measures is included at the end of this appendix.) Market potential, costs, and benefits were identified for the 38 conservation measures.

Using the results of a benefit-cost analysis and professional judgment for each conservation measure, three conservation packages—Packages A, B, and C—were developed. Package A consists of the measures San Francisco is currently implementing. Package B includes all elements of Package A plus additional measures that would expand the current conservation program to an achievable, socially acceptable program that the SFPUC believes it can fund. Package C represents an upper bound of conservation that the SFPUC considers achievable and fundable; Package C includes all elements of Package B plus several additional measures. The additional measures in Package C are based on future improvements in technology (and the information about it) that are assumed to be achievable. For example, dishwasher rebates are included only in Package C because the current models of efficient dishwashers do not show significant water savings; they are included in Package C assuming the market availability of more efficient models will improve.

Projected savings under the three packages for San Francisco are shown in Tables E.2.3 and E.2.4. As shown, a total savings of 0.64 mgd in 2030 is expected to be achieved by implementation of Package A, over the 10.3-mgd savings projected from natural fixture replacement and plumbing codes; an additional 3.29 mgd would be saved with Package B over the savings achieved by Package A and the plumbing code; and an additional 0.52 mgd would be saved with Package C over the savings achieved by Packages A and B and the plumbing code. The 2030 purchase estimate range for the retail service area assumes conservation savings of 0 to 4 mgd (for the high end purchase estimate and for the proposed water supply option, respectively).

Combined Conservation Potential

As shown in Table E.2.3, the potential savings from implementation of plumbing codes and the three identified sets of conservation measures in the combined wholesale and retail service areas range from approximately 36 to 60 mgd. As shown in Table E.2.4, estimates provided by the wholesale customers indicate projected savings from conservation programs (apart from plumbing code savings) in 2030 for the wholesale service area of approximately 13 to 15 mgd. The WSIP proposed water supply option includes 4 mgd of projected savings in 2030 for the retail service area from conservation programs, apart from plumbing code savings.

Recycled Water Potential

Recycled water has the potential to replace potable supplies for such uses as landscape irrigation, toilet flushing, and cooling towers. The SFPUC also evaluated the recycled water potential in the wholesale and retail service areas. In the wholesale service area, the SFPUC identified 14 areas with current and/or planned recycled water projects; 9 areas that currently produce recycled water totaling approximately 12.6 mgd, and additional projects considered relatively certain to be implemented in the near future, as well as those under study.[11] The study estimated that by 2020, the total average annual yield of recycled water projects in the wholesale service area (i.e., current plus new projects, including projects under study) could produce 40 to 46 mgd. Total average annual yield includes water that would be used to meet nonpotable demand not represented in the SFPUC demand estimates. **Table E.2.5** summarizes the results of the study. Information provided by the wholesale customers indicates that by 2030 an estimated 9 mgd would be used in the wholesale service area to offset projected 2030 demand (see Table E.2.5) (URS, 2006).

SFPUC has published a technical feasibility report called the *Recycled Water Master Plan* (RMC, 2006), which assesses the feasibility of recycled water projects in the Westside area of San Francisco. The feasibility analysis identifies projects with the potential to provide approximately 6.2 mgd of recycled water to irrigate Golden Gate Park, Lincoln Park, Harding Park, the San Francisco Zoo, San Francisco State University, and other locations, as well as provide a supplemental water supply for Lake Merced (RMC, 2006). The first phase of projects identified in the report would provide 4.1 mgd recycled water to this area (RMC, 2006).

2030 Purchase Estimates

Following completion of 2030 demand modeling and the conservation potential and recycled water potential studies, the wholesale customers considered conservation potential and other water supply sources and submitted purchase estimates for SFPUC water for 2030 (see **Table E.2.6**). The changes in purchase estimates from 2001 are shown in Table E.2.1. As that table shows, the 2030 estimated purchases represent a total increase of 35 to 39 mgd, or 13 to 15 percent above 2001 purchases. Table E.2.6 also shows the percentage of water supply sources (including recycled water) that is represented by purchases from the SFPUC (i.e., the percentage of demand after conservation savings are taken into account). Purchases from the SFPUC in 2030 represent approximately 72 percent of the total SFPUC service area demand (with plumbing code savings) and about 75 percent of demand adjusted for conservation. (Figure 7.3 of PEIR Chapter 7 depicts historical water deliveries for the wholesale and retail services areas as well as the projected demand on the SFPUC system [i.e., estimated purchases] to 2030.)

[11] These projects, categorized in the technical memorandum as “planned and being implemented,” are defined as projects for which agencies have conducted planning studies and may have secured financing, and on which construction had begun or was planned to begin in the coming year. However, the projects in this category are not considered completely certain.

TABLE E.2.5
SUMMARY OF RECYCLED WATER POTENTIAL FOR THE SFPUC SERVICE AREA (mgd[a])

SFPUC Service Area Recycled Water Project Areas	Recycled Water Potential (Total Average Annual Yield)				2030 Projections (Offsets Potable Demand)
	Current (2004) Recycled Water Projects	Planned Recycled Water Projects[b]	Recycled Water Projects Under Study or Previously Studied	Subtotal – Additional Potential Projects	2030 Projected Recycled Water Supply[c]

Stanford University	0	0	0.06 – 0.98	0.06 – 0.98	
City of Sunnyvale	0.81	0.18	1.3	1.48	1.50
Subtotal – SFPUC Wholesale Customer Service Area[i]	**12.6**	**6.3 – 7.8**	**20.7 – 25.6**	**27.0 – 33.4**	**9 – 10**
SFPUC Retail Service Area	**0**	**0**	**6**	**6**	**0 – 4**
Total, SFPUC Service Area[i]	**12.6**	**6.3 – 7.8**	**26.7 – 31.6**	**33 – 39.4**	**9 – 14**

a mgd = million gallons per day.
b These projects are identified in the *Wholesale Customer Recycled Water Potential Technical Memorandum* as “Planned and Being Implemented.” However, they are not considered completely certain, according to the SFPUC. Therefore, they are identified in this table as “Planned.”
c The source for this column is URS, 2006, except for SFPUC Retail Service Area, which is based on SFPUC, 2007.
d Wholesale customers served are California Water Service Company (CWS), Daly City, and Westborough Water District.
e Wholesale customers served are Palo Alto and Mountain View; RWQCP = Regional Water Quality Control Plant.
f Wholesale customers served are Palo Alto, Mountain View, and Stanford University; RWQCP = Regional Water Quality Control Plant.
g In November 2005, Redwood City informed the SFPUC of a revised purchase estimate to include 1 mgd of recycled water in lieu of 1 mgd of SFPUC purchases in 2030 (City of Redwood City, 2005). Despite this change, the overall 2030 purchase estimate remains at 300 mgd to be consistent with all the previous and ongoing WSIP studies.
h Wholesale customers served are the Cities of Milpitas, San Jose, and Santa Clara.
i Of the 12.6 mgd produced by current recycled water projects, 4.3 mgd replaces a potable water supply.

NOTE: Numbers may not sum due to rounding.

a mgd = million gallons per day.
b CWS = California Water Service Company.
c CWS–Bear Gulch District includes the former Los Trancos County Water District.
d The upper range purchase estimate assumes loss of all local water sources (surface water and groundwater) and the lower range estimate assumes continuation of local sources; both estimates assume Level B water conservation.
e The purchase estimate range reflects a range of potential groundwater usage established under a pilot project, from the sustainable yield (3.76 mgd) to the lowest annual production yield (1.34 mgd), according to Daly City's best estimate of 2030 water purchases (SFPUC, 2004).
f MID = Municipal Improvement District.
g 2030 conservation savings is based on URS 2004c and the City's UWMP as confirmed by the City (Popp, 2007).
h 2030 demand and conservation savings are based on information provided by the City of Palo Alto to the SFPUC (City of Palo Alto, 2005a).
i In November 2005, Redwood City informed the SFPUC that it would be purchasing its low-range estimate of 11.6 mgd due to anticipated implementation of 1 mgd of recycled water in 2030 (City of Redwood City, 2005a). The high-range purchase estimate total of 300 mgd published in URS 2004b remains the SFPUC 2030 purchase estimate total for planning purposes, to be consistent with the previous and ongoing WSIP studies. The purchase estimate range originally submitted apparently reflects the average of the City's estimated conservation savings range plus the originally estimated range of recycled water use.
j Portion of north San Jose only.
k Demand and purchase estimates are based on Westborough Water District's 2005 UWMP, as requested by the District in a letter to the SFPUC (Westborough Water District, 2007). The UWMP discusses ongoing and planned future demand management programs but does not quantify conservation savings in relation to the demand and purchase estimate. The District's original estimate of water purchases indicated conservation savings of 0.020 mgd (SFPUC 2004).
l The low range of the SFPUC retail customer purchase estimate reflects the identified groundwater, recycled water, and conservation programs totaling 10 mgd in San Francisco that are included as part of the WSIP proposed water supply option.

Conservation Measures

The following two tables are included with this appendix to show the conservation identified in the wholesale and retail conservation studies:

- **Table 2-2** of the *SFPUC Wholesale Customer Water Conservation Potential Technical Report* (URS 2004c), which lists the 32 conservation measures that emerged from 75 initial measures screened by the SFPUC, as described above; and
- **Table 19** of the *City and County of San Francisco Retail Water Demands and Conservation Potential* report (Hannaford and Hydroconsult, 2004), which lists the 48 measures initially identified in the conservation study.

Table 2-2
Description of Conservation Measures Selected for Further Evaluation

Conservation Measure	Measure Description
1. Residential Water Surveys	Offer indoor and outdoor water surveys to existing Single-Family and Multi-Family residential retail customers with high water use; provide customized report to homeowner.
2. Residential Retrofit	Provide owners of pre-1992 homes with retrofit kits that contain easy-to-install low flow showerheads, faucet aerators, and toilet tank retrofit devices.
3. Large Landscape Conservation Audits	Provide free landscape water audits to all public and private irrigators of landscapes larger than one acre with separate Irrigation accounts upon request.
4. Water Budgets	Provide a monthly irrigation water use budget as information on the water bill for all irrigators of landscapes larger than one acre with separate Irrigation accounts.
5. Clothes Washer Rebate	Provide a rebate on a new water efficient clothes washer for homeowners.
6. Public Information Program	Provide public education to raise awareness of conservation measures available to retail customers. Programs could include poster contests, speakers to community groups, radio and television time, and printed educational material such as bill inserts, etc.
7. Commercial Water Audits	Provide a free water audit to high water use Commercial accounts that evaluates ways for the business to save water and money.
8. ULF Toilet and Urinal Rebates	Provide rebates to pre-1994 businesses with high use fixtures for commercial ULF toilets (1.6 gal/flush) and commercial ULF urinals (1.0 gal/flush).
9. Residential ULF Toilet Rebate	Provide a rebate to homeowners to replace an existing high volume toilet with a new water efficient toilet.
10. Require 1.6 gal per flush toilets to be installed at the time of sale of existing buildings	Work with the real estate industry to require a certificate of compliance be submitted to the water utility verifying that a plumber has inspected the RSF or RMF property and efficient fixtures were either present or installed at the time of sale, before close of escrow.
11. Home Leak Detection and Repair	Use leak detection equipment to determine whether and where leaks are occurring on the premises and provide a plumber to the retail customer to repair leaks for free.
12. Rebates for 6/3 dual flush or 4 liter toilets	Provide a rebate or voucher for the retrofit of a 6/3 dual flush, 4-liter or equivalent very low water use toilet. Rebate amounts would reflect the incremental purchase cost and would be in the range of $50 to $100 per toilet replaced.

Table 2-2
Description of Conservation Measures Selected for Further Evaluation

Conservation Measure	Measure Description
13. ET Controller Rebates	Provide a rebate for the latest state of the art irrigation controllers with on-site temperature sensors or a signal from a central weather station that modifies irrigation times at least weekly (preferably daily) as the weather changes.
14. Xeriscape education and staff training at retail garden/irrigation supply houses	Sponsor training for staff of stores where plants and irrigation equipment is sold to educate sales people about the benefits of native (low water use) plants, efficiently irrigated.
15. Homeowner irrigation classes	Sponsor classes at stores where irrigation equipment is sold or other suitable venues on selection and installation of efficient equipment (drip irrigation, smart controllers, low volume sprinklers, etc.)and proper plant.
16. Promote water efficient plantings at new homes	Provide information for planting water-efficient landscaping, including avoiding strip turf sections that are difficult to water efficiently and using native plants that do not require supplemental watering. Information would be provided in brochures with the water bill, or mailed. Informational displays at Water Utility offices and nurseries could also be provided.
17. Offer incentives for replacement of clothes washers in coin-operated laundries	Offer incentives to apartment and coin-op laundry managers to retrofit or use efficient clothes washers. The rebate would either go to the manager or the washing machine leasing company.
18. Incentives for retrofitting sub-metering	Rescind any regulations that prohibit sub-metering of multi-family buildings and encourage sub-metering through water audits and direct mail promotions, and/or incentives to building owners.
19. Require sub-metering multifamily units	Require all new multi-family units to provide sub-meters on individual units. To help reduce financial impacts on tenants, regulations would be adopted that specify acceptable methods of metering and billing.
20. Rebate efficient clothes washers	Provide a rebate to new apartment complexes over a certain size with a common laundry room equipped with efficient washing machines.
21. Enforce landscape requirements for new landscaping systems (turf limitations / regulations)	Enforce existing requirements on use of native or low-water-using plants for landscaping purposes. Proof of compliance would be necessary to obtain a water connection on all new Multi-Family Residential and commercial projects. Non-compliers would face a surcharge on their water bill until they complied.
22. Restaurant low flow spray rinse nozzles	Provide free installation of 1.6 gpm spray nozzles for the rinse and clean operation in restaurants and other commercial kitchens.

Table 2-2
Description of Conservation Measures Selected for Further Evaluation

Conservation Measure	Measure Description
23. Focused water audits for hotels/motels	Provide free water audits to hotels and motels covering bathrooms, kitchens, ice machines, cooling towers, and irrigation system schedules.
24. WAVE Program (US EPA) for hotels	Provide hotels with information about the US EPA's WAVE program. This program encourages hotels to do their own water audit and then analyze their water use with the software provided. The software identifies water saving projects and computes paybacks. Hotels that agree to participate in the program also agree to install cost-effective water conserving equipment.
25. Hotel retrofit (w/financial assistance)	Following a free water audit offer participating hotels a rebate for identified water saving. Provide a rebate schedule for certain efficient equipment such as air-cooled ice machines for hotels that don't participate in an audit.
26. Award program for water savings by businesses	Sponsor an annual awards program for businesses that significantly reduce water use. Provide a plaque, presented at a lunch with the mayor.
27. Replace inefficient water using equipment	Provide a rebate for a standard list of water efficient equipment including icemakers, efficient dishwashers, cooling towers to replace once through cooling, irrigation controllers, and certain process equipment.
28. Require 0.5 gal/flush urinals in new buildings	Require new buildings be fitted with 0.5 gal/flush urinals.
29. Financial incentives for complying with water use budget	Link a landscape water budget to a rate schedule that penalizes the account holder for exceeding its water budget and rewards them for using less than the budget.
30. Financial incentives for irrigation upgrades	Provide rebates for selected types of irrigation equipment upgrade.
31. Require dedicated irrigation meters for new accounts	Require new accounts with a substantial amount of irrigated landscape have dedicated landscape meters and are charged on a separate rate schedule that recognizes the high peak demand placed on the system by irrigators.
32. Water Utility / City Department water reduction goals	Provide water use reduction goals for metered City and County accounts and offer audits and employee education.

APPENDIX E.3

Population, Employment, and Water Demand Projections

This appendix provides a more detailed analysis of the population and employment projections and the associated water demand projections discussed in the PEIR Chapter 7, Growth Inducement Potential and Indirect Effects of Growth. This appendix reviews in greater detail the population and employment projections used by the San Francisco Public Utilities Commission (SFPUC) and its wholesale customers to develop their 2030 water demand projections and subsequent water purchase requests to the SFPUC. It also provides more detail on the evolution of the Association of Bay Area Governments (ABAG) regional growth projections for the Bay Area, and compares those growth projections to the projections of population and employment growth that correspond to the water customers' projections of demand growth. Finally, it provides additional discussion of the relationship between the customer growth and demand projections and the growth projections contained in the local general plans as well as ABAG projections.

Organization of Appendix E.3

The analysis presented in this appendix begins by reviewing the water customers' projections of water demand and identifying the population and employment expectations that are the basis for those projections. These expectations establish a basis of comparison with projections prepared by regional and local planning agencies. (The assessment presented in Chapter 7 evaluates the consistency of the demand projections developed by SFPUC in consultation with the water customers with those of the regional planning agency [ABAG] and the respective local jurisdictions.)

This analysis then reviews ABAG's *Projections 2002*, which was the published set of regional projections available at the time the water demand projections were prepared, and which provided a basis for many of those projections. It goes on to trace the evolution of ABAG's projections sets through *Projections 2003* and *Projections 2005*, to establish the trend in thinking, on the part of the regional planning agency, about how the Bay Area will grow. These projections do not incorporate explicit assumptions about the Water System Improvement Program (WSIP), and consequently provide a reasonable regional framework for evaluation of the projections on which the water demand forecasts are based.

Next, this analysis describes other sets of projections– those in cities' general plans and water districts' urban water management plans (UWMPs) (to the extent they are available) – for the areas served by the SFPUC and its wholesale customers, and compares these other sets of projections and ABAG's *Projections 2005* to the employment and population projections used by the respective water customers as the basis for projecting water demand.

Finally, this appendix compares the percentage increases in employment and population projected for the water customer service areas in both *Projections 2005* and the water customer demand studies (URS, 2004; Hannaford and Hydroconsult, 2004) to the percentage increase in water demand projected for each water customer service area.

Water Demand Projections

The majority of the wholesale customers selected ABAG's *Projections 2002* as the population and employment forecasts to be used in their demand forecasting models. There were some exceptions to this approach, such as where projections developed by the jurisdictions served or the BAWSCA annual survey were used. Table 4-1 of the *SFPUC Wholesale Customer Water Demand Projections Technical Report* (URS, 2004) (referenced in this appendix as the wholesale customer demand study) identifies the source of the projection for each wholesale customer. The *City and County of San Francisco Retail Water Demands and Conservation Potential* study (Hannaford and Hydroconsult, 2004) (referenced in this chapter as the retail customer demand study) identifies the sources of demographic data used for that study.

The wholesale customer demand study shows population and employment estimates for 2001 and projections through 2030. Because the horizon year for *Projections 2002* was 2025, it was necessary for the purposes of this PEIR to extend the projections to 2030. In most cases, the projections were extended by assuming the same (numeric) amount of growth between 2025 and 2030 as was projected to occur between 2020 and 2025.

Tables E.3.1 and **E.3.2** summarize the projections of employment and population growth used for the water demand projections, by county. In Table E.3.1, two interim years – 2005 and 2025 – have been added to the boundary years shown in the wholesale customer demand study. The estimates for 2005 and 2025 were created to provide a consistent interval for comparison of the growth assumed for the water demand projections to other sets of projections (primarily ABAG's *Projections 2003* and *Projections 2005*). For wholesale customers, the interim year estimates assume a constant numeric rate of growth over the entire projection period; in other words, both employment and population would increase in a straight line with constant slope over the 29-year period (2001-2030). This assumption is consistent with the procedure used in the wholesale demand report both to create year-by-year estimates and to extend the projections to 2030. The retail customer demand study uses a base year of 2000, but includes projections for 2005 and 2025 as well as 2030.

Table E.3.2 calculates the numeric and percentage changes in employment and population that would occur in the portion of each county served by the SFPUC and its wholesale customers.

TABLE E.3.1
EMPLOYMENT AND POPULATION PROJECTIONS FOR WATER DEMAND ESTIMATES: SUMMARY BY COUNTY[a]

	Employment				Population			
	2001	2005	2025	2030	2001	2005	2025	2030
Alameda County	238,565	251,963	318,953	335,701	456,962	468,786	527,908	542,688

San Francisco	89,867	11.8%	61,978	8.0%	77,472	10.0%
Total Area Served	401,251	16.8%	276,803	11.3%	345,984	14.2%

[a] Includes only those portions of each county served by SFPUC wholesale water customers or served directly by the SFPUC (San Francisco County). Population estimates for San Mateo County include updated figures for the Westborough Water District from the district's Urban Water Management Plan .

SOURCES: URS, 2004; Hannaford and Hydroconsult, 2004; Mundie & Associates, 2006; Westborough Water District, 2005.

These employment and population projections used in the water demand models indicate the type and amount of growth that is expected by wholesale customers and the SFPUC in the service area for which water will be required, and provide a basis for comparison with ABAG's current forecasts and other forecasts for the region.

Table E.3.3 compares the amount of growth expected between 2005 and 2025 to the amount that occurred between 1985 and 2005. This table provides an indication of whether future growth is expected to exceed past growth. It indicates that the percentage change in employment between 2005 and 2025 is expected to be smaller than the percentage change observed between 1985 and 2005, except in Santa Clara County and San Francisco County. Santa Clara County, which absorbed major employment losses during the "dot com bust" at the beginning of this decade, is estimated to have lost employment during the past 20 years. As a result, the percentage gain projected for the served portions of Santa Clara County during the next 20 years, although smaller than the percentage changes expected in the served portions of Alameda and San Mateo Counties, would represent a marked positive change from the experience of the past two decades. San Francisco, which was also affected by the dot com bust (but not as severely as Santa Clara County), showed modest employment growth during the past 20 years, but is expected to gain more jobs in the future.

TABLE E.3.3
POPULATION AND EMPLOYMENT PROJECTIONS FOR WATER DEMAND ESTIMATES: EXPECTED CHANGE COMPARED TO PAST CHANGE[a]

Area	1985-2005		2005-2025	
	#	%	#	%
Employment Change				
Alameda County	74,090	53.5%	66,990	26.6%
Santa Clara County	-18,770	-4.6%	92,843	17.9%
San Mateo County	54,770	21.5%	84,627	20.6%
Total Wholesale Customers	110,090	13.7%	244,462	20.7%
San Francisco	22,360	4.0%	114,020	17.4%
Total Area Served	132,450	9.7%	358,482	19.5%
Population Change				
Alameda County	116,100	32.4%	59,122	12.6%
Santa Clara County	74,600	19.2%	78,578	16.3%
San Mateo County	113,050	18.7%	77,125	10.7%
Total Wholesale Customers	303,750	22.5%	214,825	12.9%
San Francisco	79,500	11.1%	61,978	8.0%
Total Area Served	383,250	18.5%	276,803	11.3%

[a] Includes only those portions of each county served by SFPUC wholesale water customers or served directly by the SFPUC (San Francisco County). Population estimates for San Mateo County include updated figures for the Westborough Water District from the district's Urban Water Management Plan .

SOURCES: URS, 2004; Hannaford and Hydroconsult, 2004; ABAG, 2004; Mundie & Associates, 2006; Westborough Water District, 2005.

In the areas of San Mateo County served by SFPUC wholesale customers, the percentage increase in employment is expected to be slightly smaller during the forecast period than it was during the past two decades, but the numeric change is expected to be greater (by nearly 30,000 jobs, which would be about 55 percent more than were added during 1985-2005).

Table E.3.3 further indicates that, without exception, the percentage change in population during the next two decades is expected to be smaller than the percentage change during the past two, and that, except areas of Santa Clara County served by SFPUC water customers, the numeric change is expected to be smaller as well. (The number of residents added in this portion of Santa Clara County between 2005 and 2025 is projected to exceed the number added between 1985 and 2005 by about 4,000, or five percent.)

Projections of employment and population for each wholesale customer's service area are presented in **Table E.3.4**. This table parallels county Table E.3.1 in that it provides estimates of employment and population in 2001, 2005, 2025, and 2030.

Tables E.3.5 and **E.3.6** provide information parallel to that provided in county Table E.3.2, by calculating the numeric and percentage change in employment (Table E.3.5) and population (Table E.3.6) for each wholesale customer service area during 2001-30, 2005-2025, and 2005-30.

Comparisons of ABAG and Other Forecasts

Overview of ABAG Projections

As was noted on page E.3-2, many of the wholesale customers selected the employment and population growth projections prepared by the Association of Bay Area Governments (ABAG) for use in the water demand model to forecast 2030 water demand for their service areas.[1] ABAG generally updates its projections every other year. At the time the demand projections for this project were prepared, *Projections 2002* was the current set.

Comparing Water Customers' Projections to ABAG Projections

The SFPUC wholesale customers' projections are specific to the area served by the respective water districts, while ABAG provides projections for cities – both for the area within each city's corporate limits and, where cities abut unincorporated areas, for cities and their spheres of influence or planning areas. Because most water customers' service areas are not congruent with the boundaries of ABAG projection areas, the wholesale customers' projections of employment and population growth are not directly comparable to ABAG's projections of employment and population growth.

1 The end-use demand model utilized published population and employment projections to forecast the growth in the number of applicable water accounts. Each wholesale customer selected the projections source to be used for its service area. The selected population and employment projections were input into the demand model and the growth rate from the selected projection was applied to the applicable accounts. The water demand model and the development of water demand projections is described in more detail in PEIR Appendix E.2 and in the wholesale and retail customer demand studies (URS, 2004; Hannaford and Hydroconsult, 2004).

[a] Los Trancos County Water District was acquired by CWS in 2006, and is now part of the CWS – Bear Gulch District. Because it was a separate entity when these projections were prepared, it is presented separately in this analysis.

SOURCES: URS, 2004; Hannaford and Hydroconsult, 2004; Mundie & Associates, 2006; Westborough Water District, 2005.

To compare the changing expectation of growth in the SFPUC wholesale customer service area as depicted in the evolving sets of projections produced by ABAG, therefore, this analysis assigns wholesale customers to ABAG's projection units (typically cities or, where a city is bordered by unincorporated area, subregional study areas). As suggested above, this assignment is inexact: in some cases, only part of a city is served by a wholesale customer, or the wholesale customer serves an unincorporated area that could not be segregated from other unincorporated areas in the ABAG materials. **Tables E.3.A.1** and **E.3.A.2**, in Attachment E.3.A (at the end of this appendix)**,** detail the assumptions that were made to establish a correspondence between areas served by wholesale water customers and areas for which ABAG has prepared projections of employment and population, and the resulting correspondences between water customers and ABAG areas.

Most of the discussion that follows – describing ABAG's projections for employment and population growth in the nine-county Bay Area, the four counties that include the SFUC service area, and the portions of the four counties within the SFPUC service area – is based solely on the ABAG estimates of current and future conditions. It is only when the ABAG projections are compared to the water customers' projections (e.g., beginning with **Table E.3.33** and the related text), that the correspondence between water customer service areas and ABAG jurisdictions may introduce some distortion into the analysis, because of the inexact matches between the ABAG areas and the water service areas.

ABAG Projections: Evolution from *Projections 2002* to *Projections 2005*

ABAG, the regional planning agency in the Bay Area, provides long-term demographic and economic forecasts for the nine Bay Area counties. ABAG produces a biennial *Projections* series developed from a series of computer models. The projections are utilized by regional transportation and air quality agencies, local government, and private industry. As noted above, ABAG projections were selected by many of the wholesale customers as the basis for their growth and employment projections. In addition, because ABAG is the regional planning agency in the Bay Area, the ABAG projections in general provide a useful tool for assessing assumptions and forecasts made by other agencies regarding future trends in the area.

In 2003, ABAG revised the assumptions that provide the basis for its biennial (every two year) projections, to incorporate additional assumptions about future development in the Bay Area. To lay out how this change in underlying assumptions compares to the underlying assumptions at the time water demand projections were being prepared (and to compare the projections based on those assumptions), this appendix first presents a comprehensive comparison of the ABAG *Projections 2002* with *Projections 2003*, the first year incorporating the smart growth principles, and then presents a comprehensive comparison of *Projections 2003* and *Projections 2005*, ABAG's current projections set. This process provides a look at the evolution of ABAG's expectations for growth in the Bay Area and its constituent communities.

Changes in the Underlying Assumptions

Basis for Projections 2002

ABAG's projections have historically been based on a model that forecasts growth in the region in relation to national economic and demographic trends. In this model, projections of total employment growth in the nine-county Bay Area are based on expected growth of the national economy and the relative attractiveness of the Bay Area compared to other regions. This regional forecast provides a "control total," which is then distributed among subareas within the region The subareas are based primarily on municipal jurisdictions. [2]

The allocation of growth to subareas within the region has historically been based on existing patterns of economic activity and the availability of land for commercial, industrial, and residential development, and housing opportunities for employees. The distribution process begins with jobs: new economic activities are assumed to locate near existing similar or linked activities, and trends showing growth or decline are generally assumed to continue (although not necessarily at the same rate).

Residential (household and population) growth is projected for each county, based primarily on the "cohort-survival method" (births minus deaths), with additional assumptions about net migration. The migration assumptions are based on the relationship between predicted labor force-aged population and forecast employment: if a tight labor market is expected, then in-migration is assumed to occur. Assumptions about housing costs are also used, in recognition of the fact that housing prices outside the nine-county region may be more affordable than prices within the region.

The total population for each county is distributed to specific locations within the Bay Area (and beyond) based a series of variables including employment locations, housing opportunities and costs, education, and the cost of travel. The final forecasts are refined to recognize potential constraints on land availability. Land availability estimates are based on local land use policies and regulations, such as general plans and zoning codes.

Basis for Projections Beginning with Projections 2003

Beginning in 2003, ABAG added a new policy dimension to its regional forecasts, an overlay of "smart growth" principles. ABAG defines smart growth as:

> Development that reflects higher densities, mixed use, and a higher proportion of housing and employment growth in urban areas, particularly near transit stations and along transit corridors, as well as in town centers (ABAG, 2002).

---

2 Subareas reported in the *Projections* series are "subregional study areas," which may be cities (when city limits coincide with a city's sphere of influence), city spheres of influence (considered to be each city's expected ultimate urban boundaries until modified), or "other subregional areas." ABAG also develops some projections (including population) for cities within jurisdictional boundaries (city limits). ABAG details its projections for areas as small as census tracts.

The smart growth policies have the following key impacts of the on the projections:

- Substitution of ABAG's smart growth policy-based assumptions about development potential for local land use policy assumptions. This substitution results in a geographic redistribution of development expectations. ABAG assumes that, over time – as general plans and zoning ordinances are updated – local policies will be modified to reflect smart growth principles.

- Rearrangement of the total expected growth in the region among jurisdictions, beginning in about 2010. The pattern of growth reflected in *Projections 2003* and *Projections 2005* is "mainly transit-oriented, and focuses development in urban core areas throughout the region." ABAG, the Metropolitan Transportation Commission (MTC), and the State of California are assumed to make funding recommendations and decisions linking transportation projects to the adoption and implementation of smart growth land use principles. ABAG recognizes, however, that "because of the time required to obtain incentives and make investments a reality, changes to land use patterns won't begin to occur until 2010" (ABAG, 2004).

- Increased housing production. *Projections 2003* (like its successor, *Projections 2005*) assumes that a combination of regulatory and policy changes, along with "partial government funding," will be needed "to spur an increase in overall housing production, and to channel housing toward infill sites". Specifically, the projections anticipate that the removal of barriers to infill development and an increase in (unspecified) government funds of $350 million per year will help to increase regional housing production by 5,000 units per year between 2010 and 2020, and by 7,500 units per year between 2020 and 2030.

Growth Expected by *Projections 2002* and *Projections 2003*

Projected Growth in the San Francisco Bay Area

Table E.3.7 establishes a framework for evaluating the evolution of the ABAG projections by comparing the employment projections for ABAG's entire nine-county area presented in ABAG's *Projections 2002* – the set on which most of the wholesale customer water demand projections are based – to employment projections for the nine counties in *Projections 2003*, the first set that uses the smart growth principles. This comparison illustrates the change in expectations for employment growth resulting from ABAG's shift to a smart growth policy-based projection. The table focuses on the change expected to occur between 2005 and 2025, which is the horizon year for *Projections 2002*.

TABLE E.3.7
ABAG *PROJECTIONS 2002* AND *PROJECTIONS 2003*:
EMPLOYMENT PROJECTIONS FOR THE NINE-COUNTY BAY AREA

Source of Projection	Jobs in 2005	Jobs in 2025	New Jobs, 2005-2025
Projections 2002	3,933,870	4,932,590	998,720
Projections 2003	3,848,870	4,982,800	1,133,930
% change	-2%	1%	14%

SOURCES: ABAG, 2001; ABAG, 2002.

This table shows that *Projections 2003* anticipates more employment growth within the Bay Area than did *Projections 2002*: the number of jobs is estimated to be lower in 2005, and to increase to a higher total in 2025. *Projections 2003* forecasts that the Bay Area will gain 135,210 more jobs between 2005 and 2025 than *Projections 2002* forecasts for this period; by 2025, the Bay Area is projected to have about 50,200 more jobs, according to *Projections 2003*. This adjustment in the employment projection reflects ABAG's increasing understanding of how many jobs were lost in the "dot com bust" recession in the early part of this decade, coupled with the ongoing assumption that the *Projections 2002* forecast of total employment in 2025 continued to represent a reasonable expectation for the future.

Table E.3.8 provides a similar comparison for population in the nine-county Bay Area. This table indicates that *Projections 2003* anticipates about 23 percent more population growth in the nine-county Bay Area between 2005 and 2025 than was anticipated in *Projections 2002*. This additional growth (234,100 more residents by 2025 in *Projections 2003*) is consistent with the increase in housing production forecasted in *Projections 2003* compared with *Projections 2002*, which would add 87,500 housing units between 2010 and 2025.

TABLE E.3.8
ABAG *PROJECTIONS 2002* AND *PROJECTIONS 2003*:
POPULATION PROJECTIONS FOR THE NINE-COUNTY BAY AREA

Source of Projection	Population in 2005	Population in 2025	Added Population, 2005-2025
Projections 2002	7,193,900	8,223,740	1,029,840
Projections 2003	7,193,900	8,457,800	1,263,900
% change	0%	3%	23%

SOURCES: ABAG, 2001; ABAG, 2002.

Projected Growth in the Four Water System Counties

The SFPUC water system delivers water to customers in four Bay Area counties: Alameda, Santa Clara, San Mateo, and San Francisco. The SFPUC system delivers water to 30 wholesale customers in the first three of these counties[3] and to retail customers in San Francisco.[4] (The four counties are considered here in their entirety; the following subsection considers the portion of the four-county area served within the service area of the SFPUC and its wholesale customers.)

3 There are 27 wholesale customers, but California Water Service Company (CWS) serves three distinct subgroups—Bear Gulch District, Mid-Peninsula District, and South San Francisco District —which are tracked separately in the SFPUC reports. One former wholesale customer, the Los Trancos County Water District, which was purchased by CWS and is now part of the Bear Gulch District, is also tracked separately in most of the SFPUC reports. The 30 wholesale customer entities referenced here include the CWS districts and Los Trancos as distinct entities.

4 The SFPUC also serves a few large retail customers in Alameda, San Mateo, and Tuolumne Counties, which project no change in water demand for 2030. This analysis focuses on projections of the wholesale customers and San Francisco.

To illuminate the differences between ABAG's *Projections 2002* and *Projections 2003* for the counties served by SFPUC water, **Tables E.3.9** and **E.3.10** compare employment and population projections in this four-county area. *Projections 2003* estimates that the four-county area had 81,000 fewer jobs in 2005 than did *Projections 2002,* but expects 20 percent (138,400) more jobs to be added between 2005 and 2025. By 2025, the number of jobs in the four-county area would be about two percent higher under *Projections 2003* than under *Projections 2002*.

TABLE E.3.9
ABAG *PROJECTIONS 2002* AND *PROJECTIONS 2003*:
EMPLOYMENT PROJECTIONS FOR THE FOCUSED FOUR-COUNTY AREA

Source of Projection	Jobs in 2005	Jobs in 2025	Added Jobs, 2005-2025
Projections 2002	2,989,370	3,682,510	693,140
Projections 2003	2,908,370	3,739,920	831,550
% change	-3%	2%	20%

SOURCES: ABAG, 2001; ABAG, 2002.

TABLE E.3.10
ABAG *PROJECTIONS 2002* AND *PROJECTIONS 2003*:
POPULATION PROJECTIONS FOR THE FOCUSED FOUR-COUNTY AREA

Source of Projection	Population in 2005	Population in 2025	Added Population, 2005-2025
Projections 2002	4,855,400	5,406,900	551,500
Projections 2003	4,855,400	5,695,800	840,400
% change	0%	5%	52%

SOURCES: ABAG, 2001; ABAG, 2002.

In combination with Table E.3.7, Table E.3.9 shows that:

- On a percentage basis, the four-county area accounts for greater employment losses as a result of the "dot com bust" than does the nine-county area as a whole. In the Bay Area as a whole (Table E.3.7), *Projections 2003* estimates *total* employment in 2005 that is about two percent lower than 2005 employment projected in *Projections 2002*; in the four-county area, the difference between these projections is three percent. Numerically, *Projections 2003* estimates that the nine Bay Area counties had 85,000 fewer jobs in 2005 than were forecasted in *Projections 2002,* and it estimates that the four-county area had 81,000 fewer jobs. In other words, the four-county area accounts for 95 percent of the nine-county employment adjustment for 2005 incorporated into *Projections 2003*.

- The increase in job *growth* in the four-county area anticipated by *Projections 2003* compared to *Projections 2002* – that is, about 138,400 more new jobs between 2005 and 2025 – is greater than the increase projected for the nine-county Bay Area as a whole (a difference of about 135,200 new jobs between *Projections 2003* and *Projections 2002*). This difference means that, just as the four-county area experienced most of the job loss during the dot com bust, it would account for all of the added job growth during the ensuing recovery.

Together, the comparisons of projections for the nine-county Bay Area and the four-county area indicate that employment in the Bay Area is expected to be increasingly concentrated in the four counties in which SFPUC water customers are located.

Table E.3.10 provides similar comparisons for population in the four-county area. It shows that the estimates of population in 2005 are the same in the two sets of projections, but that *Projections 2003* anticipates 52 percent more growth (840,400 new residents compared to 551,500 million) than *Projections 2002*. By 2025, *Projections 2003* projects the four counties to have about 5 percent more residents than were forecasted in *Projections 2002*.

In combination with Table E.3.8, Table E.3.10 shows that:

- The difference between *Projections 2002* and *Projections 2003* in the expected *total* population in 2025 is greater for the four-county area (about 289,000 more residents in *Projections 2003* in 2025) than for the entire nine-county Bay Area (about 234,100 more residents forecasted in 2025).

- The difference between the two sets of projections in the expected population *growth* forecasted for the 20-year period is also greater in the four-county area (with nearly 289,000 more new residents forecasted in the four counties in *Projections 2003* than were forecasted in *Projections 2002*, compared to about 234,100 more new residents in the nine counties in *Projections 2003*). (The difference in the *change* is the same as the difference in the *total* (previous bullet) are the same because the starting point – that is, population in 2005 – is the same in *Projections 2003* and *Projections 2002*.)

Together, the comparisons of projections for the nine-county and four-county areas indicate an expectation that population growth in the Bay Area will increasingly be concentrated in the four counties in which SFPUC water customers are located.

Projected Growth in the Area Served by SFPUC Water Customers

Employment Growth

ABAG projections of employment growth in the portion of the four-county area served by SFPUC water are compared in **Table E.3.11**. This table indicates that, in general, more new jobs are forecasted for this area by *Projections 2003* than were forecasted by *Projections 2002*. Overall, according to *Projections 2003*, the area would add nearly 438,300 jobs during the 20-year period, representing a 25 percent gain compared to the 2005 employment base and about 20 percent more growth than was forecast in *Projections 2002*.

Table E.3.12 provides detail about the employment projections for the ABAG cities that are served by one or more SFPUC water customers.

TABLE E.3.11
ABAG *PROJECTIONS 2002* AND *PROJECTIONS 2003*:
EMPLOYMENT PROJECTIONS FOR THE AREA SERVED BY SFPUC WATER CUSTOMERS (WHOLESALE AND RETAIL)[a]

Area	Source of Projection	Jobs in 2005	Jobs in 2025	Change, 2005-2025	
				Number	Percent
Alameda County	Proj. 2002	248,720	316,270	67,550	27.2%
	Proj. 2003	248,720	325,440	76,720	30.8%
Santa Clara County	Proj. 2002	517,310	617,590	100,280	19.4%
	Proj. 2003	499,410	608,030	108,620	21.7%
San Mateo County	Proj. 2002	382,280	465,240	82,960	21.7%
	Proj. 2003	362,460	464,870	102,410	28.3%
Total Wholesale Customers	Proj. 2002	1,148,310	1,399,100	250,790	21.8%
	Proj. 2003	1,110,590	1,398,340	287,750	25.9%
San Francisco	Proj. 2002	656,480	770,500	114,020	17.4%
	Proj. 2003	635,480	786,020	150,540	23.7%
Total Customers	Proj. 2002	1,804,790	2,169,600	364,810	20.2%
	Proj. 2003	1,746,070	2,184,360	438,290	25.1%

[a] Includes only those portions of each county served by SFPUC wholesale water customers or served directly by the SFPUC (San Francisco County).

SOURCES: ABAG, 2001; ABAG, 2002.

Table E.3.13 sorts the individual jurisdictions within the service area (a single wholesale customer may serve several jurisdictions) according to whether greater (total) employment in 2025 is expected by *Projections 2003* or *Projections 2002*. The projections are generally similar: *Projections 2003* expects that about one-half (16) of the jurisdictions will have about the same number of jobs in 2025 as were anticipated in *Projections 2002* (i.e., the projection is within 5 percent of the figure in *Projections 2002*); eight jurisdictions will have more jobs in 2025; and seven will have fewer jobs.

Table E.3.14 sorts the individual jurisdictions according to which set of projections anticipates a greater *increase* in the number of jobs between 2005 and 2025. This table differs from Table E.3.13 in that it shows the *change* in jobs during the 20-year period rather than the *total* number of jobs at the end of the period. As shown in the table, *Projections 2003* anticipates greater employment growth in 19 of the jurisdictions, about the same amount in 3,[5] and less growth in 10.

Combining the information from Tables E.3.13 and E.3.14 indicates that most of the jurisdictions in which more growth is anticipated during the next 20 years (from Table E.3.14) would be, in large part, regaining jobs lost at the beginning of this decade (reflected in a reduced ABAG estimate of employment in 2005).

5 In all of the comparison tables, “about the same” means “within five percent.”

Population Growth

Table E.3.15 compares expectations of population growth between 2005 and 2025 in the portion of the four-county area served by SFPUC water. This table indicates that *Projections 2003* expects nearly 137,000 more residents in the part of the four-county area served by SFPUC and its wholesale customers than did *Projections 2002*. This expectation represents overall growth of 350,420 residents, or about 66 percent more new residents than the 211,600 forecast by earlier set of projections.

TABLE E.3.15
ABAG *PROJECTIONS 2002* AND *PROJECTIONS 2003*:
POPULATION PROJECTIONS FOR THE AREA SERVED BY SFPUC WATER CUSTOMERS (WHOLESALE AND RETAIL)[a]

Area	Source of Projection	Population in 2005	Population in 2025	Change, 2005-2025	
				Number	Percent

	Proj 2003	481,100	552,500	71,400	14.84%
Santa Clara County	Proj 2002	473,100	545,300	72,200	15.26%
	Proj 2003	472,700	560,800	88,100	18.64%
San Mateo County	Proj 2002	727,000	800,000	73,000	10.04%
	Proj 2003	726,990	826,710	99,720	13.72%
Total Wholesale Customers	Proj 2002	1,682,800	1,877,800	195,000	11.59%
	Proj 2003	1,680,790	1,940,010	259,220	15.42%
San Francisco	Proj 2002	798,600	815,200	16,600	2.08%
	Proj 2003	798,600	889,800	91,200	11.42%
Total Customers	Proj 2002	2,481,400	2,693,000	211,600	8.53%
	Proj 2003	2,479,390	2,829,810	350,420	14.13%

[a] Includes only those portions of each county served by SFPUC wholesale water customers or served directly by the SFPUC (San Francisco County).

SOURCES: ABAG, 2001; ABAG, 2002.

Table E.3.16 provides detail about the population projections for the ABAG cities that are served by one or more SFPUC water customers.

Table E.3.17 sorts the jurisdictions served by SFPUC water according to whether greater *total* population in 2025 is expected by *Projections 2003* or *Projections 2002*. Slightly more than one-half of the jurisdictions (18 of 31) are expected to have about the same number of residents in 2025 (within 5 percent) in both sets of projections. In this case, however, most of the remaining jurisdictions (11 of 13) are expected by *Projections 2003* to have more residents in 2025, and only 2 are expected to have fewer residents.

Table E.3.18 sorts the jurisdictions according to whether greater *change* in population is expected by *Projections 2003* or *Projections 2002* in the jurisdictions served by SFPUC water. This table indicates that the same 18 jurisdictions that are expected to have greater population *growth* during the coming two decades under *Projections 2003* also are expected to have greater *total* population at the end of the 20-year period (as shown in Table E.3.17 [i.e., jurisdictions where the *Projections 2002* population as a percent of *Projections 2003* population is less than 1.00 percent]). Of the remaining 14 jurisdictions, however, 11 are expected to have less population growth with *Projections 2003* than with *Projections 2002*. Most of these 11 jurisdictions are relatively small: the population growth anticipated for these communities by *Projections 2003* ranges from 400 to 3,500 new residents over the 20-year period (except in Newark, where 6,400 new residents are expected).

TABLE E.3.16

Growth Expected by *Projections 2003* and *Projections 2005*

Projected Growth in the San Francisco Bay Area

ABAG's current set of projections, *Projections 2005*, continues to assume that Bay Area growth will begin to reflect "smart growth" principles beginning in about 2010. Accordingly, *Projections 2005* relies on the same assumptions about increased housing production introduced in *Projections 2003*. *Projections 2005* differs from *Projections 2003*, however, in that it readjusts employment and population estimates for 2005 to reflect improved information about the number of jobs lost in the dot com bust of the early part of this decade and improved estimates of the 2005 population.

Table E.3.19 compares estimates of employment in 2005, and projections of employment in 2025, from *Projections 2003* and *Projections 2005* for the nine-county Bay Area. This comparison shows a reduction in the estimate of total jobs in 2005 from about 3.8 million to about 3.5 million, an adjustment of nine percent. *Projections 2005* forecasts nearly 4.8 million jobs in 2025, down from the 5.0 million anticipated by *Projections 2003*. This future total reflects an expectation of stronger employment growth (more new jobs), but even the addition of 12 percent more jobs than were anticipated in *Projections 2003* is not sufficient to achieve the same number of jobs anticipated by that set of forecasts, given the smaller employment base estimated for 2005 in *Projections 2005*.

TABLE E.3.19
ABAG *PROJECTIONS 2003* AND *PROJECTIONS 2005*:
EMPLOYMENT PROJECTIONS FOR THE NINE-COUNTY BAY AREA

Source of Projection	Jobs in 2005	Jobs in 2025	Jobs in 2030	New Jobs, 2005-2025	New Jobs, 2005-2030
Projections 2003	3,848,870	4,982,800	5,226,400	1,133,930	1,377,530
Projections 2005	3,516,960	4,788,330	5,120,600	1,271,370	1,603,640
% change	-9%	-4%	-2%	12%	16%

SOURCES: ABAG, 2001; ABAG, 2002

Because both *Projections 2003* and *Projections 2005* extend the forecasts through 2030, that year is also included in this table. By 2030, *Projections 2005* anticipates that total employment in the nine-county Bay Area will reach 5.1 million jobs, which is within 2 percent of the *Projections 2003* forecast of 5.2 million. This total reflects the expected addition of 1.6 million new jobs during the 25-year interval from 2005, or about 16 percent more than the 1.4 million anticipated in *Projections 2003*.

Table E.3.20 provides the same comparison for population. It shows that the two sets of ABAG forecasts – *Projections 2003* and *Projections 2005* – maintain similar estimates of population in the nine Bay Area counties in 2005, and similar projections of population in the nine-county area in 2025. The projections for 2025 (8.42 million in *Projections 2005*; 8.46 million in *Projections 2003*) are within 0.5 percent of each other.

TABLE E.3.20
ABAG *PROJECTIONS 2003* AND *PROJECTIONS 2005*:
POPULATION PROJECTIONS FOR THE NINE-COUNTY BAY AREA

Source of Projection	Population in 2005	Population in 2025	Population in 2030	Added Population, 2005-2025	Added Population, 2005-2030
Projections 2003	7,193,900	8,457,800	8,780,300	1,263,900	1,586,400
Projections 2005	7,091,700	8,419,100	8,747,100	1,327,400	1,655,400
% Change	-1%	0%	0%	5%	4%

SOURCES: ABAG, 2002; ABAG, 2004.

By 2030, both sets of projections anticipate that the population of the Bay Area will exceed 8.7 million, or about 1.6 million more than in 2005. The projections for that year are also within 0.5 percent of each other.

Projected Growth in the Four Water System Counties

Table E.3.21 focuses the comparison of employment anticipated in *Projections 2003* and *Projection 2005* on the four counties in which the SFPUC system provides water. (The four counties are considered here in their entirety; the following subsection considers the portion of the four-county area within the service area of the SFPUC and its wholesale customers.) This comparison indicates a downward adjustment of the job base in 2005 by about 345,000 jobs, or 12 percent (compared to a downward adjustment of 332,000, or 9 percent, for the nine-county area). This adjustment provides further indication that most of the Bay Area job losses early in this decade were in these four counties.

TABLE E.3.21
ABAG *PROJECTIONS 2003* AND *PROJECTIONS 2005*:
EMPLOYMENT PROJECTIONS FOR THE FOCUSED FOUR-COUNTY AREA

Source of Projection	Jobs in 2005	Jobs in 2025	Jobs in 2030	New Jobs, 2005-2025	New Jobs, 2005-2030
Projections 2003	2,908,370	3,739,920	3,911,320	831,550	1,002,950
Projections 2005	2,563,600	3,516,890	3,765,020	953,290	1,201,420
% Change	-12%	-6%	-4%	15%	20%

SOURCES: ABAG, 2002; ABAG, 2004.

Table E.3.21 shows that *Projections 2005* anticipates that the four-county area will gain more employment between 2005 and 2025, and between 2005 and 2030, than did *Projections 2003*. The total numbers of jobs projected in 2025 and 2030 are, however, smaller in *Projections 2005*, as the expected growth in employment is insufficient to compensate for the reduction in 2005 employment (based on more recent, and, presumably, more accurate, information about current employment) incorporated into the forecasts.

Table E.3.22 provides the comparison *of Projections 2003* and *Projections 2005* in the four counties for population projections. This table also shows a small downward adjustment in the estimate for 2005 compared to *Projections 2003*; however, this adjustment is minor (about one percent of total population in the four-county area). *Projections 2005* anticipates more population growth in the four-county area than does *Projections 2003*, and a similar total population projected in the horizon years of 2025 and 2030 (within 0.5 percent of the total forecast in *Projections 2003*).

Projected Growth in the Area Served by SFPUC Water Customers

Employment Growth

Employment growth anticipated in the area served by SFPUC water customers by *Projections 2003* and *Projections 2005* is compared in **Table E.3.23**. This table shows that employment growth in three of the four counties is expected to follow the pattern observed in the nine-county area: *Projections 2005* anticipates greater employment growth between 2005 and 2025, and between 2005 and 2030, than does *Projections 2003*, but, because of the lower estimate of

TABLE E.3.22

	Proj 2005	1,491,530	2,032,650	2,173,400	541,120	36.3%	681,870	45.7%

[a] Includes only those portions of each county served by SFPUC wholesale water customers or served directly by the SFPUC (San Francisco County).

SOURCES: ABAG, 2002; ABAG, 2004.

employment in 2005, *Projections 2005* forecasts less *total* employment in both horizon years than does *Projections 2003*. In San Francisco, however, *Projections 2005* forecasts stronger employment *growth* through 2030, and this change lifts the *total* employment in that year higher than that projected for San Francisco in *Projections 2003*.

Table E.3.24 provides detail about the employment projections for the ABAG cities that are served by one or more SFPUC water customers. Because of format constraints, the projections for 2025 are omitted; only estimates for 2005 and projections for 2030 are shown.

a No separate projections for Guadalupe MID (part of Brisbane), Skyline County Water District (serves part of Woodside), Westborough Water District (serves part of South San Francisco), Stanford University (included by ABAG in the projections for Palo Alto), or San Jose (serves only a small portion of the city). Totals differ slightly from those shown in Table E.3.23 because the ABAG jurisdictions for which employment projections are reported in this table differ in geography from the water customer areas (see Tables E.3.A.1 and E.3.A.2).
b Fremont, Newark, and Union City are served by the Alameda County Water District.
c Los Altos Hills is served by the Purissima Hills Water District.
d Palo Alto projections include Stanford University
e This footnote deleted.
f Atherton, Portola Valley, and part of Woodside are served by CWS - Bear Gulch District. All of Portola Valley (including the portion previously served by Los Trancos County Water District, which is now a part of CWS) and Woodside are included in these projections.
g Belmont is served by the Mid-Peninsula Water District, which also serves parts of San Carlos.
h Colma is served by CWS - South San Francisco District
i Foster City is served by Estero MID, which also serves a portion of San Mateo. The projections for San Mateo are included in the projections for CWS - Mid-Peninsula District.
j Half Moon Bay and the adjacent unincorporated area (included in these figures) are served by the Coastside County Water District.
k The City of Menlo Park Water Agency serves only a portion of the City of Menlo Park (less than half of the city's population). These figures are for the entire city.
l Pacifica is served by the North Coast County Water District.
m Redwood City Water Agency also serves portions of San Carlos and Woodside.
n Parts of San Carlos and San Mateo are served by CWS - Mid Peninsula District. Both cities are included here in their entirety.
o South San Francisco is served by CWS - South San Francisco District + Westborough Water District.

SOURCES: ABAG, 2002; ABAG, 2004.

Table E.3.25 sorts the individual jurisdictions within the service area (a single water customer may comprise several jurisdictions) according to whether greater employment in 2030 is expected by *Projections 2005* or *Projections 2003*. In this case, 8 of the 31 jurisdictions are expected to have about the same total employment in 2030 (within 5 percent) in both sets of projections, 11 of the jurisdictions are expected by *Projections 2005* to have more employment in 2030, and 12 are expected to have less.

a Number of jobs in 2030 in *Projections 2005* is within five percent of the number of jobs in 2030 in *Projections 2003*.
b Number of jobs in 2030 forecast in *Projections 2005*.
c Stanford University is included within the City of Palo Alto in the ABAG projections. Only a small portion of the City of San Jose is within the district that obtains water from the SFPUC. It is considered misleading to include figures for all of San Jose in this analysis.
d Half Moon Bay plus Half Moon Bay (unincorporated).

SOURCES: ABAG, 2002; ABAG, 2004.

For comparison, as shown in Table E.3.13, *Projections 2003* expected 16 jurisdictions to have about the same employment in 2025 as did *Projections 2002*; 8 were expected to have more, and 7 were expected to have less. This comparison with the previous projections suggests that, although employment estimates for 2005 have again been readjusted downward in *Projections 2005*, expectations of future employment growth are now stronger than they were previously.

Table E.3.26 sorts the individual jurisdictions within the service area according to whether greater *increases* in employment between 2005 and 2030 are expected by *Projections 2005* or *Projections 2003*. Supporting the conclusions of the preceding paragraph, this table shows that *Projections 2005* forecasts greater employment growth than does *Projections 2003* for 25 of the 31 areas, about the same amount of growth for 5 areas, and less growth for only 1 area.

Population Growth

Population growth forecasted in *Projections 2003* and *Projections 2005* for the portion of the four-county area served by SFPUC water is summarized in **Table E.3.27**. This table shows that *Projections 2005* anticipates greater *total* population in three of the counties (Alameda, Santa Clara, and San Francisco) in 2025, and greater population in all four in 2030, than does *Projections 2003*.

TABLE E.3.27
ABAG *PROJECTIONS 2003* AND *PROJECTIONS 2005*:
POPULATION PROJECTIONS FOR THE AREA SERVED BY SFPUC WATER CUSTOMERS (WHOLESALE AND RETAIL)[a]

Area	Source of Projection	Population in 2005	Population in 2025	Population in 2030	Change, 2005-2025		Change, 2005-2030

	Proj 2005	716,100	818,800	840,900	102,700	14.3%	124,800	17.4%
Total Wholesale Customers	Proj 2003	1,680,790	1,940,010	1,993,130	259,220	15.4%	312,340	18.6%
	Proj 2005	1,653,100	1,933,200	2,002,200	280,100	16.9%	349,100	21.1%
San Francisco	Proj 2003	798,600	889,800	935,100	91,200	11.4%	136,500	17.1%
	Proj 2005	798,000	890,400	924,600	92,400	11.6%	126,600	15.9%
Total Customers	Proj 2003	2,479,390	2,829,810	2,928,230	350,420	14.1%	448,840	18.1%
	Proj 2005	2,451,100	2,823,600	2,926,800	372,500	15.2%	475,700	19.4%

[a] Includes only those portions of each county served by SFPUC wholesale water customers or served directly by the SFPUC (San Francisco County).

SOURCES: ABAG, 2002, ABAG, 2004.

The table also shows that *Projections 2005* forecasts greater population *growth* in every county than does *Projection 2003*, during the 20-year period from 2005 through 2025, and greater *growth* in three of the four counties (excluding San Francisco) during the 25-year period from 2005 through 2030.

Table E.3.28 provides detail about the population projections for the ABAG cities that are served by one or more SFPUC water customers. Because of format constraints, the projections for 2025 are omitted; only estimates for 2005 and projections for 2030 are shown.

Table E.3.29 sorts the jurisdictions according to whether *Projections 2005* anticipates greater total population in 2030 than does *Projections 2003*. This table shows that, in most jurisdictions (28 of the 31), the projections are about the same. *Projections 2005* expects one jurisdiction (Millbrae) to have more residents in 2030, and two (Half Moon Bay and Colma) to have fewer.

a No separate projections for Guadalupe MID (part of Brisbane), Skyline County Water District (serves part of Woodside), Westborough Water District (serves part of South San Francisco), Stanford University (included by ABAG in the projections for Palo Alto), or San Jose (serves only a small portion of the city). Totals differ slightly from those shown in Table E.3.27 because the ABAG jurisdictions for which employment projections are reported in this table differ in geography from the water customer areas (see Tables E.3.A.1 and E.3.A.2).
b Fremont, Newark, and Union City are served by the Alameda County Water District.
c Los Altos Hills is served by the Purissima Hills Water District.
d Palo Alto projections include Stanford University
e This footnote deleted.
f Atherton, Portola Valley, and part of Woodside are served by CWS - Bear Gulch District. All of Portola Valley (including the portion previously served by Los Trancos County Water District, which is now a part of CWS) and Woodside are included in these projections.
g Belmont is served by the Mid-Peninsula Water District, which also serves parts of San Carlos.
h Colma is served by CWS - South San Francisco District
i Foster City is served by Estero MID, which also serves a portion of San Mateo. The projections for San Mateo are included in the projections for CWS - Mid-Peninsula District.
j Half Moon Bay and the adjacent unincorporated area (included in these figures) are served by the Coastside County Water District.
k The City of Menlo Park Water Agency serves only a portion of the City of Menlo Park (less than half of the city's population). These figures are for the entire city.
l Pacifica is served by the North Coast County Water District.
m Redwood City Water Agency also serves portions of San Carlos and Woodside.
n Parts of San Carlos and San Mateo are served by CWS - Mid Peninsula District. Both cities are included here in their entirety.
o South San Francisco is served by CWS - South San Francisco District + Westborough Water District.

Conclusions about ABAG Growth Projections

The evolution of ABAG forecasts of employment and population growth in the Bay Area paints a picture of changed expectations of growth in the nine-county Bay Area, the four-county area in which SFPUC water customers are located, and the area served by SFPUC water customers, in generally consistent ways.

- Expectations of future *total* employment increased between *Projections 2002* and *Projections 2003*, and then decreased between *Projections 2003* and *Projections 2005*.

  The reduction shown in *Projections 2005* results primarily from ongoing adjustments to the estimate of employment in 2005. Projections of *growth* between 2005 and 2025, and between 2005 and 2030, have been increased in successive sets of forecasts, but these increases do not completely offset the cumulative reductions in beginning year (2005) employment that have been made as the impacts of the dot com bust in the early part of this decade have become clearer; as a result, *total* employment expected at the end of the forecast period is lower in the later projections.

  The successive sets of projections show that *Projections 2003* anticipated greater employment in 2025 than *Projections 2002*, but *Projections 2005* anticipate less employment in 2025 than either *Projections 2002* or *Projections 2003*, and less employment in 2030 than *Projections 2003* in all of the geographic areas considered. This summary comparison is shown in **Table E.3.31**.

TABLE E.3.31
ABAG PROJECTIONS OF EMPLOYMENT IN 2025: SUMMARY COMPARISON

Area	Year	*Projections 2002*	*Projections 2003*	*Projections 2005*
Nine-County Bay Area	2025	4,932,590	4,982,800	4,788,330
	2030		5,226,400	5,120,600
Four-County Area	2025	3,682,510	3,739,920	3,516,890
	2030		3,911,320	3,765,020
SFPUC Water Customers	2025	2,169,600	2,184,360	2,032,650
	2030		2,265,410	2,173,400

SOURCES: Tables E.3.7, E.3.9, E.3.11, E.3.19, E.3.21, E.3.23.

- Expectations of future population increased between *Projections 2002* and *Projections 2003*, and then decreased slightly between *Projections 2003* and *Projections 2005*. The future population anticipated by *Projections 2005* is, however, greater than the population anticipated by *Projections 2002*.

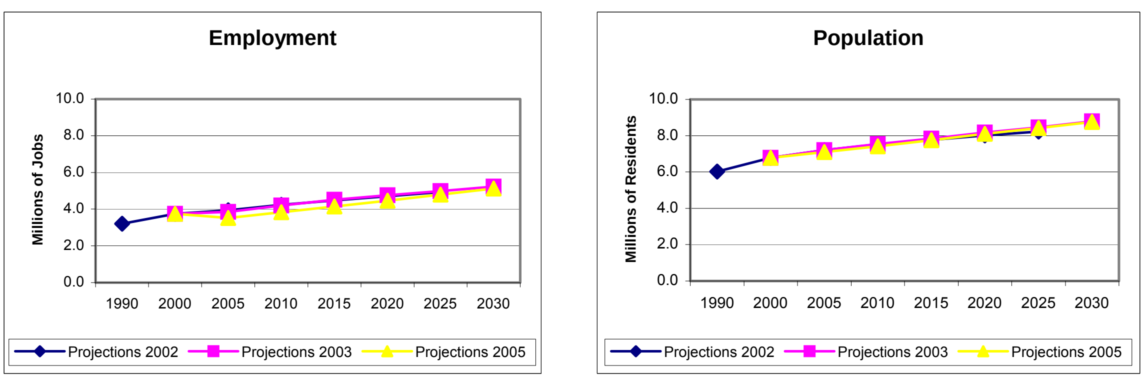
  The increases result primarily from the smart growth assumptions that were initiated with *Projections 2003*. These assumptions *rearrange* population growth (but not employment growth) within the Bay Area, compared to assumed population growth trends in previous projections sets, locating it generally in urban areas that have transit stations and/or transit corridors, and *add* growth based on the assumption that barriers to infill development will be removed and increasing government assistance for housing production will be provided (ABAG 2002). The summary of population comparisons is shown in **Table E.3.32**.

TABLE E.3.32
ABAG PROJECTIONS OF POPULATION IN 2025: SUMMARY COMPARISON

Area	Year	*Projections 2002*	*Projections 2003*	*Projections 2005*
Nine-County Bay Area	2025	8,223,740	8,457,800	8,419,100
	2030		8,780,300	8,747,100
Four-County Area	2025	5,406,900	5,695,800	5,681,700
	2030		5,943,500	5,924,700
SFPUC Water Customers	2025	2,693,000	2,829,810	2,823,600
	2030		2,928,230	2,926,800

SOURCES: Tables E.3.8, E.3.10, E.3.17, E.3.20, E.3.22, E.3.28.

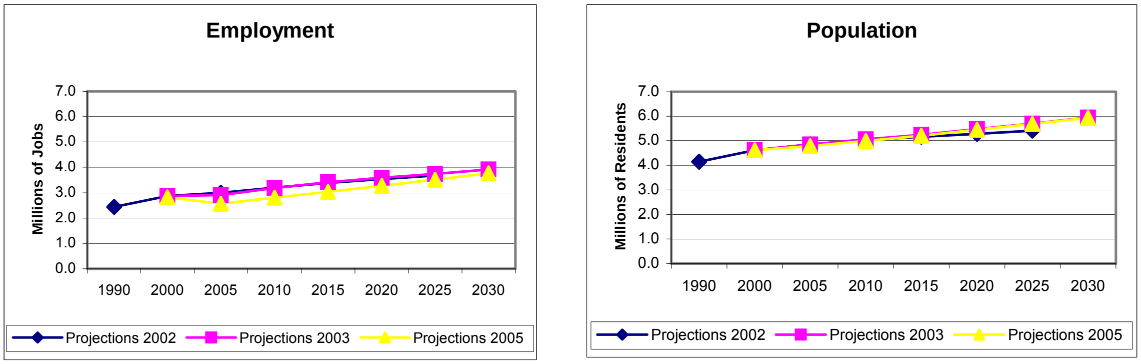
Figures E.3.1 and **E.3.2** provide a summary comparison of the thee projections sets for the nine-county bay area and the four counties that are partially served by the SFPUC and its wholesale customers. The figures illustrate that, notwithstanding the changes incorporated into *Projections 2003* and *Projections 2005*, the three sets of projections are similar both for the nine-county Bay Area (Figure E.3.1) and for the four-county area that is partially served by SFPUC water[6] (Figure E.3.2). The employment graphs reflect the lower estimates of 2005 employment presented in *Projections 2003* and *Projections 2005*, and the more rapid growth expected between 2005 and 2030 that would make up for most of the job losses in the early part of this decade.



SFPUC Water System Improvement Program ▪ 203287

Figure E.3.1
ABAG Projections of Employment and Population in the Nine-County Bay Area

6 SFPUC water serves all of San Francisco County and portions of Alameda, Santa Clara, and San Mateo Counties.



SFPUC Water System Improvement Program ▪ 203287

Figure E.3.2
ABAG Projections of Employment and Population in the Four County Area (Partially) Served by SFPUC Water

Other Growth Projections

The ABAG projections reviewed above are the only comprehensive set of employment and population projections that cover the area served by SFPUC water. There are, however, other planning documents that include projections of population and/or jobs, and these documents provide additional context for considering the San Francisco and wholesale customer demand projections. Most of the SFPUC wholesale customers, or the cities they represent, have adopted urban water management plans, which include projections to 2030. Cities and counties served by SFPUC water have general plans that typically include projections of employment and population, and these projections provide indications of whether the demand forecasts are consistent with or more ambitious than the adopted planning policies. **Table E.3.33** compares projections of employment from these local sources to employment anticipated by ABAG's *Projections 2005*.

For each source, the table shows the expected employment in the most distant year for which the general plan has a forecast. In some cases, the projections from different sources are similar; in others, they diverge. Reasons for differences between sources may include:

- Age of the projection source. *Projections 2005* was prepared during 2004. Some of the general plans were prepared 10 or more years ago. The water customers updated their urban water management plans in 2005. Some of the UWMPs utilize more recent ABAG projections than were available when the water demand studies were undertaken.

- Methodology. Some local projections may be based more on the development capacity of the land available for development (e.g., as designated in the general plan) than on demand factors such as economic growth and comparative advantage of a location in the community.

- Area covered. General plans typically cover a city's "planning area," which may be larger than its corporate limits or sphere of influence in cases where there is unincorporated land adjacent to the city limits. Because UWMPs are produced by the water customers for their service areas,

[a] Employment shown is for the year of the most distant employment projection available in the general plan or other relevant local document (see note b). For example, employment figures in all columns for cities in the group titled "Cities with GP Employment Projections for 2010" are employment projected for or estimated in 2010.
[b] Employment estimates are from each city's general plan (GP) or the general plan's EIR.
[c] Estimates for years between 2001 and 2030 are derived by Mundie & Associates, based on linear interpolations of the water customers' projections presented in URS 2004.
[d] UWMP does not forecast employment (some, but not all, UWMPs do forecast commercial, industrial, and other types of nonresidential accounts).
[e] Estero MID (Foster City and part of San Mateo) projection for 2010 is 26,652.
[f] Figure shown is for the portion of Menlo Park (less than half of the city's population) served by the SFPUC wholesale customer, the City of Menlo Park water agency.
[g] CWS – Mid-Peninsula District (parts of the cities of San Mateo and San Carlos plus unincorporated areas) projection for 2010 is 86,034.
[h] CWS – Bear Gulch District (Atherton, parts of Menlo Park, Portola Valley, and Woodside, plus unincorporated areas) projection for 2020 is 46,093.

TABLE E.3.33 (Continued)
COMPARISON OF GENERAL PLAN EMPLOYMENT PROJECTIONS TO
ABAG *PROJECTIONS 2005*, UWMPS, AND WATER CUSTOMER DEMAND PROJECTIONS
FOR GENERAL PLAN PROJECTION YEAR

[i] CWS – South San Francisco District (Colma, parts of Daly City and South San Francisco, plus unincorporated areas) plus Westborough Water District projection for 2020 is 59,466.
[j] Alameda County Water District (cities of Fremont, Newark, and Union City) projection is 151,092 in 2005; 160,853 in 2010, and 197,456 in 2020.
[k] Figure shown is for CWS – South San Francisco District (Colma, parts of Daly City and South San Francisco, plus unincorporated areas) plus Westborough Water District.
[l] Figure shown is for Town of Hillsborough water agency, which also serves some unincorporated area.
[m] Figure shown is for the City of Burlingame water agency, which also serves some unincorporated areas.
[n] Figure shown for *Projections 2005* includes ABAG's unincorporated Half Moon Bay.
[o] Projection for Purissima Hills Water District (part of Los Altos Hills and some unincorporated areas) is 457.
[p] Figure shown is for the City of San Jose water agency, which serves only a small part of the City of San Jose.

SOURCES: ABAG, 2004; ACWD, 2005; City and County of San Francisco, 2004; City of Burlingame, 2005; City of Daly City, 2004; City of Daly City,2005; City of East Palo 2001; City of East Palo Alto, 2006; City of Foster City, 2001; City of Fremont, 2003; City of Hayward, 2002; City of Hayward, 2005; City of Menlo Park, 1994; City of Menlo Park. 2006, City of Millbrae,1998; City of Millbrae, 2005; City of Milpitas, 2002a; City of Milpitas, 2005; City of Mountain View, 2002; City of Mountain View, 2005; City of Newark, 2002;City of Palo Alto, 2002; City of Palo Alto, 2005; City of Redwood City, 2005; City of San Mateo, 2001; City of Santa Clara, 2002; City of Santa Clara, 2005; City of South San Francisco, 2002; City of Sunnyvale, 2002; City of Sunnyvale, 2005; City of Union City, 2002; Coastside County Water District,2005; CWS-Mid-Peninsula, 2005; CWS-South San Francisco, 2006; Hannaford and Hydroconsult, 2004; Mid-Peninsula Water District, 2005; SFPUC, 2005; Town of Atherton, 2002; Town of Colma, 1999; Town of Hillsborough, 2002; Westborough Water District, 2005; URS, 2004.

the area covered in these plans would be the same as the area considered for the water demand projections. However, in many cases the service area boundaries do not coincide with boundaries covered in cities' general plans or the areas covered in ABAG projections; some service areas include unincorporated areas or portions of multiple cities. As noted elsewhere in this analysis, the ABAG areas that were assigned to water customer service areas are not congruent with those areas (see **Attachment E.3.A, Tables E.3.A.1** and **E.3.A.2** for correspondence between water customer service areas and ABAG areas).

In 13 of the 20 cases for which direct comparisons are available, Table E.3.33 shows that water customer projections of employment in the given general plan projection year exceed *Projections 2005* employment. This result is expected, because most of the water customer projections are based on extensions of *Projections 2002*, which anticipated higher overall employment in the near term and future years for most jurisdictions than does *Projections 2005*.

Table E.3.34 compares population projections contained in local general plans, urban water management plans, SFPUC demand documents, and *Projections 2005*. In almost all cases, Table E.3.34 indicates that future population levels anticipated by *Projections 2005* or the city's general plan exceed the population levels anticipated in the relevant water customer projection.[7] In most cases, *Projections 2005* contains the highest forecast. This pattern is consistent with ABAG's assumptions that smart growth principles and increased housing production will be incorporated into planning policy and practice in the future, especially after 2010.

[7] In Foster City, the water customer projection is higher than any of the others, but the water customer, which is Estero MID, serves a portion of San Mateo in addition to the City of Foster City.

a Population shown is for the year of the most distant population projection available in the general plan, housing element, or other relevant local document (see note b). For example, populations in all columns for cities in the group titled “Cities with GP Population Projections for 2005” are populations projected for or estimated in 2005.

b Population estimates are from each city’s general plan (GP) or the general plan’s EIR.

c Estimates for years between 2001 and 2030 are derived by Mundie & Associates, based on linear interpolations of water customer projections, except for the 2020 San Francisco projection, which is included in the Retail Demand Study (Hannaford and Hydroconsult, 2004).

d CWS – South San Francisco District (Colma, parts of Daly City and South San Francisco, plus unincorporated areas) UWMP projection for 2020 is 64,050, and Westborough Water District (which serves part of South San Francisco) UWMP projection for 2020 is 14,150; the CWS-South San Francisco water customer projection for 2020 is 56,006 and the Westborough Water District water customer projection is the same as its UWMP projection (14,150).

TABLE E.3.34 (Continued)
COMPARISON OF GENERAL PLAN POPULATION PROJECTIONS TO ABAG PROJECTIONS 2005, UWMPS, AND WATER CUSTOMER DEMAND PROJECTIONS FOR GENERAL PLAN PROJECTION YEAR

[e] Figures shown are for Estero MID (Foster City and part of San Mateo).
[f] Mid-Peninsula Water District (Belmont, part of San Carlos, and portions of unincorporated San Mateo County) UWMP projection for 2010 is 26,130; water customer projection is 26,925.
[g] Figures shown are for the City of Menlo Park water agency, which serves part of Menlo Park (less than half of the city's population).
[h] CWS – Mid-Peninsula District (parts of the cities of San Mateo and San Carlos plus unincorporated areas) UWMP projection for 2010 is 129,070; water customer projection is 126,746. Part of San Mateo is served by Estero MID.
[i] CWS – Bear Gulch District (Atherton, parts of Menlo Park, Portola Valley, and Woodside, plus unincorporated areas) UWMP projection for 2020 is 57,730; water customer projection for 2020 is 71,125.
[j] Figures shown are for City of Daly City water agency, which serves part of Daly City.
[k] Alameda County Water District (cities of Fremont, Newark, and Union City) projection is 358,066 in 2020.
[l] Based on Milpitas General Plan.
[m] The UWMP (Table 2) reports three population projections: the draft general plan (2006), ABAG subregional (2005), and adjusted draft general plan (2001), although the draft general plan (2006) does not include a projection for 2020. The projections for 2020 are, respectively, 43,400 (based on a straight-line interpolation from projections shown for 2005 and 2025), 47,700, and 43,400.
[n] Figure is for Household Population in 2020 as shown in the Retail Demand Study (Hannaford and Hydroconsult, 2004)
[o] Purissima Water District (part of Los Altos Hills and some unincorporated areas) water customer projection is 6,763.
[p] Los Trancos County Water District was acquired by CWS in 2006, and is now part of the CWS – Bear Gulch District. Because it was a separate entity when these projections were prepared, it is presented separately in this analysis.
[q] CWS – Bear Gulch District (Atherton, parts of Menlo Park, Portola Valley, and Woodside, plus unincorporated areas) UWMP projection for 2030 is 59,220; water customer projection is 73,719 (excluding Los Trancos).

SOURCES: ABAG, 2004; ACWD, 2005; CWS-Mid-Peninsula, 2005 ;CWS-South San Francisco, 2006; City and County of San Francisco, 2004; City of Belmont, 2002; City of Burlingame, 2002a; City of Burlingame, 2005; City of Daly City, 2004; City of Daly City, 2005; City of East Palo Alto, 1999; City of East Palo Alto, 2006; City of Foster City, 2001; City of Fremont, 2003; City of Half Moon Bay, 1993; City of Hayward, 2002; City of Hayward, 2005; City of Menlo Park, 1994; City of Menlo Park, 2006; City of Millbrae, 1998; City of Millbrae, 2005; City of Milpitas, 2002b; City of Milpitas, 2005; City of Mountain View, 2002; City of Mountain View, 2005; City of Newark, 2002; City of Palo Alto, 1998; City of Palo Alto, 2005; City of San Bruno, 2003; City of San Bruno, 2007; City of San Mateo, 2001; City of Santa Clara, 2002; City of Santa Clara, 2005; City of South San Francisco, 2002; City of Sunnyvale, 2002; City of Sunnyvale, 2005; City of Union City, 2002; Coastside County Water District, 2005; Estero MID, 2005; Hannaford and Hydroconsult, 2004; Mid-Peninsula Water District, 2006; SFPUC, 2005; Town of Atherton, 2002; Town of Colma, 1999; Town of Hillsborough, 2002; URS, 2004, Westborough Water District, 2005.

Tables E.3.35 and **E.3.36** provide a different comparison of the projections published by the various water customers, local general purpose governments, and ABAG: instead of focusing on the most distant future year of general plan projections, they focus on employment and population forecasts for 2030.

In just over half of the cases for which direct comparisons are available (11 of 20), Table E.3.35 shows that water customer projections of employment in 2030 exceed *Projections 2005* employment in that year. As previously noted (regarding Table 3.33) this result is expected because most of the water customer projections are based on extensions of *Projections 2002*, which anticipated higher overall employment in 2025 (that projection's horizon year) than does *Projections 2005* (for a comparison, see Table E.3.31). In some cases, too, the water customer encompasses a greater area than the city.

In most cases, Table E.3.36 shows that water customer projections of population in 2030 are smaller than the *Projections 2005* estimates for that year. This result is also expected: because most of the customer projections are based on *Projections 2002*, they do not incorporate ABAG's smart growth assumptions, which include increased housing production (and, consequently, population) after about 2010.

TABLE E.3.35
COMPARISON OF GENERAL PLAN EMPLOYMENT PROJECTIONS TO ABAG *PROJECTIONS 2005*, UWMPS, AND WATER CUSTOMER DEMAND PROJECTIONS FOR 2030

	General Plan Employment Projection	UWMP Employment in 2030	SFUC Water Customer Employment Projection for 2030	*Projections 2005* Employment in 2030

a Alameda County Water District (cities of Fremont, Newark, and Union City) projection for 2030 is 221,858.
b Estero MID (Foster City and part of San Mateo) projection for 2030 is 31,840.
c Figure shown is for the portion of Menlo Park (less than half of the city's population) served by the SFPUC wholesale customer, the City of Menlo Park Water Agency).
d CWS – Bear Gulch District (Atherton, parts of Menlo Park, Portola Valley, and Woodside, plus unincorporated areas) projection for 2030 is 47,774.
e Figure shown is for the City of Mountain View Water Agency, which serves most of Mountain View.
f CWS – Mid-Peninsula District (parts of the cities of San Mateo and San Carlos plus unincorporated areas) projection for 2030 is 100,568.
g Figure shown is for CWS – South San Francisco District (Colma, parts of Daly City and South San Francisco, plus unincorporated areas) and Westborough Water District combined.
h Figure shown is for the Town of Hillsborough Water Agency, which also serves some unincorporated area.
i Figure shown is for the Mid-Peninsula Water District, which also serves a portion of San Carlos and some unincorporated areas.
j Figure shown is for the City of Burlingame Water Agency, which also serves some unincorporated area.
k Figure shown is for the portion of Daly City served by the City of Daly City Water Agency.
l Figure shown is for the Coastside County Water District, which also serves unincorporated Half Moon Bay.
m Purissima Hills Water District (part of Los Altos Hills and some unincorporated area) projection for 2030 is 457.
n A portion of Portola Valley is in the Los Trancos County Water District, has no nonresidential accounts. (Los Trancos was acquired by CWS in 2006, and is now part of the CWS – Bear Gulch District.)
o Figure shown is for the City of San Bruno Water Agency, which also serves some unincorporated areas.
p Includes ABAG's "unincorporated Half Moon Bay."
q Employment projections were not provided for Stanford because it uses other parameters to forecast growth in non-residential accounts.

a CWS – South San Francisco District (Colma, parts of Daly City and South San Francisco, plus unincorporated areas) UWMP projection for 2030 is 60,150; water customer projection for 2030 is 59,584.
b Estero MID (Foster City and part of San Mateo) projection for 2030 is 40,096.
c Mid-Peninsula Water District (Belmont, part of San Carlos, and portions of unincorporated San Mateo County) UWMP projection for 2030 is 28,930; water customer projection is 27,997.
d Figure shown is for the City of Burlingame Water Agency, which also serves some unincorporated area.
e Figure shown is for the portion of Menlo Park (less than half of the city's population) served by the City of Menlo Park Water Agency.
f CWS – Bear Gulch District (Atherton, parts of Menlo Park, Portola Valley, and Woodside, plus unincorporated areas) projection for 2030 is 73,719; UWMP population projection is 59,220 in 2030.
g Figure shown is for the City of Mountain View Water Agency, which serves most of Mountain View.
h CWS – Mid-Peninsula District (parts of the cities of San Mateo and San Carlos plus unincorporated areas) water customer population projection for 2030 is 139,834; UWMP population projection for 2030 is 134,010.
i The Housing Element of the Daly City General Plan projects this population within the city limits and a population of 120,000 within the (planning) area that corresponds to the ABAG subregional study area.
j Figure shown is for the portion of Daly City served by the City of Daly City Water Agency.
k Parts of Daly City and South San Francisco are served by CWS – South San Francisco District.
l Alameda County Water District (cities of Fremont, Newark, and Union City) projection for 2030 is 379,931.
m Figure shown is for the Coastside County Water District, which also serves unincorporated Half Moon Bay.
n Based on Milpitas General Plan.
o San Bruno UWMP (City of San Bruno,2007) shows two population projections for 2030: 50,700, based on ABAG's *Projections 2005*, and 48,229, based on the City's Adjusted Draft General Plan.
p Figure shown is for the City of San Bruno Water Agency, which also serves some unincorporated areas.
q Figures shown are for the CWS – South San Francisco District plus Westborough Water District. For the Westborough Water District, the water customer projection is the same as the UWMP projection.
r Figure shown is for the Town of Hillsborough Water Agency, which also serves some unincorporated area.
s Purissima Hills Water District, (part of Los Altos Hills and some unincorporated area) projection is 6,763.
t Los Trancos County Water District was acquired by CWS in 2006, and is now part of the CWS – Bear Gulch District. Because it was a separate entity when these projections were prepared, it is presented separately in this analysis.
u Includes a portion of Portola Valley.
v Portola Valley is served by CWS – Bear Gulch District; a portion of the city was previously served by the Los Trancos County Water District, which is now part of CWS – Bear Gulch.

SOURCE: See sources for Table E.3.34.

Summary: Comparison of Employment and Population Projections to Water Demand Projections

The review of employment and population projections presented above traces the evolution of ABAG's projections for Bay Area counties and communities from *Projections 2002*, which provided the basis for most water customer forecasts of future demand for water, through *Projections 2003*, which applied smart growth principles to the forecasts, and *Projections 2005*, which updated the smart growth-based forecasts. As shown in Tables E.3.31 and E.3.32, ABAG's projections of both employment and population were greater with *Projections 2003* than with *Projections 2002*. *Projections 2005* anticipated less total employment and population in 2030 than *Projections 2003*, but more in 2025 than *Projections 2002*. The downward adjustments of employment between *Projections 2003* and *Projections 2005* reflect improved understanding of the magnitude of job losses in the early 2000s: although *Projections 2005* anticipates more employment growth between 2005 and 2030 than did *Projections 2003*, the increased growth does not make up for the adjusted starting point.

Tables E.3.37 and **E.3.38** provide final comparisons: they compare the percentage increases in employment and population to the expected percentage increase in water demand in each water customer service area. Table E.3.37 compares increased water demand to the employment and population forecasts in ABAG's *Projections 2005*, while Table E.3.38 compares increased water demand to employment and population forecasts used by the customers themselves.

There are two critical differences between Table E.3.37 and E.3.38: (1) in Table E.3.37, the geographic areas covered by the ABAG projections on the one hand and the customers' projections of water demand on the other are not congruent, and distortions in area may distort the comparisons of percentage change (see **Tables E.3.A.1** and **E.3.A.2** for the correspondence between ABAG areas used in the table and water customer service areas), and (2) the water customers' projections are based primarily on *Projections 2002*. If the greatest proportion of water demand is associated with population (rather than employment), then the water demand projections are likely to be lower than forecasts based on *Projections 2005* (see text above).

Table E.3.37 indicates that, with only two exceptions, the percentage increases in water demand forecast by the water customers are smaller than the percentage changes in population and employment anticipated by *Projections 2005*. The exceptions are:

- *Hayward*: the water customer forecast shows a 38 percent increase in water demand; *Projections 2005* shows a 34 percent increase in employment and a 17 percent increase in population.

- *Purissima Hills Water District*: the water customer forecast shows an increase of 38 percent in water demand; *Projections 2005* anticipates increases of about 8 percent in both employment and population. Note, however, that (1) the water district includes some unincorporated areas that are not captured in the ABAG figures reported here, and (2) the district is quite small, with district-estimated employment of about 400 and population of about 6,000 in 2001.

[a] Includes only those portions of each county served by SFPUC wholesale water customers or served directly by the SFPUC (San Francisco County).
[b] Los Trancos County Water District was acquired by CWS in 2006, and is now part of the CWS – Bear Gulch District. Because it was a separate entity when these projections were prepared, it is presented separately in this analysis.
[c] Population estimates from the Westborough Water District's 2005 Urban Water Management Plan.

SOURCES: URS, 2004; Hannaford and Hydroconsult, 2004; Westborough Water District, 2005

The figures in Table E.3.38 indicate that, with only a few exceptions, the water customers themselves anticipate smaller increases in water demand than they do in employment and population. This relationship between water demand and employment/population growth reflect that other factors also influence the rate of water consumption. These factors could include changes in land use patterns such as higher-density development that results in less open landscaped area, shifts toward landscaping with drought-tolerate plants, and the effects of plumbing codes that require low-flow appliances in all new development and fixture replacement over time in existing homes and businesses. As a result of these types of changes, the rate of increase in water demand is lower than the rate of increase in population and employment.

In three cases, the water customer's forecast of the percentage increase in water demand exceeds its forecasts of the percentage increases in *both* employment *and* population:

- *Hayward*: the forecast shows an increase of 38 percent in water demand, compared to 25 percent in employment and 13 percent in population.
- *Milpitas*: the forecast shows an increase of 36 percent in water demand, compared to 34 percent in employment and 34 percent in population.
- *Purissima Hills*: the forecast shows an increase of 38 percent in water demand, compared to 8 percent in employment and 10 percent in population.

All three customers anticipate growth in a new category of high-water-use residential accounts associated with development of larger residences with larger landscaped areas and substantially higher water usage than older residences. Hayward also expects growth in renovated single family residences, commercial, and industrial accounts that will have higher water usage than existing accounts in those categories. Milpitas anticipates growth of high water uses commercial accounts. Milpitas also expects to increase the use of recycled water which offset some of the increase in its future demand.

In three other cases, the water customer's forecast of the percentage increase in water demand exceeds its forecasts of the percentage increases in *either* employment *or* population:

- *Brisbane*: the forecast shows an increase of 86 percent in water demand, compared to 228 percent in employment but only 37 percent in population.
- *Guadalupe Valley MID*: the forecast shows an increase of 108 percent in water demand, compared to 23 percent in employment but 160 percent in population.
- *Menlo Park*: the forecast shows an increase of 15 percent in water demand, compared to 27 percent in employment but only 11 percent in population.
- *San Jose*: the forecast shows an increase of 20 percent in water demand, compared to 28 percent in employment but only 20 percent in population.

ATTACHMENT E.3.A

Table E.3.A.1 establishes a correspondence between the boundaries of wholesale customers in Alameda, Santa Clara, and San Mateo Counties and the jurisdictions/areas for which ABAG publishes population and employment projections. Table E.3.A.2 assigns jurisdictions to the respective water districts.

TABLE E.3.A.1

Westborough Water District	San Mateo	South San Francisco (part)	

[a] Los Trancos County Water District was acquired by CWS in 2006, and is now part of the CWS – Bear Gulch District. Because it was a separate entity when these projections were prepared, it is presented separately in this analysis.

TABLE E.3.A.2
CORRESPONDENCE OF ABAG JURISDICTIONS WITH WHOLESALE CUSTOMER WATER CUSTOMERS

Wholesale Water Customers	Corresponding Jurisdiction(s)
Alameda County Water District	Fremont, Newark, Union City
Brisbane Guadalupe Valley MID	Brisbane
Burlingame[a]	Burlingame
Coastside County Water District	Half Moon Bay, unincorporated HMB
CWS - Bear Gulch District[a,b] Los Trancos County Water District[n] Skyline County Water District	Atherton, Portola Valley, Woodside[l]
CWS - Mid Peninsula District[a]	San Carlos, San Mateo[j]
CWS - South San Francisco District[a,c] Westborough Water District[h]	Colma, South San Francisco[m]
Daly City[i]	Daly City
East Palo Alto	East Palo Alto
Estero MID[d]	Foster City
Hayward	Hayward
Hillsborough[a]	Hillsborough
Menlo Park	Menlo Park[k]
Mid-Peninsula Water District[a,e]	Belmont
Millbrae	Millbrae
Milpitas	Milpitas
Mountain View	Mountain View
North Coast County Water District	Pacifica
Palo Alto Stanford University	Palo Alto
Purissima Hills Water District[a]	Los Altos Hills
Redwood City[a,f]	Redwood City
San Bruno[a]	San Bruno
San Jose[g]	(None)
Santa Clara	Santa Clara
Sunnyvale	Sunnyvale

a Correspondence excludes non-segregable unincorporated areas that are not included in the ABAG definition of the jurisdiction.
b Portion of Menlo Park served by CWS – Bear Gulch District assigned to Menlo Park.
c Portion of Daly City served by CWS – South San Francisco District assigned to Daly City.
d Portion of San Mateo served by Estero MID assigned to San Mateo.
e Portion of San Carlos served by Mid-Peninsula Water District assigned to CWS – Mid-Peninsula District.
f Portion of San Carlos served by Redwood City assigned to CWS – Mid-Peninsula District; portion of Woodside served by Redwood City assigned to CWS – Bear Gulch District.
g Portion of North San Jose/Alviso served by San Jose Water District is not assigned.
h Portion of South San Francisco served by Westborough Water District assigned to CWS – South San Francisco District.
i Includes portion of Daly City served by CWS – South San Francisco District.
j Includes portions of San Carlos served by Mid-Peninsula Water District and Redwood City.
k Includes portions of Menlo Park served by CWS – Bear Gulch District
l Includes portion of Portola Valley served by Los Trancos Water District (now a part of CWS – Bear Gulch District) and portions of Woodside served by Redwood City and Skyline County Water District.
m Includes portion of South San Francisco served by Westborough Water District.
n Los Trancos County Water District was acquired by CWS in 2006, and is now part of the CWS – Bear Gulch District. Because it was a separate entity when these projections were prepared, it is presented separately in this analysis.

APPENDIX E.4

Growth Trends and Policies of a Selection of Jurisdictions

To supplement information on forecasted population and employment growth presented in PEIR Chapter 7 and provide a more in-depth understanding of service area growth trends, this appendix takes a more detailed look at the growth trends and policies of San Francisco and a selection of jurisdictions (and a university) served by wholesale customers. A selection of jurisdictions served by wholesale customers in each county of the wholesale service area are included. These jurisdictions represent a range of sizes and include, but are not limited to, the largest city (San Francisco), some of the other larger cities in the wholesale service area, and some of the cities projecting relatively substantial increases in water demand in 2030. in each county of the wholesale service area.

Summaries of growth trends and policies are presented for the jurisdictions and university listed below. The profiles are based primarily on information in BAWSCA agency profiles (BAWSCA, 2005), the general plans of the respective jurisdictions, and contacts with city planning departments. The population of each jurisdiction from Census 2000 (U.S. Census Bureau, 2000), and population estimates for 2005 and 2006 from the U.S. Census Bureau, ABAG, and the California Department of Finance (DOF) (U.S. Census Bureau, 2006; ABAG, 2004; California Department of Finance 2006) are included to provide a sense of recent growth.

- Alameda County: Fremont, Newark, Union City, and Hayward
- Santa Clara County: Milpitas, Santa Clara, Stanford University, and Sunnyvale
- San Mateo County: East Palo Alto, Redwood City, San Mateo, and South San Francisco
- San Francisco (City and County)

E.4.1 Alameda County

Fremont

Overview

Fremont is bordered by San Francisco Bay to the west, the foothills and mountains of the Diablo Range to the east, Union City and Hayward to the north, and Milpitas and San Jose to the south (refer to Figure 7.2 in PEIR Chapter 7). Fremont also borders—and encircles—the city of Newark. According to the Fremont General Plan (adopted in 1991[1]), the city's land use mix

[1] Updated land use and housing elements, also cited herein, were a adopted in 2003.

consists of approximately 29 percent single-family and multifamily residences, 3 percent retail/commercial space, 13 percent industrial space, and 55 percent open space[2] (City of Fremont, 1991).

Water Service

Fremont is served by the Alameda County Water District (ACWD), which also includes the cities of Newark and Union City. The ACWD service area encompasses approximately 103 square miles in southwestern Alameda County, on the east side of San Francisco Bay (refer to Figure 7.1 in PEIR Chapter 7). The ACWD serves a population of about 323,000 people, providing water to the cities of Fremont, Newark, and Union City. The ACWD consists primarily of single-family, owner-occupied homes. Residential accounts represent approximately 64 percent of ACWD's current total water demand; commercial and industrial accounts represent approximately 22 percent; and other uses and unaccounted-for water represent 7 and 8 percent of demand, respectively. According to the BAWSCA agency profile, the SFPUC supplies approximately 24 percent of the ACWD's water, while water from the State Water Project, local groundwater, and local surface water meet the remaining need (URS, 2004; BAWSCA, 2005).

Growth Trends and Policies

Fremont grew rapidly following its incorporation in 1956, with population increasing fourfold (to 100,000) by 1970. The population doubled again over the next three decades, to 203,413 in 2000 (City of Fremont, 2003a; U.S. Census Bureau, 2000). Population estimates since 2000 vary somewhat. The U.S. Census Bureau estimates Fremont's 2005 population to be 200,468, a 1.4 percent decrease, whereas the California DOF estimates Fremont's 2006 population to be 210,158, a 3.3 percent increase from 2000. These figures, ABAG estimates for 2005, and the buildout projections of the general plan are shown in **Table E.4.1**.

The Fremont Municipal Code does not include a growth ordinance per se, but the stated purposes of sections of the code governing subdivisions (Section 8-1101) and development agreements (Section 8-7101) include the promotion of orderly growth and development (City of Fremont, 2007).

The Fremont General Plan is a statement of the community's vision of its long-term or ultimate physical form and contains goals, policies, and programs intended to guide decision-making for future development in the city (City of Fremont, 1991). Goals related to growth management articulated in the 2003 Fremont General Plan Land Use Element include conservation of the city's open space resources (Goal LU 4) and protection of "sensitive hill face and uses in the remainder of the hill area" consistent with the area's character and environmental constraints (Goal LU 6). Buildout under the 1991 Fremont General Plan is expected to occur by 2010 and result in a total population of approximately 201,100 (less than the actual population in 2000) (City of Fremont, 1991). The more recent housing element (City of Fremont, 2003a) projects that the population will increase by 25,800 between 2000 and 2020 (i.e., from 203,413 to 229,213). The average household size is projected to be 3.17 in 2010 (City of Fremont, 2003b).

---

[2] Percentages derived from area information (acreage and square footage) provided in the Fremont General Plan.

TABLE E.4.1
CURRENT POPULATION ESTIMATES AND FORECASTS OF SELECT JURISDICTIONS

	Actual Population	Current Population Estimates			Forecasts

City and County of San Francisco	776,733	739,426	798,000	798,680	(2020) 811,100	859,200	849,942	924,600	97%

a ACWD = Alameda County Water District; U.S. Census, ABAG, Department of Finance (DOF), and general plan figures are the combined estimates for Fremont, Newark and Union City.
b The Newark general plan projection shown is from the 2002 housing element. The general plan (adopted in 1992) projected a buildout population of 51,942 by the year 2007.
c The general plan population is based on the population shown in the general plan.
d The general plan figure for Santa Clara is the average of the range projected in the general plan at buildout of 124,800 to 135,000.
e The SFPUC provides 100 percent of Redwood City's potable water. The remaining 8 percent of demand indicated here is met by recycled water.
f The city of San Mateo is served by the CWS–Mid-Peninsula District and Estero MID, both of which serve other jurisdictions as well; therefore, the 2030 population assumed by the wholesale customers is not comparable to projections for the city. The SFPUC supplies all of the CWS–Mid Peninsula District's and Estero MID's water.
g The customer-selected projection is the combined 2030 estimates for the CWS–South San Francisco District (which also serves Colma and a small portion of unincorporated San Mateo County), based on the 2004 demand study, and the Westborough Water District, based on the district's 2005 UWMP. The SFPUC would supply approximately 85 percent of the CWS–South San Francisco District's water supply in 2030 and 100 percent of Westborough Water District's. The other figures are for South San Francisco only.

Newark

Overview

Newark is bordered on all sides by the city of Fremont—to the north, east, and south by developed areas of Fremont, and to the west by salt ponds, wetlands, and other areas of the Fremont baylands (refer to Figure 7.2 in PEIR Chapter 7). According to the Newark General Plan, the city's land use mix consists primarily of residential neighborhoods, with several key commercial shopping areas and smaller neighborhood commercial areas, industrial uses located primarily along the western edge of the developed part of the city, and salt evaporation ponds and processing facilities on the extreme western side of the city(City of Newark, 1992a).

Water Service

Newark, along with Fremont and Union City, is served by the ACWD. Refer to the description of ACWD under Fremont water service, above.

Growth Trends and Policies

Newark grew most rapidly in the 1960s, with the population nearly tripling (from 9,911 in 1960 to 27,157 in 1970). The population growth continued at a somewhat lower rate in the ensuing decades, increasing by approximately 18 percent in the 1970s and 1980s and 12 percent in the 1990s (City of Newark, 2002). According to the U.S. Census, the city's population was 42,471 in 2000. Population estimates since 2000 vary somewhat. The U.S. Census Bureau estimates Newark's 2005 population to be 41,956, a 1.2 percent decrease, whereas the DOF estimates Newark's total population to be 43,486 as of January 1, 2006, a 2.4 percent increase from 2000 (see Table E.4.1).

Newark does not have an adopted growth management ordinance; policies contained within the general plan are intended in part to manage growth in the city (Slafter, 2005). The Newark General Plan (adopted in 1992) contains goals, policies, and programs intended to direct public and private decision-making and guide future growth and change within the city (City of Newark 1992a). The general plan identifies six study areas with the most potential for change, including areas along the city's western and southern boundaries as well as an "infill[3] area," where development would result from development of the few remaining vacant sites or change in the existing uses within urbanized Newark.

Buildout under the general plan is expected to occur in 2007 and result in a total population of approximately 51,942 (City of Newark, 1992b). The more recent (2002) housing element projects a population of 49,800 in 2020, as shown in Table E.4.1. The housing element cites ABAG projections that the city will grow by about 13.5 percent by 2010 and at a lower rate (approximately 3 percent) between 2010 and 2020, as sites for new development are depleted (City of Newark, 2002).

[3] "Infill" development generally refers to development of individual or small groups of vacant parcels that are surrounded by development.

Union City

Overview

Union City is bordered on the west by a salt marsh that is within the Hayward city limits, on the east by the foothills of the Diablo Range, on the north by Hayward, and on the south by Fremont (refer to Figure 7.2 in PEIR Chapter 7). The city's land use mix consists of approximately 18 percent residential uses, 3 percent commercial, 3 percent public/institutional, 58 percent agricultural and open space, and 9 percent vacant land or miscellaneous uses such as rights-of-way and canals (City of Union City, 2002b).

Water Service

Union City, along with Fremont and Newark, is served by the ACWD. Refer to the description of ACWD under Fremont water service, above.

Growth Trends and Policies

The city grew rapidly from the 1960s through the 1980s, from a population of approximately 7,000 in 1962 to 45,000 in 1983 (City of Union City, 2002c); growth continued through the 1990s, and in 2000 the city had a population of 66,869 according to the U.S. Census. Population estimates since 2000 vary somewhat. The U.S. Census Bureau estimates Union City's 2005 population to be 69,176, a 3.5 percent increase, whereas the DOF estimates Union City's total population to be 71,752 as of January 1, 2006, a 7.3 percent increase from 2000 (see Table E.4.1).

Union City does not have an adopted growth management ordinance. A prior growth management ordinance was revoked about 10 years ago, and since then the general plan has guided growth in the city (Leonard, 2005). The Union City General Plan (2002c) contains goals and policies to guide future development in the city. The general plan identifies several physical constraints that present challenges in planning for future growth, including sensitive wetland habitat near the city's western border, steep topography on the east side of the city, and limited available land. Infill development and redevelopment strategies are therefore identified as the primary means for accommodating future growth. The general plan identifies five business districts, which are generally underutilized or have obsolete uses, that can be redeveloped to help the city achieve housing and job growth goals (City of Union City, 2002c). Buildout under the general plan is expected to occur in 2020 and result in a total population of approximately 80,100 (City of Union City, 2002a).

Hayward

Overview

Hayward is located in western Alameda County, on the east side of San Francisco Bay (refer to Figure 7.2 in PEIR Chapter 7). The city encompasses approximately 61 square miles and is bordered on the west by the Bay, on the east by unincorporated Alameda County and the city of Pleasanton, on the south by Fremont and Union City, and on the north by the unincorporated communities of San Lorenzo, Ashland, and Castro Valley, and by other unincorporated Alameda County lands.

Water Service

Hayward owns and operates its own water system (which is maintained and operated by the City's Public Works Department Utilities Division) and receives all of its water from the SFPUC. The Hayward water system serves the entire city, except for a small area in the northern part of the city that is served by the East Bay Municipal Utility District (EBMUD). The service area population was 144,500 as of 2005. Residential accounts represent approximately 57 percent of Hayward's current total water demand; commercial and industrial accounts represent about 34 percent; other uses represent 4 percent; and unaccounted-for water represents 5 percent (BAWSCA, 2005).

Growth Trends and Policies

Hayward grew rapidly in the 1950s with the opening of Interstate 580, from a population of 14,000 in 1950 to 72,000 in 1960. Industrial development surged in the 1960s and 1970s, and multifamily residential housing grew through the 1980s; by 1990, the city's population was 111,000. Residential development in the 1990s predominantly consisted of infill development in the form of single-family detached homes on smaller lots and, toward the end of the decade, townhouses or single-family attached units. Today, Hayward is highly urbanized. Although only about 50 percent of the total area within the city limits is in urban use, the remaining land is either baylands (marshes and salt ponds, 9 square miles), rangelands (5 square miles), or under water (within San Francisco Bay, 17 square miles) (City of Hayward, 2002a). Current land uses include 29 percent residential uses, 5 percent commercial, 14 percent industrial, 31 percent institutional, and 21 percent categorized as agricultural/rural, vacant, or other/unknown (City of Hayward, 2002b). According to the Census 2000, Hayward had a total population of 140,030 in 2000. Population estimates since 2000 vary somewhat. The U.S. Census Bureau estimates Hayward's 2005 population to be 140,293, a 0.2 percent increase, whereas the DOF estimated Hayward's total population to be 146,398 as of January 1, 2006, a 4.5 percent increase from 2000 (see Table E.4.1).

Hayward does not have an adopted growth management ordinance; policies contained within the general plan are intended in part to manage growth in the city (Rizk, 2005). The Hayward General Plan (adopted in 2002) serves as a policy guide for determining physical development in the city through 2025. The general plan includes policies that encourage the use of "smart growth" principals in long-range planning and development.[4] The City of Hayward expects continued growth through 2025, with the general plan guiding a gradual transition of certain areas from lower to higher density. Buildout under the general plan is expected to occur in 2025 and

4 The general plan states that, while there is no universally accepted definition of smart growth, smart growth principles generally include those that would foster development that revitalizes central cities and suburbs, supports public transit, and preserves open space and agricultural lands by encouraging more infill development, more concentrated development, and more redevelopment, especially in areas served by transit or close to major employment centers (City of Hayward, 2002b).

result in a total population of approximately 160,300 for the city itself and 190,700 for the Hayward Planning Area, which includes the communities of Cherryland and Fairview (City of Hayward, 2002a). The general plan also includes a policy to evaluate annexing unincorporated islands[5] and adjoining urbanized county areas within Hayward's sphere of influence (City of Hayward, 2002a; City of Hayward, 2002b).

E.4.2 Santa Clara County

Milpitas

Overview

Milpitas occupies an area of about 13.6 square miles and is located southeast of the south end of San Francisco Bay in northern Santa Clara County (refer to Figure 7.2 in PEIR Chapter 7). It is bordered by Fremont on the north, the foothills of the Diablo Range on the east, and San Jose on the south and west.

Water Service

The City of Milpitas owns and operates its own water system; it receives approximately 65 percent of its water from the SFPUC and the rest from the Santa Clara Valley Water District (SCVWD). In general, residents receive SFPUC water, while the SCVWD primarily serves industrial and commercial areas. Residential accounts represent approximately 43 percent of the city's total water demand; commercial/industrial uses represent 29 percent; other uses account for 23 percent; and unaccounted-for water represents approximately 4 percent of total demand (BAWSCA, 2005). According to the Milpitas general plan, the city's land uses consist of approximately 25 percent residential, 4 percent commercial, 14 percent industrial, 17 percent public facilities and parks, 5 percent transportation facilities (e.g., major streets, freeways, and rail), and 35 percent undeveloped lands (City of Milpitas, 2002a).

Growth Trends and Policies

While the origins of the city of Milpitas go back to the latter part of the 18th century, most of the city has developed in the last 30 years. Between 1980 and 1990 the city grew at an average annual rate of 3 percent, from a 1980 population of 37,820 to 50,690, and between 1990 and 2000 at an average annual rate of 2.2 percent. The city's growth rate between 1980 and 2000 was roughly twice that of Santa Clara County as a whole (City of Milpitas, 2002a). The city's population in 2000 was 62,698 (Census 2000). Population estimates since 2000 vary somewhat. The U.S. Census Bureau estimates Milpitas's 2005 population to be 63,383, a 1.1 percent increase, whereas the DOF estimates Milpitas's total population to be 65,276 as of January 1, 2006, a 4.1 percent increase from 2000 (see Table E.4.1). (The 2002 general plan update projected a population of 67,300 for 2005.)

[5] By "islands" the general plan refers to pockets of unincorporated area within and adjacent to the City's industrial corridor (Hayward, 2004b).

Milpitas does not have an adopted growth management ordinance. Policies contained within the general plan are intended in part to manage growth in the city (Duncan, 2005). The City has adopted an Urban Growth Boundary (UGB), which delineates the ultimate extent of the urbanized area. The UGB was approved by local voters in 1998 and is intended to remain in place through 2018. According to the housing element (City of Milpitas, 2002b), the UGB does not include provisions related to residential development capacity or growth control and was primarily created as a hillside protection measure. The land use element includes polices related to the UGB (City of Milpitas, 2002a).

The Milpitas general plan, *2002 Update of the 1994 General Plan* (City of Milpitas, 2002a), serves as a policy guide for determining physical development in the city. The 2002 general plan update incorporates the 2002 Midtown Milpitas Specific Plan, which includes mixed-use development and new, very-high-density multifamily development. The revised general plan also includes transit-oriented development and gateway office overlay designations. According to the general plan, the rapid growth in the region has left little room in the flatlands for expansion of the city boundaries. With the Midtown Milpitas Specific Plan, the city's general plan population at buildout is projected to be 77,100 (City of Milpitas, 2002a; City of Milpitas, 2002c).

According to the 2002 housing element, approximately 87 percent of the development capacity to meet Milpitas' identified share of regional housing need is located within developed areas, and approximately 95 percent of the residential development capacity consists of higher density housing sites. The analysis of infrastructure and public services constraints concluded that adequate water supply is not a constraint to developing the city's fair share housing allocation (City of Milpitas 2002b).

City of Santa Clara

Overview

Santa Clara is located at the south end of San Francisco Bay; it is bordered by San Jose to the north, east, and south, and Sunnyvale and Cupertino to the west (refer to Figure 7.2 in PEIR Chapter 7).

Water Service

The City of Santa Clara owns and operates its own water system; the city's service area encompasses nearly 19.4 square miles. Local groundwater is the primary source of potable water. The SFPUC supplies approximately 15 percent of the city's water (URS, 2004; BAWSCA, 2005). According to the Santa Clara General Plan, the city normally receives about 30 percent of its water from the SFPUC and the SCVWD, and the remaining 70 percent from the city's 28 wells (City of Santa Clara, 2002). SFPUC water is delivered to the northern portion of the city, and SCVWD water is delivered to the southwestern portion of the city. Santa Clara also operates a recycled water system; tertiary-treated effluent from a plant jointly operated with San Jose is available for landscape irrigation and certain industrial uses (BAWSCA, 2005).

The northern portion of Santa Clara is predominantly commercial/industrial, and the southern portion is primarily residential (URS, 2004). Residential accounts represent approximately 45 percent of total water demand; commercial/industrial uses represent approximately 46 percent; other uses represent 7 percent; and unaccounted-for water represents 2 percent of total demand (BAWSCA, 2005). As of 2000, land uses consisted of approximately 37 percent residential, 6 percent commercial, 22 percent industrial, 30 percent public facilities (including institutional, educational, parks, and rights-of-way), 4 percent vacant, and 0.2 percent mixed use (City of Santa Clara, 2002).

Growth Trends and Policies

Santa Clara has grown by more than 800 percent since 1950, from a population of 11,702 in 1950 to 102,361 in 2000. The city's fastest growth occurred between 1950 and 1960, when the city experienced a fivefold population increase (to 58,850). Between 1960 and 1980, the population increased by nearly 50 percent (to 87,700). Since then, constraints on available land for residential development have limited new housing development and thus population growth. According to the housing element, the city grew by 7 percent between 1980 and 1990 and by 9 percent between 1990 and 2000 (City of Santa Clara, 2002). The city's population in 2000 was 102,361 (Census 2000), with 135,370 jobs and 39,630 dwelling units in the city (City of Santa Clara, 2002). Population estimates since 2000 vary somewhat. The U.S. Census Bureau estimates Santa Clara's 2005 population to be 105,402, a 3.0 percent increase, whereas the DOF estimates Santa Clara's total population to be 110,771 as of January 1, 2006, an 8.2 percent increase from 2000 (see Table E.4.1).

The 1992 Santa Clara General Plan (with land use and housing element updates in 2002) serves as a policy guide for determining physical development in the city through 2010. The general plan projects continued growth in the city through the development and redevelopment of underutilized properties and recognizes the need for preservation and enhancement of single-family areas. According to the general plan, the city is essentially built out; however, there is potential for development, redevelopment, and expansion at various locations in the city. The general plan identifies a number of sites for new development, including some sites distributed throughout the city and some in specific areas, such as along the El Camino Real corridor and the area northeast of Agnew Road (City of Santa Clara, 2002). Buildout under the general plan is expected to occur in 2010 and result in a total population ranging from 124,800 to 135,000, about 151,280 jobs, and up to 12,556 additional dwelling units (City of Santa Clara, 2002).

Stanford University

Overview

Stanford University comprises approximately 8,200 acres in Santa Clara and San Mateo Counties. Approximately 4,000 acres containing the university's academic, open space, and agricultural land are located in unincorporated Santa Clara County, on the border of San Mateo County. The university is generally bordered on the northwest by Menlo Park, on the southeast, east, and south by Palo Alto, and on the west by Portola Valley and unincorporated Santa Clara County.

Water Service

The university's water system, operated by the Stanford Utilities Division, primarily serves the central campus, which comprises approximately 2,000 acres (3.1 square miles). Approximately 70 percent of the university's water supply—and all of its potable water—is supplied by the SFPUC; approximately 8 percent of total supply is groundwater, and approximately 22 percent is nonpotable surface (lake) water used for irrigation (BAWSCA, 2005).

According to the Stanford University Community Plan, land uses in the central campus area consist of the academic campus, open space, and low- and moderate-density residential uses (Santa Clara County, 2000). Residential uses account for approximately 35 percent of water demand; commercial/industrial uses represent about 24 percent; other uses represent 40 percent; and unaccounted-for water represents approximately 1 percent of demand (BAWSCA, 2005). The current cumulative building area on campus is approximately 12.3 million gross square feet (gsf).

Growth Trends and Policies

Stanford was founded in 1891; most new development at the campus, in the form of academic buildings, support services, and student housing, has occurred since World War II. Since 1960, the building area has almost tripled, from 4,363,375 gsf to 12,294,230 in 2000. Growth since 1960 represents an average annual addition of approximately 198,300 square feet of building area. The campus building area includes approximately 9,760 units of undergraduate and graduate housing. (Stanford University is not shown in Table E.4.1 because most of the data presented in the table do not apply to the university. The Stanford Water Utility serves only the university, whereas ABAG, DOF, and the Census Bureau data are developed for cities and counties.)

The 1995 Santa Clara County General Plan sets goals and overall policy direction for physical development and land use in unincorporated areas of the county. The Stanford Community Plan (adopted as an amendment of the General Plan in 2000) refines the policies of the general plan as they apply to Stanford lands within the county. The community plan identifies policies and establishes various land use designations. The plan emphasizes two basic principles of the Santa Clara County General Plan: compact and efficient urban development, and conservation of natural resources. However, the community plan is not intended to define the long-term development potential of Stanford's unincorporated lands in terms of the amount or location of development beyond the planning horizon (Santa Clara County, 2000).

In the community plan, the concept of urban growth boundaries promoted in the county general plan is applied to the university in the form of an Academic Growth Boundary (AGB). According to the community plan, development at Stanford must occur within the AGB; furthermore, the AGB will remain in the established location for a period of at least 25 years and may only be modified within this period by a fourth-fifths vote of all members of the board of supervisors. In addition to the 25-year time limitation, the AGB cannot be modified until the total building area on the central campus reaches 17,300,000 square feet. At the rate of 200,000 square feet of additional development per year (the historical growth rate at the campus), a total of 5 million square feet would be added in 25 years, for a total building area in the central campus, excluding housing, of 17,300,000 square feet. The community plan indicates that an additional 2,035,000 gsf of academic and academic support space and 3,018 additional housing units may be constructed through 2010.

Development on the campus is also regulated by a general use permit issued by Santa Clara County. Concurrent with development of the community plan, Stanford University applied to the County to revise its general use permit, requesting an additional 2,035,000 square feet of academic and support space, 2,000 housing units for students, and 350 units for postdoctoral fellows. These facilities would result in the development of 3,485,000 square feet of new building area on the campus between 2000 and 2010. A revised general use permit was issued in 2000.

City of Sunnyvale

Overview

Sunnyvale is located at the southwest end of San Francisco Bay (refer to Figure 7.2 in PEIR Chapter 7). The city is bordered on the north by San Francisco Bay, on the west by Mountain View and Los Altos, on the south by Cupertino, and on the east by Santa Clara and San Jose.

Water Service

The City of Sunnyvale owns and operates its own water system. The service area for the water utility is contiguous with the city limits; however, CWS serves several small areas within the city. The city's water service area encompasses nearly 24 square miles (URS, 2004; BAWSCA, 2005). The 1996 water resources sub-element of the Sunnyvale General Plan indicates that the SFPUC provides approximately 40 percent of the city's water and the SCVWD provides approximately 50 percent; the remaining 10 percent is from local groundwater sources (City of Sunnyvale, 1996). BAWSCA's more recent agency profiles indicate that the SFPUC provides approximately 42 percent, with SCVWD, CWS, and local groundwater providing the balance (BAWSCA, 2005). Residential accounts represent approximately 58 percent of total water demand; commercial/industrial uses represent 23 percent; other uses represent 17 percent; and unaccounted-for water represents 2 percent of demand (BAWSCA, 2005). According to the general plan, the city's land use mix consists of approximately 41 percent residential; 6 percent commercial; 18 percent industrial; 10 percent public facilities; 14 percent baylands, creeks, and sloughs; and 11 percent categorized as "other," which includes public and private schools and religious, military, park, agricultural, and vacant land uses (City of Sunnyvale, 1997).

Growth Trends and Policies

Between 1950 and 2000, Sunnyvale changed from an agricultural area and location for heavy industry to a center for high technology. The city's first surge of growth in the 1950s established its basic development pattern. The city continued to grow rapidly until the mid-1970s. Today Sunnyvale is nearly built out, and infill development, redevelopment, and revitalization activities predominate (City of Sunnyvale, 2002). The city's population in 2000 was 131,760 (Census 2000). Population estimates since 2000 vary somewhat. The U.S. Census Bureau estimates

Sunnyvale's 2005 population to be 128,902, a 2.2 percent decrease, whereas the DOF estimates the city's population to be 133,544 as of January 1, 2006, a 1.4 percent increase over 2000 (see Table E.4.1).

Sunnyvale does not have an adopted growth management ordinance. Growth in the city is managed through the general plan and zoning ordinance (Zarrin, 2006). The Sunnyvale General Plan is the principal policy document guiding future conservation and development of the city. It includes both long-term goals and policies and shorter term "action statements" to guide local government decisions (City of Sunnyvale, 2002). Growth-related policies of the land use and transportation element include promotion of integrated and coordinated local land use and transportation planning, protection of regional environmental resources through local land use practices, and protection of the integrity of the city's residential, industrial, and commercial neighborhoods (City of Sunnyvale, 1997). Buildout under the general plan is expected to occur in 2025 and result in a total population of 154,600 (City of Sunnyvale, 2002).

E.4.3 San Mateo County

City of East Palo Alto

Overview

East Palo Alto is located at the southern end of the San Francisco Peninsula on the populous west side of San Francisco Bay (refer to Figure 7.2 in PEIR Chapter 7). The city is bordered by the Bay to the east, Menlo Park to the north and west, and Palo Alto to the south.

Water Service

East Palo Alto's public water system is operated under contract through the city's Department of Public Works by American Water Company[6] (City of East Palo Alto, 2006). The city's service area encompasses approximately 2.5 square miles and covers most of the city. The SFPUC is the city's only source of supply. (Two other water companies, the Palo Alto Mutual Water Company and the O'Conner Tract Mutual Cooperative Water Company, which are not SFPUC customers, also provide water to small sections of the city.) Residential accounts represent approximately 68 percent of the municipal water system's total water demand; commercial/industrial accounts represent about 13 percent; other uses represent about 9 percent; and unaccounted-for water represents 10 percent (BAWSCA, 2005). According to the city's general plan, land uses consist of approximately 52 percent residential, 2 percent commercial, 6 percent industrial, 7 percent institutional, and 33 percent open space, conservation resource management, agricultural, or vacant lands (City of East Palo Alto, 1999b).

[6] Previously, the city's water system had been operated by San Mateo County under the name East Palo Alto Waterworks District; the city took over the water distribution system from the county in 2001.

Growth Trends and Policies

Prior to the city's incorporation in 1983, East Palo Alto was part of unincorporated San Mateo County. The area historically regarded as East Palo Alto was much larger than the city's current area of 2.5 square miles. Between the late 1940s and 1960s, areas previously part of East Palo Alto were annexed to Menlo Park and Palo Alto. Economic activities in East Palo Alto have included farming, ranching, and brick manufacturing. Today, the city has a mix of small industrial, agricultural, and commercial businesses. Since its incorporation, the city has grown dramatically—by 29 percent between 1980 and 1990 (from a population of 18,292 to 23,451) and by 26 percent between 1990 and 2000. However, development of additional housing has not kept pace with the population growth, resulting in an increase in household size from 2.7 people per housing unit in 1980 to 4.2 people per housing unit in 2000 (City of East Palo Alto, 2001). The city's population in 2000 was 29,506 (Census 2000). Population estimates since 2000 are similar. The U.S. Census Bureau estimates East Palo Alto's 2005 population to be 32,242, a 9.3 percent increase, and the DOF estimates the city's population to be 32,083 as of January 1, 2006, an increase of 8.7 percent over 2000 (see Table E.4.1).

East Palo Alto does not have any growth management ordinances in effect (Banico, 2005). The East Palo Alto General Plan (City of East Palo Alto, 1999b) serves as a policy guide for determining the appropriate physical development and character for the city. The general plan identifies infill properties as the site of much of the new development that will occur in the city, and emphasizes redevelopment or renovation of major portions of the community as critical to achieving fiscal stability (City of East Palo Alto, 1999b). East Palo Alto expects continued growth through general plan buildout. Buildout is projected to occur in 2020, with a population of 34,600 (City of East Palo Alto, 1999a).

City of Redwood City

Overview

Redwood City is located in the geographic center of the San Francisco Peninsula, near the southern end of San Mateo County (refer to Figure 7.2 in PEIR Chapter 7). The city is bordered by the Bay to the east, San Carlos, Belmont, and Foster City and unincorporated county land to the north and west, Woodside to the west, and Atherton. Menlo Park , and unincorporated land to the south.

Water Service

Redwood City owns and operates its own water utility and supplies water to portions of Woodside, San Carlos, and unincorporated areas of the county. The city's service area includes about 83,000 residents and covers roughly 35 square miles. Redwood City purchases all of its potable water from the SFPUC (BAWSCA, 2005). The area within the city's boundaries is roughly divided between land and water areas, with 54 percent land area and 46 percent water area. According to the Redwood City General Plan (City of Redwood City, 1990), 46 percent of the city's land area is in residential development, the city's predominant land use; other uses include public and quasi-public land uses (14 percent), commercial land use (10 percent), industrial land use (6 percent), and streets and rights-of-way (25 percent).

Growth Trends and Policies

At the time San Mateo County was formed, in 1856, Redwood City was the only bayside settlement that resembled a real town, and in 1867 it became the county's first incorporated city. By 1870, the city had a population of more than 700, which nearly doubled by 1880. While the city continued to grow steadily in the ensuing decades, the postwar population influx that occurred throughout California from 1940 to 1960 created the most dramatic growth in Redwood City's history—from 12,453 to 46,290 (City of Redwood City, 1990). During the 1970s and 1980s, changes in industry and housing occurred, with the craft industries of the city's early years giving way to high-technology and information-age industries (City of Redwood City, 1990). The 1990 Redwood City General Plan indicated that the city was expected to reach a population of 70,000 by the year 2000 (Redwood City, 1990, Chapter 4, p. 4-1). The EIR for the Downtown Precise Plan cites ABAG's *Projections 2005* forecasts for the city (not including its sphere of influence) of 87,100 in 2020. The city's population in 2000 was 75,402 (Census 2000). Population estimates since 2000 vary somewhat. The U.S. Census Bureau estimates Redwood City's 2005 population to be 73,114, a 3.0 percent decrease, whereas the DOF estimates the city's population to be 76,087 as of January 1, 2006, a 0.9 percent increase over 2000 (see Table E.4.1).

Redwood City is essentially built out, and future development will be accommodated through infill development, including the redevelopment of industrial sites and development along the El Camino Real corridor. In May 2006, the Planning Commission adopted principals to guide its general plan update (currently underway) and provide the foundation for general plan elements. These guiding principals include (among others) planning for sustainability, which recognizes the city's long-term obligations to future residents and encourages development that conserves natural resources; working to develop attractive, convenient transportation alternatives to the automobile; and designing for active pedestrian and bicycle-friendly streets and public spaces (City of Redwood City, 2006). The City's recently adopted Downtown Precise Plan (City of Redwood City, 2007a) provides for housing in the downtown area that is affordable to a range of incomes, mixed residential and commercial development, and the concentration of retail development in certain areas proximate to civic buildings and activities, so that access to transit and parking, customers, and destination identity for a variety of land uses are shared. The plan is intended to revitalize the downtown area and serve as a tool to help the city meet its goals and achieve sustainable development (City of Redwood City, 2007a). The City Council approved the "moderate intensity" alternative of the plan, which would allow development of 2,500 additional residential units as well as specified amounts of office, retail and lodging in the downtown planning area (City of Redwood City, 2007b). According to the plan's EIR, neither of the development alternatives considered (a maximum intensity alternative and a moderate intensity alternative) would permit buildout totals that were substantially different from buildout allowed under existing zoning, the City expected that achieving permitted buildout totals was more likely to be realized with adoption of the precise plan; (City of Redwood City, 2007c).

Redwood City's Franklin Project Phase I, a development that includes residential units and retail within walking distance of the Caltrain station and downtown area, was the first project to receive a grant from the City/County Association of Governments of San Mateo County (C/CAG) Transit Oriented Development (TOD) Incentive Program. The C/CAG's TOD Incentive Program won the Environmental Protection Agency's National Award for Smart Growth in 2002 (U.S. EPA, 2002).

City of San Mateo

Overview

The city of San Mateo is located in the middle of the San Francisco Peninsula (refer to Figure 7.2 in PEIR Chapter 7). The city is bordered by the Bay to the east, Burlingame to the north, Hillsborough to the west, and Belmont to the south.

Water Service

San Mateo is served by the CWS–Mid-Peninsula District, which is located in central San Mateo County; this water district also serves San Carlos and adjacent unincorporated portions of San Mateo County, including the Highlands and Palomar Park (refer to Figure 7.1 in PEIR Chapter 7). In 2001, the CWS–Mid-Peninsula District served 120,856 residents and covered approximately 17 square miles. All of the district's water is supplied by the SFPUC, as local water storage is not feasible and groundwater of adequate quantity and quality is not available (BAWSCA, 2005).

Growth Trends and Policies

San Mateo's development began in earnest with the establishment of a stagecoach stop along the Old County Road (El Camino Real [Highway 82]) in the 1850s. With the advent of the railroad in the 1860s, the center of city activity shifted to the area along Third Avenue and B Street. The city was incorporated in 1894 and remained a relatively small, rural community until the 1940s. The city grew substantially during World War II and the following years, from a population of 19,405 in 1940 to 69,870 by 1960, and its economic base shifted toward office and retail sectors (City of San Mateo, 1990).

During the 1970s and 1980s, population growth slowed, increasing by only 16,000, while both retail space and office space increased significantly. Retail uses are now largely concentrated at Hillsdale Shopping Center, along El Camino Real, and office uses are concentrated in office parks along the Highway 92 corridor and, to a lesser extent, the downtown area. According to the general plan, these changes have altered the image of San Mateo as a "bedroom community" to a place where people can both live and work as well as an important subregional office retail center (City of San Mateo, 1990).

The general plan characterizes San Mateo as becoming a larger, more diverse, and more complex community, but also as one with a slowing growth rate due to the continued decrease in average household size, limited vacant land, and high local land values. The population of the city and its sphere of influence was expected to increase from an estimated 92,482 in 2000 to 100,700 in

2010 (City of San Mateo, 2001). According to the Census 2000, the city's population in 2000 was 92,482. Population estimates since 2000 vary somewhat. The U.S. Census Bureau estimates San Mateo's 2005 population to be 91,081, a 1.5 percent decrease, whereas the DOF estimates the city's population to be 94,315 as of January 1, 2006, a 2 percent increase over 2000 (see Table E.4.1).

The City of San Mateo does not have growth management policies, as the city is largely built out. Future growth is expected to be accommodated through redevelopment on infill sites (Ring, 2006). An example of such development is the San Mateo Rail Corridor Transit-Oriented Development Plan, which was adopted in 2005. Implementation of the plan is expected to improve access to Caltrain stations and provide higher density housing that will help alleviate some of the measures throughout the Bay Area for both affordable and market-rate housing (City of San Mateo, 2005).

City of South San Francisco

Overview

South San Francisco is located at the northern end of the San Francisco Peninsula (refer to Figure 7.2 in PEIR Chapter 7). The city is bordered by the Bay to the east, Colma to the north, Daly City and Pacifica to the west, and San Bruno to the south.

Water Service

South San Francisco is served by CWS–South San Francisco District, which also serves Colma, part of unincorporated San Mateo County, and a small part of Daly City, and Westborough Water District. CWS-South San Francisco encompasses approximately 11.2 square miles; in 2001, it served a population of 49,207. Land use in the water district service area includes both residential and commercial areas (City of South San Francisco, 1999). In FY 2001/2002 approximately 89 percent of the CWS-South San Francisco's water supply was provided by the SFPUC (BAWSCA, 2005). The remaining water demand in the CWS–South San Francisco service area is met by groundwater supply (City of South San Francisco, 1999). Westborough Water District encompasses approximately 1 square mile; in 2000 it served a population of 13,033 (Westborough Water District, 2005). Land use in the service area is primarily residential with some commercial land uses. In FY 2001/2002, 100 percent of Westborough's supply was provided by the SFPUC (BAWSCA, 2005).

Growth Trends and Policies

Steel mills and other industries began to locate in South San Francisco following construction of the Southern Pacific Railroad line between San Francisco and San Jose (1904 to 1907). When the city incorporated in 1908 it had 1,989 residents and 14 major industries. The city's steel and shipbuilding industries continued to grow through the 1920s and World War II, and helped to spur residential growth. South San Francisco's fastest period of growth was during the war and postwar period; between 1940 and 1960, the population increased sixfold, from approximately

6,000 to over 39,000. This growth, achieved through extensive annexation and residential subdivision, was fueled by continued industrial growth. Almost half of the city's existing housing units were built between 1940 and 1959. In the 1960s, drainage and fill of marshlands made shoreline areas available for development. Over the past 30 years, the city's industrial base has slowly transformed, with warehousing, research, and biotechnology replacing steel production and other heavy industries. Since the 1960s, infill development has been the primary means of accommodating growth and change along major arteries west of Highway 101, although major expansion has occurred in the Westborough area and the area east of Highway 101. South San Francisco contains 8.3 percent of San Mateo County's population (City of South San Francisco, 1999). The city's population in 2000 was 60,552 (Census 2000). Population estimates since 2000 vary slightly. The U.S. Census Bureau estimates South San Francisco's 2005 population to be 60,735, a 0.3 percent increase, whereas the DOF estimates the city's population to be 61,824 as of January 1, 2006, a 2.1 percent increase over 2000 (see Table E.4.1).

The city identifies the Terrabay multi-use development project, on the south slopes of San Bruno Mountain, as its last phase of expansion. Future growth is expected to be limited to redevelopment and a few remaining unincorporated islands within the city. The general plan projects that the city's growth rate will be much slower over the 20-year horizon of the plan than the growth experienced in the 10 years before its publication (in 1999). The general plan forecasts a buildout population of 67,400, although buildout is not necessarily expected to occur within the 20-year horizon of the plan (City of South San Francisco, 1999).

E.4.4 City and County of San Francisco

Overview

San Francisco is located at the northern tip of the San Francisco Peninsula. The city is surrounded by water on three sides: to the west by the Pacific Ocean, and to the north and east by San Francisco Bay. The city is bordered to the south by San Mateo County and the cities of Daly City and Brisbane.

Water Service

The City and County of San Francisco (CCSF) owns its own water system, which is maintained and operated by the SFPUC. The SFPUC is the retail water supplier for all of the city's water users. The SFPUC regional water system meets 100 percent of the city's potable water demand and about 97 percent of total demand. Nonpotable groundwater, which is not linked hydraulically to the SFPUC water system, supplements the city's potable supply and is used for landscape irrigation at Golden Gate Park, the San Francisco Zoo, and along the Great Highway. According to the *City and County of San Francisco Retail Water Demands and Conservation Potential* (Hannaford and Hydroconsult, 2004), in 2000 (the study's base year) residential water use accounted for approximately 57 percent of the city's water use; commercial, industrial, and municipal uses accounted for approximately 33 percent; other uses (which include builders and contractors and docks and shipping) accounted for less than 1 percent (0.3 percent); and unaccounted-for water represented about 10 percent. For 2005, this distribution of water use was expected to shift slightly, with 56 percent residential use, 35 percent nonresidential, 0.3 percent builders/ contractors and docks/shipping, and 9 percent unaccounted-for water (Hannaford and Hydroconsult, 2004).

Growth Trends and Policies

San Francisco was incorporated as a city on April 15th, 1850. The County of San Francisco and the City of San Francisco were established as separate entities by the state legislature in 1850 and were combined by the legislature in 1856.[7] At that time, San Francisco's population was approximately 30,000 (CCSF, 2006a; CCSF, 2006b). By 1900, the city had grown approximately tenfold, to 342,782 residents (U.S. Census Bureau, 1995).

The city grew steadily for most of the first half of the 20th century, with the population increasing more than 20 percent each decade from 1900 to 1930. There was little change between 1930 and 1940, and between 1940 and 1950 the city grew by 22 percent, to a population of 775,357. In each of the next three decades the city's population declined somewhat, decreasing by 12 percent overall between 1950 and 1980. By 1980 this downward trend reversed, and the city grew by 7 percent each decade between 1980 and 2000, to a population of 776,733 (an increase of only 0.2 percent above the 1950 population) (U.S. Census Bureau, 1995; U.S, Census Bureau, 2000). Population estimates since 2000 vary somewhat. The U.S. Census Bureau estimates San Francisco's 2005 population to be 739,426, a 4.8 percent decrease, whereas the DOF estimates the city's population to be 798,680 as of January1, 2006, a 2.8 percent increase from 2000 (see Table E.4.1).

According to the general plan housing element, San Francisco is a "mature built-up city with very few large open tracts of land to develop" (CCSF, 2004). The *Citywide Action Plan* (CCSF, 2006c) "explores comprehensively the issue of how to meet the need for housing and jobs in ways that capitalize upon and enhance the best qualities of San Francisco as a place." Under this plan, the planning department is developing policy initiatives "for supporting and encouraging higher density, mixed-use—primarily residential—infill in selected transit-rich corridors."

In a November 2005 letter to ABAG, San Francisco's interim planning director indicated the CCSF's disagreement with the 2030 population projections contained in ABAG's *Draft Projections 2005* (provided to the CCSF prior to publication). The letter indicated that the CCSF expected less growth than was projected in *Draft Projections 2005*, despite its efforts to implement smart growth principles and increase development densities along major transit corridors (Macris, 2004). According to the CCSF, the forecast of job and household growth presented in its *2002 Land Use Allocation*—which estimates more growth in both jobs and households than forecasted in *Projections 2002*, but less than forecasted in the *Draft Projections 2005*—is a more realistic projection. The *2002 Land Use Allocation* estimates that San Francisco will add 23,144 housing units between 2000 and 2030 (for a total of 373,513, a 13 percent

7 When the City and County were combined, the part of San Francisco County south of the city's corporate boundary became part of San Mateo County.

increase) and 151,807 jobs in the same period (for a total of 786,000, a 24 percent increase) (Macris, 2004). The published estimates in *Projections 2005* (of 829,090 jobs and 398,280 households by 2030) (ABAG, 2004) are somewhat lower than those presented in the draft document, but are still greater than estimates presented in San Francisco's *2002 Land Use Allocation*.

E.4.5 Summary of Growth Trends and Policies of Select Jurisdictions

The jurisdictions profiled in the preceding section are a sample of cities in the service area. These jurisdictions represent a range of sizes and include some of the larger cities and some of the cities projecting relatively substantial increases in water demand by 2030. As the profiles indicate, these cities are largely urbanized, typically experienced their most rapid period of growth in the postwar decades through the 1970s, and are largely built out. Milpitas and East Palo Alto have experienced high rates of growth more recently (over the past 30 years) and are also highly urbanized. On average, San Francisco's population has been stable over the past 50 years. While none of these jurisdictions has adopted growth management ordinances per se, their general plans include policies to manage growth, in some cases including the establishment of urban growth or hillside protection boundaries (or, in the case of Stanford University's community plan, an analogous academic growth boundary). Most of the general plans identify infill development and redevelopment and/or revitalization of previously developed areas (strategies consistent with smart growth policies) as the principal means of accommodating future growth.

In addition to the general plan projections discussed above, Table E.4.1 presents a comparison between the 2030 population projections used for the wholesale customer water demand forecasts and ABAG *Projections 2005* forecasts, for both 2030 and the buildout years for the respective general plans. (Table E.4.1 includes subtotals for Fremont, Newark, and Union City for comparison with the ACWD projection.)

As the table shows, the population projections used for the WSIP water demand projections are reasonably consistent with the population projections in the jurisdictions' general plans, although the stated general plan projection years do not extend to 2030. The general plans of three cities—Milpitas, Sunnyvale, and East Palo Alto—expect more population at buildout than is assumed for the 2030 water demand projections. The general plan projections for the jurisdictions served by the other water customers (that can be compared) are within 11 percent of the population projections used for the water demand forecasts, although the general plan projection years are 2010 or 2020. This comparison suggests that the population growth estimated in the water demand projections for these jurisdictions has largely been addressed in the jurisdictions' general plans, and has been fully addressed in the case of three of the cities.

The projected 2030 population projection used for Hayward in the demand study is about 2 percent higher than that presented in the city's general plan. The 2030 population assumed for San Francisco in the demand study is about 5 percent higher than projected in the city's general plan. The 2030 population assumed for the ACWD demand forecast is about 6 percent higher than projections in the respective general plans (considering the projections in the Fremont, Newark, and Union City General Plans combined). The demand study projection for Redwood City is about 7 percent higher than that presented in the city's general plan. The population assumed for South San Francisco in the demand study (for CWS-South San Francisco and Westborough Water District, as updated by Westborough Water District's UWMP) is about 8 percent higher than the combined general plan projections of South San Francisco and Colma, which is also served by the CWS-South San Francisco, and the projection used for the Santa Clara demand forecast is about 8 percent higher than the population projected (for 2010) in the general plan.. (The 2030 population for the CWS–Mid-Peninsula District and Stanford University estimated in the demand study are not directly comparable to the growth projected in the San Mateo General Plan and the Stanford University Community Plan.)

The ABAG projections for 2030, which incorporate smart growth assumptions (as discussed in PEIR Section 7.3 and Appendix E.3), are somewhat higher than either the general plan or WSIP demand study projections (see Table E.4.1).

APPENDIX E.5

Summary of Planned Growth – Impacts and Mitigation Measures

This appendix supplements information presented in PEIR Chapter 7, Growth Inducement Potential and Secondary Effects of Growth. As discussed in Chapter 7, the environmental impact reports (EIRs) prepared for the general plans, area plans and specific plans of the jurisdictions within the SFPUC service area identify impacts associated with planned growth in the respective jurisdictions and identify measures to mitigate those impacts. **Table E.5.1** summarizes the impacts and mitigation measures identified in the EIRs and CEQA Findings prepared for those planning documents. These environmental impacts are the secondary environmental effects of growth supported in part by the proposed project (see Chapter 7). Table E.5.1 is intended to provide a summary overview of the impacts and mitigation measures identified in the relevant planning document EIRs for jurisdictions served by SFPUC water, and does not purport to reflect the full scope and intent of those EIRs. For a complete discussion of the impacts, please refer to the specific EIRs.

The following EIRs and City Council and Board of Supervisors resolutions were reviewed and are summarized in Table E.5.1. These documents are incorporated by reference into this Draft PEIR, pursuant to CEQA Guidelines 15150. Please see Section 1.3.5 in PEIR Chapter 1, Introduction, for a list of locations where documents incorporated by reference are available for public review.

- City of Belmont San Juan Hills Area Plan EIR, State Clearinghouse #86122320 (1988), Western Hills Area Plan EIR, State Clearinghouse #89051615 (1990)
- City of Brisbane 1993 General Plan EIR, State Clearinghouse #93071072 (1994)
- City of East Palo Alto General Plan EIR, State Clearinghouse #98051028 (1999)
- City of Foster City General Plan EIR, State Clearinghouse #92073017 (1993)
- City of Fremont General Plan EIR, State Clearinghouse #90030675 (1991)
- City of Hayward General Plan EIR, State Clearinghouse #2001072069 (2002)

• Participate in and promote local and regional planning efforts to improve air quality.			X							X	X										
• Provide site features and implement measures to encourage use of alternative modes of travel (to single-passenger vehicles) and reduce vehicle trips. (Such measures include implementing improvements to bicycle and pedestrian circulation systems and working with local and regional planning and transportation agencies to improve public transit services.)	X	X	X					X	X	X	X		X			X	X	X			X
• Implement selected roadway and/or intersection improvements to maximize the efficiency of the circulation system.		X	X				X									X					
• Implement general plan measures to reduce soil erosion and associated air quality impacts.																	X				
• Implement general plan measures that reduce dependence on automobile use and improve the efficiency of the existing transportation system.																	X				
• Reduce negative effects caused by roadways and rail lines on visual quality, air quality and noise.										X											
• Require adequate buffers, ventilation systems, and other measures to reduce impacts of odors or toxic emissions.												X									
• Implement general plan natural resource chapter policies regarding air quality impacts.															X						
• Facilitate mixed-use development and maintain jobs/housing balance.																X					
• Reduce diesel emissions.																				X	
BIOLOGICAL RESOURCES																					
Impacts																					
• Impact(s) on/loss of special-status animal or plant species		S				S			S		S		S		S		S			S	
• Impacts on biological resources due to individual or cumulative impacts on wetlands, riparian habitat, or other sensitive habitat	S	S	S	S, U	S	S		S		S	S	S	S	U	S		S		U	S	
• Conflicts with local policies or ordinances protecting biological resources													S		S					S	
• Cumulative impacts on biological resources			S																	S	

S = Significant mitigable impact U = Significant and unavoidable impact X = Mitigation measure identified in Environmental Impact Report

TABLE GROWTH E.5.1 (Continued)
SIGNIFICANT MITIGABLE (S) AND SIGNIFICANT UNAVOIDABLE (U) IMPACTS OF GROWTH IDENTIFIED BY GENERAL AND SPECIFIC PLAN ENVIRONMENTAL IMPACT REPORTS IN PROJECT AREA

	JURISDICTION																				
Impact	Belmont[a]	Brisbane[b]	East Palo Alto[c]	Foster City[d]	Fremont[e]	Hayward[f]	Menlo Park[g]	Millbrae[h]	Milpitas[i]	Mountain View[j]	Newark[k]	Palo Alto[l]	Redwood City[m]	San Bruno[n]	San Jose[o]	City of San Mateo[p]	San Mateo County[q]	City of Santa Clara[r]	Santa Clara County[s]	Stanford University[t]	Union City[u]
• Disruption of wildlife migration or travel corridors																				S	
Mitigation Measures																					
• Negotiate any necessary streambed alteration agreements with the California Department of Fish and Game.	X					X															
• Plant native species for revegetation and landscaping purposes.	X																				
• Implement the San Bruno Mountain Habitat Conservation Plan.		X																			
• Implement general plan policies and programs to protect biological resources.		X			X						X						X				
• Conduct project-specific environmental review and implement mitigation.		X	X									X	X								
• Obtain all applicable resource agency permits prior to development within areas under the jurisdiction of federal, state, or local resource agencies.			X																		
• Coordinate with all applicable resource agencies to ensure that required mitigation protocols and design modifications are incorporated during the early stages of project review.													X								
• Where impacts on special-status species may occur, coordinate with relevant resource agencies as early as possible and substantially complete the consultation prior to or in conjunction with project environmental review.			X																		
• Require project-specific surveys conducted by qualified professionals according to established protocols to determine on-site resources and appropriate site-specific mitigation measures.			X	X		X			X				X							X	
• Protect and preserve open space areas and design any improvements in open space areas to minimize adverse impacts on habitats and other open space values.				X				X		X											
• Exclude development in environmentally sensitive areas that would result in a net loss of significant wetlands.				X																	
• Avoid wetlands and replace them where avoidance is infeasible.																				X	
• Include a program in the general plan to conduct a detailed wetland delineation study of vacant sites to accurately determine the extent of jurisdictional wetlands.								X													
• Maximize open space preservation opportunities in the development review process.								X													
• Protect and restore plant and wildlife habitats.				X						X							X			X	
• Protect wildlife from the hazards of urbanization.										X											
• Implement the identified program to mitigate impacts on California Tiger Salamander.																				X	
• Develop a program to educate the public and landowners about sensitive biotic resources in the area and best management practices for preserving those resources.																			X		
CULTURAL RESOURCES																					
Impacts																					
• Disturbance of historical resource(s)		S	S		S			S	S		S		S, U		S		S			S	
• Disturbance of archaeological resource(s)			S			S		S		S	S		S		S		S	S		S	
• Disturbance of paleontological resource(s)								S		S						S	S			S	
• Disturbance of human remains								S		S						S				S	
• Disturbance of unknown subsurface cultural resources	S	S			S	S						S									
• Cumulative impacts on historical resources																			U	U	
• Cumulative impacts on historical, archaeological, or paleontological resources																	U			S	

S = Significant mitigable impact U = Significant and unavoidable impact X = Mitigation measure identified in Environmental Impact Report

TABLE GROWTH E.5.1 (Continued)
SIGNIFICANT MITIGABLE (S) AND SIGNIFICANT UNAVOIDABLE (U) IMPACTS OF GROWTH IDENTIFIED BY GENERAL AND SPECIFIC PLAN ENVIRONMENTAL IMPACT REPORTS IN PROJECT AREA

	JURISDICTION																				
Impact	**Belmont[a]**	**Brisbane[b]**	**East Palo Alto[c]**	**Foster City[d]**	**Fremont[e]**	**Hayward[f]**	**Menlo Park[g]**	**Millbrae[h]**	**Milpitas[i]**	**Mountain View[j]**	**Newark[k]**	**Palo Alto[l]**	**Redwood City[m]**	**San Bruno[n]**	**San Jose[o]**	**City of San Mateo[p]**	**San Mateo County[q]**	**City of Santa Clara[r]**	**Santa Clara County[s]**	**Stanford University[t]**	**Union City[u]**
Mitigation Measures																					
• Implement general plan policies and programs and measures identified in the general plan EIR to protect cultural resources.		X			X	X		X			X	X	X		X		X	X			
• Conduct project-specific review and implement identified mitigation consistent with general plan cultural resource policies.		X	X			X			X				X								
• If any cultural resources are found, halt work and protect the site from disturbance until a qualified archaeologist / cultural resources specialist has evaluated the resources and identified appropriate site-specific mitigation.	X					X															
• If human remains are found, halt work and notify the county coroner; implement subsequent specified actions and investigations as applicable, consistent with California Public Resources Code Section 5097.98.						X															
• Identify sensitive paleontological resources prior to commencement of development activities and recover sensitive fossils.			X																		
• Conduct the proposed work consistent with the state and federal standards for historic resources.									X												
• Implement CEQA Guidelines Section 15064.5 provisions for the accidentally discovery of historic or archeological resources.									X												
• Maintain documentation of significant archeological and historical sites.										X											
• Develop standard practices or contingency plans for archeological materials that are unearthed during construction.										X											
• Support the preservation of historic buildings and structures.									X	X						X					
• Implement measures to protect historic, archaeological, and paleontological resources.																				X	
GEOLOGY AND SOILS																					
Impacts																					
• Exposure to earthquake fault rupture hazards						S												S			
• Exposure to hazards from strong seismic ground shaking	S	S	S		S	U		S		S	S							S	U		
• Exposure to seismic-related ground failure, including liquefaction		S	S			S		S			S		S					S			
• Exposure to landslides	S	S				S															
• Exposure to flooding, including flooding as a result of levee or dam failure																S					
• Soil erosion or the loss of topsoil	S	S									S		S				S				
• Cumulative impacts on soil resources																	U				
• Damage to structures or utilities caused by soils with high shrink-swell potential						S															
• Hazards, including architectural and/or structural damage, due to differential settlement								S													
• Exposure of new development on or downslope of unstable slopes to rockfall or landslide hazards	S																				
• Exposure to seismic-, geologic-, and/or flood-related hazards														U	S		S				
• Cumulative impacts associated with exposure to natural hazards																	U				
Mitigation Measures																					
• Prohibit off-road vehicle use and implement an erosion control plan.	X																				
• Prohibit grading during the rainy season (Oct. 15 - April 15).	X																				

S = Significant mitigable impact U = Significant and unavoidable impact X = Mitigation measure identified in Environmental Impact Report

TABLE GROWTH E.5.1 (Continued)
SIGNIFICANT MITIGABLE (S) AND SIGNIFICANT UNAVOIDABLE (U) IMPACTS OF GROWTH IDENTIFIED BY GENERAL AND SPECIFIC PLAN ENVIRONMENTAL IMPACT REPORTS IN PROJECT AREA

	JURISDICTION																				
Impact	**Belmont**[a]	**Brisbane**[b]	**East Palo Alto**[c]	**Foster City**[d]	**Fremont**[e]	**Hayward**[f]	**Menlo Park**[g]	**Millbrae**[h]	**Milpitas**[i]	**Mountain View**[j]	**Newark**[k]	**Palo Alto**[l]	**Redwood City**[m]	**San Bruno**[n]	**San Jose**[o]	**City of San Mateo**[p]	**San Mateo County**[q]	**City of Santa Clara**[r]	**Santa Clara County**[s]	**Stanford University**[t]	**Union City**[u]
• Implement the geologic hazard policy map and engineering geology map, table of geological criteria for development, and related policies and mitigation measures.	X																				
• Implement general plan policies and programs to mitigate potential geologic and seismic hazards.		X			X			X							X		X				
• Implement general plan policies and programs to mitigate impacts on soils.											X										
• Conduct/require site-specific environmental review that characterizes site-specific soils, geology, and seismic conditions, conduct site-specific geotechnical review as applicable, and implement identified measures to mitigate project-specific impacts from expansive or corrosive soils and geologic and seismic hazards.		X	X			X		X					X								
• Use open space easements and other regulatory techniques to prohibit development and avoid public safety hazards in areas where geologic instability or faulting is identified.			X																		
• Adopt and enforce the most recent state seismic requirements and applicable standards for structural design of new development and redevelopment (e.g., the Uniform Building Code and California Building Code).			X			X				X								X			
• Promote disaster preparedness in the community with the disaster simulation program. Adopt a disaster preparedness plan and continue to conduct simulation exercises.			X																		
• Require new development within the Alquist Priolo Special Study Zone to comply with applicable regulations pertaining to fault rupture hazard.						X															
• Determine the expansion potential of clay soils on a project-specific basis. Remove or amend and compact highly expansive soils under new buildings. Drain surface water away from buildings to minimize shrink-swell potential.						X															
• Minimize disruption of vegetation during construction and implement measures to reduce soil movement, in accordance with best management practices.						X															
• Continue programs to educate residents about seismic hazards.										X											
• Develop an ordinance to upgrade unreinforced masonry buildings.										X											
• Continue to update the city's emergency preparedness plan.										X											
• Prohibit reduction in creek capacity, implement flood control measures and the San Mateo Creek capital improvement program, and conduct public information programs.																X					
• Implement County plans and policies to reduce impacts; however substantial property damage and loss of life could occur in a major earthquake.																			X		
HAZARDS AND HAZARDOUS MATERIALS																					
Impacts																					
• Release of or exposure to hazardous materials		S	S			S		S							S	S	S			S	
• Exposure to the risk of loss, injury or death involving wildland fires		S														S					
• Hazards associated with unreinforced masonry buildings		S																			
• Increased risk of structural fires and the degree of damage sustained from industrial chemical fires			S																		
• Exposure to soil and/or groundwater contamination		S						S	S	U											
• Safety hazard(s) related to aircraft overflights											S										

S = Significant mitigable impact U = Significant and unavoidable impact X = Mitigation measure identified in Environmental Impact Report

TABLE GROWTH E.5.1 (Continued)
SIGNIFICANT MITIGABLE (S) AND SIGNIFICANT UNAVOIDABLE (U) IMPACTS OF GROWTH IDENTIFIED BY GENERAL AND SPECIFIC PLAN ENVIRONMENTAL IMPACT REPORTS IN PROJECT AREA

Impact	JURISDICTION																				
	Belmont[a]	Brisbane[b]	East Palo Alto[c]	Foster City[d]	Fremont[e]	Hayward[f]	Menlo Park[g]	Millbrae[h]	Milpitas[i]	Mountain View[j]	Newark[k]	Palo Alto[l]	Redwood City[m]	San Bruno[n]	San Jose[o]	City of San Mateo[p]	San Mateo County[q]	City of Santa Clara[r]	Santa Clara County[s]	Stanford University[t]	Union City[u]
• Potential impacts related to emergency response											S		S				S				
• Increased exposure to man-made and natural hazards																	S				
• Increased exposure to fire hazard in rural areas																	S				
• Impacts on vegetation, water and wildlife resources from elimination of vegetation to reduce fire hazards																	S				
• Cumulative effects from increased exposure to man-made hazards																	U				
Mitigation Measures																					
• Implement general plan programs and policies that address public safety hazards in the planning area.		X						X			X				X		X	X			
• Conduct project-specific environmental review and implement identified measures to mitigate identified potential hazards.		X	X						X							X		X			
• Implement measures identified in the Precise Plan EIR to reduce traffic impacts and ensure the adequacy of project-level emergency-response provisions.													X								
• Adopt and maintain a disaster preparedness plan including emergency response for accidents involving hazardous materials and promote disaster preparedness in the community.			X																		
• Continue to participate in the National Flood Insurance Administration program and investigate the availability of levee reconstruction funding.			X																		
• For proposed projects within the planning area of the airport, ensure consistency with the Airport Land Use Plan and participate in future amendments to the plan.			X																		
• Cooperate with federal, state, and local agencies to effectively regulate and manage hazardous waste.			X																		
• Prior to development of or in proximity to a reported hazardous material site, implement specified measures, including appropriate site assessment, remediation, and follow-up investigation.						X			X												
• Include programs in the general plan to map and remediate potential hazardous soils sites in the city.								X													
• Implement measures to minimize the risks from the use of or accidental exposure to hazardous materials.										X							X				
• Support NASA/Ames as the future federal operator of Moffett Field.										X											
• Implement a risk management plan.																				X	
HYDROLOGY AND WATER QUALITY																					
Impacts																					
• Degradation of surface water and/or groundwater quality		S	S					S			S							S		S	
• Increases in impervious surfaces and/or alternations to drainage resulting in exposure to flood hazards and/or the need for new drainage facilities		S	U			S	S								S			U			
• Degradation of surface water quality from construction activities and/or post-construction uses						S							S								
• Water pollution from stormwater runoff							U								S						
• Exposure of people and property to flooding						S		S		S							S				
• Increased bank erosion and bed sedimentation, risks of landslides, and impacts on new structures as a result of increased runoff from inadequately designed uphill drainage systems	S																				
• Direct and/or cumulative impacts on the hydrologic regime					S															S	
• Increased demands on groundwater resources											S										

S = Significant mitigable impact U = Significant and unavoidable impact X = Mitigation measure identified in Environmental Impact Report

TABLE GROWTH E.5.1 (Continued)
SIGNIFICANT MITIGABLE (S) AND SIGNIFICANT UNAVOIDABLE (U) IMPACTS OF GROWTH IDENTIFIED BY GENERAL AND SPECIFIC PLAN ENVIRONMENTAL IMPACT REPORTS IN PROJECT AREA

	JURISDICTION																				
Impact	Belmont[a]	Brisbane[b]	East Palo Alto[c]	Foster City[d]	Fremont[e]	Hayward[f]	Menlo Park[g]	Millbrae[h]	Milpitas[i]	Mountain View[j]	Newark[k]	Palo Alto[l]	Redwood City[m]	San Bruno[n]	San Jose[o]	City of San Mateo[p]	San Mateo County[q]	City of Santa Clara[r]	Santa Clara County[s]	Stanford University[t]	Union City[u]
• Flood hazards, including hazards related to potential dam failure											S	S				S					
• Increases in impervious surfaces from cumulative development resulting in increasing frequency and severity of downstream flooding												U								S	
Mitigation Measures																					
• Implement general plan programs and policies that address impacts on drainage facilities and flood control channels and that control erosion and sedimentation.	X	X			X			X			X				X						
• Conduct project-specific environmental review and implement identified mitigation of construction and operational impacts. Include specified requirements such as adherence to best management erosion and sedimentation control practices and calculations to determine the adequacy of site drainage facilities and public facilities.		X				X	X						X							X	
• Require new development projects and substantial redevelopment projects to incorporate as applicable best management practices of the National Pollutant Discharge Elimination System permit and requirements of other applicable plans to control runoff pollutants and sedimentation.			X															X			
• Establish an advisory network of representatives having jurisdiction over the San Francisquito Creek to ensure the community needs for flood control and infrastructure maintenance are met.			X																		
• Identify deficiencies in local storm drainage systems and determine and implement needed improvements and maintenance.			X																		
• Implement general plan policies and programs that protect against dam failure inundation.					X																
• Cooperate with other agencies in preparing plans and developing projects to alleviate flooding potential in newly mapped floodplain areas. Require new developments in mapped 100-year flood zones to provide evidence of flood control protection and compliance with applicable regulations of flood management agencies.						X															
• Reopen the Marsh Road water storage and treatment facility, implement drainage capital improvements, and conduct hydrologic studies.							X														
• Include a policy in the general plan requiring finished floor elevations for new structures to be completed above the 8.2 feet NGVD and requiring other improvements constructed below 8.2 NGVD to be built to withstand temporary inundation.								X													
• Establish pollution control measures that keep pollutants from entering storm drain systems.										X											
• Ensure proper use, storage and disposal of toxic chemicals to prevent soil contamination.										X											
• Implement improvements and policies recommended by the Storm Drainage Task Force.	X																				
• Require ongoing technical evaluations of dam safety and cooperation with relevant entities to implement project-specific mitigation measures included in the technical studies.												X									
• Provide adequate storm drainage systems in new development in coordination with the Santa Clara Valley Water District and the San Mateo County Flood Control District.												X									
• Prohibit reduction of creek capacity.																X					
• Implement flood control measures.																X					

S = Significant mitigable impact U = Significant and unavoidable impact X = Mitigation measure identified in Environmental Impact Report

TABLE GROWTH E.5.1 (Continued)
SIGNIFICANT MITIGABLE (S) AND SIGNIFICANT UNAVOIDABLE (U) IMPACTS OF GROWTH IDENTIFIED BY GENERAL AND SPECIFIC PLAN ENVIRONMENTAL IMPACT REPORTS IN PROJECT AREA

	JURISDICTION																				
Impact	Belmont[a]	Brisbane[b]	East Palo Alto[c]	Foster City[d]	Fremont[e]	Hayward[f]	Menlo Park[g]	Millbrae[h]	Milpitas[i]	Mountain View[j]	Newark[k]	Palo Alto[l]	Redwood City[m]	San Bruno[n]	San Jose[o]	City of San Mateo[p]	San Mateo County[q]	City of Santa Clara[r]	Santa Clara County[s]	Stanford University[t]	Union City[u]
• Implement the San Mateo Creek Capital Improvement Project.																X					
• Conduct a comprehensive drainage study that includes a survey of maintenance needs for the city's creeks and channels; develop funding, maintenance, and public education programs addressing water quality and flood control issues and develop an enforcement program for illegal dumping in creeks and channels.																X					
• Raise levees to 108 feet.																X					
• Require public notification of flood hazards.																X					
• Implement general plan that reduce exposure to flood hazard.																	X				
• Manage stormwater runoff.															X					X	
• Maintain groundwater recharge.																				X	
• Protect water quality.																				X	
• Support flood control improvements that reduce flood hazards. Regulate the type, location and intensity of land uses within flood-prone areas. Require expansion of storm drainage facilities where needed to serve new development.																		X			
LAND USE & PLANNING																					
Impacts																					
• Conflict(s) with an applicable land use plan, policy, and/or regulation					S			U													
• Land use incompatibilities	S			S	S	S		U		S		S			S	S	S		S		
• Intensification of land uses or substantial changes in land use density, scale, and/or character			S	S	S			U			S				S		S		S		
• Loss of open space or agricultural lands or the premature urbanization of rural areas					S										U		S		S		
• Potential failure or underutilization of neighborhood commercial centers				S																	
• Division of an established community						S															
• Increases in the existing oversupply of jobs							U														
• Visual, traffic and other environmental impacts of constructing a bicycle connection across El Camino Real												S									
• Inefficient land use patterns																	S		S		
• Cumulative land use impacts																	U				
Mitigation Measures																					
• Implement applicable general plan land use programs and policies that address the clustering of development, resource protection, zoning code modification(s), potential impacts of intensified land uses, conflicts between incompatible land uses, impacts on open space, and/or golf course development.	X		X		X			X									X		X		
• Encourage open space dedications and assessment fees.	X																				
• Work with San Mateo and the Mid-Peninsula Open Space District to maintain a buffer between the planning area and Sugarloaf Mountain.	X																				
• Review implementation of the general plan and land use policy map to identify the effect of land development and use in the community on City revenues and costs of providing public facilities and services.			X																		
• Develop a design and improvement plan as part of the City's capital improvement plan.			X																		
• Prepare area or specific plans for neighborhoods identified in the general plan.			X																		

S = Significant mitigable impact U = Significant and unavoidable impact X = Mitigation measure identified in Environmental Impact Report

TABLE GROWTH E.5.1 (Continued)
SIGNIFICANT MITIGABLE (S) AND SIGNIFICANT UNAVOIDABLE (U) IMPACTS OF GROWTH IDENTIFIED BY GENERAL AND SPECIFIC PLAN ENVIRONMENTAL IMPACT REPORTS IN PROJECT AREA

	JURISDICTION																				
Impact	Belmont[a]	Brisbane[b]	East Palo Alto[c]	Foster City[d]	Fremont[e]	Hayward[f]	Menlo Park[g]	Millbrae[h]	Milpitas[i]	Mountain View[j]	Newark[k]	Palo Alto[l]	Redwood City[m]	San Bruno[n]	San Jose[o]	City of San Mateo[p]	San Mateo County[q]	City of Santa Clara[r]	Santa Clara County[s]	Stanford University[t]	Union City[u]
• Provide adequate resources to enforce the zoning ordinance and other ordinances to achieve the desire level of physical quality in the city.			X																		
• Conduct project-specific environmental review, including design and architectural review as applicable, and implement identified mitigation consistent with general plan land use policies.				X		X					X	X					X		X		
• Monitor commercial and industrial development annually (and prepare a written report every two years) to determine whether land use element policies should be changed.							X														
• Preserve, protect, and enhance the character of residential, retail, and commercial districts and ensure compatibility between the residential, retail, commercial, and industrial districts.										X											
• Preserve mobile home parks, and assure safe construction of mobile and modular housing.										X											
• Ensure that zoning, building regulations and public works requirements are equitable and City processes are efficient.										X											
• Adopt and apply performance standards for review of mixed use developments.												X									
• Construct an at-grade pedestrian/bicycle crossing as specified in the general plan EIR.												X									
• Implement City Concept, Community Development, Aesthetic, Cultural, and Recreational chapter policies of the general plan.															X						
• Prevent incompatible land uses; avoid concentrations of potentially incompatible uses; adopt design policies.																X					
• Establish 20-year growth limits as recommended in the plan's urban growth boundary policy.																			X		
• Deny expansion of commercial development into viable agricultural land and emphasize in-fill to meet these needs (to be implemented by the LAFCO).																			X		
• Implement the appropriate recommendations of the agricultural preserve study																			X		
• Conduct studies and implement recommendations on recreational vehicle park needs and golf course development.																			X		
MINERAL RESOURCES																					
Impacts																					
• Impacts of mineral extraction operations on land, water, air, biological resources																	S				
• Depletion of non-renewable mineral resources																	S				
• Cumulative impacts from the depletion of non-renewable resources and permanent alteration of landforms																	U				
Mitigation Measures																					
• Promote growth management and sphere of influence planning.																	X				
• Maintain the County land use database to monitor land conversion rates, the health of the rural economy, and impacts on resources from land use changes.																	X				
• Implement general plans and policies that require identification of significant mineral resource areas and the buffering of extraction activities from incompatible land uses.																	X				

S = Significant mitigable impact U = Significant and unavoidable impact X = Mitigation measure identified in Environmental Impact Report

TABLE GROWTH E.5.1 (Continued)
SIGNIFICANT MITIGABLE (S) AND SIGNIFICANT UNAVOIDABLE (U) IMPACTS OF GROWTH IDENTIFIED BY GENERAL AND SPECIFIC PLAN ENVIRONMENTAL IMPACT REPORTS IN PROJECT AREA

Impact	JURISDICTION																				
	Belmont[a]	Brisbane[b]	East Palo Alto[c]	Foster City[d]	Fremont[e]	Hayward[f]	Menlo Park[g]	Millbrae[h]	Milpitas[i]	Mountain View[j]	Newark[k]	Palo Alto[l]	Redwood City[m]	San Bruno[n]	San Jose[o]	City of San Mateo[p]	San Mateo County[q]	City of Santa Clara[r]	Santa Clara County[s]	Stanford University[t]	Union City[u]
NOISE																					
Impacts																					
• Exposure to or generation of excessive noise levels or groundborne vibration		S	S	S	S	S		S				S	S		S		S	S		S	
• Substantial permanent increase in ambient noise levels				S		S											S				
• Substantial temporary or periodic increase(s) in ambient noise levels						S															
• Exposure of additional residents or businesses to excessive noise levels from aircraft overflights		U																U			
• Exposure of adjacent land uses to noise from future light rail line.															S						
• Short-term noise impacts during construction	S		S			U		S		S			S		S					U	S
• Increased noise levels particularly from vehicular traffic	U	S	S		U	S	U			U	S	S		U	S, U	S					
Mitigation Measures																					
• Implement general plan programs and policies that reduce noise impacts.		X		X				X				X			X		X				
• Implement/require measures to reduce construction noise (e.g., requiring limits on construction hours, use of hospital-grade mufflers on equipment, use of sound barriers or baffles, and/or limits on the number of active building permits issued).	X					X		X					X		X					X	
• Conduct project-level environmental review and implement identified mitigation.		X	X		X	X				X			X			X		X		X	
• Use noise and land use compatibility standards to guide review of development proposals.			X	X	X							X									
• Require all new development to meet general plan and airport land commission noise attenuation standards through building code requirements.																		X			
• Enforce applicable noise insulation standards of the state building code (Title 24) and adopt and enforce local noise ordinances.			X										X								
• Implement specified measures to address traffic noise (e.g., periodic review of truck routes for noise impacts on sensitive land uses, enforcement of vehicle noise standards, limitations on truck operations, and/or installation of noise barriers)	X		X	X			X														
• Encourage other agencies to reduce noise levels generated by roadways, railways, airports, and other facilities.					X																
• Work with Caltrans to quantify and mitigate noise impacts associated with extension of state highways.					X																
• Locate noise-sensitive uses away from noise sources and less sensitive uses closer to noise sources.					X	X															
• Include incremental traffic generated by new development in the analysis of a proposed a project's contribution to traffic noise.						X															
• Evaluate proposed new developments near railroad rights of way for potential vibration impacts and incorporate engineering recommendations in development design.						X															
• Develop a noise abatement mitigation plan.																					X
POPULATION AND HOUSING																					
Impacts																					
• Substantial population and/or job growth in the area					S			U			S							U		U	
• New or increased demand for special housing needs											S										

S = Significant mitigable impact U = Significant and unavoidable impact X = Mitigation measure identified in Environmental Impact Report

TABLE GROWTH E.5.1 (Continued)
SIGNIFICANT MITIGABLE (S) AND SIGNIFICANT UNAVOIDABLE (U) IMPACTS OF GROWTH IDENTIFIED BY GENERAL AND SPECIFIC PLAN ENVIRONMENTAL IMPACT REPORTS IN PROJECT AREA

Impact	JURISDICTION																				
	Belmont[a]	Brisbane[b]	East Palo Alto[c]	Foster City[d]	Fremont[e]	Hayward[f]	Menlo Park[g]	Millbrae[h]	Milpitas[i]	Mountain View[j]	Newark[k]	Palo Alto[l]	Redwood City[m]	San Bruno[n]	San Jose[o]	City of San Mateo[p]	San Mateo County[q]	City of Santa Clara[r]	Santa Clara County[s]	Stanford University[t]	Union City[u]
• Increased demand for housing and related impacts on housing affordability			S	S	S															S	
• Jobs/housing imbalances, oversupply of jobs							S														
• Failure to meet population growth projections, resulting in additional population growth in other jurisdictions.																					U
Mitigation Measures																					
• Implement general plan programs and policies that address impacts related to population growth and housing demand.			X	X	X			X			X										
• Implement regional and local land use, transportation and infrastructure plans designed to accommodate the projected growth and reduce associated environmental impacts.			X																		
• Regularly update the employment database to assess actual job development with respect to projections and apprise infrastructure planning agencies of results.					X																
• Require affordable housing of all development within the community development agency project area and provide other incentives to encourage development of affordable units.				X																	
• Regularly monitor and report to the Planning Commission the amount of commercial and industrial development being permitted, as a basis for considering changes to land use element policies. When development approaches currently projected levels, conduct a traffic analysis as specified to provide a basis for City Council consideration of changes to the land use and transportation and circulation elements.							X														
• Implement general plan land use programs and policies that address jobs/housing imbalances.									X												
• Identify additional housing sites and condition new academic space on the construction of housing.																				X	
• Implement traffic and service mitigation measures.																				X	
• Implement general plan air quality policies and programs.																		X			
PUBLIC SERVICES																					
Impacts																					
• Increased demand for fire protection services			S		S			S		S	S	S								S	
• Increased demand for police protection services			S		S					S	S	S				S				S	
• Increased demand for schools, including cumulative demand			S		S	S	U	S		S	S	U							S, U	S	
• Increased demand for parks and/or deterioration of parks and recreational facilities from increased use			S		S	S				S	S						S			S	
• Increased demand for public services other than fire and police protection, schools, and parks					S					S	S							U			
• Overcrowding of city governmental offices and/or inefficient dispersion of city services resulting from the need for additional city personnel					S																
• Economic impacts if demands on infrastructure exceed collected development impact fees		S																			
• Impacts on existing and demand for new infrastructure															S		S				
• Increased demand for public services														S	S						

S = Significant mitigable impact   U = Significant and unavoidable impact   X = Mitigation measure identified in Environmental Impact Report

TABLE GROWTH E.5.1 (Continued)
SIGNIFICANT MITIGABLE (S) AND SIGNIFICANT UNAVOIDABLE (U) IMPACTS OF GROWTH IDENTIFIED BY GENERAL AND SPECIFIC PLAN ENVIRONMENTAL IMPACT REPORTS IN PROJECT AREA

	JURISDICTION																				
Impact	Belmont[a]	Brisbane[b]	East Palo Alto[c]	Foster City[d]	Fremont[e]	Hayward[f]	Menlo Park[g]	Millbrae[h]	Milpitas[i]	Mountain View[j]	Newark[k]	Palo Alto[l]	Redwood City[m]	San Bruno[n]	San Jose[o]	City of San Mateo[p]	San Mateo County[q]	City of Santa Clara[r]	Santa Clara County[s]	Stanford University[t]	Union City[u]
Mitigation Measures																					
• Implement specified general plan programs and policies and mitigation identified in the general plan EIR that address funding for and the provision and maintenance of community services and/or facilities.			X		X			X		X	X	X			X	X			X		
• Impose development impact fees to cover the costs of needed infrastructure.		X			X																
• Conduct project-specific review to assess required levels of public services and implement identified mitigation			X		X										X						
• Cooperate with school districts regarding enrollment projections, the collection of school impact fees, and/or implement other specified measures to provide for and maintain adequate educational services.			X	X	X	X		X										X	X		
• Maintain an emergency preparedness plan to maximize the efforts of emergency service providers and minimize human suffering and property damage during disasters.			X																		
• Encourage regional recreation and parks districts to plan, acquire, and/or construct new recreation and park facilities.						X															
• Encourage the incorporation of park and recreation facilities into major development projects.						X															
• Reopen closed schools, increase the use of temporary facilities, and limit development.							X														
• Implement general plan policies that address increased demands on public services.															X						
• Maintain police and fire services and school capacity.																				X	
RECREATION																					
Impacts																					
• Increased demand for new or expanded parks and/or recreational facilities			S			S						S			S		S				
• Loss and/or degradation of open space				U	S												S			U	
• Cumulative impacts on overused park facilities																	U		U		
• Inefficient or ineffective park and recreation facility operations due to duplicative or ambiguous jurisdictional roles																	S				
• Infringement of other land uses on park lands and natural habitats																	S				
• Impacts of park creation on alternative land uses																	S				
Mitigation Measures																					
• Implement general plan policies and programs to improve, expand, acquire, and/or develop park and recreational facilities			X	X	X										X		X				
• Implement various methods to acquire parkland and improve access to open space and recreational facilities			X																		
• Implement general plan land use and open space policies that address impacts on open space and the protection of sensitive lands.				X	X												X				
• Conduct planning and environmental studies for the expansion or acquisition and construction of parks and recreational facilities to meet increased demand.						X															
• Review development projects to ensure the adequate provision of park facilities.						X						X									
• Cluster development in Lathrop Development District.																				X	
• Encourage the use of less-utilized parks in the County.																			X		
• Implement park improvements and dedicate new trails.																				X	

S = Significant mitigable impact U = Significant and unavoidable impact X = Mitigation measure identified in Environmental Impact Report

TABLE GROWTH E.5.1 (Continued)
SIGNIFICANT MITIGABLE (S) AND SIGNIFICANT UNAVOIDABLE (U) IMPACTS OF GROWTH IDENTIFIED BY GENERAL AND SPECIFIC PLAN ENVIRONMENTAL IMPACT REPORTS IN PROJECT AREA

Impact	JURISDICTION																				
	Belmont[a]	Brisbane[b]	East Palo Alto[c]	Foster City[d]	Fremont[e]	Hayward[f]	Menlo Park[g]	Millbrae[h]	Milpitas[i]	Mountain View[j]	Newark[k]	Palo Alto[l]	Redwood City[m]	San Bruno[n]	San Jose[o]	City of San Mateo[p]	San Mateo County[q]	City of Santa Clara[r]	Santa Clara County[s]	Stanford University[t]	Union City[u]
TRAFFIC AND TRANSPORTATION																					
Impacts																					
• Increased traffic relative to existing traffic and the capacity of the street system	S	U	U		S					S	U	U		U		U	S	U		S	
• Degradation of levels of service on area roads or highways	U			S, U		U	U		U			S, U	U				S				U
• Increased vehicle delays at area intersections		S							U				S, U							U	
• Increased vehicle delays at intersections in adjacent cities		U																		U	
• Declines of average speeds on individual roadway segments							S														
• Cumulative traffic impacts on roadway segments and/or intersections	U								U				S, U				U		U		
• Traffic safety impacts	S											S					S				
• Impacts on parking capacity												S					S				
• Traffic congestion interference with transit service and/or bicycle levels of service												S									
• Constraints on providing for bicycle and pedestrian travel as a result of increased competition for use of roads and highways by motor vehicles																	S				
• The loss of 40 homes for Hillsdale Boulevard widening																U					
• Construction traffic impacts																				S	
Mitigation Measures																					
• Implement general plan and/or local transportation plan programs and policies and measures identified in the general plan EIR to mitigate traffic and circulation impacts.		X	X		X	X				X	X						X				X
• Encourage adjacent jurisdictions to consent to improvements required of project developers.		X																			
• Coordinate planned development in the city with needed improvements to the regional circulation system.			X																		
• Work with transit agencies to improve local transit service, develop new transportation facilities, and encourage public transit ridership.			X	X																	
• Implement measures to encourage the use of alternative modes of travel and reduce vehicle trips.	X		X	X							X						X	X	X	X	
• Coordinate traffic signals, improve intersection capacity, and implement other operational measures to maximize the efficiency of the circulation system.			X						X											X	
• Support and participate in regional transportation planning.			X								X	X					X	X			
• Require project-specific transportation studies and implement identified mitigation measures.			X	X																X	
• Implement Transportation Systems Management Programs.				X												X		X			
• Add various combinations of turn lanes, through lanes, off- and on-ramps, and/or widen lanes at intersections where unacceptable levels of service occur.	X						X		X			X				X					
• Continue to implement the city's traffic safety program and continue to monitor, identify, and implement safety programs at high-accident intersections.												X									
• Implement measures to reduce traffic impacts on local streets.												X								X	
• Participate in regional efforts to achieve jobs/housing balance and traffic improvements.																X					
• Purchase homes at fair market value and assist resident relocation.																X					
• Expand highway capacity to relieve some bottlenecks.																			X		
• Encourage higher densities and supportive uses around transit stations.																		X			

S = Significant mitigable impact   U = Significant and unavoidable impact   X = Mitigation measure identified in Environmental Impact Report

TABLE GROWTH E.5.1 (Continued)
SIGNIFICANT MITIGABLE (S) AND SIGNIFICANT UNAVOIDABLE (U) IMPACTS OF GROWTH IDENTIFIED BY GENERAL AND SPECIFIC PLAN ENVIRONMENTAL IMPACT REPORTS IN PROJECT AREA

	JURISDICTION																				
Impact	Belmont[a]	Brisbane[b]	East Palo Alto[c]	Foster City[d]	Fremont[e]	Hayward[f]	Menlo Park[g]	Millbrae[h]	Milpitas[i]	Mountain View[j]	Newark[k]	Palo Alto[l]	Redwood City[m]	San Bruno[n]	San Jose[o]	City of San Mateo[p]	San Mateo County[q]	City of Santa Clara[r]	Santa Clara County[s]	Stanford University[t]	Union City[u]
• Evaluate Zoning Ordinance parking standards to require only the minimum necessary parking.																		X			
• Implement policies that require road improvements to increase safety on rural roads.																	X				
• Implement parking provisions described in the general plan EIR.												X									
UTILITIES																					
Impacts																					
• Need for new or expanded water service or wastewater treatment facilities	S		S	S	S			S	S		S										
• Need for new or expanded stormwater drainage facilities											S					S	S				
• Increased water demand				U	S										S	U	S

• Increased demand for solid waste services				S								S									
• Cumulative impacts associated with solid waste management																	U				
• Increased demand for public utilities	S									S											
• Cumulative demand on drainage facilities outside the city's control												U									
Mitigation Measures																					
• Provide additional infrastructure.	X																				
• Comply with service provider development requirements.	X																				
• Establish a technical network as specified to ensure that the community's utility-related needs are met.			X																		
• Review development projects for consistency with water and sewer infrastructure requirements established in approved development plans and agreements.			X																		
• Encourage coordination between land use and water supply planning and protection of water supply sources.															X		X				
• Implement general plan water supply policies pertaining to the use of wells in urban areas, water supply planning for rural areas, and the encouragement of conservation and reclamation.																					
• Encourage the implementation of water conservation measures.			X	X	X			X	X		X				X	X	X			X	
• Upgrade the current water distribution system to accommodate required service.			X																		

S = Significant mitigable impact U = Significant and unavoidable impact X = Mitigation measure identified in Environmental Impact Report

TABLE GROWTH E.5.1 (Continued)
SIGNIFICANT MITIGABLE (S) AND SIGNIFICANT UNAVOIDABLE (U) IMPACTS OF GROWTH IDENTIFIED BY GENERAL AND SPECIFIC PLAN ENVIRONMENTAL IMPACT REPORTS IN PROJECT AREA

	JURISDICTION																				
Impact	Belmont[a]	Brisbane[b]	East Palo Alto[c]	Foster City[d]	Fremont[e]	Hayward[f]	Menlo Park[g]	Millbrae[h]	Milpitas[i]	Mountain View[j]	Newark[k]	Palo Alto[l]	Redwood City[m]	San Bruno[n]	San Jose[o]	City of San Mateo[p]	San Mateo County[q]	City of Santa Clara[r]	Santa Clara County[s]	Stanford University[t]	Union City[u]
• Implement Natural Resource chapter policies to mitigate potential water supply impacts.															X						
• Implement general plan policies that encourage water conservation and recharge in park and recreation facilities.																	X				
• Implement general plan policies to find an alternative disposal site to meet the city's future disposal needs.					X																
• Work with San Mateo to ensure the adequacy of the wastewater treatment plant.				X																	
• Implement general/community plan programs and policies to reduce waste and promote recycling.				X	X							X					X	X		X	
• Implement specified general plan policies and programs that address the adequacy of and improvements to the existing utility infrastructure and the potential for using recycled water.								X	X		X										
• Implement environmental management chapter policies and action programs pertaining to the provision of utilities and urban services.										X											
• Implement measures identified in the Precise Plan EIR to ensure adequate wastewater treatment and transmission capacity.													X								
• Implement general plan policies that require provision of adequate wastewater systems and coordination of wastewater management, land use, and water supply planning.															X		X				
• Improve the wastewater collection system.																				X	
• Work with water districts to secure additional supplies.																X					
• Work with the County to secure permits to use the Apanolio canyon to provide adequate landfill capacity.																X					
• Implement general plan policies that encourage buffering of landfills from more sensitive land uses.																	X				
• Implement general plan policies that address impacts associated with solid waste management.																	X				
• Implement a comprehensive sewer system study and storm drainage system study.																X					
ENERGY																					
Impacts																					
• Large and wasteful increases in energy consumption					U																
• Increased demand for energy, including electricity and natural gas	S		S					S			S						S				
• Increased demand for automobile fuel	S							S													
• Incremental increase in the use of non-renewable energy resources																	S				
• Cumulative energy-related impacts																	U				
Mitigation Measures																					
• Require compliance with California Administrative Code Title 24 (Building Code) energy conservation standards.	X		X					X													
• Encourage project proponents to incorporate energy conservation techniques in proposed projects. Provide brochures with information on energy efficient building and site design at the public counter.			X																		
• Operate construction equipment to avoid unnecessary use of fuel.	X																				
• Promote energy efficient building and site design for all new public buildings, and install energy saving devices in new public buildings and retrofit existing public buildings.	X		X														X				
• Promote retrofit programs to reduce energy usage and reduce emissions associated with energy consumption.			X																		

S = Significant mitigable impact U = Significant and unavoidable impact X = Mitigation measure identified in Environmental Impact Report

APPENDIX E.6
Project Level Impacts of Growth

General plans aim to provide for orderly development within the planning area and incorporate policies to reduce the adverse impacts of such development, as discussed in the WSIP PEIR Chapter 7. Mitigation measures have been identified in the EIRs of adopted general plans to reduce the adverse impacts related to growth (refer to Appendix E, Section E.5, Table E.5.1). As part of WSIP PEIR analysis, a selection of EIRs of major projects currently being undertaken in the SFPUC service area were reviewed. The purpose of the review was to assess whether, at least for the small selection of EIRs reviewed, the mitigation measures identified in general plan EIRs were being implemented at the project level.

The thresholds for large projects contained in SB 610 were used to guide identification of the projects for this assessment.(i.e., residential developments with more than 500 units; retail uses with more than 500,000 square feet of floor space; office buildings with more than 250,000 square feet of floor space; hotels or motels with more than 500 rooms; industrial uses occupying more than 40 acres or having more than 650,000 square feet of floor area; and mixed-use projects that include any use or combination as large as the above uses).

The specific impacts of a project necessarily depend on its particular circumstances, such as the location and nature of the project. Nevertheless, the review of current development projects in the service area and review of impacts and mitigation measures presented in **Table E.6.1** indicates that the impacts of growth are being mitigated consistent with the measures identified to reduce those impacts in the respective general plan EIRs.

The Projects

This appendix summarizes the impacts and mitigation measures identified for the following projects:

- One Quarry Road Residential Project, Brisbane
- Electronics for Imaging, Inc., Vintage Park Development, Foster City
- Elmwood Residential Commercial Development, Milpitas
- Abbott Labs, Redwood City
- Palo Alto Medical Foundation, San Carlos

One Quarry Road Residential Project, Brisbane

The proposed project consists of the redevelopment of an existing quarry for residential and open space uses. The project site is 144.4 acres, including the Guadalupe Valley Quarry and surrounding undeveloped land; it is located northeast of the main ridge of San Bruno Mountain in unincorporated San Mateo County, approximately three-quarters of a mile west of central Brisbane. The project includes subdivision of the site and construction of 148 single-family detached residences, three condominiums totaling 61 townhouses, a main access road, and internal roadways. A 600,000-gallon water tank would be constructed on a bench in the quarry wall, and associated utilities, landscaping, and lighting would be developed to serve the project. The residential development includes a 2.7-acre city park, a 0.29-acre neighborhood tot-lot, and 13.5 acres of common landscaped space. The residential areas would occupy roughly 19 acres plus 16.5 acres of common landscaped area and parks. The remaining land would be divided between relatively undisturbed open space surrounding the residential development (58 acres) and reclaimed quarry slopes (43 acres). Impacts and mitigation measures identified in the One Quarry Road Residential Project EIR are presented in Table E.6.1. Brisbane voters rejected the project in November 2006, when project approval was placed on the city ballot as Measure B. The EIR prepared for the project nevertheless provides a means to compare project-level impact assessment and mitigation with the city's general plan EIR.

Electronics for Imaging, Inc., Foster City

The EIR prepared for this project serves as a master EIR for one project component (a proposed master plan amendment) and a project-level EIR for the other project component (the proposed construction of several phases of the proposed development). The amendment to the Vintage Park Master Plan proposes development of 750,000 to 1,000,000 square feet of space for offices, research and development, and light industry instead of the nearly 1,500 multifamily residential units and 60,000 square feet of support retail space allowed under the current master plan. The project-level development includes construction of three buildings. Impacts and mitigation measures identified in the Electronics for Imaging EIR are presented in Table E.6.1.

Elmwood Residential and Commercial Development, Milpitas

The proposed project consists of a 59-acre residential, commercial, and recreational development surrounding the Santa Clara County Elmwood Correctional Facility east of Interstate 880 and north of Great Mall Parkway in the city of Milpitas. The project includes the development of approximately 680 residential units (315 condominium units, 110 of which would be available for sale to qualified moderate-income households; 165 single-family detached homes; and 203 townhomes), 180,000 square feet of auto mall building space (to accommodate approximately three auto dealerships), six acres of public park (including Hetch Hetchy park/trail improvements, Elmwood Park, and West Able Street Public Park), and approximately 8.4 acres for two private park/recreation areas (one within the single-family home area and one within the proposed condominium area). To accommodate the proposed development, the project also proposes to amend the Milpitas General Plan, the Midtown Specific Plan, and the city's zoning map; it also proposes approval of a planned unit development map, site and architectural plans, and a use permit for exceptions to development standards. Impacts and mitigation measures identified in the Elmwood EIR are presented in Table E.6.1.

Abbott Laboratories, Redwood City

Abbott Laboratories consists of a master-planned research center at the foot of Chesapeake Drive on Redwood City's bayfront, adjacent to the Port of Redwood City small-boat launch facility and the Stanford Rowing Club. The project proposes to remove salt processing structures and equipment and to construct approximately 541,000 square feet of manufacturing, research and development, and offices in four buildings around a central green space. The project includes an onsite multilevel parking garage, a greenbelt around a portion of the site, and a publicly accessible linear waterfront park; it would also set aside land to construct a replacement facility for the Marine Sciences Institute. The institute would be responsible for the planning and execution of its new facility within the design guidelines established in the project's master plan. The project proposes subdividing the site into eight lots: six for the proposed buildings of the Abbott Laboratories campus, a separate lot for the Marine Sciences Institute, and a common area lot for private roadways, utilities, and landscaping. The project would be constructed in three phases over a 10-year period. Impacts and mitigation measures identified in the Abbott Laboratories EIR are presented in Table E.6.1.

The Palo Alto Medical Foundation–San Carlos Center, San Carlos

The proposed Palo Alto Medical Foundation–San Carlos Center (PAMF–SCC) project involves the closure and demolition of industrial manufacturing facilities, implementation of an approved remedial action plan at the site, and construction of medical facilities. The 18.1-acre project site is located at 301 Industrial Road, northwest of the Holly Street/Highway 101 interchange in east San Carlos. Existing structures at the site include four main buildings, a wastewater treatment plant, a hazardous waste storage area, other smaller structures, and surface parking. Structures occupy approximately 42 percent of the site; areas not covered by structures are paved (except for minor landscaping along the street frontage). Following closure and decommissioning by the current owner, the site would be remediated according to the approved remedial action plan. The RWQCB would be the lead agency overseeing site remediation, with review and concurrence by the Department of Toxic Substances Control and San Mateo County. The proposed medical facility includes a 478,500-square-foot medical building (including a detached 12,500-square-foot central plant), two aboveground parking garages with approximately 1,245 spaces, and a clock tower. The medical building would house a hospital, medical offices, an ambulatory care clinic, and ancillary/supporting uses. The project would occupy approximately 7.2 acres (40 percent) of the site and would increase the area of permeable surface from zero to about 4.5 acres. Impacts and mitigation measures identified in the PAMF–SCC EIR are presented in Table E.6.1.

TABLE E.6.1
SIGNIFICANT IMPACTS AND MITIGATION MEASURES IDENTIFIED
IN ENVIRONMENTAL IMPACT REPORTS OF RECENT MAJOR PROJECTS IN THE SFPUC SERVICE AREA

Impact	One Quarry Road Project (Brisbane)	Electronics for Imaging (Foster City)	Elmwood Residential and Commercial Development Project (Milpitas)	Abbott Laboratories (Redwood City)	Palo Alto Medical Foundation (San Carlos)
Aesthetics					
Impacts					
• Negative aesthetic effect or degradation of existing views	S				
• Conflicts with design guidelines previously adopted for the site		S			
• Creation of new source(s) of light and/or glare	S			S	
Mitigation Measures					
• Amend design guidelines as recommended prior to project approval		X			
• Confine illumination to the project site; shield and orient light sources to minimize their visibility from outside the site; complete and submit a photometrics site plan analysis with each of the project's building phases for review and approval by the city's community development services director				X	
• Relocate and reconfigure specified site plan features (water tank, townhouses, and single-family houses) to reduce or eliminate their visual prominence	X				
• Use nonreflective paint and nonglare fixtures	X				
• Provide appropriate structural and/or vegetative screening for sensitive adjacent uses	X			X	
Agricultural Resources					
Impacts – No significant impacts identified					
Air Quality					
Impacts					
• Construction-related air quality impacts (construction vehicle emissions and particulate matter)		S		S	S
• Fugitive dust emissions during construction	S		U		
• Operational air quality emissions from new area and mobile sources					U
• Increased regional air pollutant emissions from traffic generated by the project		U			
• Cumulative impacts on regional air quality in the Bay Area			U		U
Mitigation Measures					
• Implement BAAQMD- and EIR-specified construction dust control measures	X	X	X	X	X
• Provide site features and implement measures to encourage the use of alternative modes of travel (alternatives to private vehicles) and reduce vehicle trips		X	X		X
• Allow only natural gas fireplaces, pellet stoves, or EPA-certified wood-burning stoves; prohibit conventional open-hearth fire places			X		

Impact	One Quarry Road Project (Brisbane)	Electronics for Imaging (Foster City)	Elmwood Residential and Commercial Development Project (Milpitas)	Abbott Laboratories (Redwood City)	Palo Alto Medical Foundation (San Carlos)
• Use reflective/high albedo roofs and light-colored construction materials to increase the reflectivity of paved surfaces and include shade trees near buildings to shield buildings from the sun and reduce local air temperature and energy demand			X		
Biological Resources					
Impacts					
• Impact(s) on sensitive or special-status animal or plant species	S		S		S
• Degradation of riparian habitat or other sensitive habitat	S		S		
• Impact(s) on protected wetlands, either individually or in combination with known or probable impacts of other activities	S		S		
• Conflicts with an adopted habitat conservation plan	S				
• Displacement of native plants, including important wildlife food plants, by invasive exotic plants	S				
• Disturbance of burrowing owls and/or permanent loss of owl habitat			S		
• Disturbance of active raptor nests, the nests of sensitive bird species, or other nesting bird species	S		S		S
• Cumulative impacts on nesting birds					S
Mitigation Measures					
• Fulfill the city's obligations under the habitat conservation plan in light of the change of site status from an unplanned to a planned parcel	X				
• Develop, implement, and monitor a varicolored lupine establishment plan in consultation with U.S. Forest Service	X				
• Oversee maintenance of slopes to maximize safety and minimize adverse impacts on butterfly food plants	X				
• Construct chain-link fences acceptable to the property owner and the California Department of Fish and Game (CDFG) along the perimeter of developed areas and along access roads to prevent people from entering sensitive habitat areas	X				
• Post interpretive signage at specified areas to educate homeowners about San Bruno Mountain habitat and the detrimental effects of exotic plants	X				
• Provide new homeowners with the current Open Space and Ecology Committee brochure and make reasonable, ongoing efforts to educate homeowners about exotic plants and the habitat of San Bruno Mountain	X				
• Indicate in conditions, covenants, and restrictions attached to individual properties that no pets will be allowed outside the owner's lot unless under the control of a responsible person by leash or other means	X				
• Revise grading plan so that stonecrop on the site is outside project's grading limits	X				

Impact	One Quarry Road Project (Brisbane)	Electronics for Imaging (Foster City)	Elmwood Residential and Commercial Development Project (Milpitas)	Abbott Laboratories (Redwood City)	Palo Alto Medical Foundation (San Carlos)
• Conduct appropriately timed survey for nesting raptors before removing any eucalyptus trees and for nesting loggerhead shrikes before removing any shrubs; establish a 250-foot buffer around any nests that are found, within which no vegetation will be removed until the young birds have fledged	X				
• Indicate in conditions, covenants, and restrictions attached to individual properties that the use on private property of any invasive non-native plant species that could displace butterfly food plants will be prohibited; provide information to the homeowners association and individual homeowners about invasive species; invite homeowners to an informational meeting conducted by a local environmental organization to educate residents about the sensitive environment adjoining the project site, and the potential impact of invasive plant species on butterfly habitat; hold annual meetings between the homeowners association and each homeowner to verify that invasive plants are not being planted; require the homeowners association to remove any invasive plants from areas for which it is responsible	X				
• Remove invasive exotic plant species found in both the revegetated and undisturbed areas of the project site; preclude the use of invasive exotic species from landscaping in common areas; and maintain common areas to ensure exotic invasive species are removed	X				
• Verify the prepared wetland delineation with the U.S. Army Corps of Engineers; apply for relevant permits, waivers, and certifications for jurisdictional wetlands determined to occur on the site	X				
• Develop and implement a mitigation plan to replace the lost watercourse consistent with requirements of the RWQCB and CDFG	X				
• Identify the species of gumplant at the site and, if it is a special-status species, include the species in the planting mix used for slope benches	X				
• Conduct appropriately timed surveys (to be conducted by a qualified botanist) to determine the presence or absence of special-status plant species; if special-status plants are detected, contact the CDFG and develop appropriate protocols for relocating the plants and conducting future monitoring at the site			X		
• Prepare a stormwater pollution prevention plan that specifies measures to minimize impacts on biological resources (in particular special-status fish species) resulting from stormwater runoff			X		
• Avoid disturbance of trees and shrubs during nesting season; if construction during nesting season cannot be avoided, conduct preconstruction surveys for nesting birds and implement protective measures if active nests are identified			X		X
• Prior to discing for fire or weed control, conduct a burrowing owl nesting/occupancy survey as prescribed by the CDFG; implement appropriate relocation protocols if burrows are identified within project impact area; provide for replacement of habitat with offsite mitigation habitat that has been approved by the CDFG; conduct preconstruction surveys no more than 30 days prior to any ground-disturbing activity			X		

Impact	One Quarry Road Project (Brisbane)	Electronics for Imaging (Foster City)	Elmwood Residential and Commercial Development Project (Milpitas)	Abbott Laboratories (Redwood City)	Palo Alto Medical Foundation (San Carlos)
• Obtain a nationwide permit from the U.S. Army Corps of Engineers, a streambed alteration agreement permit from the CDFG, and an RWQCB Section 401 water quality certification and/or waiver of discharge requirements prior to filling waters or constructing any facilities in or affecting waters at or near the site			X		
• Prior to demolition or construction near drainage channels, install appropriate exclusion fencing to prevent red-legged frogs from entering the site					X
Cultural Resources					
Impacts					
• Disturbance of archaeological resources			S	S	S
• Disturbance of paleontological resources					S
• Disturbance of architectural or historic resources				S	
• Disturbance of human remains			S		S
Mitigation Measures					
• Monitor future ground-disturbing activities (to be monitored by qualified archaeologist)			X	X	
• If any cultural resources are found, halt work in the vicinity until the find has been evaluated by a qualified archaeologist/cultural resources consultant and a mitigation plan has been developed			X		X
• If avoidance of the resource is not feasible, prepare and execute a plan for the methodical excavation and documentation of those portions of the site that would be adversely affected; conduct construction activities in the vicinity of the find in accordance with current professional standards and do not recommence until the archaeological work is completed					X
• If cultural resources are found, inform project personnel that collecting significant historical or unique archaeological resources discovered during project development is prohibited by law					X
• If any human remains are uncovered during future construction activity, halt work and notify the county coroner immediately; if the coroner determines the remains are Native American, contact the Native American Heritage Commission pursuant to state regulations			X	X	X
• Provide a photographic record of existing structures and equipment on the project site prior to demolition; submit the photographs to the Redwood City Historic Resources Advisory Committee to be used at the committee's discretion				X	
Geology and Soils					
Impacts					
• Exposure to seismic or geologic hazards	S	S	S	S	
• Substantial soil erosion or the loss of topsoil				S	
• Damage to structures or utilities caused by soils with high shrink-swell potential			S	S	
• Location of structures on strata or soil that is unstable or that would become unstable as a result of the project	S				
• Exposure of facilities, including buildings, parking structures, and underground utilities, to corrosive soils				S	

Impact	One Quarry Road Project (Brisbane)	Electronics for Imaging (Foster City)	Elmwood Residential and Commercial Development Project (Milpitas)	Abbott Laboratories (Redwood City)	Palo Alto Medical Foundation (San Carlos)
• Hazards, including architectural and/or structural damage, due to differential settlement	S	S			
• Exposure to rockfall hazards	S				
Mitigation Measures					
• Conduct earthworks and foundation design in accordance with all recommendations contained in project geotechnical reports	X				
• Base grading and foundation design on the anticipated strong seismic shaking associated with a future major earthquake on the San Andreas fault	X				
• Prepare and submit to the city for approval an earthquake preparedness and emergency response plan for all public facilities	X				
• Prepare an earthquake hazards information document prior to marketing residential units for sale	X				
• Reconfigure the proposed townhouse pad to improve fill slope stability; construct fill slopes by excavating a slot key	X				
• Limit the differential fill thickness below individual buildings as specified	X				
• Conduct a geotechnical investigation to determine the feasibility of placing the water tank at the proposed location; redesign the water storage component of the project to ensure stability of the site and post-earthquake water supply; replace the proposed single tank with three smaller tanks; and reinforce the rock cut slope surrounding the water tanks	X				
• Construct an adequate rockfall catchment along the base of the planned final quarry slopes	X				
• Incorporate all recommendations of the slope stability analysis into the project	X				
• Cut and rebench quarry slopes by mechanical means where rock conditions are suitable for ripping with heavy-duty equipment; where blasting is required, use control methods to minimize over-breaking and loosening of final rock surfaces and to protect worker safety	X				
• Install subdrains beneath the deep fills to be put in place in the southeastern portion of the site	X				
• Design and construct a retaining wall, catchment basin, or other engineered feature to retain slope debris in areas of mapped landslides; establish a geologic hazard abatement district or other mechanism approved by the city to be responsible for all bench maintenance and slope repair	X				
• Comply with all aspects of the California Surface Mining and Reclamation Act regarding approval of land uses that are incompatible with mineral production at the project site	X				
• Conduct site-specific geotechnical and soils investigation(s) as specified and incorporate all measures identified to mitigate impacts		X	X	X	
• Install cathodic protection system on the project site to protect underground metallic fittings, appurtenances, and piping from corrosion				X	
• During construction, comply with erosion and sediment control measures in accordance with local stormwater requirements, construction best management practices, and State Water Resources Control Board National Pollution Discharge Elimination System requirements				X	

Impact	One Quarry Road Project (Brisbane)	Electronics for Imaging (Foster City)	Elmwood Residential and Commercial Development Project (Milpitas)	Abbott Laboratories (Redwood City)	Palo Alto Medical Foundation (San Carlos)
Hazards and Hazardous Materials					
Impacts					
• Hazards resulting from the routine transport, use, or disposal of hazardous materials	S			S	
• Hazards associated with petroleum-contaminated soils and the potential presence of petroleum hydrocarbons and polycyclic aromatic hydrocarbons in the soil and groundwater	S				
• Exposure of construction workers or the public to hazardous materials, including lead-based paint and/or materials containing asbestos	S		S		
Mitigation Measures					
• Assess existing structures for the presence of hazardous materials (assessment to be conducted by a qualified professional); if found, remove and dispose of hazardous materials in accordance with applicable state and federal regulations	X		X		
• Test the ground-mounted electrical transformers for PCBs; if found, remove and dispose of the materials in accordance with state and federal regulations			X		
• Remediate previously identified contaminated soils to below RWQCB risk-based thresholds or thresholds developed by a site-specific human health risk assessment prepared by a qualified professional	X				
• Investigate presence and extent of contaminants in soils and groundwater; coordinate this investigation and remediation with the removal of the underground oil storage tank	X				
• Adhere to existing federal, state, and local regulations regarding management and handling of hazardous materials	X				
• Include an area evacuation and business evacuation plan as part of the business plan submitted to the county health services agency and the city fire department; in conjunction with the fire department, conduct onsite hazardous materials training as needed or at least every 18 months				X	
Hydrology and Water Quality					
Impacts					
• Increases in impervious surface area and/or the alteration of area drainage resulting in flood hazards or the need for new drainage facilities	S	S	S	S	
• Water pollution from stormwater runoff	S			S	
• Placement of structures within a 100-year floodplain			S	S	
• Degradation of surface water quality due to construction activities and/or post-construction uses	S	S	S	S	
Mitigation Measures					
• Design and implement site drainage plan, in accordance with applicable standards and requirements, to address lot grading, paved areas, site facilities, and landscaping; demonstrate adequacy of conveyance structures; and incorporate appropriate filtration and control structures to direct, control, and filter runoff	X	X	X	X	
• Reduce the amount of impervious surface to the extent feasible	X		X		

Impact	One Quarry Road Project (Brisbane)	Electronics for Imaging (Foster City)	Elmwood Residential and Commercial Development Project (Milpitas)	Abbott Laboratories (Redwood City)	Palo Alto Medical Foundation (San Carlos)
• Design detention basins to contain runoff during the design storm event and enhance water quality	X				
• Stipulate in conditions, covenants, and restrictions attached to site properties the manner in which drainage facilities are to be monitored and maintained to sustain conveyance capacity	X				
• Construct new storm drain pipe as specified to alleviate existing flood hazard and accept increased project flows	X				
• Prepare and submit to the city for approval a construction stormwater pollution prevention plan (SWPPP) that includes best management practices to reduce construction impacts on surface water quality	X				
• Prepare and implement a SWPPP that includes best management practices to reduce potential impacts on surface water quality over the life of the project	X			X	
• Prepare and distribute to all potential occupants a water quality information document prior to purchase of the housing units	X				
• Conduct a final floodplain study demonstrating that existing sheet flows through the project will be accommodated without affecting adjacent floodplains more than is allowed by the Federal Emergency Management Agency (FEMA)			X		
• Design and construct residential and commercial structures to conform with applicable city requirements for structures in a floodplain			X		
• Design the new bridge to meet creek flow standards and all other applicable standards of the U.S. Army Corps of Engineers and the city			X		
• Provide storm drain system signs and/or stenciling to discourage illegal dumping into storm drains, catch basins, and/or filled inlets	X		X		
• Implement best management practices to protect water quality, including, at a minimum, erosion control, sediment transfer reduction, and dust control measures			X		
• Require in conditions, covenants, and restrictions for all future residential development: good housekeeping practices for handling potentially harmful material and controls to prevent and reduce pollutant discharge to stormwater for common landscaped areas and open space; material disposal and recycling controls to discourage illegal dumping of unwanted material into storm drains; a prohibition against dumping waste products into storm drains; and maintenance requirements for private streets, parking lots, and storm drain facilities to control and remove pollutants			X		
• Require as a condition of approval for future commercial development that educational flyers and other materials be provided to all owners/tenants to increase understanding of water quality best management practices and ensure that measures are implemented within private and open space areas to control and limit exposure to potential pollutants			X		
• Require that commercial operators be responsible for inspection, maintenance, and repair of sediment and oil filtering devices for the pretreatment of runoff from paved areas			X		

Impact	One Quarry Road Project (Brisbane)	Electronics for Imaging (Foster City)	Elmwood Residential and Commercial Development Project (Milpitas)	Abbott Laboratories (Redwood City)	Palo Alto Medical Foundation (San Carlos)
• Construct a levee to the specified minimum elevation to satisfy FEMA requirements to prevent 100-year flood water inundation of the project site; conduct a geotechnical investigation as specified to determine whether soil material and compaction would satisfy city levee requirements				X	
• Utilize integrated pest management techniques to minimize the use of pesticide sprays as specified by the county pollution prevention program				X	
• In addition to compliance with applicable regulations, establish a construction buffer of at least 1 meter along drainage channels within which no construction activities would occur (improvement measure for less-than-significant impact)					X
Land Use and Planning					
Impacts					
• Conflict with existing zoning designation		S			
• Conflict of parking areas and landscaping with existing utility easement		S			
• Conflicts with elements of the general plan					S/SU
• Cumulative land use impacts					SU
Mitigation Measures					
• Approve requested rezoning prior to project approval		X			
• Submit final improvement plans for review and comment to the utility with an easement through the site		X			
• Implement the measure identified in the analysis of noise impacts					X
• Implement the measure identified in the analysis of transportation impacts to reduce impacts at four specified intersections (cumulative effects at the intersections would not be reduced to a less-than-significant level)					X
• Implement the measure identified in the analysis of transportation impacts to reduce mobile-source air pollutants					X
Mineral Resources					
Impacts					
• Incompatibility of the project with mineral production at the project site	X				
Mitigation Measures					
• Comply with all aspects of the California Surface Mining and Reclamation Act regarding approval of the proposed land use and make appropriate findings regarding the benefits and disadvantages of quarry operations and the benefits to the community of new housing	X				
Noise					
Impacts					
• Short-term noise impacts during construction		S	S	S	
• Construction vibration from pile driving					U
• Cumulative construction noise and vibration					U
• Exposure to excessive noise levels (roadway noise and/or stationary noise sources)			S		S

Impact	One Quarry Road Project (Brisbane)	Electronics for Imaging (Foster City)	Elmwood Residential and Commercial Development Project (Milpitas)	Abbott Laboratories (Redwood City)	Palo Alto Medical Foundation (San Carlos)
Mitigation Measures					
• Implement management practices as specified to limit construction noise (may include limiting construction hours to minimize impacts on nearby uses, use of mufflers on equipment and maintaining equipment in good working order, locating noise sources as far as possible from nearby sensitive receptors, and limiting idling times for equipment and vehicles with internal combustion engines)		X	X	X	X
• Use hydraulically or electrically powered impact tools (e.g., jack hammers and pavement breakers) wherever feasible; where use of pneumatically powered tools is unavoidable, use an exhaust muffler on compressed air exhaust and external jackets on the tools themselves where feasible				X	
• Establish a process for responding to and tracking complaints pertaining to construction noise				X	
• If pile driving would be conducted outside specified hours (consistent with provisions for exceptions), erect plywood barriers as specified on site boundary and hire acoustical consultants to recommend additional site-specific measures to reduce pile-driving noise				X	
• Implement vibration abatement strategies to reduce vibration impacts on the adjacent residents					X
• Develop a noise attenuation plan to be implemented at the commercial portion of the site; noise control measures in the plan may include construction of noise barriers and site planning to avoid locating noise-generating operations adjacent to residential property boundaries			X		
• To reduce parking noise, construct a noise barrier fence along the northern site boundary where it adjoins single-family residences			X		
• Conduct acoustic study and implement recommendations, including noise insulation features to ensure interior noise levels do not exceed the specified threshold			X		X
Population and Housing					
Impacts					
• Potential conflicts with housing design requirements for persons with disabilities	S				
• Conflicts with affordable housing requirements or housing element designation of site for affordable housing	S	S			
• Jobs/housing imbalances (and consequent impacts on housing prices, commute times, and other effects)				S	
Mitigation Measures					
• Include in site plans units suitable for persons with disabilities	X				
• Comply with the city's affordable housing requirements either by providing the appropriate percentage of units affordable to low- and moderate-income households or by paying to the city fees in lieu of affordable housing units	X				
• Revise the housing element to provide adequate alternative housing sites, consistent with land use element designations, and remove all text related to providing housing at the project site		X			

Impact	One Quarry Road Project (Brisbane)	Electronics for Imaging (Foster City)	Elmwood Residential and Commercial Development Project (Milpitas)	Abbott Laboratories (Redwood City)	Palo Alto Medical Foundation (San Carlos)
• Pay the required fee per square foot for Phases 2 and 3 of the project if the city adopts a jobs/housing linkage program requiring such a fee before those phases are developed				X	
• Increase the residential development potential in the city through land use and zoning changes				X	
Public Services					
Impacts					
• Increased demand for fire protection services	S	S	S	S	
• Increased demand for police protection services	S	S	S	S	
• Increased use of parks, resulting in physical deterioration and increased maintenance demands			S		
• Increased demand for public services other than fire and police protection, schools, and parks	S				
• Cumulative increases in demand for police, fire, emergency, and childcare services				S	
• Cumulative increases in demand for schools				S	
Mitigation Measures					
• Incorporate fire protection design features and equipment as specified for all buildings within 50 feet of wildland; implement a 30-foot firebreak or other fire buffer program approved by the fire chief	X				
• Locate and design site structures and infrastructure to ensure adequate access by fire department vehicles and equipment		X			
• Fund additional water mains, to be installed by the city, as required by the city fire department to ensure adequate water supply for fire suppression activities				X	
• Comply with all applicable requirements of the Uniform Fire Code				X	
• Design and light parking structures to reduce auto thefts and burglary		X			
• Provide security lighting for the landscaped waterfront perimeter				X	
• Provide private security measures, including security personnel, to protect people and property at the site; submit plans for each development phase to the police department for review to identify additional design measures to enhance site security				X	
• Increase police staffing levels as indicated and provide for associated vehicles and equipment		X			
• Contribute a fair share portion of the costs associated with fire, police, park/landscape maintenance needed to serve the new residential development, as determined by a study to be conducted by the city	X		X		
• Use a qualified vector control professional to eliminate ground squirrels and feral cats from the site; submit site landscape plans to the city's vector control unit for review, for the purpose of identifying potential rat harborage areas and/or food sources, and for approval of pest proofing measures contained in the plan	X				
• Provide adequate childcare services for the children of project employees; if feasible, provide an onsite childcare facility				X	

Impact	One Quarry Road Project (Brisbane)	Electronics for Imaging (Foster City)	Elmwood Residential and Commercial Development Project (Milpitas)	Abbott Laboratories (Redwood City)	Palo Alto Medical Foundation (San Carlos)
Recreation					
Impacts – See Public Services regarding impacts on parks; no other significant recreation impacts identified					
Traffic and Transportation					
Impacts					
• Impacts related to site access roadways	S				
• Increased traffic relative to existing traffic and the capacity of the street system				U	
• Freeway traffic impacts			U	U	U
• Increased vehicle delays at area intersection(s)		S	S	S	
• Temporary construction impacts on traffic circulation and safety				S	
• Increase traffic safety concerns				S	
• Impacts on parking					S
• Cumulative traffic impacts on roadway segments and/or intersections			U	S, U	U
• Cumulative freeway traffic impacts					S
Mitigation Measures					
• Submit plans for the main and secondary access roads to the city engineer for review and concurrence with city and American Association of State Highway and Transportation Official Standards (recommended measure: design the secondary access road for two-way traffic)	X				
• Pay for signal warrant analyses at specified intersections and contribute fair share of costs of signal(s) determined by the city engineer to be needed			X		
• Working with the city and Caltrans, as applicable, make roadway and/or signal modifications, potentially including installation of turn lanes, combinations of turn lanes and through lanes, or warning signals; widening of lanes at specified intersections; and modification of traffic signal phasing		X		X	
• Contribute fair share of traffic mitigation fees to fund improvements to areas and/or roadways affected by the project			X	X	
• Submit a construction traffic management plan for review and approval by the city's engineering and construction division				X	
• Implement increasingly aggressive measures as part of the proposed transportation demand management (TDM) program				X	
• Implement a TDM program, including specified measures throughout the life of the project, with the objective of achieving the trip reductions specified in general plan Transportation Policy 9					X
• Design the main access driveway to ensure proper operation of the signalized intersection (recommended for a less-than-significant impact)					X
Utilities					
Impacts					
• Need for new or expanded water and/or wastewater treatment facilities	S		S		U

Impact	One Quarry Road Project (Brisbane)	Electronics for Imaging (Foster City)	Elmwood Residential and Commercial Development Project (Milpitas)	Abbott Laboratories (Redwood City)	Palo Alto Medical Foundation (San Carlos)
• Need for new or expanded stormwater drainage facilities	S				
Mitigation Measures					
• Provide additional infrastructure	X		X	X	
• Pay pro rata share for the installation of all needed water supply and sewer lines and for pump station improvements	X				
• Integrate water conservation measures and design features into the project's design to reduce overall water demand associated with the project (recommended for a less-than-significant impact)		X			
• Retain public ownership and responsibility for maintenance of onsite water lines, obtain approval from Estero MID for relocation of the water transmission line, and relocate it within water line easements; avoid locating structures or undertaking pile-driving activities in close proximity to water lines unless adequate shoring is provided; and avoid use of special or costly surfacing materials over the public water line easements to reduce the costs for reconstruction if future maintenance work is necessary (recommended for a less-than-significant impact)		X			
• Fund onsite improvements to the existing sewer system or lift station (recommended for a less-than-significant impact)		X			
• Purchase adequate public water system and sewer system capacities for the development; fees for this purpose cover treatment plant operations, sewage collection, and a proportional share of replacement costs for a new sewage pump station			X		
• Obtain nonpotable water supply from the city's planned recycled water program and contribute fair share of the cost of implementing the program; implement the city's landscape guidelines to reduce demand for irrigation water; implement best management practices identified by the California Urban Water Conservation Council; and retain an independent civil engineer or water specialist to monitor actual water use to ensure estimated water demand is consistent with actual demand				X	
• Include water-saving fixtures, appliances, and irrigation systems in site buildings and landscaping, and design landscaping with drought-resistant and other low-water-use plants (recommended for a less-than-significant cumulative impact on water supply)					X
• Purchase from the sewer authority sufficient dry-weather treatment capacity to accommodate the projected increase in sewage generated by the proposed project (to be performed by the city) and reimburse the city for all costs associated with this purchase (to be performed by the project applicant)				X	
• Fund one of three identified sanitary sewer improvement alternatives				X	
• Implement measures to reduce solid waste generation and encourage recycling		X		X	
• Implement measures to encourage the recycling of construction and demolition debris during the construction phase				X	X
Energy					
Impacts					
• Increased demand for energy, including electricity and natural gas				X	

Impact	One Quarry Road Project (Brisbane)	Electronics for Imaging (Foster City)	Elmwood Residential and Commercial Development Project (Milpitas)	Abbott Laboratories (Redwood City)	Palo Alto Medical Foundation (San Carlos)
Mitigation Measures					
• Require improvements to conform with all requirements of Title 24 and the Uniform Building Code to reduce energy demands (recommended for a less-than-significant impact)		X			
• Implement the specified energy conservation measures, including use of energy-efficient heating, cooling, and lighting fixtures				X

1 Reference noise levels represent the highest noise level by equipment type (without controls) listed in Table 4.10-4 at 50 feet. Reference noise level for tunneling activities includes a crane, and is based on noise measurements taken at the Hollywood Hills Tunnel project (entrance shaft), which involved similar tunneling construction techniques.

2 Noise control reductions represent the difference between the highest noise levels listed in Table 4.10-4 with controls versus without controls.

TABLE F-2
ESTIMATED MAXIMUM TRUCK NOISE LEVELS AT NEARBY RECEPTORS IN SUNOL VALLEY REGION

Project and Receptor Location	Hourly Truck Volume	Hourly Leq in dBA at 50 feet[1]	Distance Between Closest Project & Receptor	Distance Adjustment	Adjusted Leq	Ambient and Sleep Interference Criterion	Unmitigated Leq Exceeds Criterion?
New Irvington Tunnel Project (SV-4)

Appendix G
Hazardous Materials

APPENDIX G
Hazardous Materials

This appendix supplements the information provided in Section 4.14 of the WSIP PEIR. It provides an overview of the federal and state hazardous materials regulatory framework.

Regulatory Framework

Hazardous materials and hazardous wastes are extensively regulated by various federal, state, regional, and local regulations, with the major objective of protecting public health and the environment. This appendix summarizes the overall regulatory framework governing hazardous materials management.

Federal Regulations – General Hazardous Materials

The U.S. Environmental Protection Agency (U.S. EPA) is the lead agency responsible for enforcing federal regulations that affect public health or the environment. The primary federal laws and regulations include: the Resource Conservation and Recovery Act of 1974 (RCRA); the Comprehensive Environmental Response, Compensation and Liability Act of 1980 (CERCLA); and the Superfund Amendments and Reauthorization Act of 1986 (SARA). Federal statutes pertaining to hazardous materials and wastes are contained in Title 40 of the Code of Federal Regulations.

RCRA was enacted to provide a general framework for the national hazardous waste management system, including the determination of whether hazardous wastes are being generated, techniques for tracking wastes to eventual disposal, and the design and permitting of hazardous waste management facilities. In 1984, the Hazardous and Solid Waste Amendment was enacted to better address hazardous waste; this amendment began the process of eliminating land disposal as the principal hazardous waste disposal method. Other specific areas covered by the amendment include the regulation of carcinogens, listing and delisting of hazardous wastes, permitting for hazardous waste facilities, and leaking underground storage tanks.

CERCLA, also known as Superfund, was enacted to ensure that a source of funds was available to clean up abandoned hazardous waste sites, compensate victims, address releases of hazardous materials, and establish liability standards for responsible parties. SARA amended CERCLA in 1986 to increase the Superfund budget, modify contaminated site clean up criteria and schedules, and revise settlement procedures. SARA also provides a regulatory program and fund for underground storage tank cleanups and the Emergency Planning and Community Right-to-Know Program (EPCRA).

In 1976, Congress passed the Toxic Substances Control Act (TSCA) which was implemented in 1979. This act governs the manufacture, processing, distribution in commerce, use, cleanup, storage, and disposal of polychlorinated biphenyls (PCBs). Since 1978, the U.S. EPA has promulgated numerous rules further addressing all aspects of the life cycle of PCBs. The most recent rule was the “Final Rule: Amendments to the TSCA PCB Disposal Regulations Including Amendments to the PCB Notification and Manifesting Rule” promulgated on June 24, 1999. This rule is deregulatory in nature and provides individuals with more flexibility in their PCB disposal practices while continuing to provide protection from unreasonable risk.

State and Regional Regulations – General Hazardous Materials

The California Department of Toxic Substances Control (DTSC) and the Regional Water Quality Control Board (RWQCB) are the primary state agencies regulating hazardous materials in California. These agencies are part of the Cal-EPA. The RWQCB is authorized by the State Water Resources Control Board to enforce provisions of the Porter-Cologne Water Quality Control Act of 1969. This act gives the RWQCB authority to require groundwater investigations when the quality of groundwater or surface waters of the state is threatened, and to require remediation of the site if necessary. The DTSC is authorized by the U.S. EPA to regulate the management of hazardous substances, including the remediation of sites contaminated by hazardous substances.

California hazardous materials laws incorporate federal standards but are often stricter than federal laws. The primary state laws include: the California Hazardous Waste Control Law (HWCL), the state equivalent of RCRA; and the Carpenter-Presley-Tanner Hazardous Substances Account Act (HSAA), the state equivalent of CERCLA. State hazardous materials and waste laws are contained in the California Code of Regulations, Titles 22 and 26.

The HWCL, enacted in 1972 and administered by the DTSC, is the basic hazardous waste statute in California and has been amended several times to address current needs, including bringing the state law and regulations into conformance with federal laws. This act implements the RCRA “cradle-to-grave” waste management system in California but is more stringent in its regulation of non-RCRA wastes, spent lubricating oil, small-quantity generators, transportation and permitting requirements, as well as in its penalties for violations. The HWCL also exceeds federal requirements by mandating the recycling of certain wastes, requiring certain generators to document a hazardous waste source reduction plan, requiring permitting for federally exempt treatment of hazardous wastes by generators, and implementing stricter regulation of hazardous waste facilities.

The HSAA, enacted in 1981, addresses similar concerns as CERCLA. The primary difference is in how liability is assigned for a site with more than one responsible party. This is important for petroleum cleanup sites because federal law is usually used to force responsible-party cleanups; state law is used for petroleum cleanup sites that are exempt from CERCLA.

Other relevant State of California statutes include:

- The Toxic Pit Cleanup Act of 1984 and the Toxic Injection Well Act of 1985, which were established to provide a regulatory framework for open pits or injection wells as a means of hazardous waste or disposal.
- The Hazardous Waste Management Act of 1986, which coordinates the state's implementation of federal landfill bans and authorizes landfill bans for non-RCRA hazardous wastes.
- The Aboveground Petroleum Storage Act of 1989, which requires the owner or operator of aboveground petroleum storage tanks to file a storage statement with the State Water Resources Control Board if tank storage exceeds 10,000 gallons and holds petroleum or petroleum product that is liquid at ambient temperatures. In addition, the tank or tanks must be registered if they are subject to federal requirements; this potentially expands the requirement for a storage statement to any tank over 660 gallons or aggregate storage of 1,320 gallons.
- The Hazardous Waste Source Reduction and Management Act, which, beginning in 1991, required large-quantity generators to document the hazardous wastes being generated and to prepare a documented waste reduction plan.
- The Hazardous Waste Treatment Permitting Reform Act of 1992, which required a permit for any hazardous waste treatment by a generator beginning on April 1, 1993. This statute established a new, tiered permitting program whereby onsite treatment facilities are permitted or authorized to operate subject to different levels of regulatory requirements, depending on the nature and size of the treatment activity. Amendments to this statute adopted in 1993–1996 have enacted certain exemptions and modified compliance requirements.
- The Hazardous Waste Management Reform Act of 1995, which required the DTSC to revise its regulations to more closely conform to federal hazardous waste identification criteria and essentially eliminate land disposal restrictions for California-only hazardous wastes, among other major changes. However, many of these changes have been deferred to a DTSC advisory committee for further study and are not expected to be implemented for several years, and in certain cases, not at all.

The Bay Area Air Quality Management District, a regional regulatory agency, may impose specific requirements on remediation activities to protect ambient air quality from dust or other airborne contaminants.

APPENDIX H1

Hydrologic Modeling Conducted for the WSIP Water Supply and System Operations Impact Assessment

Table of Contents

List of Tables

List of Figures

1. Introduction

This technical appendix summarizes the methodology and results of the hydrologic analyses conducted for the water supply and system operations impact assessment for the Program Environmental Impact Report (PEIR) on the Water System Improvement Program (WSIP). It includes descriptions of the analysis conducted by the PEIR consultant team using output data derived from the San Francisco Public Utilities Commission’s (SFPUC) water supply planning model, the Hetch Hetchy/Local Simulation Model (HH/LSM) and provided by the SFPUC. This type of analysis is also referred to as “post-processing” of data, since it involves manipulating information following the completion of the model runs. The HH/LSM analyzes system operations based on historical hydrology, including actual hydrological sequences and events, and the model allows the SFPUC to predict the consequences of changes to the system's facilities and/or operations. The SFPUC’s model was used to predict potential impacts on water resources in the affected watersheds resulting from the proposed program, variants, and alternatives developed in the PEIR. The HH/LSM is similar to the tools used by other water purveyors in the United States to plan system improvements.

A detailed description of the HH/LSM is provided in the *Water Supply System Modeling Report, Hetch Hetchy/Local Simulation Model* (SFPUC, 2007) and is incorporated herein by this reference. This appendix, Appendix H1, provides descriptions of the model runs and the methods used to post-process and analyze the HH/LSM data. Appendix H2 –Modeling Analysis – Water Supply and System Operations, prepared by the SFPUC, presents further data and explanation of the HH/LSM raw data output as it relates to system operations; modeling data were used to support the PEIR impact assessment of water supply and system operations. Appendix H3, Temperature Modeling Report, describes the model and analytical methodology used to predict temperature changes in the Tuolumne River below La Grange Dam, and presents the modeling results. A full compilation of post-processed model data for the proposed program, variants and CEQA alternatives proposed according to the methodology presented in this document and used in the PEIR impact assessment is available for review at the SF Planning Department and the SFPUC offices.

The post-processing effort included summarizing the myriad of data derived from the HH/LSM modeling in a uniform, succinct format to allow for the analysis of potential hydrologic impacts of the proposed program, variants, and alternatives compared to existing conditions. In certain instances the variants and alternatives are also compared to the proposed program. The PEIR team utilized the post-process results to identify potential direct impacts on hydrology (stream flow and reservoir water levels) in the affected watersheds as well as potential indirect impacts on related resources, including geomorphology, surface water quality, groundwater, fisheries, terrestrial biological resources, recreation, and visual resources. In addition to the results of this analysis, the authors of the PEIR relied on additional post-processing and analysis provided by the SFPUC and presented in Appendix H2.

This appendix is organized as follows:

1. **Modeling Scenarios** – An explanation of the model runs analyzed for the PEIR. Further explanation of the model runs is provided in Appendix H2.

2. **Hydrologic Modeling Methodology and Model Output Data** – A brief explanation of the HH/LSM, with reference to the SFPUC's modeling documentation, *Water Supply System Modeling Report, Hetch Hetchy/Local Simulation Model* (SFPUC, 2007), which provides greater detail on the operation of HH/LSM. Review of the data provided by the HH/LSM, with a focus on data used in the post-processing analysis.

3. **Post-processing Hydrological Analysis Methodology** – Discussion of the analyses performed on the HH/LSM data. Analyses included statistical summaries, calculation of reservoir levels, and hydrologic analyses to predict creek and river flows. Description of the quality control methodology implemented for the analysis of the model results.

4. **Index of Post-processed Model Results** – An index of the hydrological analyses prepared for the PEIR impact assessment.

2. Modeling Scenarios

The scenarios analyzed in the PEIR were developed through collaboration with the SFPUC, San Francisco Planning Department, Major Environmental Analysis (MEA) Division, and the PEIR consultants. The SFPUC provided input regarding the existing conditions, proposed program, and variants as well as the technical feasibility of alternatives. The MEA and PEIR consultants provided input into the baseline conditions, variants and CEQA alternatives. The SFPUC then conducted model runs for the selected scenarios using the HH/LSM and provided the output data to the PEIR team for post-processing analysis.

The scenarios are organized and discussed in the order presented below. The code presented in brackets after each scenario name is the reference used by the SFPUC to denote the model run. Tables 1 through 3 summarize the major assumptions of each scenario.

2.1 Baseline(s)

The existing conditions or environmental setting, as defined under California Environmental Quality Act (CEQA) Section 15125, represents the physical environmental conditions as they exist at the time of the Notice of Preparation (NOP) and "will normally constitute the baseline physical conditions by which a lead agency determines whether an impact is significant." Therefore, it follows that once the physical baseline conditions are established, impacts can be assessed by comparing changes that would result from implementation of the proposed program to the baseline condition. The NOP for the WSIP PEIR was issued in September 2005, and thus the year 2005 conditions generally represent existing (baseline) conditions for the PEIR analysis.

In most cases, the PEIR description of the baseline reflects the regional system facilities and water supply operations in 2005. However, to be meaningful, the baseline must represent the expected variability of environmental conditions that could reasonably be expected in the future, based on the present and historical state of such conditions. In this PEIR, because hydrology varies widely over time and cannot be properly represented at a specific point in time, the baseline for hydrology reflects a sufficiently long record to allow assessment of long-term variability. Therefore, the "existing conditions" in this PEIR are presented in terms of an 82-year depiction of hydrology (1920 to 2002) to provide a depiction of the range of environment conditions that occur within the varying hydrology of California. Current (2005) operating conditions are analyzed using these 82-years of hydrology to determine how the current system would perform over a range of hydrologic conditions.

In addition to the baseline model runs, actual flow data, diversions, reservoir levels and releases were reviewed to aid in the determination of significance impacts.

Existing Conditions with "Calaveras Down" [MEA3CHR]

As described above, the baseline condition used for the PEIR analysis to determine the significance of impacts is generally represented by the SFPUC facilities and system operating conditions in 2005 in all cases but hydrology. Thus, as described in Chapter 2 of the PEIR, the 2005 average annual customer purchase request is estimated at 265 million gallons per day (mgd), and system operations are restricted due to Division of Safety of Dams (DSOD) requirements that limit the storage capacity of Calaveras Reservoir. This baseline, also referred to as "Calaveras Down," does not represent the SFPUC's historical operating conditions, since operation of Calaveras Reservoir at its full capacity has been a fundamental part of the regional water system prior to DSOD restrictions.

Conditions Prior to 2002 with "Calaveras Up" [MEA2A]

This baseline scenario was developed to simulate 2005 conditions, except with Calaveras Reservoir at its historical operating capacity. It essentially represents conditions prior to 2002 before the DSOD restriction was in place, and applies the 2005 average annual customer purchase request of 265 mgd. This scenario was not used to determine the significance of impacts, but in some cases was helpful in understanding the variable conditions prior to 2002.

2.2 Proposed Program

The SFPUC's proposed program, also referred to as the WSIP in this PEIR, is described in detail in Chapter 3 of the PEIR. The WSIP is the main focus of the PEIR.

Proposed Program [MEA5HIN]

The proposed program represents conditions in 2030 with 300 mgd average annual customer purchase requests, the WSIP water supply sources in place, and all WSIP facility improvement projects constructed and in operation. It includes supplemental dry-year water sources and a maximum drought rationing policy of 20 percent.

Table 1 provides a summary of the model scenarios analyzed.

2.3 Variants

The WSIP variants are variations of the proposed program that are designed to meet or exceed all WSIP goals and objectives but differ with respect to water supply source or drought-year level of service. The variants are not intended to be alternatives to the proposed program that would lessen or avoid environmental impacts as required by CEQA. The SFPUC requested that the potential environmental impacts of the variants be included in the PEIR. Further detail on the variants is provided in Chapter 8 of the PEIR.

WSIP Variant 1 – All Tuolumne [MEA4HIN]

The water supply for WSIP Variant 1 would be identical to that proposed for the WSIP, except that to accommodate the estimated 35-mgd average annual increase in purchase requests (from 265 to 300 mgd) by the year 2030, customers would predominately be served with additional water from the Tuolumne River watershed. As with the proposed program and existing conditions (2005), local watershed runoff would supplement supply from Tuolumne River watershed. And, similar to the proposed program, water from the Westside Basin Groundwater Program would also serve the purchase requests. The water supply would not include the 10 mgd from implementation of the local groundwater projects, recycled water projects, and additional conservation programs in San Francisco, however does include the conjunctive use and regional groundwater projects. In all other respects, WSIP Variant 1 would include the same water supply sources and construction of nearly all the same facilities as the proposed program.

WSIP Variant 2 – Regional Desalination for Drought [MEA30H]

The water supply for WSIP Variant 2 would be identical to that proposed for the WSIP, except that during drought years the SFPUC would receive water from a proposed regional desalination plant instead of water transfers from the Turlock and Modesto Irrigation Districts (TID and MID). Under this variant, the SFPUC, through its participation in the Bay Area Regional Desalination Project, would receive additional potable water supply during drought periods, either directly or indirectly from the regional desalination plant, to meet the WSIP water supply and delivery

TABLE 1
SUMMARY OF EXISTING CONDITIONS AND PROPOSED PROGRAM

Program Element	Existing Condition, 2005, with Calaveras Down (CEQA Baseline) [MEA3CHR]	Existing Condition, Pre-2002 Condition with Calaveras Up [MEA2A]	Proposed Program, 2030 Conditions [MEA5HIN]
Planning Year	2005	2005	2030
Customer Purchase Request (annual average)	265 mgd	265 mgd	300 mgd
Water Supply Sources (during nondrought and drought periods)	▪ Peninsula watershed (with Lower Crystal Springs Reservoir operating at reduced levels based on DSOD restrictions) ▪ Alameda watershed (with Calaveras Reservoir operating at reduced levels based on DSOD restrictions) ▪ Tuolumne River	▪ Peninsula watershed (with Lower Crystal Springs Reservoir operating at reduced levels based on DSOD restrictions) ▪ Alameda watershed (with Calaveras Reservoir at historical capacity, pre-2002) ▪ Tuolumne River	▪ Peninsula watershed (with Lower Crystal Springs Reservoir restored) ▪ Alameda watershed (with Calaveras Reservoir restored) ▪ Tuolumne River, with increased annual diversion over 2005 conditions ▪ Recycled water/ groundwater/conservation in San Francisco, 10 mgd
Supplemental Dry-Year Water Supply Sources (for implementation during drought periods)	None	None	▪ Additional Tuolumne River diversions from TID and MID transfers of 23 mgd (average over design drought) ▪ Westside Basin conjunctive use, 6 mgd (average over design drought)
Maximum Drought Rationing Policy	No defined limit but assumed incidental rationing of up to 25%	No defined limit but assumed incidental rationing of up to 25%	20%
System Firm Yield	219 mgd	223 mgd	256 mgd
WSIP Facility Improvement Projects	None	None	All 22 WSIP PEIR projects

DSOD = Division of Safety of Dams; TID = Turlock Irrigation District; MID = Modesto Irrigation District.

reliability objectives. WSIP Variant 2 would include all the same facilities as the proposed program, with the addition of a regional desalination plant.

WSIP Variant 3 – 10% Rationing [MEA31H]

The water supply sources and facilities for WSIP Variant 3 would be identical to those for the proposed program. This variant would reduce the maximum rationing during drought years from 20 to 10 percent, surpassing the WSIP system performance objective for dry-year delivery. The additional water supplies needed to meet this enhanced performance would come from the Tuolumne River through augmentation of TID and MID transfers during drought years.

Table 2 provides a summary of the WSIP variants.

TABLE 2
SUMMARY OF WSIP VARIANTS

Program Element	Variant 1 [MEA4HIN] All Tuolumne	Variant 2 [MEA30H] Regional Desalination for Drought	Variant 3 [MEA31H] 10% Rationing
Planning Year	2030	2030	2030
Customer Purchase Request (annual average)	300 mgd	300 mgd	300 mgd
Water Supply Sources (during nondrought and drought periods)	▪ Local watersheds (with Calaveras and Lower Crystal Springs Reservoirs restored) ▪ Tuolumne River, with 5 mgd increased average annual diversion over the Proposed Program	▪ Local watersheds (with Calaveras and Lower Crystals Springs Reservoirs restored) ▪ Tuolumne River, with 7 mgd less average annual diversion over the Proposed Program ▪ Recycled water/ groundwater/conservation in San Francisco, 10 mgd	Approximately the same as proposed program (less than 1 mgd average annual increase in diversion from Tuolumne)
Supplemental Dry-Year Water Supply Sources (for implementation during drought periods)	▪ Westside Basin conjunctive use, 6 mgd (average over design drought) [Same as proposed program]	▪ Potable water from regional desalination plant, 23 mgd (average over design drought) ▪ Westside Basin conjunctive use, 6 mgd (average over design drought)	▪ Additional Tuolumne River diversions from TID and MID transfers of 35 mgd (average over design drought) ▪ Westside Basin conjunctive use, 6 mgd (average over design drought)
Maximum Drought Rationing Policy	20%	20%	10%
System Firm Yield	256 mgd	256 mgd	268 mgd
Facility Improvement Projects	20 of the 22 WSIP PEIR projects; two projects would not be implemented: local groundwater and recycled water projects in San Francisco	All projects 22 WSIP PEIR projects plus Bay Area Regional Desalination Plant and associated pumping plant(s) and pipelines needed for intertie facilities	All 22 WSIP PEIR projects

TID = Turlock Irrigation District; MID = Modesto Irrigation District.

2.4 CEQA Alternatives

As required under CEQA, alternatives were developed that would feasibly attain most of the WSIP's basic objectives, but that would avoid or substantially lessen any significant adverse environmental effects of the WSIP. The No Program Alternative, also required by CEQA, was also analyzed. Further detail on the CEQA alternatives is provided in Chapter 9 of the PEIR.

CEQA Alternative 1 – No Program Alternative [MEA37H]

Under the No Program Alternative, customer purchase requests from the SFPUC (water demand) would increase from an annual average of 265 mgd in 2005 to 300 mgd in 2030, and the SFPUC would continue to rely on water supply sources from local watersheds and the Tuolumne River. The SFPUC would construct only those WSIP facility improvement projects that are mandated by or previously agreed upon with regulatory agencies to represent the likely scenario that would occur in the event the WSIP is not implemented. There would be no supplemental dry-year water supply sources. The additional water demand would be served, to the extent possible, from increased diversions from the Tuolumne River as well as the increased use of local watershed supplies, primarily associated with the restoration of storage at Calaveras Reservoir.

CEQA Alternative 2 – No Purchase Request Increase [MEA40H]

Under the No Purchase Request Increase Alternative, the total customer purchase requests to be served by the regional system by 2030 would be limited to 275 mgd, consisting of 184 mgd for the wholesale customers and 91 mgd for the retail customers. The increased water demand would be served through additional Tuolumne River diversions, increased use of local watershed supplies from restoration of Calaveras Reservoir, and 10 mgd from recycled water, groundwater, and conservation projects in San Francisco. During drought sequences, this supply would be supplemented by additional Tuolumne River diversions through a water transfer with TID and MID as well as through implementation of the Westside Basin Groundwater Program. This alternative assumes that 21 of the 22 WSIP facility improvement projects would be built, with the exception being the Lower Crystal Springs Dam Improvements project.

CEQA Alternative 3 – Aggressive Conservation/Recycling and Local Groundwater [MEA42H]

Under the Aggressive Conservation/Recycling and Local Groundwater Alternative, the customer purchase requests in 2030 would be 300 mgd, which would be met in large part through additional water conservation, water recycling, and groundwater programs beyond those already assumed in the 2030 demand projections. Up to 19 mgd of the demand would be met through regional recycled water/groundwater/conservation projects within the regional service area but outside of San Francisco, and 10 mgd of recycled water/groundwater/conservation in San Francisco. There would be no supplemental dry-year supply sources. This alternative assumes that 20 of the 22 WSIP facility improvement projects would be built, with the exceptions being the Lower Crystal Springs Dam Improvements project and the Westside Basin Groundwater Program.

Table 3 provides a summary of the WSIP CEQA alternatives analyzed.

Further detail on the modeling scenarios analyzed for the PEIR is provided in Appendix H2.

TABLE 3
SUMMARY OF WSIP CEQA ALTERNATIVES

Program Element	No Program Alternative [MEA37H]	No Increased Purchase Request Alternative [MEA40H]	Aggressive Conservation and Water Recycling Alternative [MEA42H]
Planning Year	2030	2030	2030
Customer Purchase Request (annual average)	300 mgd	275 mgd	300 mgd
Water Supply Sources (during nondrought and drought periods)	▪ Local watersheds (with Calaveras Reservoir restored and Crystal Springs Reservoir at its existing capacity) ▪ Tuolumne River, with 8 mgd increased average annual diversion over 2005 conditions	▪ Local watersheds (with Calaveras Reservoir restored and Crystal Springs Reservoir at its existing capacity) ▪ Tuolumne River, with 3 mgd increased average annual diversion over 2005 conditions ▪ Recycled water/ groundwater/conservation in San Francisco, 10 mgd	▪ Local watersheds (with Calaveras Reservoir restored and Crystal Springs Reservoir at its existing capacity) ▪ Tuolumne River, with 5 mgd increased average annual diversion over 2005 conditions ▪ Recycled water/ groundwater/conservation in San Francisco, 10 mgd ▪ Regional recycled water/ groundwater/conservation, in service area outside of San Francisco, 19 mgd
Supplemental Dry-Year Water Supply Sources (for implementation during drought periods)	None	▪ Additional Tuolumne River diversions from TID and MID transfers of 1 mgd (average over design drought) ▪ Westside Basin conjunctive use, 6 mgd (average over design drought)	None
Maximum Drought Rationing Policy	No defined limit, but assumed incidental rationing up to 30%	20%	20%
System Firm Yield	226 mgd	233 mgd	226 mgd
Facility Improvement Projects	4 of 22 WSIP PEIR projects	21 of 22 WSIP PEIR projects	20 of 22 WSIP PEIR projects plus regional recycled water and groundwater projects outside of San Francisco

TID = Turlock Irrigation District; MID = Modesto Irrigation District.

3. Water Supply Planning Model

3.1 Model Description

The data analysis for the PEIR was performed on output data from the SFPUC's HH/LSM. The following is a brief review of the HH/LSM. For a comprehensive discussion of HH/LSM design and operation, refer to *Water Supply System Modeling Report, Hetch Hetchy/Local Simulation Model* (SFPUC, 2007).

The HH/LSM is a computerized mathematical model used by the SFPUC to assist in the evaluation of its water system operations. The HH/LSM incorporates information about key aspects of the SFPUC regional water system, including facilities (i.e., reservoir and conveyance capacities) and operating procedures and "rules" that determine how and when water is moved through the system to the SFPUC's customers. The operating procedures and rules include responses to seasonal variation in demand, allocation of demand to customer groups, and procedures to maximize the use of local watershed supplies, while "rules" include responses to regulatory requirements for instream flows and compliance with Raker Act obligations. Operation of the regional water system can be generally delineated between rules and strategies affecting the operation of the Bay Area water system, and rules and strategies affecting the operation of the Hetch Hetchy system.

The HH/LSM is personal-computer-based and is written in Fortran code, with spreadsheet input and output interfaces. The model can be modified to incorporate changes in operation assumptions or to allow the testing of possible modifications to the infrastructure and/or operation of San Francisco facilities, or other facilities affecting regional system operations (i.e., TID's and MID's operation of Don Pedro Reservoir). Certain hydrologic and hydraulic parameters are "input driven," allowing the user to modify hydrology and the representation of physical characteristics such as reservoir capacity, preferred operational storage levels, water demands and certain operational decisions.

The model simulates system operations over the course of an 82-year sequential hydrologic period from July 1920 through September 2002. The model incorporates actual historical information about the hydrology (the amount of runoff as snowmelt and/or rainfall) that occurred in each year over the 82-year record for each of the three watershed areas under consideration: the Tuolumne River, the Alameda Creek, and the Peninsula watersheds. This 82-year period includes many different types and sequences of actual hydrological events that occurred, ranging from flood events to droughts of different magnitude and duration. The long-term 82-year historical record is used in the model to represent the range of hydrologic conditions that could occur in the future and to assess how the system would perform in terms of an assumed system configuration and assumed operational objectives.

The model uses a watershed runoff forecasting routine (for snowmelt and rainfall) that projects the amount of runoff in the Tuolumne River Basin. The amount of expected runoff is then compared against the availability of reservoir storage to capture the runoff and the expected releases required from the reservoir to meet downstream requirements and diversions to San

Francisco. If a reservoir is projected to spill, the model can simulate operational releases that would likely be made in those situations in order to enhance power generation from the system. This forecasting and decision process occurs continuously each month of the period being modeled.

The model simulates sequential hydrologic events on a monthly time step. That is, the model simulates the operation of facilities on a continuum, from one month to the next, one year to the next for 82 years. This method of modeling allows the investigation of sequential hydrologic events varying in duration as well as varying in distribution of runoff. However, because the input and results are depicted as monthly volumes of water, a drawback of this monthly time-step approach is that the results may not adequately depict the day-to-day variations of operations, hydrology, or operational decisions that can occur in less than monthly intervals. In these instances, additional supplemental analysis is developed.

The HH/LSM is used iteratively; that is, the model input is adjusted following a review of the results from a model study. The model simulates system performance and operations for a recurrence of historical hydrologic events. Parameters reviewed are typically the simulated delivery of water to San Francisco customers and reservoir levels and releases. Model inputs that affect model decisions are adjusted until a simulation achieves an accepted, or desired, performance of the scenario being modeled. Results from the scenarios described above were compared to illustrate the effects of alternative system objectives and requirements, operational assumptions, and system configurations.

System operations during drought periods require more complex planning and system management than during nondrought years, and the SFPUC's drought planning uses as a backdrop the concept of a "design drought" and "system firm yield." System firm yield is a measure of the amount of water that can be delivered to customers without shortages during all anticipated hydrologic sequences. This yield is also comparable to the amount of delivery that would occur on average across the design drought period. The design drought is a planning tool developed by the SFPUC to anticipate and plan for drought. For planning purposes, the SFPUC uses a design drought that contemplates a more severe drought than historical events, and evaluates the system firm yield assuming the system is experiencing the design drought. This premise is founded on experience that illustrates that drought sequences can get more extreme as our hydrologic record lengthens. Studies suggest that there is a 30 percent chance that the SFPUC system will experience a drought in the next 75 years equal to or more severe than the 1987–1992 drought (Beck, 1994). The SFPUC uses a design drought based on the hydrology of the six years of the worst historical drought (1977–1992) plus the 2.5 years of the 1976–1977 drought, for a combined total of an 8.5-year design drought sequence.

For the purposes of the PEIR, the HH/LSM is the best available tool to predict potential impacts on water resources in the affected watersheds resulting from the proposed program, variants, and alternatives. HH/LSM output was used to provide quantitative estimates of changes that would occur with implementation of the WSIP compared to the existing condition.

The HH/LSM is typical of water supply planning models utilized in California. With its diversity in weather—ranging from flood events to multi-year sequences of drought—California hydrology warrants the evaluation of water supply projects over a long sequence of years to measure system performance and reliability. The SFPUC, like other major California water purveyors, employs models to evaluate the effect of California hydrology on its ability to provide water supply (and to evaluate its system's effect on the environment). The East Bay Municipal Utility District and other municipal water purveyors use comparable models for the purpose of water supply planning. The California Department of Water Resources and U.S. Bureau of Reclamation use the CalSim II model, which employs the same approach as the HH/LSM to evaluate the statewide water supply. Appropriately, the HH/LSM focuses narrowly on the SFPUC water system, but provides information that integrates into the overall California river system. In fact, the Department of Water Resources and Bureau of Reclamation use results from the HH/LSM in the evaluation of statewide water resources.

3.2 Model Limitations

The HH/LSM model is the best available tool for depicting the overall regional water system operations, and a number of limitations inherent in the model have been supplemented by additional data.

For example, HH/LSM was used to estimate baseline and with-WSIP water levels in all of the SFPUC's reservoirs except Pilarcitos Reservoir. Model results for the Pilarcitos watershed were not directly used to analyze existing and projected water levels in Pilarcitos Reservoir or flows in Pilarcitos Creek. The model does not currently reflect a complete contemporary depiction of the physical operation of the watershed's facilities. Although adequate for SFPUC systemwide water supply planning purposes, HH/LSM results for the Pilarcitos watershed at times requires supplemental refinement and analysis.

HH/LSM was also used to estimate baseline and with-WSIP flows in the Tuolumne River and Alameda Creek. However, the model results were not solely relied upon when evaluating flows in creeks immediately downstream of SFPUC reservoirs that are normally minimal or affected by SFPUC operations for time periods less than a month in duration. This is because the model uses a monthly time interval. The model does not simulate day-to-day variations in water levels or releases to a stream, but instead provides an average water level and an average release in a given month. The inability of the model to illustrate short-term variations is generally not problematic when simulating continuous phenomena like storage or water level in a reservoir or flow in a perennial stream. The modeling limitation requires additional considerations such as operator experience when simulating intermittent phenomena such as infrequent spills or releases from reservoirs that may last only a few days.

Flow in San Mateo Creek downstream of Lower Crystal Springs Dam provides an example. The SFPUC system operators rarely release water from Crystal Springs Reservoir to San Mateo Creek, and flow in the creek below the dam typically occurs only from seepage from the dam and groundwater infiltration. Because releases to the creek are not required, the SFPUC operators attempt to capture and retain as much runoff as possible from the upper San Mateo Creek watershed in Crystal Springs Reservoir. In all but wet years, the SFPUC captures all of the runoff from the upper watershed. In wet months of wet years, the operators of the reservoir obtain frequent weather forecasts and manage the reservoir to capture as much runoff as possible from the sequence of winter storms that cross the watershed. The operator's decisions with respect to reservoir management are made on a day-to-day, sometimes hour-to-hour, basis. In certain circumstances during wet hydrologic conditions the operators will release to the creek due to a lack of predictability of the weather and an ability to manage the reservoir and other system-wide facilities through the event without releases.

Because the HH/LSM does not simulate, on a monthly time step, the day-to-day changes in operations which give rise to releases from Crystal Springs Reservoir to San Mateo Creek cannot be modeled. Consequently, the model does not always provide a refined absolute prediction of the magnitude and timing of infrequent and short-term releases from the reservoir. Similarly, the model does not provide a precise prediction of the magnitude and timing of release from San Antonio Reservoir and flow in San Antonio Creek downstream of the reservoir. However, HH/LSM results were sufficient to provide general trends of the effects of the WSIP upon these parameters.

For the reasons noted above, HH/LSM results were not used to predict water levels in Pilarcitos Reservoir, flows in Pilarcitos Creek, or the magnitude and timing of spills or releases from Crystal Springs and San Antonio Reservoirs. In these cases, the likely effects of the WSIP were determined by a review of historical data and consultation with individuals cognizant of past and predicted future reservoir operating practices.

In additional instances such as the analyses of flow effects below Hetch Hetchy Reservoir and Alameda Creek Diversion Dam, HH/LSM results have been refined or tiered from to provide additional insight to the effects of the WSIP upon stream flow for time periods less than a month in duration.

3.3 Model Output Data

The HH/LSM outputs data in a monthly time-step for each model simulation. Once the operation of the system is modeled under a particular set of assumptions, the model provides output information about how the system performs under that scenario in terms of water in reservoir storage, releases, water deliveries, and other parameters associated with the system's reservoirs, conveyance facilities, and treatment plants. The model provides information representing monthly volumes of water, although certain parameters have been converted to flow rates.

The SFPUC conducted the model runs analyzed in the PEIR. Model runs were provided to the PEIR team in spreadsheet format. Multiple revisions of the model runs occurred through an iterative process with the PEIR consultant team in order to ensure that the appropriate assumptions were used under each scenario, consistent with the PEIR impact analysis.

Table 4 lists key output information calculated by the model. Highlighted rows denote data that were used in the post-processing analysis.

TABLE 4

Coastside CWD = Coastside County Water District; MG = million gallons; MGD = million gallons per day; MWh = megawatt-hours; MID = Modesto Irrigation District; SJPL = San Joaquin Pipelines; TID = Turlock Irrigation District; WTP = water treatment plant.

4. Hydrologic Computations and Data Presentation

4.1 Hydrologic Year Types

The HH/LSM produces a set of results for a hydrologic sequence of 82 years, 12 months each year. While at times it is necessary to evaluate the results from month to month and year to year, in many instances the illustration and understanding of results can be achieved by a grouping within water year types. Each year in the 82-year period of historical hydrology was ranked and grouped into hydrologic year types according to an appropriate wetness indicator. Three different groupings (referred to as indices) were used in the PEIR analysis according to the specific hydrologic system in which the affected facilities are located. The hydrologic year types are defined differently for different areas affected by the WSIP in order to accurately reflect each area's unique hydrology.

Each index contains five hydrologic year-type categories. The three indices and corresponding year-type categories are as follows:

Tuolumne Index	Wet (W) Above Normal (AN) Normal (N) Below Normal (BN) Dry (D)
San Joaquin Index (Reflects the existing San Joaquin Valley Water Year Hydrologic Classification)	Wet (W) Above Normal (AN) Below Normal (BN) Dry (D) Critically Dry (CD)
Five Reservoir Index	Wet (W) Above Normal (AN) Normal (N) Below Normal (BN) Dry (D)

Tuolumne Index

Hydrologic year types for the Tuolumne River above Don Pedro Reservoir were developed for this analysis. The year types were classified based on the SFPUC's calculation of unimpaired flow for the Tuolumne River at La Grange Dam. The years were ranked as simple percentiles. The 20 percent of years when unimpaired inflow to Don Pedro Reservoir was lowest were designated dry years; the next driest 20 percent of years were designated below-normal years, and so on.

San Joaquin Index

Hydrologic year types for the Tuolumne River below La Grange Dam and Don Pedro Reservoir are classified according to the Department of Water Resources' San Joaquin Valley Water Year Classification (San Joaquin Index). The San Joaquin Index was used to analyze Don Pedro and La Grange operations because release requirements from Don Pedro Reservoir at La Grange are tied to this index. The San Joaquin Index was not readily applicable to the entire Tuolumne River system because this index is based on all inflow into the San Joaquin River, not just contributions from the Tuolumne River. As such, the San Joaquin Index ranking of year types is at times inconsistent with runoff from the Tuolumne system alone.

Five Reservoir Index

Hydrologic year types for the Alameda Creek and Peninsula watersheds are also classified by the 20 percent grouping technique and are based on local stream gauge data and the SFPUC's estimation of flow into its five San Francisco Bay Area reservoirs (Calaveras, San Antonio, Crystal Springs, Pilarcitos, and San Andreas Reservoirs). Annual flow into each of the reservoirs was aggregated for each water year. The 20 percent of years when total runoff into the five reservoirs was lowest were designated dry years; the next driest 20 percent of years were designated below-normal years, and so on.

Table 5 illustrates how these hydrologic year types apply over the historical record. Note that the table is organized according to rank, and that the water year corresponding to a given rank may vary from index to index. For instance, for all three indices, 1983 is ranked as the wettest year; however, the second-ranked year in the Tuolumne Index is 1995, in the San Joaquin Index is 1969, and in the Five Reservoir Index is 1998. The differences in rank reflect the differences in hydrology between the upper Tuolumne River watershed, the San Joaquin Valley, and the Bay Area.

4.2 Computations and Data Presentation

General Approach

The analysis of HH/LSM data focused on reservoir storage, releases, diversions, and deliveries. Data were analyzed according to the three portions of the regional system, the Tuolumne River, Alameda, and Peninsula systems, which correspond to the three respective watersheds that would be affected by the proposed water supply and system operations changes. The following sections outline the general approach to the analysis of each system. Specific data sets were extracted from the model output and then ranked, statistically analyzed, summarized, and charted. The ultimate use of these data was to allow for comparison between the existing condition and the WSIP, WSIP variant, or CEQA alternative. As such, seven separate discrete comparisons were performed:

1. Existing Condition [MEA3CHR] vs WSIP [MEA5HIN]
2. Existing Condition [MEA3CHR] vs Variant 1, All Tuolumne [MEA4HIN]
3. Existing Condition [MEA3CHR] vs Variant 2, Regional Desalination for Drought [MEA30H]

7. Existing Condition [MEA3CHR] vs CEQA Alternative 3, Aggressive Conservation and Water Recycling [MEA42H]

Comparisons were made by generating annual and monthly statistics for all years in the sequence as well as for each of the indexed year types (e.g., wet, above normal, etc.). The analysis performed can generally be divided into two primary hydrologic regimes: reservoir releases to rivers/creeks and reservoir storage.

Reservoir Releases/Spills to Rivers and Creeks

The HH/LSM predicts both reservoir releases and spills. Reservoir releases involve a release of impounded water through a reservoir's adit to the watercourse downstream of the dam. Releases are generally made to control water levels in the reservoir or to meet minimum flow requirements in the watercourse below the reservoir. Reservoir spills happen when impounded water discharges from a dam's spillway. Spills generally occur during periods of high flow when the reservoir is full. Reservoirs are usually operated to avoid spills by releasing water through the adits. For the purpose of this analysis, releases and spills were aggregated for each month of model output and reported as a release from each respective reservoir. Spills and releases were not considered separately, since both contribute to flow in the watercourse downstream of the reservoir.

Each comparison of reservoir releases to watercourses included a comparison of baseline data and WSIP/variant/alternative data related to annual average releases, monthly average releases, and changes in monthly releases for all months and each year type over the 82 years of historical hydrology analyzed. The monthly value for a given year type was calculated as the average of all values for a given month within that year type. An example of a monthly comparison is provided in **Table 6**. Statistics were also generated for each monthly release including average, minimum, maximum, median and standard deviation. Comprehensive tables were also generated detailing the monthly release for all 82-years of hydrology for both the existing condition and the WSIP/variant/alternative being analyzed as well as the changes to releases in any given month. This full data set essentially gave the reviewer access to the full model output in a compact format to aid in identifying trends or single-year anomalies and extremes in the data.

Monthly averages were charted, as were the 82,years of chronological releases, to visually detect trends and regularly occurring changes between the existing condition and the WSIP/variant/alternative being reviewed. Where relevant, additional charting was developed to highlight the percentage of monthly change for the 82-year hydrologic sequence, highlighting trends or single anomalies and extremes.

Reservoir Storage and Water Surface Elevation

Reservoir storage was presented on a monthly basis for each hydrologic year type and as an average for all years. This exercise was performed for all reservoirs in the SFPUC system as well as for Don Pedro Reservoir. Impoundments at the Alameda Creek Diversion Dam and Stone Dam do not have sufficient storage to warrant the exercise. Percent change between the existing condition and WSIP were also calculated and tabulated, including highlighting of months within year types with a change from the existing condition. An example of a monthly comparison for reservoir water surface elevation is provided in **Table 7**.

Reservoir water surface elevations were generated based on storage-elevation data provided by the SFPUC for each reservoir. Storage-elevation data did not generally include datum information, and several curves were incomplete. Datums were assumed to be U.S. Geological Survey (USGS) National Geodetic Vertical Datum 29; however; it is likely that some elevation data were provided on Crystal Springs Datum, which is 3.75 feet lower than the USGS datum. In the case of incomplete curve data, data extrapolations were performed to extend the curve over the full operating range of the reservoir, which was considered sufficient for the analysis being performed. **Figure 1** presents an example of a storage-elevation curve used to generate reservoir elevation data.

Similar to the release data, monthly data were provided in tabular format for all months in the 82-year sequence to give the reviewer access to the full data set.

Tuolumne River System

The Tuolumne River system encompasses SFPUC facilities within the Tuolumne River watershed. These included Hetch Hetchy Reservoir, Lake Lloyd, Lake Eleanor, Kirkwood and Holm Powerhouses, and the diversion/power tunnels. Don Pedro Reservoir is also included in the system. Although this reservoir is not an SFPUC-operated facility, the SFPUC maintains a water bank in Don Pedro Reservoir, and Tuolumne system operations are directly linked to the water rights and entitlements of TID and MID, which own and operate Don Pedro Reservoir. Also, SFPUC operations affect water availability at Don Pedro Reservoir and thus have an indirect influence upon Don Pedro Reservoir releases to the Tuolumne River below La Grange Dam.

The following is a list of locations within the Tuolumne River system analyzed using HH/LSM data.

Releases to Rivers/Creeks

1. Hetch Hetchy Reservoir releases to the Tuolumne River
2. Don Pedro Reservoir releases at La Grange Dam to the Tuolumne River
3. Lake Lloyd releases to Cherry Creek
4. Lake Eleanor releases to Eleanor Creek
5. Kirkwood Powerhouse releases to the Tuolumne River at Early Intake
6. Holm Powerhouse releases to Cherry Creek
7. Sum of Releases calculated at the Cherry Creek confluence

Reservoir Storage

8. Hetch Hetchy Reservoir storage and water levels
9. Lake Lloyd storage and water levels
10. Lake Eleanor storage and water levels
11. Don Pedro Reservoir storage and water levels

These analysis locations are shown in **Figure 2**.

Data for releases from each of the reservoirs were obtained directly from the HH/LSM output data. Reservoir releases presented in this analysis include both spills and releases from the respective dam.

Kirkwood Powerhouse releases, which represent flow returned to the Tuolumne River at Early Intake, were calculated based on the capacity of Mountain Tunnel. The instantaneous capacity of Mountain Tunnel was assumed to be 650 cubic feet per second (cfs) and scaled to a monthly capacity. Releases from Kirkwood Powerhouse were calculated as the difference between flow in Canyon Power Tunnel (upstream of Kirkwood) and the monthly capacity of Mountain Tunnel (downstream of Kirkwood). Holm Powerhouse releases were assumed to be the same as diversions from Lake Lloyd to Cherry Power Tunnel, which is an HH/LSM output.

Releases at the Cherry Creek confluence are a summation of all reservoir and powerhouse releases to the Tuolumne River. Each of the releases on the Tuolumne River above the Cherry Creek confluence or on Cherry Creek or Eleanor Creek is implemented such that all SFPUC-controlled flow of the Tuolumne River occurs upstream from the confluence where Cherry Creek

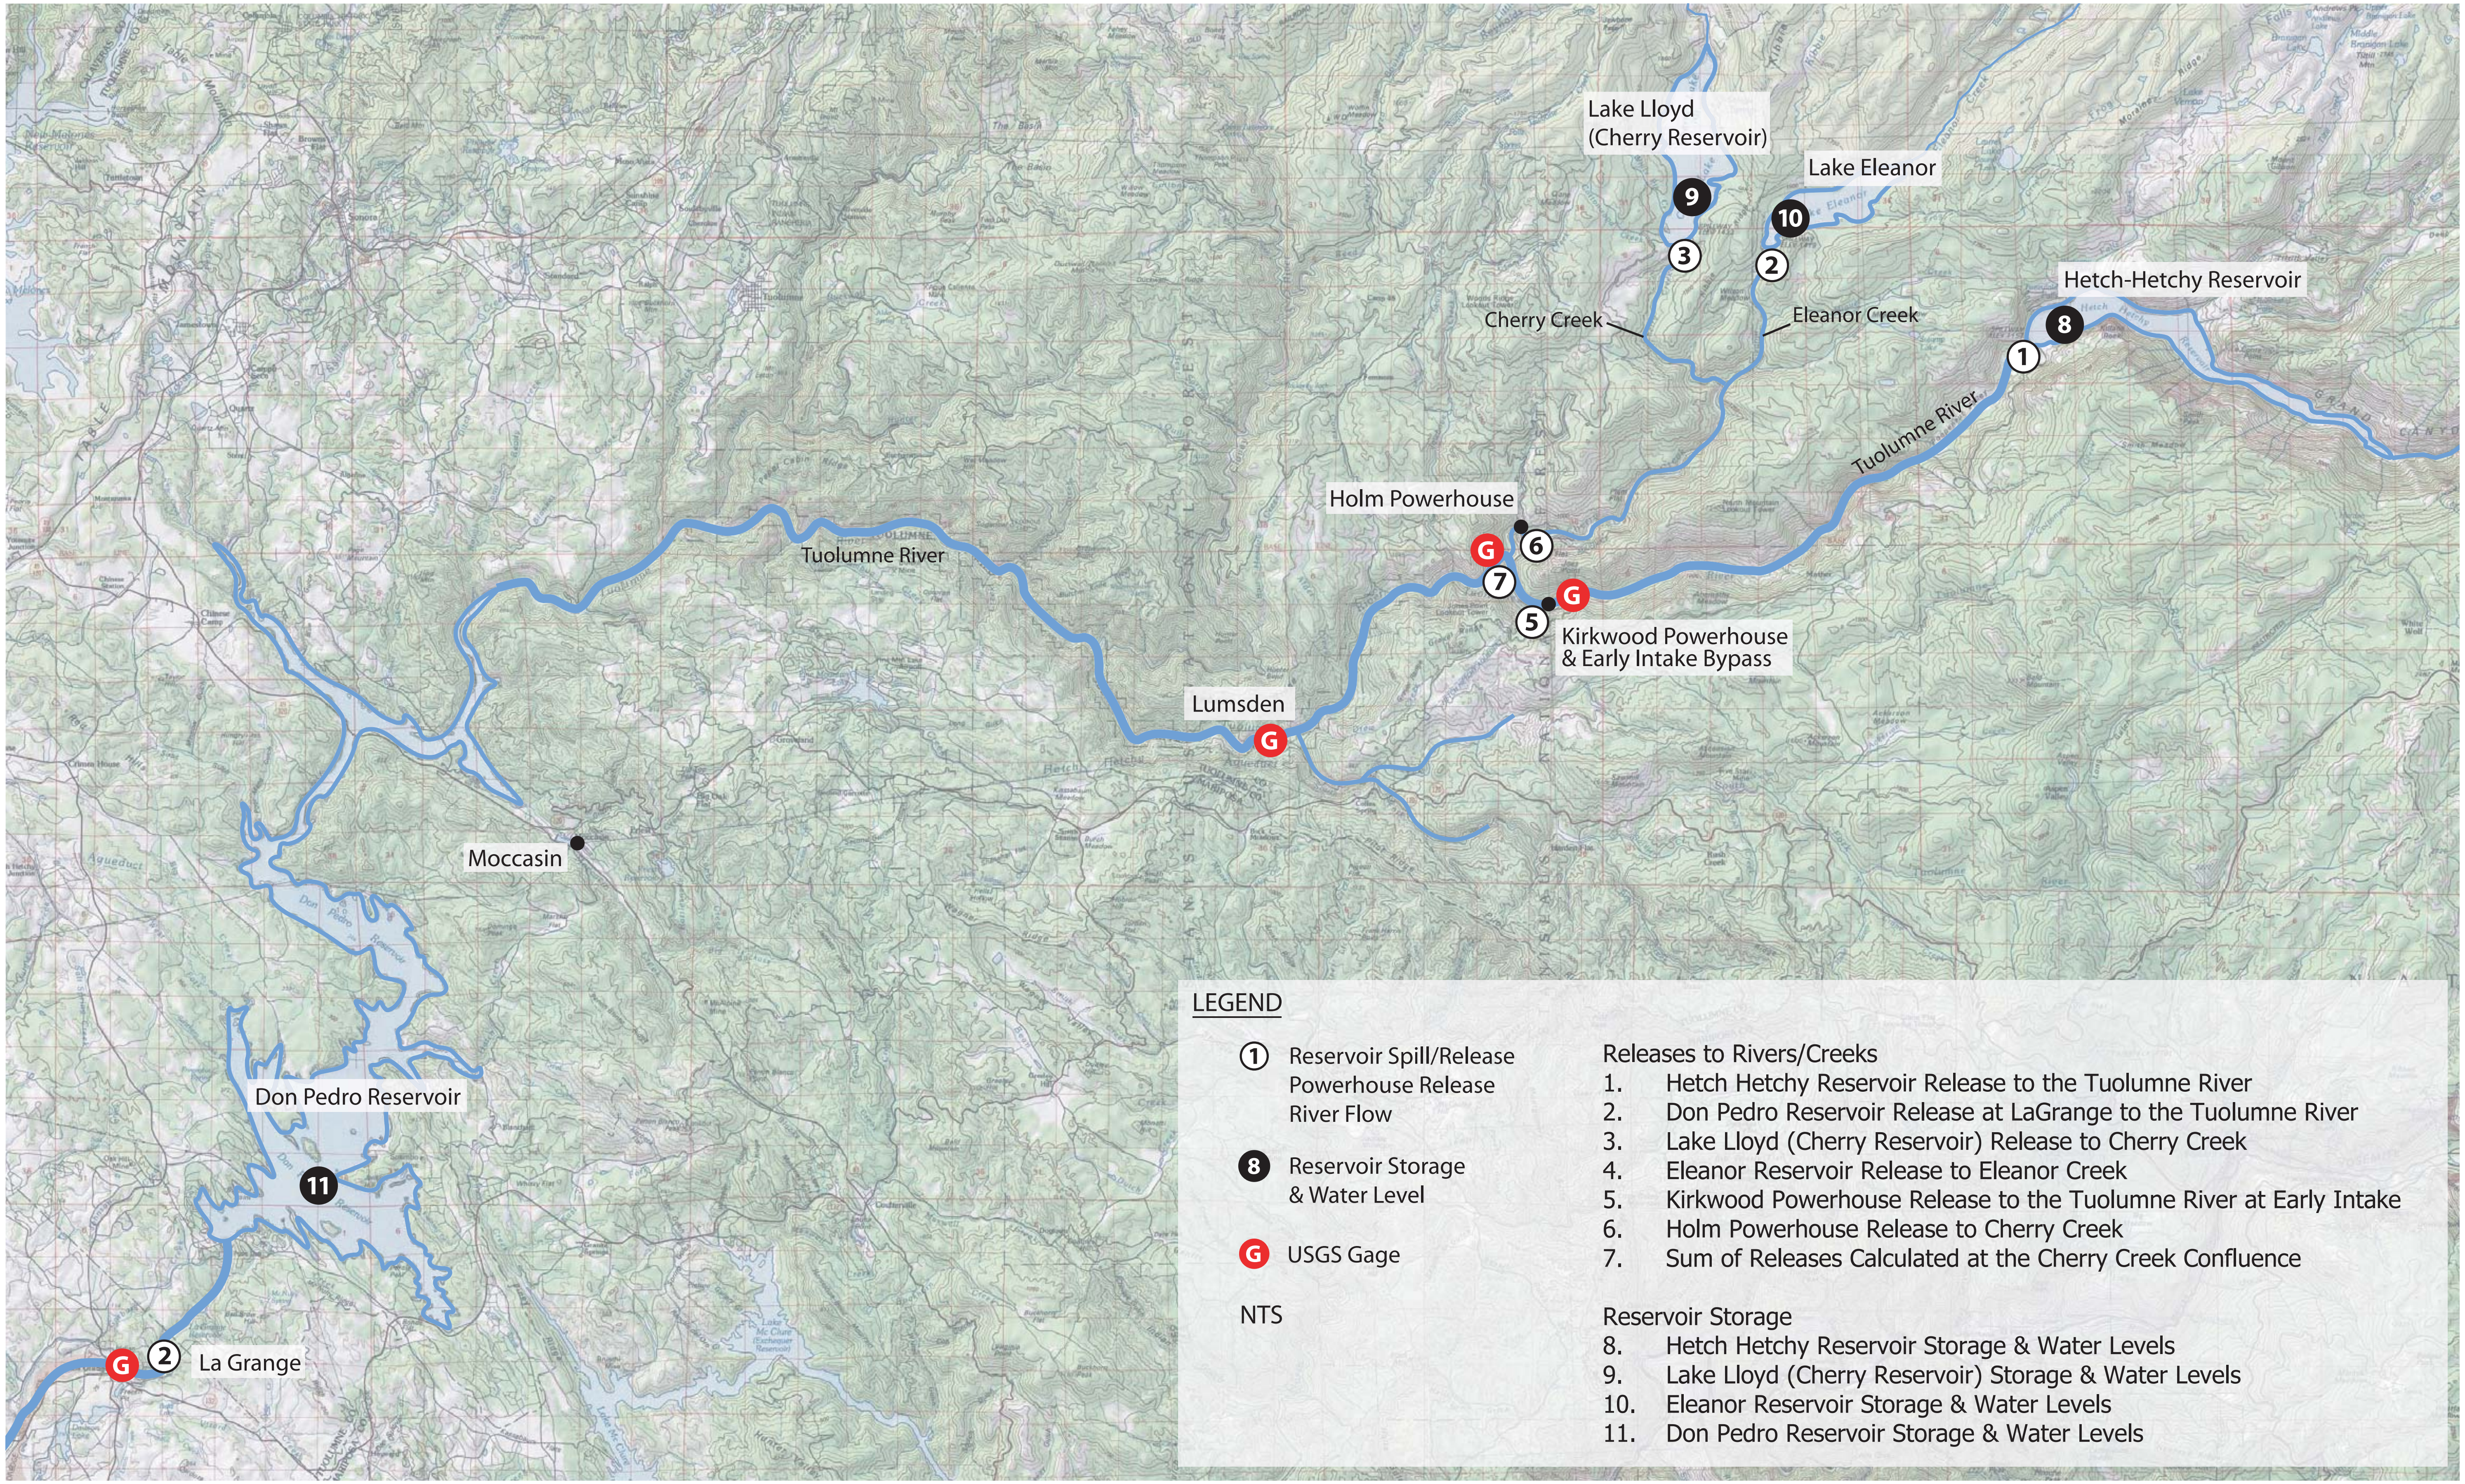

Figure 2 (Model Appendix 1)
Tuolumne System Flow and Storage Analysis Locations

THIS PAGE INTENTIONALLY LEFT BLANK

joins the Tuolumne River. The summation of controlled releases was made to provide a point of comparison for the reach of the Tuolumne River between the Cherry Creek confluence and Don Pedro Reservoir. Absent from the calculation are monthly accretions over the 82-year record from the watersheds between the dams and the confluence, as these data were not readily available. These accretions would not be affected by system operations and thus would not change from model run to model run. Therefore, the calculation of absolute flows at the Cherry Creek confluence is lower than actual flow, but any change in flow rates between scenarios identified by the calculation is accurate.

Reservoir storage was readily available from HH/LSM output, and water surface elevations were calculated using SFPUC-supplied storage-elevation curves.

In addition to the analyses listed above for the Tuolumne River system, statistics were developed for the summary tables. The summary tables provide a single-page review of pertinent statistics, allowing comparison across the WSIP, variants, and CEQA alternative model runs. Most statistics presented in the Tuolumne River system summary table are self-explanatory.

Additional calculations were performed using HH/LSM output to develop minimum release statistics. Releases from each of the reservoirs were compared against monthly minimum release requirements. The number of months in the record where releases were at minimum flow requirements was calculated as a point of comparison between model runs. For instance, in the existing condition, releases from Hetch Hetchy Reservoir are at minimum levels in 837 months out of 987 in the record. For the proposed program, 846 months out of the record would have releases occurring at the minimum requirements, representing an increase in the frequency of minimum flow conditions of 0.9 percent.

Calculations were also made as part of the cumulative analysis for additional releases to the Tuolumne River at La Grange Dam for the proposed TID Regional Surface Water Supply Project. For the TID project, it was assumed that 66 cfs would be released from La Grange Dam year-round to supply water to the downstream infiltration gallery and treatment plant, and an additional 34 cfs could be released from La Grange Dam during the irrigation season, diverted at the infiltration gallery, and conveyed to the Ceres Main Canal for agricultural use. The release for agricultural purposes was assumed to occur from mid-March to mid-October. Releases at La Grange under the proposed program, as predicted by the HH/LSM, and estimated releases for the proposed TID project were aggregated and compared against the existing condition for the cumulative analysis presented in Chapter 5, Section 5.7, of the PEIR.

Alameda Creek System

The Alameda Creek system encompasses SFPUC facilities in the Sunol Valley region. These include Calaveras Reservoir, Alameda Creek Diversion Dam, and San Antonio Reservoir. Local watercourses include Alameda Creek, Arroyo Hondo, Calaveras Creek, and San Antonio Creek. The following is a list of locations within the Alameda system analyzed using HH/LSM data.

Releases to Rivers/Creeks

1. Diversions from upper Alameda Creek to Calaveras Reservoir
2. Calaveras Reservoir releases to Calaveras Creek
3. San Antonio Reservoir releases to San Antonio Creek
4. Flow in Alameda Creek below the diversion dam (1)
5. Flow in Alameda Creek below the Calaveras Creek confluence (2)
6. Flow in Alameda Creek below the San Antonio Creek confluence (3)

Reservoir Storage

7. Calaveras Reservoir storage and water levels
8. San Antonio Reservoir storage and water levels

These analysis locations are shown in **Figure 3**, and the three flow locations in Alameda Creek (numbers shown in parenthesis after analysis locations 4, 5, and 6) are described in more detail below and in **Figure 4**.

Data for releases from Calaveras and San Antonio Reservoirs were obtained directly from the HH/LSM output data. Reservoir releases presented in this analysis include both spills and releases from the respective dam. The HH/LSM also provided output data on diversions from the Alameda Creek Diversion Dam to Calaveras Reservoir.

In addition to the releases and diversions, average monthly flow in Alameda Creek was estimated at three locations to aid in the impact analysis. Calculations were made for the following three locations:

1. Below the diversion dam
2. Below the Calaveras Creek confluence (below Calaveras Reservoir)
3. Below the San Antonio Creek confluence (below San Antonio Reservoir)

Figure 4 presents a flow schematic of the major components of the water balance on Alameda Creek. Evaporative and groundwater losses were not included in the balance, since these losses are not expected to vary substantially among the scenarios.

Flow at each of these locations was derived from HH/LSM output data combined with calculated flow for runoff volumes, using the methodology provided by the SFPUC (Hannaford, 2004). The basis of calculations for the flow at each location is shown in **Table 8**.

Reservoir storage was readily available from HH/LSM output data, and water surface elevations were calculated using SFPUC-supplied storage-elevation curves.

In addition to the analyses listed above for the Alameda Creek system, statistics were developed for the summary tables. Statistics presented in the Alameda Creek system summary table are self-explanatory.

TABLE 8
CALCULATION OF FLOWS IN ALAMEDA CREEK

Alameda Creek Flow Location	Unimpaired Flow	Current Impaired and Proposed Flows
1. Below the Diversion Dam	SFPUC Calculation Data Source:[a]	= (Unimpaired Flow) – (Diversion to Calaveras Reservoir) Data Source:[a,b]
2. Below the Calaveras Creek Confluence	= (Unimpaired Flow at 1) + (Accretion 1) + (Calaveras Reservoir inflow) Data Source:[a,b,c]	= (Flow at 1) + (Accretion 1) + (Calaveras Reservoir Release) + (Calaveras Reservoir Spill) Data Source:[b,c]
3. Below the San Antonio Creek Confluence	= (Unimpaired Flow at 2) + (Accretion 2) + (San Antonio Reservoir inflow) Data Source:[b,c]	= (Flow at 2) + (Accretion 2) + (San Antonio Reservoir Release) + (San Antonio Reservoir Spill) – (Calaveras Reservoir Release/Recapture) Data Source:[b,c]

Data Source Notes:

[a] Unimpaired flow at Alameda Creek Diversion Dam is from the SFPUC, file "AlamedaCkOnlyAtDiversion.xls."
[b] HH/LSM output source of data for existing and proposed program conditions for: diversion to Calaveras Reservoir; Calaveras Reservoir inflow; Calaveras Reservoir release/recapture; Calaveras Reservoir spill; San Antonio Reservoir inflow; San Antonio Reservoir release; San Antonio Reservoir spill.
[c] Accretion 1 = average monthly runoff volume from drainage area between diversion dam and confluence of Alameda and Calaveras Creeks = (unimpaired inflow to San Antonio Reservoir) x (0.253).
Accretion 2 = average monthly runoff volume from drainage area between Calaveras/Alameda Creek and San Antonio/Alameda Creek confluences = (unimpaired inflow to San Antonio Reservoir) x (0.221).

Peninsula Watershed System

The Peninsula watershed system encompasses SFPUC facilities in the Peninsula watershed. These include Upper and Lower Crystal Springs Reservoirs, San Andreas Reservoir, Pilarcitos Reservoir, and Stone Dam. Local watercourses include San Mateo Creek and Pilarcitos Creek. The following is a list of locations within the Peninsula system analyzed using HH/LSM data.

Releases to Rivers/Creeks

1. Lower Crystal Springs Reservoir releases to San Mateo Creek

Reservoir Storage

2. Upper/Lower Crystal Springs Reservoir storage and water levels
3. San Andreas Reservoir storage and water levels

These analysis locations are shown in **Figure 5**.

Data for releases from Upper/Lower Crystal Springs to San Mateo Creek were readily available from the HH/LSM output data. Releases from Upper/Lower Crystal Springs Reservoir presented in this analysis include both spills and releases from the dam. San Antonio Reservoir releases/spills to San Mateo Creek (which flows to Lower Crystal Springs Reservoir) did not occur in the 82 years of hydrology, so tables were not generated for this location. Additionally, as discussed above in Section 3.2, Model Limitations, Pilarcitos Reservoir storage and release as

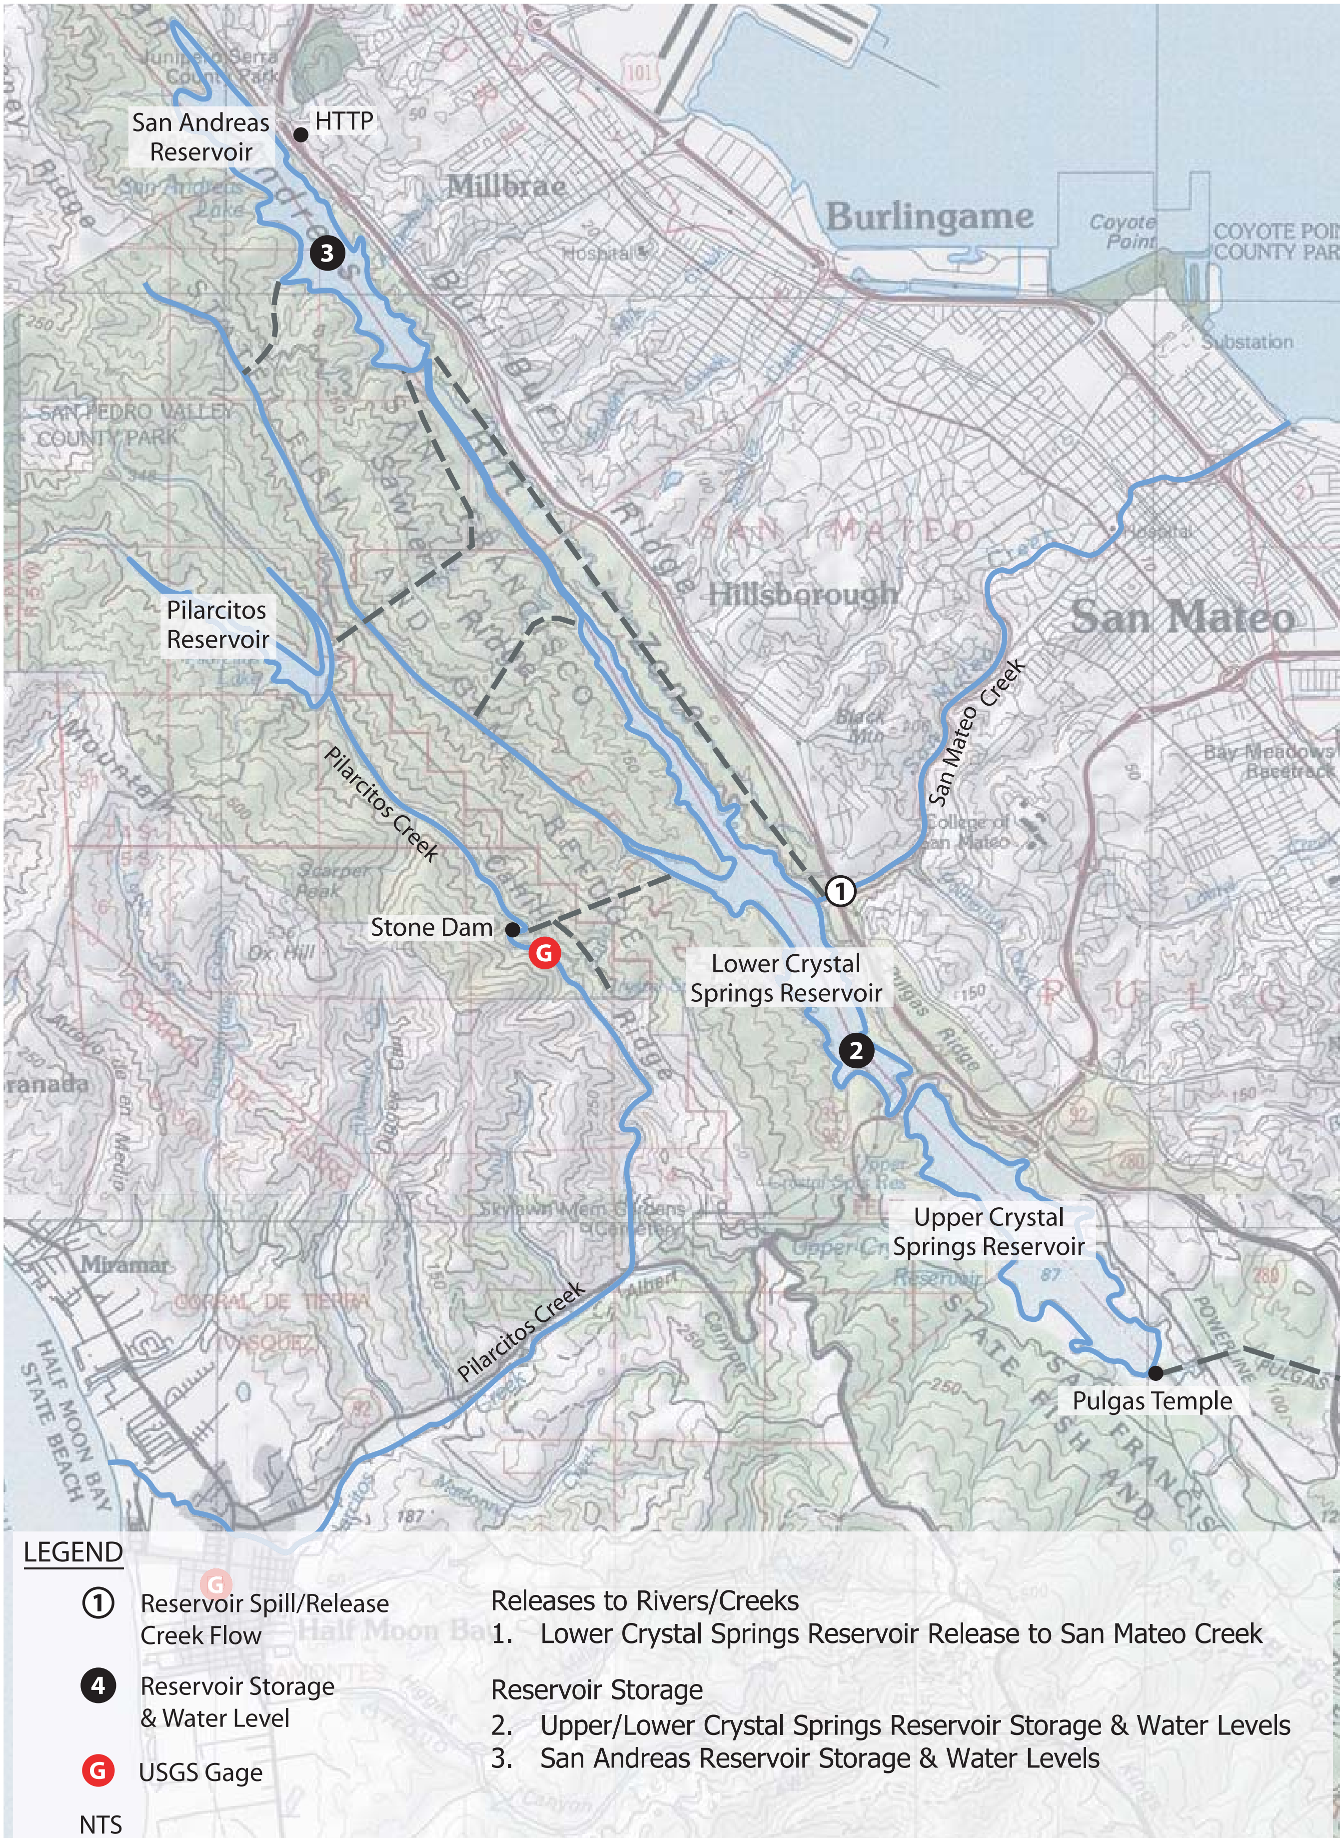

Figure 5 (Appendix H1)
Peninsula System Flow and Storage Analysis Locations

well as Stone Dam release predicted by the HH/LSM model were not analyzed due to inaccuracies in the model for these two facilities. Supplemental analysis of these two facilities, as well as all facilities in the Peninsula System, is provided in Appendix H2, Hydrologic Modeling Assumptions and Results.

Reservoir storage data for Upper/Lower Crystal Springs and San Andreas were readily available from HH/LSM output, and water surface elevations were calculated using SFPUC-supplied storage-elevation curves.

In addition to the analyses listed above for the Peninsula watershed system, statistics were developed for the summary tables. Statistics presented in the Peninsula watershed system summary table are self-explanatory.

5. Post-processed Model Outputs

Summaries of the analyses performed according the methodology outlined in this document are provided in **Tables 9**, **10**, and **11**. The tables correspond to each of the three systems, Tuolumne, Alameda and Peninsula, respectively.

Complete results from the HH/LSM model output analysis are available for review at the SF Planning Department and the SFPUC offices. An index of these tables and a table of contents for each system analysis is provided below.

APPENDIX H2

Hydrologic Modeling – Supporting Information

[Additional discussion on water resources modeling was prepared as part of the Comments and Responses document. Please refer to Section 13.3, Updated Water System Assumptions and Modeling (Vol. 7, Chapter 13), and to Appendix O, Hydrologic Modeling – Additional Supporting Information (Vol. 8).]

APPENDIX H2-1

Memorandum

Subject: **HH/LSM Assumptions and Results – Proposed WSIP**
From: **Daniel B. Steiner**
Date: **March 18, 2007**

1. Introduction

This memorandum summarizes assumptions for, and discusses the interpretation of, Hetch Hetchy Local Simulation Model (HH/LSM) results for the simulation of the Water System Improvement Program ("WSIP" or the "proposed program"). Table 1-1 and Table 1-2 summarize the program/setting characteristics and modeling assumptions, and the performance and hydrologic results, respectively, for the WSIP as they compare to the modeled existing setting (2005, with Calaveras Reservoir constrained by the California Division of Safety of Dams (DSOD) restrictions) and the pre-2002 setting (with Calaveras Reservoir operation prior to DSOD restrictions).

The hydrology of the proposed program is primarily discussed in terms of a comparison to the baseline condition of the Program Environmental Impact Report (PEIR), i.e., the simulated current (2005) operation of the regional system, assuming that the operation of Calaveras and Crystal Springs Reservoirs is constrained by DSOD restrictions. Primary hydrologic parameters such as projected water deliveries, reservoir storage, and stream flows are compared, and additional parameters that assist in identifying causes of hydrologic changes are also described as needed. Key hydrologic factors that lead to environmental impact assessment are illustrated.

Notes for Table 1-1 and Table 1-2

1. Baseline condition represents the existing conditions at the time of NOP publication in September 2005. This is the baseline used to assess WSIP program impact and impact significance. This setting indicates DSOD restrictions on Calaveras and Crystal Springs Reservoirs.

2. This baseline condition represents a system configuration and operation prior to the DSOD storage restriction (pre-2002).

3. More features and elements of the WSIP exist. Only features affecting the hydrologic analysis are illustrated.

4. The time horizon for the setting of the scenario. The baseline condition scenarios are depicted for recent conditions, while the proposed WSIP, variants, and alternatives are depicted for the future at full buildout and implementation, i.e., conditions in the year 2030.

5. HH/LSM model simulation study name.

6. The customer purchase request (demand) information is based on the demand and request studies prepared by the SFPUC in coordination with the wholesale customers (SFPUC/URS 2004). This demand on the regional water system includes both the SFPUC retail customers and wholesale customers. The current (2005) average annual demand is 265 mgd and the projected 2030 average annual demand is 300 mgd, assuming the SFPUC adopts the updated wholesale customer purchase requests as part of the Master Sales Agreement renewal with these customers (due in 2009).

7. Certain scenarios include the development of additional water supply from a combination of recycled water projects, groundwater projects, and conservation, utilized every year and not subject to reduction during drought.

8. The average annual demand for supplies from the combination of the SFPUC local watershed and Tuolumne River, as well as programs not included in the regional water conservation, reclamation, and groundwater programs shown.

9. Modeled results for SFPUC deliveries, with supplies added for regional water conservation, reclamation, and groundwater programs. Total deliveries and supply will be less than full customer purchase requests due to rationing in some years.

10. Shows only the features that affect hydrologic results of the system operation simulations. Additional projects are included in the WSIP, variants, and alternatives.

11. Illustrates the frequency and severity of water supply action or severity of system-wide rationing. Only years in which variable water supply component is implemented or rationing occurs are shown. "DD" illustrates the shortage results for years included in the prospective drought period of the SFPUC Design Drought. These years contribute to establishing system operation protocols, but are not included in the hydrologic assessment analyses.

12. Rationing policy cap: The SFPUC WSIP level of service goal is to maintain rationing on the regional system at no more than 20% during any one year of drought. Some alternatives do not achieve this level of service goal. Performance is indicated for both the Design Drought ("DD") sequence and "Historical" hydrologic sequence.

13. Water supply elements develop water in different amounts from year to year, and, in some instances, they only develop water during dry years. This information is provided to compare local watershed supplies, Tuolumne River supplies, and other identifiable water supplies used to meet system purchase requests. Values are stated in units of average annual quantities during the simulated historical sequence.

14. Results from HH/LSM analysis of each scenario. Values represent the average annual production of each element of supply during the design drought period.

15. Simplified calculation of system deliveries during the SFPUC design drought. The value represents the application of system-wide shortages to the demand level being met with SFPUC local watershed, Tuolumne, and other developed supplies, and does not include supplies from regional water conservation or from recycled water or groundwater projects. Average value may be slightly misstated (up to 3 mgd) due to metric of analysis that does not account for differences in residual storage between studies. "Nominal" firm yield represents the yield of each scenario after adjustment for minor residual storage differences.

16. Supplemental releases from Calaveras Reservoir for fisheries (1997 MOU) of up to 6,300 AFY and the Alameda Creek Recapture project are tied to implementation of the Calaveras Dam replacement project. When the dam is replaced and capacity restored, both the flow release and recapture will occur. The release requirement is based on the supplementation of other occurring flows below Calaveras Reservoir, sometimes not requiring the full 6,300 acre-feet.

17. SFPUC actions are assumed to leave MID/TID diversions unchanged so that the SFPUC effects on the Tuolumne River below La Grange Dam are isolated and possibly overstated. The Districts' diversions are assumed to be constant among the scenarios to provide comparable results of SFPUC-alone effects.

18. Participation in the San Joaquin River Agreement is assumed. Although the agreement expires after 2010, it is assumed that a subsequent similar agreement or requirement of the Districts will occur. HH/LSM does not explicitly model the Districts' participation in the agreement; however, its participation if modeled would result in only minor differences in results and would not change impact conclusions.

19. From HH/LSM results for modeling the SFPUC Design Drought Period.

20. From HH/LSM results for modeling the system operations for the historical hydrologic period 1921-2002. Values indicate average annual quantities during the simulated historical period.

2. Proposed WSIP

The San Francisco Public Utilities Commission (SFPUC) proposes to adopt and implement the WSIP to increase the reliability of the Regional Water System. The WSIP is a program to implement the service goals and system performance objectives established by the SFPUC for the Regional Water System in the areas of water quality, seismic reliability, delivery reliability, and water supply through the year 2030.

The WSIP level of service objectives for water supply are to: (1) fully meet customer purchase requests in non-drought years through planning year 2030, estimated at 300 ,million gallons per day (mgd) average annual delivery; and (2) provide drought-year delivery with a maximum system-wide delivery reduction (rationing) of 20 percent in any one year of a drought. These objectives correspond to a required system firm yield of 256 mgd in 2030. System firm yield is defined as the average annual water delivery that can be sustained throughout an extended drought. The current firm yield of the system is 219 mgd under the current restricted operating conditions that limit storage levels in Calaveras and Crystal Springs Reservoirs. In the setting prior to restrictions to the operation of the reservoirs, the system firm yield is estimated to be 226 mgd.

During non-drought years, the SFPUC would serve the increased 35 mgd in purchase requests through a combination of conservation, water recycling, groundwater supply programs, increased diversions from the Tuolumne River, and greater utilization of Bay Area watershed supplies associated with the restoration of operational storage capacity (primarily at Calaveras Reservoir). The SFPUC would implement conservation, water recycling, and groundwater supply programs in the SFPUC retail service area to achieve the equivalent of 10 mgd of supply per year, in all years. These programs would be in addition to demand management and conservation measures already accounted for in the 2030 purchase request for the retail service area.

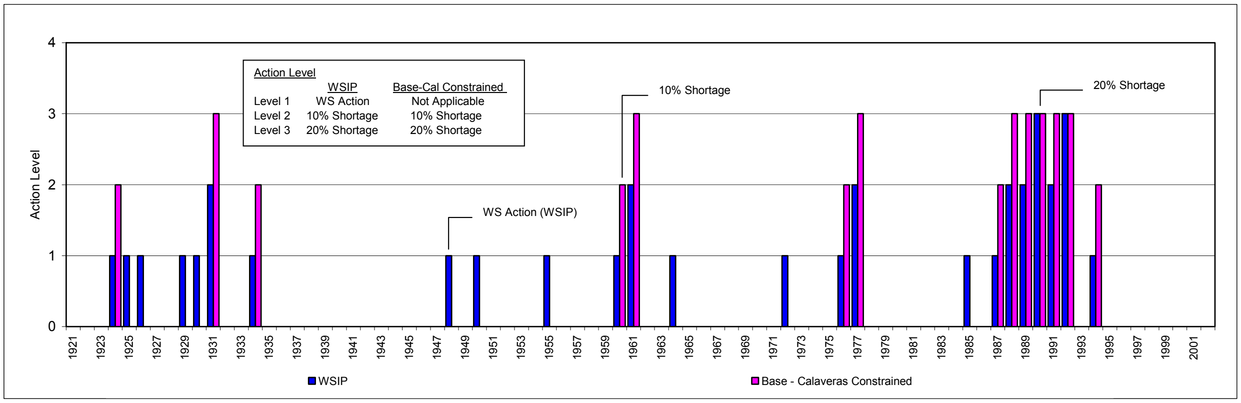
In most years, the SFPUC could serve the projected 2030 water purchases of 300 mgd with its existing sources of water supply; however, these sources alone have not allowed for full water deliveries during past droughts, and they would be insufficient during future droughts as purchase requests increase. The SFPUC proposes to serve this 2030 need for increased system firm yield (i.e., water supply during a drought scenario) with a combination of conservation, water recycling, and groundwater programs in the SFPUC retail service area; water transfers from the Turlock Irrigation District (TID) and Modesto Irrigation District (MID); a groundwater conjunctive-use program, incorporating the Westside Basin Groundwater Program; and restoration of reservoir operating capacity at Crystal Springs and Calaveras Reservoirs. System-wide rationing is limited to no more than 20 percent in any year, with a firm yield of 256 mgd throughout an extended drought.

2.1 Water Deliveries and Drought Response Actions

With a current system-wide purchase request of approximately 265 mgd, the Regional Water System cannot provide full deliveries during all anticipated drought sequences. Drought response actions (delivery shortages) are necessary at the onset of a drought to provide a viable, albeit reduced, supply throughout the duration of drought. Because the Regional Water System has limited current resources, rationing of the SFPUC supply by more than 20 percent may be required during an extended drought. With the proposed program, the purchase requests would increase from 265 mgd to 300 mgd, with 10 mgd of this request satisfied by conservation, recycling, and groundwater programs in the city of San Francisco. In the future, the Regional Water System would experience a net demand of 290 mgd. The additional net demand and increase in the water supply reliability of the Regional Water System would be served by the water supply programs described above. Table 1-1 compares the drought response actions for the proposed program and base-Calaveras constrained settings. Figure 2.1-1 illustrates the drought response actions for the simulated 82-year historical period (1921-2002).

In Figure 2.1-1, years with bars showing a “1” or greater level of action indicate periods when a supplemental water supply action is initiated. In the WSIP setting, the action is the use of the Westside Basin Groundwater Program to supplement SFPUC water deliveries. The water transfer from MID/TID is also occurring during these periods. Action levels greater than “1” indicate the imposition of delivery shortages (rationing) to SFPUC customers.

Figure 2.1-1
Drought Response Actions – WSIP and Base-Calaveras Constrained



In modeling parlance, there is no level 1 action level in the base setting. Without supplemental resources, the existing system only has the delivery shortage measure available to cope with drought. This shortage measure is imposed during level 2 (10 percent) and level 3 (20 percent). These percentages of shortage are applied to both the WSIP and the base settings for these action levels. As evidenced in Figure 2.1-1, rationing would be required more frequently and with greater severity in the base-Calaveras constrained setting (level 2 and level 3 actions).

Figure 2.1-2 illustrates the same information in comparing the WSIP setting to the base-Calaveras unconstrained setting. The same general differences occur between the WSIP and the base-Calaveras unconstrained settings. The WSIP would decrease the frequency of imposed water delivery shortages, and at times reduce the severity of shortages.

Figure 2.1-2
Drought Response Actions – WSIP and Base-Calaveras Unconstrained

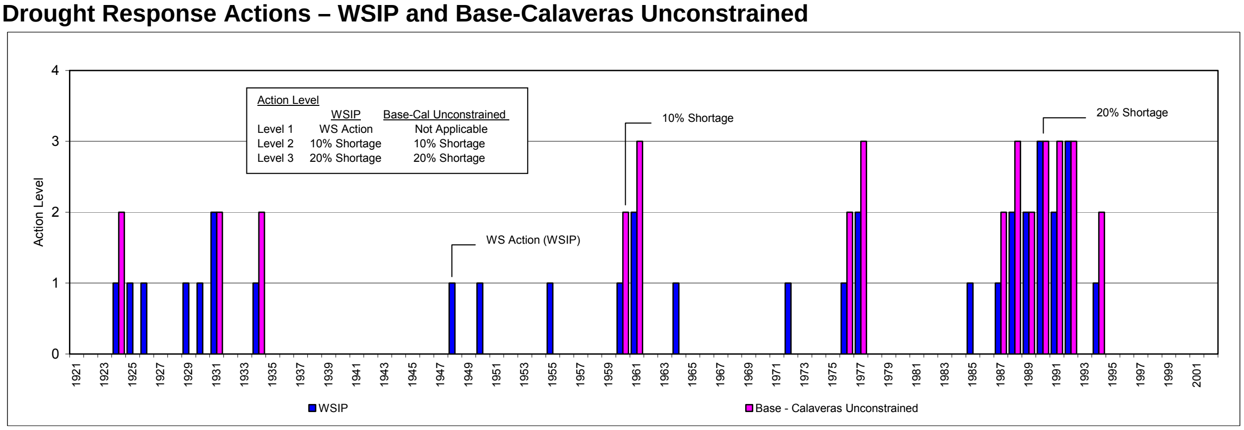


Figure 2.1-1 and Figure 2.1-2 illustrate that, when compared to the base settings, the WSIP setting triggers the supplemental resource (Westside Basin Groundwater Program) at an early indication of drought and during periods, when in the base settings there were no supplemental resources available to the system. The utilization of the supplemental resource during these times results in the elimination or reduction, or at least a non-increase in the severity, of delivery shortage.

Although not illustrated in Figure 2.1-1 or Figure 2.1-2, Table 1-1 shows the delivery shortages anticipated during the entire SFPUC Design Drought. Shortages during the Design Drought with the WSIP are maintained within the objective to limit the severity of shortage to no more than 20 percent. With the existing system (Calaveras and Crystal Springs Reservoirs constrained), the 20-percent-limitation (cap) objective cannot be achieved during the last 18 months of the Design Drought, and a 25-percent shortage is applied. The system's yield in this setting is 219 mgd. In the base-Calaveras unconstrained setting, the 20-percent limitation could be achieved; however, the frequency of imposing that level of rationing exceeds the SFPUC objective for the Design Drought.

The difference in water deliveries between the proposed program and the base-Calaveras constrained settings is shown chronologically for the 82-year simulation in Table 2.1-1. The differences all indicate an increase in deliveries due to an increase in the level of purchase requests, and an increase in the reliability of delivery. The annual (fiscal year-based) increase of approximately 9,100 million gallons represents the basic increase in delivery associated with an increase in purchase request from 265 mgd to 290 mgd. The annual increase of approximately 6,500 mgd indicates years during which the Westside Basin Groundwater Program provides a supplemental supply to the system and offsets the demand needed from other SFPUC resources. The positive difference following this period, approximately 11,800 million gallons per year, represents years when replenishment of the Westside Basin Groundwater Program is necessary after the draw from the program. The years that show other levels of additional deliveries represent years when shortages are reduced in the WSIP setting compared to the base-Calaveras constrained setting.

Table 2.1-2 presents the same information in comparing the WSIP setting with the base-Calaveras unconstrained settings. The results for system-wide deliveries are predominantly the same, except for periods when the base-Calaveras unconstrained setting has slightly improved water supply reliability (less rationing) than the base-Calaveras constrained setting. During these periods, the increase in deliveries due to the WSIP would be slightly less than that of the base-Calaveras constrained setting.

2.2 Diversions from Tuolumne River

The metric for illustrating the SFPUC diversion from the Tuolumne River Basin is the flow through the San Joaquin Pipeline (SJPL). Table 2.2-1 illustrates the difference in diversions to the SJPL between the proposed program and the base-Calaveras constrained settings. Evident in the operation is the increase in summer diversions associated with the increase in the conveyance capacity of the SJPL. Regardless of an increase in purchase requests, the availability of increased conveyance capacity would increase diversions during the summer to retain storage in the Bay Area reservoirs, typically exercising the SJPL at its maximum capacity. The increase in purchase requests would require the utilization of the maximum capacity for a longer period into the fall. Generally, fewer diversions would occur during the late fall and early winter because of the lesser drawdown of the Bay Area reservoirs (requiring less replenishment), and because systematic maintenance within Hetch Hetchy facilities (lessening available conveyance capacity) would impair diversions in the WSIP setting. The increase in diversions during the winter and spring would result from the need to replenish Bay Area reservoir storage after the maintenance period, serve increased purchase requests and top off Bay Area reservoir storage prior to summer. The difference in SJPL diversions between the WSIP setting and the base-Calaveras constrained setting is illustrated in Figure 2.2-1. The difference in average monthly diversion through the SJPL is shown by year type for the 82-year simulation period.

Table 2.2-2 illustrates the average monthly diversion through the SJPL, by year type, for the 82-year simulation period for the proposed program and the base-Calaveras constrained settings. The table illustrates a trend of less diversion of water from the Tuolumne River Basin in wetter years (as Bay Area reservoir watersheds provide more supply during those years) than in drier years. Table 2.2-3 illustrates the same form of information in comparing diversions through the SJPL between the WSIP and the base-Calaveras unconstrained settings.

Table 2.1-1

Difference in Total System-wide Delivery (MG)

WSIP minus Base - Calaveras Constrained

2.3 Hetch Hetchy Reservoir and Releases

The additional draw of water for the additional deliveries of the WSIP will generally result in an increase in draw from Hetch Hetchy Reservoir. Figure 2.3-1 illustrates a chronological trace of the simulation of Hetch Hetchy Reservoir storage and stream releases. Shown in Figure 2.3-1 are the results for the WSIP, base-Calaveras constrained ("Base – Calaveras Constrained") and base-Calaveras unconstrained ("Base – Calaveras Unconstrained") settings. Supplementing the Figure 2.3-1 representation of Hetch Hetchy Reservoir storage are Table 2.3-1 Hetch Hetchy Reservoir Storage (WSIP), Table 2.3-2 Hetch Hetchy Reservoir Storage (Base - Calaveras Constrained), and Table 2.3-3 Difference in Hetch Hetchy Reservoir Storage (WSIP minus Base – Calaveras Constrained).

Table 2.3-3 illustrates the difference in Hetch Hetchy Reservoir storage between the WSIP and base-Calaveras constrained settings. Immediately after Hetch Hetchy Reservoir is filled (May or June, and then continuing through July), occasional differences in storage would occur, typically during a multi-year drought sequence or during an occasional single year when the reservoir does not fill. No reduction in yearly storage during that period would indicate that the same amount of water is being passed through the reservoir, regardless of the size of the conveyance capacity of the SJPL or the purchase request. Water not diverted to the SJPL would return to the Tuolumne River at Kirkwood Powerhouse or Moccasin Reservoir and flow to Don Pedro Reservoir. In the late summer and early fall, storage levels would consistently be slightly different (lower) between the two settings, as additional diversions to the SJPL would retain Bay Area reservoir storage. The additional storage depletion would be somewhat ameliorated later in the fall and into winter as SJPL diversions are reduced because of lower Bay Area reservoir replenishment needs and conveyance system maintenance. The storage difference would become almost neutral in December with the WSIP setting because of the additional conveyance maintenance that would occur in the WSIP (and which does not occur in the base-Calaveras constrained setting). The maintenance impairs diversions to the SJPL. After December, storage in the reservoir associated with the WSIP setting again would be affected as replenishment of Bay Area reservoir storage resumes following the maintenance period and because of increased purchase requests. During drier years, there is a difference in storage between the WSIP and base-Calaveras constrained settings; the alternative setting results in a lower amount of storage in the reservoir by the end of April. Figure 2.3-2 illustrates the reservoir storage, averaged by year type, for the WSIP setting. Figure 2.3-3 illustrates the average difference in storage, averaged by year type, for the two settings during the 82-year simulation. Figure 2.3-4 illustrates the average monthly storage in Hetch Hetchy Reservoir for the 82-year simulation, and the range in storage for each month for the WSIP and base-Calaveras constrained settings.

The difference in storage in Hetch Hetchy Reservoir attributed to the diversion effects of the WSIP would manifest into differences in releases from O'Shaughnessy Dam to the stream. A different amount of available reservoir space in the winter and spring due to the WSIP would lead to a different ability to regulate inflow, thus potentially changing the amount of water released to the stream (which is above minimum release requirements). Figure 2.3-1 illustrates the stream release from O'Shaughnessy Dam for the WSIP and base settings. Supplementing Figure 2.3-1 are Table 2.3-4 and Table 2.3-5, which illustrate the stream release from O'Shaughnessy Dam for the WSIP and base-Calaveras constrained settings. Table 2.3-6 illustrates the difference in stream releases between the WSIP and base-Calaveras constrained settings. Compared to the base-Calaveras constrained setting, the WSIP setting typically results in a lesser stream release, predominantly during May or June, which reflects the months when releases to the stream above minimum release requirements are made in anticipation of the reservoir being filled. In a few exceptions to this circumstance, an increase in release to the stream occurs. Several of these exceptions are considered anomalous within modeling, the results of only shifting releases from one month to another. The other exceptions occur due to the balancing of reservoir storage among the Hetch Hetchy system and the Bay Area reservoirs. The decrease in releases is the result of a more depleted reservoir, which is the result of greater demands between the settings.

Table 2.3-6 illustrates the difference in stream release between the WSIP and base-Calaveras constrained settings, expressed in terms of a monthly volume (acre-feet) of flow. The difference in monthly flow below O'Shaughnessy Dam indicates a potential change in releases between the WSIP and base-Calaveras constrained settings, ranging from a decrease of approximately 46,000 acre-feet to an increase of approximately 13,000 acre-feet. Considering the manner in which releases are determined and made to the stream, quantifying the effect of these changes in terms of average monthly flow (in cubic feet per second [cfs]) is not always meaningful.[1] Assuming that a change in release volume equates to a delay or earlier initiation of releasing 6,000 acre-feet per day, the difference in stream release from O'Shaughnessy Dam between the WSIP and base-Calaveras constrained settings would range from delayed releases up to 8 days to an addition of up to 2 days of release. Normally, the effect of a delay in release would not affect the year's peak stream release rate during a year.

2.4 Lake Lloyd and Lake Eleanor

Compared to the operation in the base-Calaveras constrained setting, the operation of Lake Lloyd and Lake Eleanor are simulated to be only slightly different in the WSIP setting. Figure 2.4-1 illustrates a chronological trace of the simulation of Lake Lloyd storage and stream releases. Figure 2.4-1 shows the results for the WSIP and base settings. The operation resulting for the WSIP setting is essentially the same as for the base-Calaveras constrained setting, except during the prolonged drought of 1987-1992. During this drought period, there is a greater draw from Hetch Hetchy Reservoir in the WSIP setting compared to the base-Calaveras constrained setting. The additional draw of water reduces the amount of water released from Hetch Hetchy Reservoir to Don Pedro Reservoir in the WSIP setting, which, to satisfy MID/TID entitlements to inflow, is met with additional releases from Lake Lloyd.

Figure 2.4-2 illustrates an almost identical operation of Lake Eleanor between the WSIP and base-Calaveras constrained settings. Also shown in Figure 2.4-2 is the operation for the base-Calaveras unconstrained setting. Any difference that occurs in the Lake Eleanor operation would be caused by a small change in operation at Lake Lloyd that would affect the operation of the Cherry-Eleanor Tunnel between the two watersheds. Any difference that occurs in the simulations is associated more with modeling discretion than with any substantive likely difference in operation.

Supplementing the Figure 2.4-1 representation of Lake Lloyd stream releases is Table 2.4-1, which illustrates the differences in stream release between the WSIP and base-Calaveras constrained settings. The one notable difference in operation of the 82-year simulation occurs during the year following the rare 1987-1992 drought sequence, when the additional draw from Lake Lloyd storage described above would require replenishment. In this one occurrence, the release to the stream above the minimum release requirement that would occur in the base-Calaveras constrained setting would not occur in the WSIP setting. Table 2.4-2 illustrates releases for the WSIP and base-Calaveras constrained settings, and shows almost no difference in releases between the two settings.

2.5 Flow below Tuolumne River and Cherry River Confluence

The flow that occurs below the confluence of the Tuolumne River and Cherry River is considered important to recreational activity (white water rafting) during the May-through-September period. To estimate the affect of WSIP on the occurrence of flow at this location, HH/LSM monthly volumetric flow results were post-processed to reflect the daily and hourly shaping potential currently exercised by Hetch Hetchy operators to satisfy water and power objectives while accommodating the desires of recreational interests. Figure 2.5-1 and Figure 2.5-2 illustrate the controlled flow below Hetch Hetchy facilities below the confluence of the Tuolumne River and Cherry River, averaged by year type, for the WSIP and base-Calaveras constrained settings. Illustrated are the combined flow elements of: 1) stream releases from O'Shaughnessy Dam, Lake Lloyd, and Lake Eleanor; 2) the return of Canyon Tunnel diversions through Kirkwood Powerhouse that exceed the Mountain Tunnel diversion; and 3) diversions through Holm Powerhouse. For this analysis, the monthly volumes of diversion through Holm Powerhouse have been shaped into a release of 4 hours per day for 6 days a week. The other flow elements represent the

Figure 2.5-1

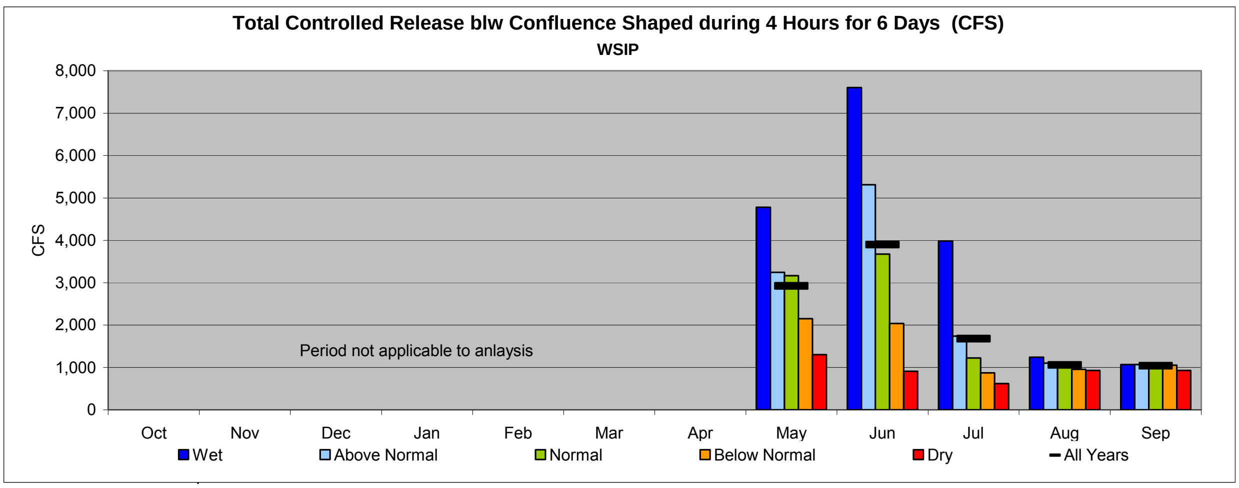

Figure 2.5-2

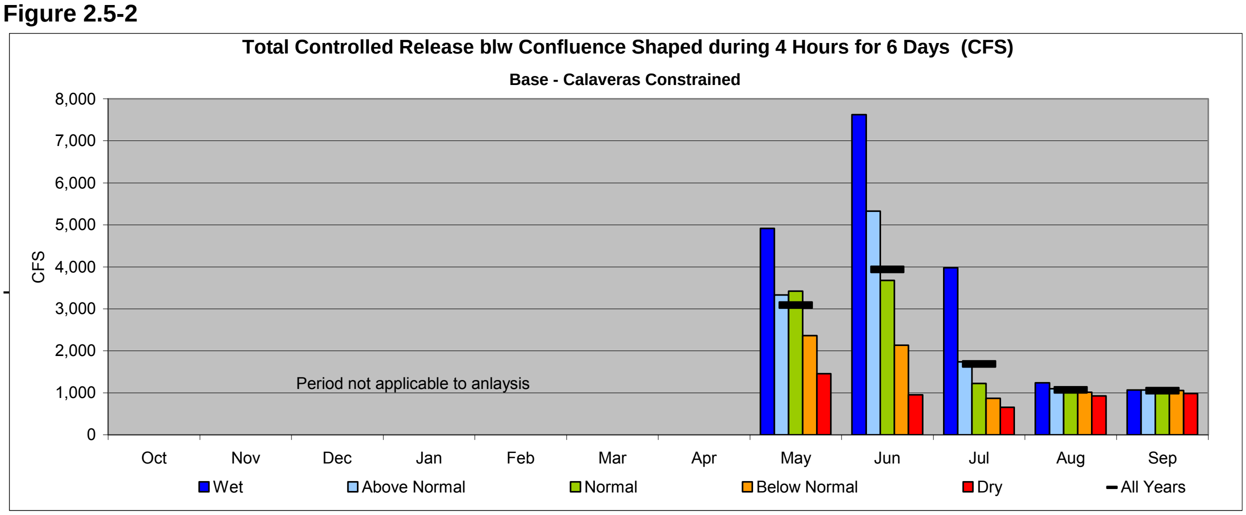
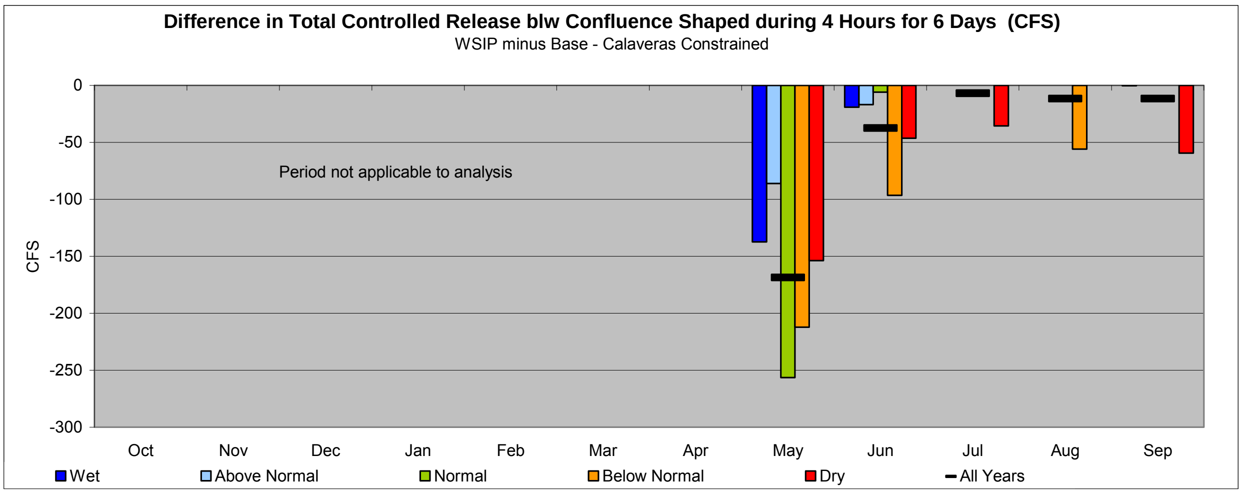


average daily flow rate associated with the monthly volume of flow. Figure 2.5-1 and Figure 2.5-2 illustrate that the HH/LSM operation protocols for reservoir operation incidentally result in approximately 1,000 cfs of flow below the confluence if Holm Powerhouse releases are shaped. This opportunity occurs in both the WSIP and base-Calaveras constrained settings. The flow rates illustrated in this analysis do not reflect either the occasional shaping opportunities that occur with Kirkwood Powerhouse releases or the unregulated flow that enters the streams below O'Shaughnessy Dam, Lake Lloyd, and Lake Eleanor; both of these factors would increase the illustrated flow rate. The difference in flow between the two settings that could occur during the concentrated period of flow is illustrated in Figure 2.5-3.

Figure 2.5-3



More detailed review of the 82-year simulation of operations indicates that, in only 2 months of the simulation do circumstances in the WSIP setting result in the shaped flow crossing the threshold to below 1,000 cfs, compared to levels greater than 1,000 cfs in the base-Calaveras constrained setting. In both the WSIP and base-Calaveras constrained settings, in some dry and critical years, circumstances could result in a shaped flow of less than 1,000 cfs; however, results indicate that the WSIP setting would rarely increase the frequency of such an occurrence.

2.6 Don Pedro Reservoir and La Grange Releases

A change in Don Pedro Reservoir operation is caused by changes in inflow to the reservoir. The changes in inflow to the reservoir are the result of net changes within the operation of the upstream SFPUC facilities, described previously, and other changes in SFPUC operations associated with diversions to the Holm, Kirkwood, and Moccasin Powerhouses. Figure 2.6-1 illustrates a chronological trace of the simulation of Don Pedro Reservoir storage and Tuolumne River stream releases from La Grange Dam. Figure 2.6-1 presents the results for the WSIP and base settings.

Supplementing the Figure 2.6-1 representation of Don Pedro Reservoir storage are Table 2.6-1 Don Pedro Reservoir Storage (WSIP), Table 2.6-2 Don Pedro Reservoir (Base – Calaveras Constrained), and Table 2.6-3 Difference in Don Pedro Reservoir Storage (WSIP minus Calaveras Constrained). The results illustrate that, throughout many years, the storage in Don Pedro Reservoir associated with the WSIP setting would differ from the storage in the WSIP setting, and that this difference would almost always be less storage. Compared to the base-Calaveras constrained setting, the differences in storage indicate the decreases to the inflow of Don Pedro Reservoir due to greater SFPUC demands and SJPL diversions in the WSIP setting. The decreases in inflow typically occur from winter through early summer. Table 2.6-4 illustrates the difference in inflow to Don Pedro Reservoir between the WSIP and base-Calaveras constrained settings. Generally, the difference is an annual amount of about 30,000 acre-feet, approximating the additional delivery of the SFPUC. The season of inflow reduction is associated with the direct increase in diversion to the SJPL and the replenishment operation of Hetch Hetchy Reservoir. Figure 2.6-2 illustrates the seasonal change in Don Pedro Reservoir inflow, averaged by year type.

Figure 2.6-2

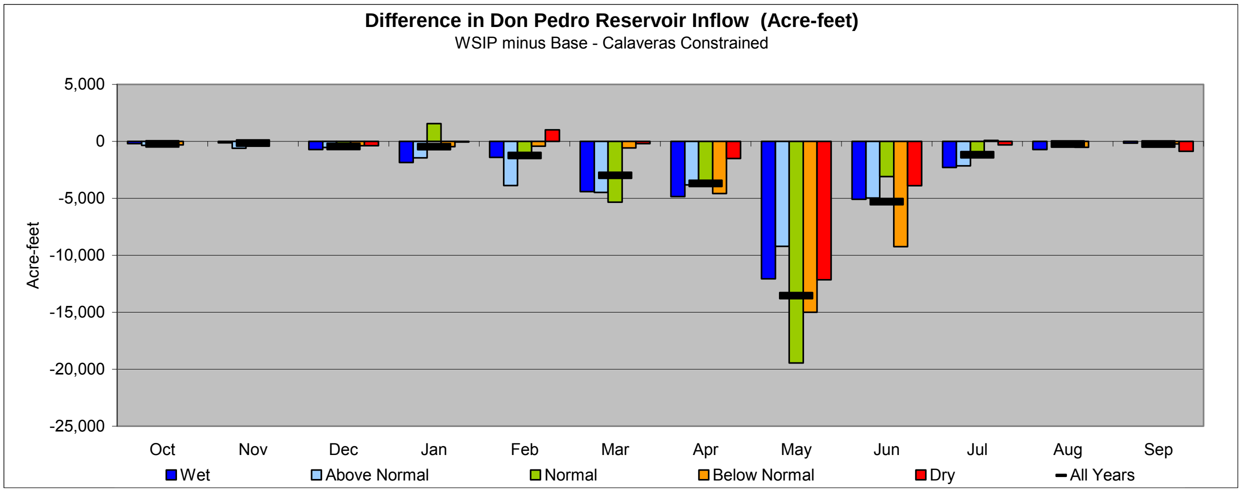

Figure 2.6-1 and Table 2.6-3 illustrate that, during drought sequences, the reduction in inflow to Don Pedro Reservoir can accumulate from year to year. Compared to the base setting, the WSIP would result in lower Don Pedro Reservoir storage during some part of most years, and more predominantly during multi-year drought periods. Figure 2.6-3 illustrates the Don Pedro Reservoir storage for the WSIP setting, averaged by year type. Figure 2.6-4 illustrates the difference in reservoir storage, averaged by year type, in comparing the WSIP and base-Calaveras constrained settings. Also shown is the average difference in storage for the two settings during the 82-year simulation.

Table 2.6-3 illustrates that, in some years (approximately one-third of the years, i.e., the wettest of years), the storage in Don Pedro Reservoir would not be substantially different, because large inflows to the reservoir during these years would require the management of storage (release of flow above minimum stream requirements) to satisfy flood control requirements. During the other years, the reduction in storage could range from a single year's additional diversions by the SFPUC to over 200,000 acre-feet (1993) from the accumulation of several years of additional diversions by the SFPUC. For example, the greatest draw from reservoir storage occurs during the drought of 1976-1977 (during which the WSIP would not cause an incremental additional draw from storage), and the greatest difference in reservoir draw between the base-Calaveras constrained setting and the WSIP occurs during the year of the 1987-1992 drought.

Figure 2.6-5 illustrates the average monthly storage in Don Pedro Reservoir for the 82-year simulation, and the range in storage for each month for the WSIP and base-Calaveras constrained settings. The difference in storage in Don Pedro Reservoir attributed to the upstream effects of the WSIP would affect releases from La Grange Dam to the stream. A difference in the amount of available reservoir space in the winter and spring due to the WSIP would lead to a difference in the ability to regulate inflow, thus potentially changing the amount of water released to the stream that is above minimum release requirements. During periods when inflow differs and Don Pedro Reservoir is at maximum storage capacity within the flood control storage limitation, a change in inflow would directly manifest as a change in release from La Grange Dam (a change in either more or less flow). Figure 2.6-1 illustrates the stream release from La Grange Dam for the WSIP and base settings.

Figure 2.6-3

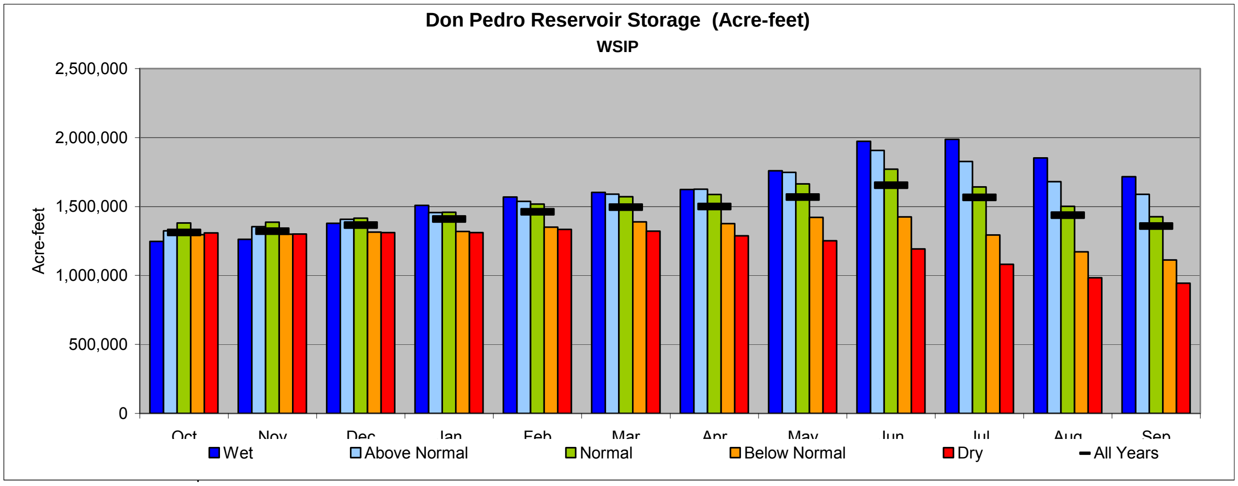

Figure 2.6-4

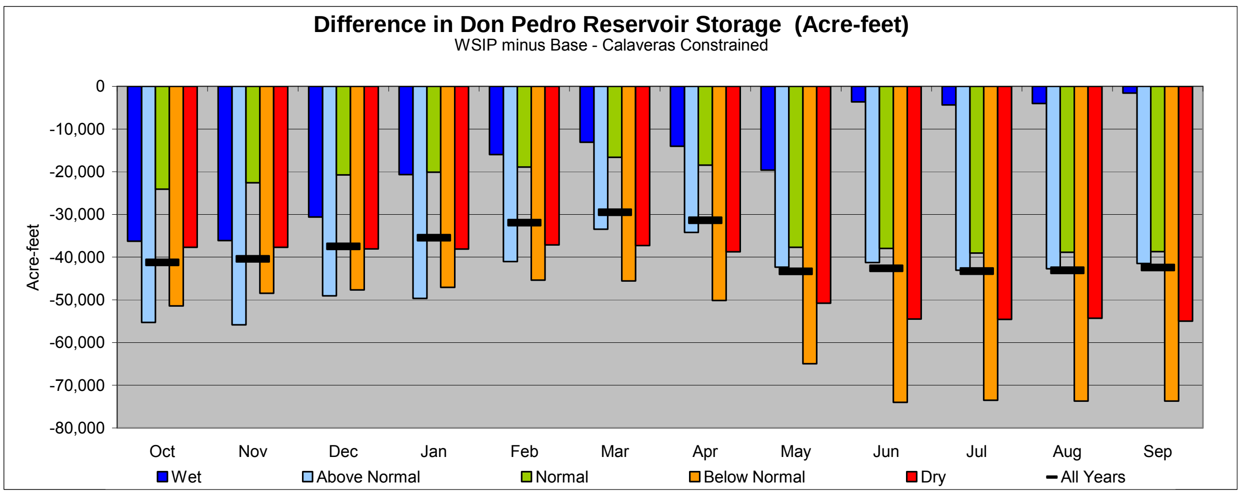

Figure 2.6-5

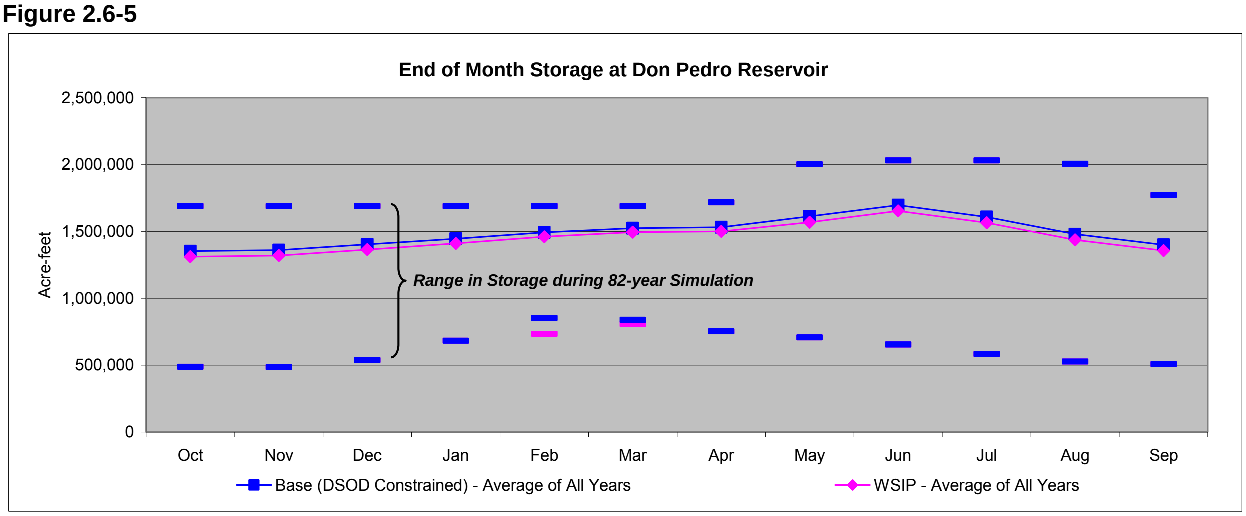

Supplementing Figure 2.6-1 are Table 2.6-5 and Table 2.6-6, which illustrate the releases to the Tuolumne River from La Grange Dam for the WSIP and base-Calaveras constrained settings. Table 2.6-7 shows the difference in stream releases between the WSIP and base-Calaveras constrained settings. Consistent with the periods showing changes in Don Pedro Reservoir storage, stream releases following the draw down periods would indicate a reduction. The additional depletion of reservoir storage would manifest as a reduction in subsequent releases below La Grange Dam to replenish reservoir storage. The same information shown in Table 2.6-7 is illustrated in Table 2.6-8, arranged in descending order of San Joaquin River index. The differences in releases to the Tuolumne River from La Grange Dam would occur only when there would otherwise be releases in excess of minimum Federal Energy Regulatory Commission (FERC) flow requirements, typically during wetter years. Occasional minor reductions in releases would also occur during winter, when the direct diversion of additional water by the SFPUC would lead to a commensurate reduction in inflow to Don Pedro Reservoir. If Don Pedro Reservoir is passing inflow for flood control, a similar commensurate reduction in release would occur. Table 2.6-7 illustrates the decrease in monthly flow below La Grange Dam that would occur, up to approximately 188,000 acre-feet in one month (June 1993). This reduction is associated with the additional replenishment of Don Pedro Reservoir caused by the additional diversions of the SFPUC during the drought of 1987-1992. The effects of the SFPUC diversions accumulate in Don Pedro Reservoir throughout the drought period. Using an assumption that a change in release volume equates to a delay or acceleration of releasing 6,000 acre-feet per day means that the difference in stream release from La Grange Dam between the WSIP and the base-Calaveras-constrained settings would be a delay in releases above minimum FERC flow requirements up to an entire month. Normally, the effect of the delay in release would not affect the year’s peak stream release rate during a year. However, infrequently, and, in this instance (the WSIP’s affect upon stream releases), an elimination of all flows could occur during this year (rather than an exceedance of minimum FERC flow requirements). Such a large and lengthy reduction in flow would not be common, and would occur only because of the multi-year droughts.

Comparing the WSIP and base-Calaveras constrained settings, Table 2.6-9 illustrates the releases to the Tuolumne River below La Grange Dam; their differences are provided in terms of monthly volumetric flow averaged within year types.

Table 2.6-5

Total La Grange Release to River (Acre-feet)

WSIP

2.7 Calaveras and San Antonio Reservoirs, Alameda Creek and Downstream

Compared to the base-Calaveras constrained setting, Calaveras Reservoir operations would substantively change in the WSIP setting. With the restoration of Calaveras Reservoir operating capacity, the reservoir would operate with a larger storage capacity. Compared to the base-Calaveras unconstrained setting, the WSIP operation of Calaveras Reservoir would generally be the same, but its range of reservoir fluctuation would typically be less. Figure 2.7-1 illustrates a chronological trace of the simulation of Calaveras Reservoir storage and stream releases from Calaveras Dam. Shown in Figure 2.7-1 are the results for the WSIP and base settings.

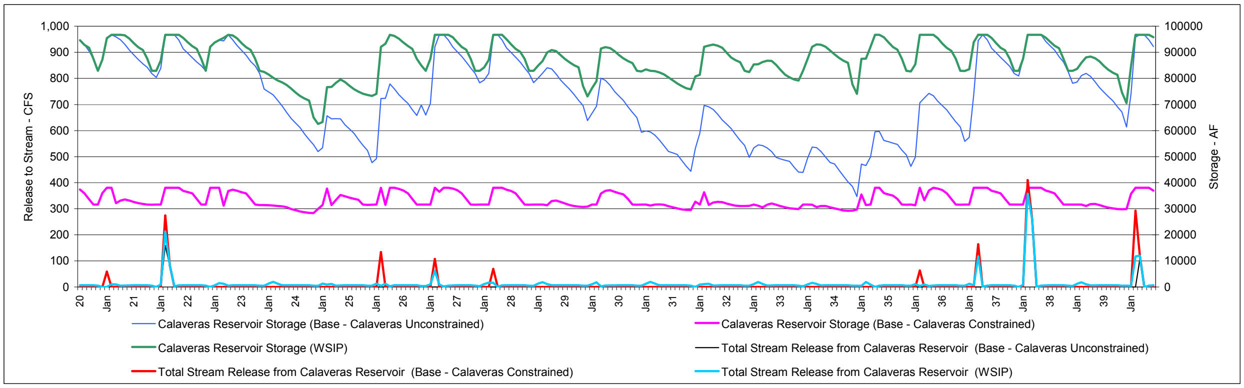
The current operation of Calaveras Reservoir (base-Calaveras constrained setting) is modeled to be greatly constrained, to vary only within a limited storage range. Although a within-year cyclic operation occurs for the conservation of local watershed runoff, there is relatively little reservoir storage available for year-to-year carryover and multi-year drought use. In the WSIP setting, a greater within-year cyclic operation occurs, providing for a greater use of local watershed runoff. Also, during prolonged periods of drought (i.e., multiple years in duration), reservoir storage would be drawn to supplement runoff available to the regional system and other water supply resources.

When compared to the base-Calaveras unconstrained setting, the WSIP operation retains greater storage within a year and for longer periods during a drought. Although greater purchase requests and a greater level of water supply delivery occur in the WSIP setting, Calaveras Reservoir storage would incidentally be operated “fuller” than before. Within a year, more storage would be retained in Calaveras Reservoir during the summer because of additional conveyance capacity in the SJPL, lessening the burden of storage releases from the Bay Area reservoirs. Although the target storage (operational buffer) for the fall draw down of the reservoir would sometimes result in the same amount of storage in either setting, storage during the summer in the WSIP setting would be greater, for a longer period of time. Retained storage also occurs in the WSIP setting because of the reduced use of Calaveras Reservoir and San Antonio Reservoir supplies for the maintenance of desired minimum water production at Sunol Valley Water Treatment Plant (Sunol Valley WTP). In the WSIP setting, water required for Sunol Valley WTP production can be acquired from the SJPL.

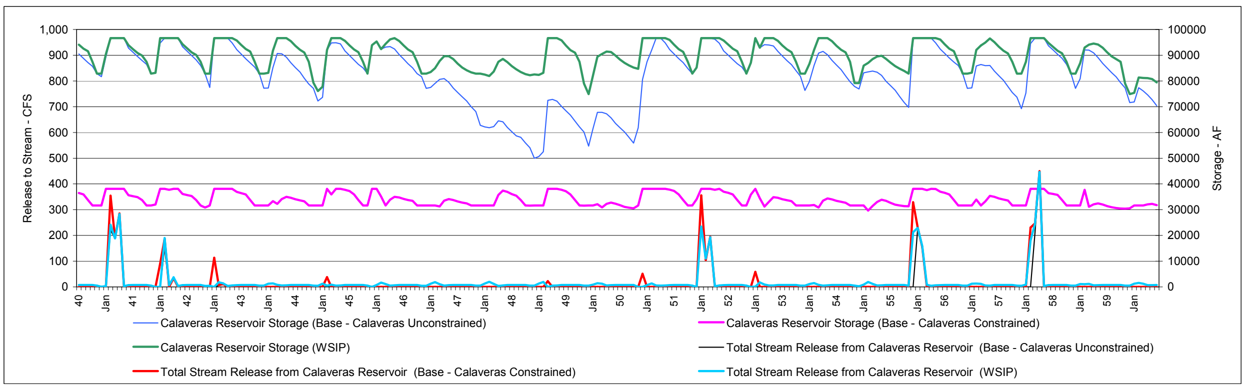
Figure 2.7-2 illustrates the average monthly storage in Calaveras Reservoir for the 82-year simulation, and the range in storage for each month for the WSIP and base-Calaveras constrained settings. Figure 2.7-3 illustrates the same form of information for the WSIP and base-Calaveras unconstrained settings.

Figure 2.7-1
Calaveras Reservoir Storage and Stream Release

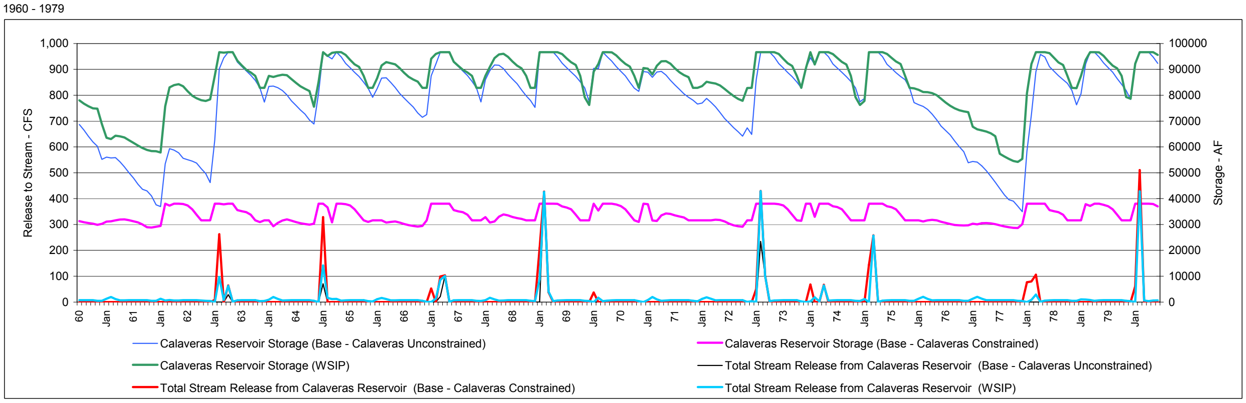
1920 - 1939



1940 - 1959



1960 - 1979



1980 - 2002

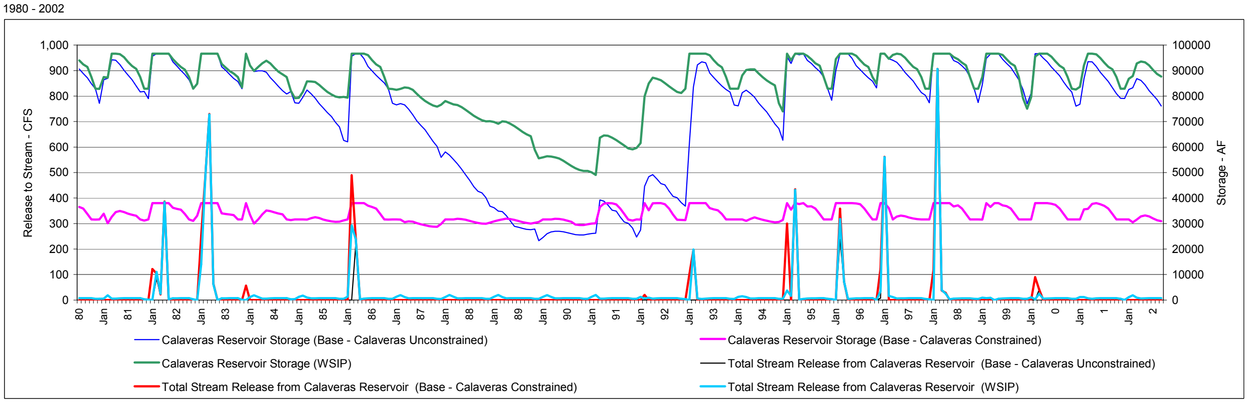


Figure 2.7-2

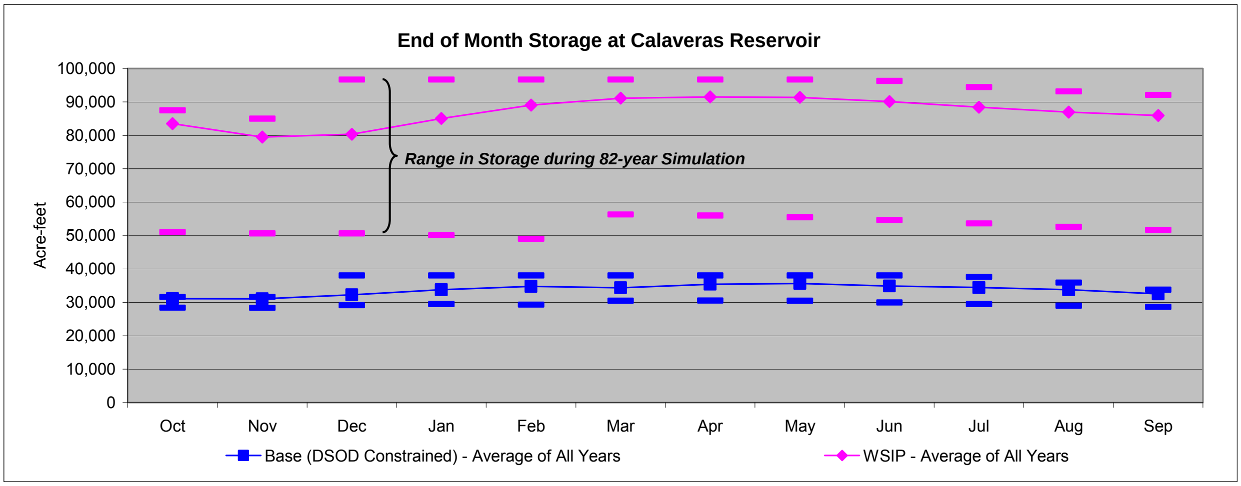

Figure 2.7-3

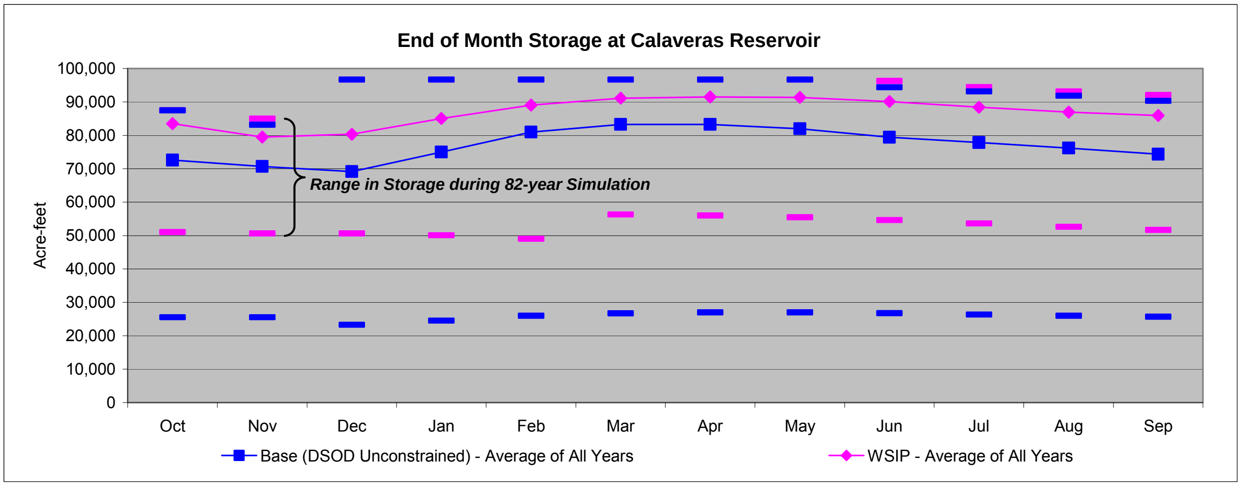

In the WSIP setting (as compared to the base-Calaveras constrained setting), there would be two categorical changes in releases to Calaveras Creek below Calaveras Dam: the addition of flows representing the flow objectives associated with the1997 Memorandum of Understanding (MOU); and the reduction of stream releases during wetter-year/wetter-season flows due to the restored operational capacity of Calaveras Reservoir. Supplementing the Figure 2.7-1 representation of Calaveras Dam stream releases is Table 2.7-1, illustrating releases for the WSIP and base-Calaveras constrained settings and the difference in releases between the two.

Table 2.7-2 illustrates the same form of information for Calaveras Dam releases to the stream in comparing the WSIP setting to the base-Calaveras unconstrained setting. The difference in releases between the settings is, again, the result of two factors: the additional flows representing the flow objectives associated with the1997 MOU; and the reduction of stream releases during wetter-year/wetter-season flows due to restored Calaveras Reservoir operational capacity.

Compared to the base-Calaveras constrained setting, diversions from Alameda Creek to Calaveras Reservoir would increase in the WSIP setting. With the current constraints on Calaveras Reservoir storage, diversions to Calaveras Creek are rejected. With the restoration of operational storage in the reservoir, the opportunity to divert water into the reservoir would increase.

To provide a context to the amount of water diverted at Alameda Creek Diversion Dam, Table 2.7-3 illustrates the estimated runoff (inflow) to the dam, averaged by year type. Table 2.7-4 compares diversions to Calaveras Reservoir in the WSIP and base-Calaveras constrained settings. An increase in diversions during the winter season due to WSIP operation would generally occur during normal or wetter year types, as reservoir storage space would accommodate diversions. During summer in all years and during all periods in below normal and normal years, diversions would continue as they do currently. A few exceptions would occur when diversions would be reduced from that of the base-Calaveras constrained setting.

Table 2.7-5 illustrates the same form of information in comparing diversions to Calaveras Reservoir between the WSIP and base-Calaveras unconstrained settings. In this comparison, less water would be diverted to Calaveras Reservoir in the WSIP setting, because of the greater amount of storage retained by the reservoir than in the base-Calaveras unconstrained setting. As described above with regard to Calaveras Reservoir storage, even with an increase in deliveries and releases for the downstream fishery the reduction in Sunol Valley WTP diversions would result in a greater retention of storage in the reservoir. A fuller reservoir would result in a greater frequency of periods when diversions from Alameda Creek would be rejected.

Commensurate with changes in diversions from Alameda Creek to Calaveras Reservoir would be changes to the flow below the Alameda Creek Diversion Dam. Table 2.7-6 illustrates the flow below the Alameda Creek Diversion Dam for the WSIP and base-Calaveras constrained settings. Table 2.7-6 illustrates that, opposed to diversions to Calaveras Reservoir, flow passing Alameda Creek Diversion Dam would decrease in the WSIP setting. With operational capacity restored at Calaveras Reservoir, there would be more opportunity (and need) to divert Alameda Creek flows; thus, flow passing the dam would be reduced.

Comparing the WSIP and base-Calaveras unconstrained setting, there would more flow passing Alameda Creek Diversion Dam in the WSIP setting. As described above concerning diversions of these settings, a more frequent rejection of the diversions in the WSIP setting would occur than in the base-Calaveras unconstrained setting. Table 2.7-7 illustrates these modeling results.

The increase or decrease in flow passing the Alameda Creek Diversion Dam would occur non-systematically, not necessarily at the beginning or end of a winter season. The month (or shorter period) during which the change would occur would be governed by the coincidence of many factors, including reservoir storage, system-wide conveyance maintenance, and current hydrology.

Flow below the confluence of Alameda Creek and Calaveras Creek is affected by releases from Calaveras Dam to the stream, flow passing Alameda Creek Diversion Dam, and unregulated flow below Alameda Creek Diversion Dam and Calaveras Dam. Table 2.7-8 illustrates the flow below the confluence for the WSIP and base-Calaveras constrained settings, and the difference in inflow between the two. The notable differences between the WSIP and the base-Calaveras constrained settings are the addition of stream flows representing the 1997 MOU and the reduction of wetter-year/wet-season flows due to the restoration of Calaveras Reservoir storage.

Table 2.7-9 illustrates the same form of information in comparing flows below the confluence for the WSIP and base-Calaveras unconstrained settings. As described above, in the WSIP setting, Calaveras Reservoir would retain more storage than in the base-Calaveras unconstrained setting, which would lead to additional rejection of water from Alameda Creek and an increase in spills of Calaveras Creek water from Calaveras Reservoir. In combination with fishery releases from Calaveras Dam to Calaveras Creek, more flow in all years would occur below the confluence.

A flow recapture facility in Alameda Creek below Calaveras Reservoir is incorporated in the WSIP setting. This facility is assumed to recapture flows explicitly released from Calaveras Dam in the representation of the 1997 MOU. The effect of the recapture is a reduction in the flow that occurs below the confluence of Alameda and Calaveras Creeks, but only to the extent that releases were explicitly made from Calaveras Reservoir. Flows below this diversion have been estimated and noted as the flow above the Alameda and San Antonio Creek confluence. Table 2.7-10 illustrates the flow at this location for the WSIP and base-Calaveras constrained settings. The flows identified at this location indicate flow occurring below the confluence of Alameda and Calaveras Creeks (described above), with the addition of estimated unregulated stream accretions between the Alameda-Calaveras Creek confluence and the Alameda-San Antonio Creek confluence minus the water assumed to be recaptured (diverted) by the SFPUC from the creek. The same form of information is illustrated in Table 2.7-11 in comparing the WSIP and base-Calaveras unconstrained settings.

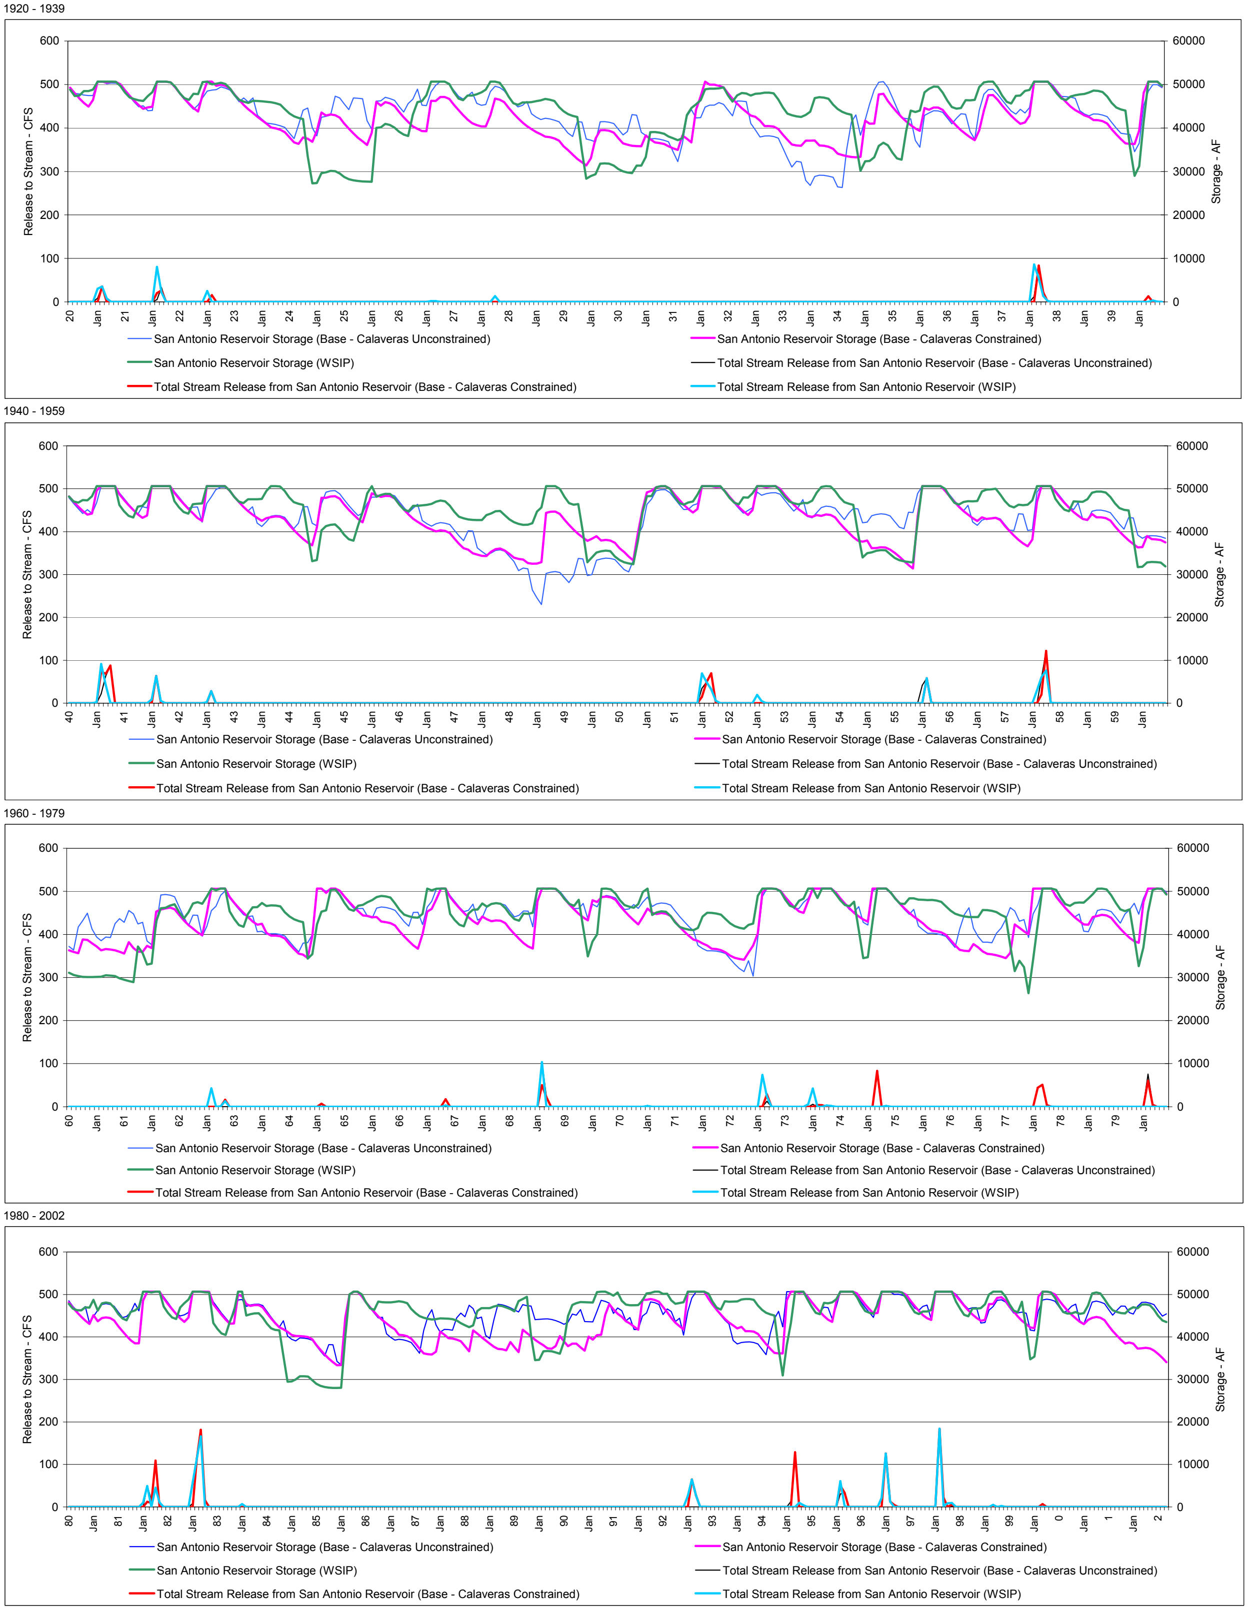
The difference in San Antonio Reservoir storage between the WSIP and base-Calaveras constrained settings is the result of several factors, and is predominantly due to the restoration of the operational capacity of Calaveras Reservoir, the use of SJPL flow for maintenance of Sunol Valley WTP production, and the maintenance of Hetch Hetchy conveyance. Figure 2.7-4 illustrates a chronological trace of the simulation of San Antonio Reservoir storage and stream releases from the dam. Shown in Figure 2.7-4 are the results for the WSIP and base settings. In the base-Calaveras constrained setting, the limited operating storage capacity at Calaveras Reservoir leads to a different operation at San Antonio Reservoir, one that draws relatively more stored water for system demands when the draw from Calaveras Reservoir is constrained due to limited storage. The resultant effect is that the WSIP setting would retain more storage in San Antonio Reservoir than in the base-Calaveras constrained setting. The exception to this outcome is during cyclic maintenance of Hetch Hetchy conveyance that will constrain Hetch Hetchy diversions every year, but most dramatically every fifth year. During these periods, additional water will be drawn from San Antonio Reservoir and the other Bay Area reservoirs to serve system-wide deliveries when limited or no water will be available from Hetch Hetchy. The coincidence of wet local Bay Area watershed hydrology, reservoir storage balancing among the Bay Area reservoirs, and maintenance affects the severity of draw down and rate of replenishment of San Antonio Reservoir.

Figure 2.7-4
San Antonio Reservoir Storage and Stream Release



Also affecting the magnitude of draw from San Antonio Reservoir are modeling assumptions for the balancing of total Bay Area reservoir storage among the five major SFPUC reservoirs. The model balances storage between reservoirs by way of an input file by the modeler concerning the relative draw (percentage) from each reservoir under various storage conditions. These are discretionary input in the model, and the logic and relative percentages are meant to mimic the current practice and discretion of the system operators based on recognition of the physical conveyance constraints within the system and the ability of each reservoir to provide yield and water delivery security. The logic currently favors the retention of storage in the peninsula reservoirs for security reasons, and thus the provision of additional water between the settings is balanced between San Antonio and Calaveras Reservoir.

Compared to the base-Calaveras unconstrained setting, relative changes in San Antonio Reservoir operations in the WSIP generally lead to conclusions that mirror the differences experienced for the comparison to the base-Calaveras constrained operation. The WSIP setting would typically result in a reservoir less drawn upon, except during periods when system-wide conveyance maintenance would additionally burden Bay Area reservoir storage. Figure 2.7-5 illustrates the average monthly storage in San Antonio Reservoir for the 82-year simulation, and the range in storage for each month for the WSIP and base-Calaveras constrained settings. Figure 2.7-6 illustrates the same form of information in comparing the WSIP and base-Calaveras unconstrained settings.

Figure 2.7-5

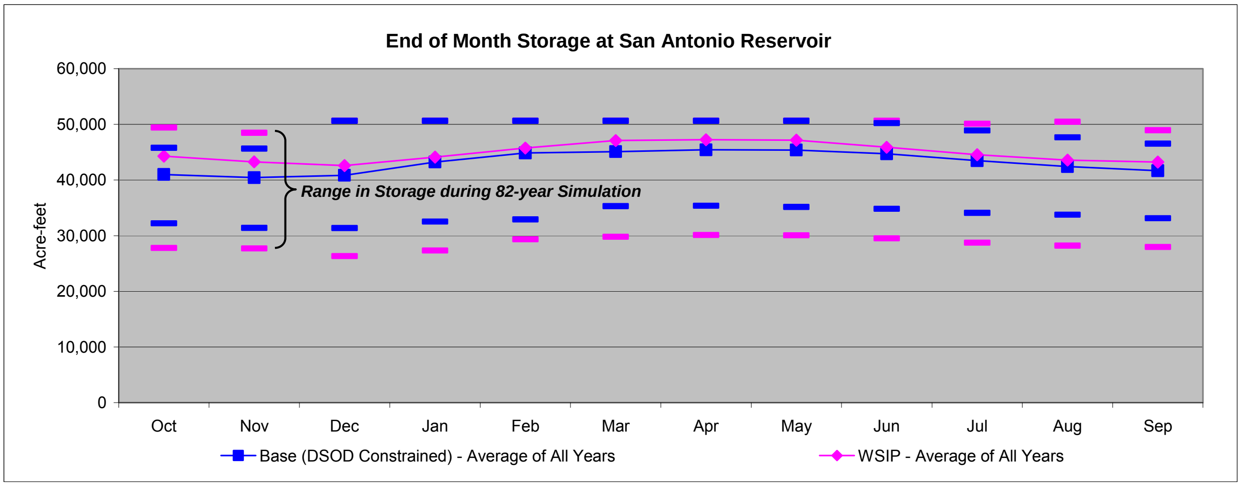


Figure 2.7-6

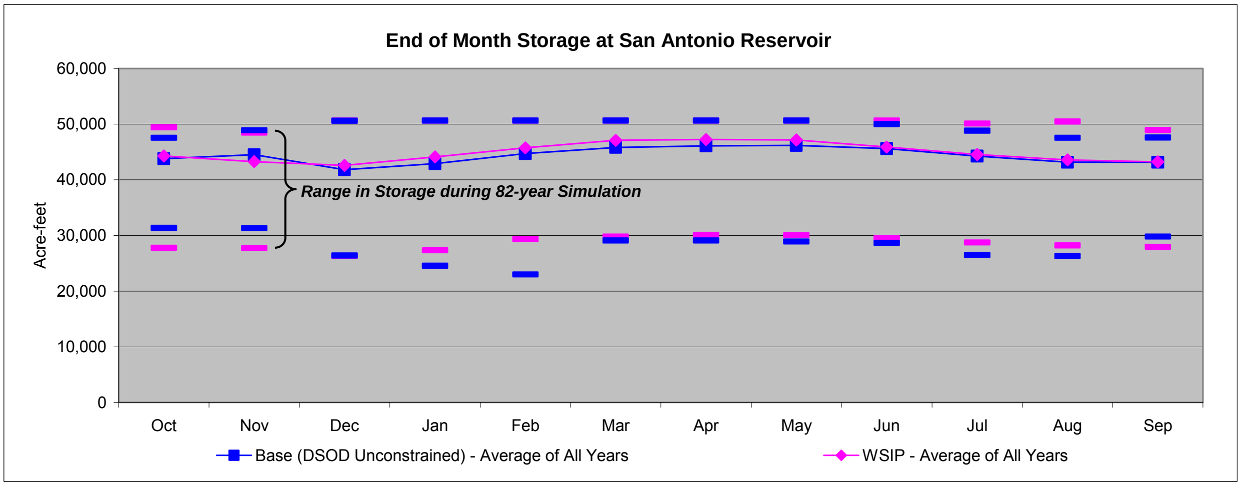

There would very little change in stream releases below San Antonio Reservoir between the WSIP and base settings. With storage conditions lower at some times and higher at other times, a difference in the ability to regulate reservoir inflow and avoid stream releases is expected. Given the sometimes rigid constraints within the modeling assumptions, the model will overestimate the frequency and magnitude of stream releases from San Antonio Reservoir under any of the investigated settings. The flexibility that occurs in actual operations would likely avoid most of the releases represented by the model. The modeled stream releases from San Antonio Reservoir and difference between releases for the WSIP setting and base-Calaveras constrained setting are shown in Table 2.7-12. The differences among the two settings range from increases to decreases in flow. This modeled circumstance reflects the different resulting storage operation between the two settings as seen in Figure 2.7-4. As described above, the model will overestimate the frequency and magnitude of releases from San Antonio Reservoir, and the actual releases from San Antonio Reservoir in any setting and the difference between settings are expected to be minor. Table 2.7-13 illustrates the same form of information in comparing the WSIP and base-Calaveras unconstrained settings.

Flow below the confluence of Alameda and San Antonio Creeks is influenced by releases from San Antonio Reservoir and flow arriving at the location from Alameda Creek, which includes upstream impairment by SFPUC operations and facilities. Table 2.7-14 illustrates the flow below the confluence for the WSIP and base-Calaveras constrained settings, and the differences in flow between the two. The differences are particularly due to the effects of the restoration of Calaveras Reservoir operating capacity in the WSIP setting. The same form of information for the flow below the San Antonio Creek and Alameda

Creek confluence is illustrated in Table 2.7-15 in comparing the WSIP and base-Calaveras unconstrained settings.

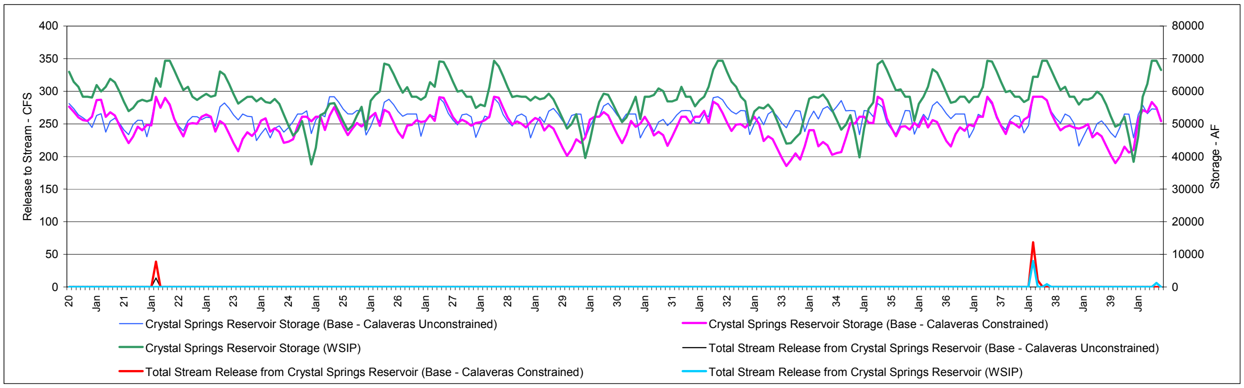
2.8 Crystal Springs and San Andreas Reservoirs

Fundamental to the difference in storage operations between the WSIP setting and the base settings is the restoration of reservoir operation capacity in the WSIP setting, which does not occur in the base settings. The result is the operation of Crystal Springs Reservoir at a higher maximum storage in the WSIP setting. Figure 2.8-1 illustrates a chronological trace of the simulation of Crystal Springs Reservoir storage and stream releases from Springs Dam. Shown in Figure 2.8-1 are the results for the WSIP and base settings.

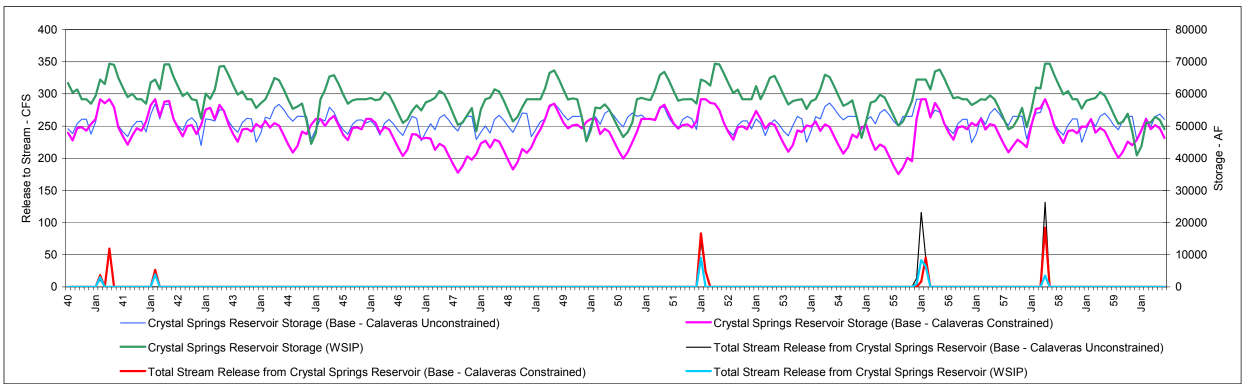
Compared to the base-Calaveras constrained setting, the WSIP setting would generally result in a shifting of the maximum storage level and the range of reservoir operation to a greater volume (elevation); the lower end of the monthly operating range would normally be greater in storage than in the base-Calaveras constrained setting. In some years, the variation from maximum storage to minimum storage may increase in the WSIP setting.

Figure 2.8-1
Crystal Springs Reservoir Storage and Release

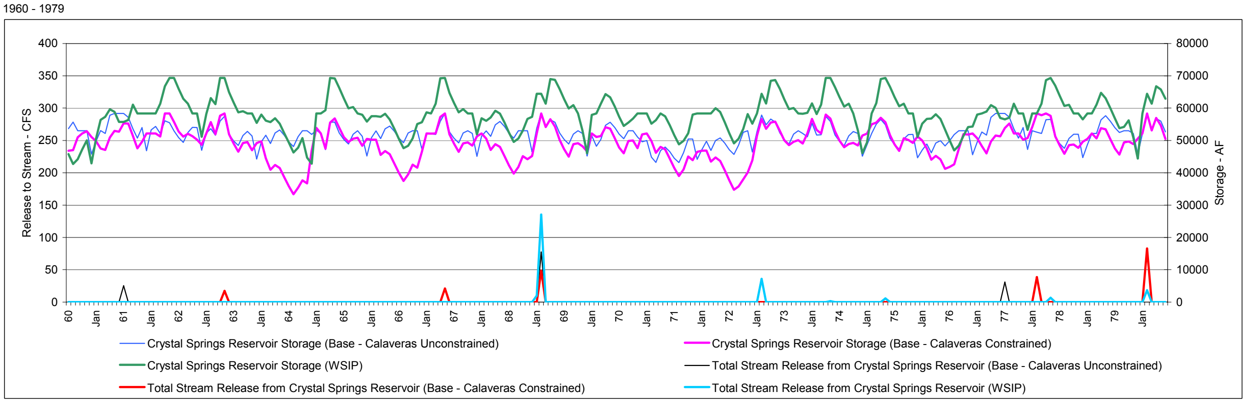
1920 - 1939



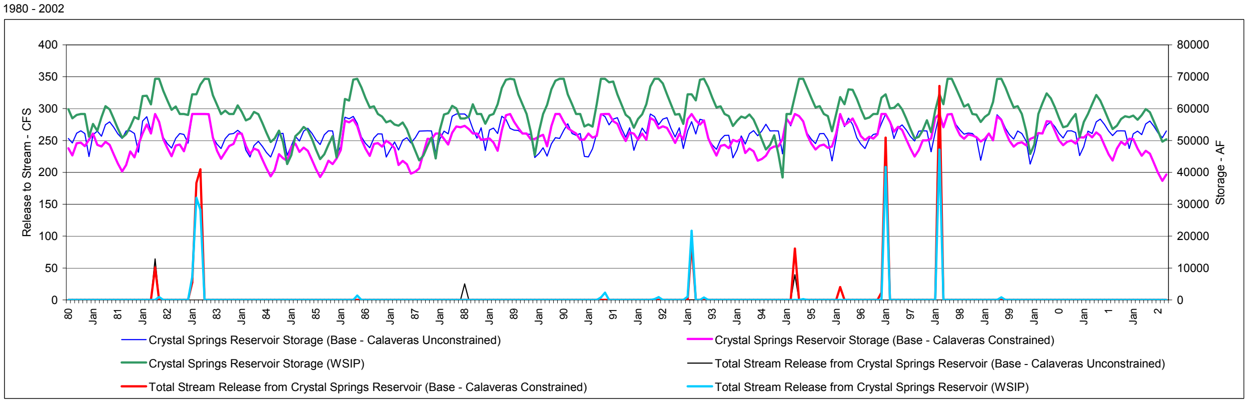
1940 - 1959



1960 - 1979



1980 - 2002



The comparison of the WSIP setting to the base-Calaveras unconstrained setting is about the same as for the comparison to the base-Calaveras constrained setting. The differences are slightly less pronounced because the base-Calaveras unconstrained setting results in a less exercised reservoir than the base-Calaveras constrained setting. The base-Calaveras unconstrained setting typically draws less water cyclically from Crystal Springs Reservoir due to the ability of Calaveras Reservoir to serve system-wide deliveries.

Figure 2.8-2 illustrates the average monthly storage in Crystal Springs Reservoir for the 82-year simulation, and the range in storage for each month for the WSIP and base-Calaveras constrained settings. Consistent with the discussion above, the WSIP setting would result in reservoir storage operating at a higher average and higher upper-range than the base-Calaveras constrained setting. This circumstance predominantly occurs due to the restoration of the operating capacity of Crystal Springs Reservoir. The same form of information is illustrated in Figure 2.8-3 in comparing the WSIP and base-Calaveras unconstrained settings.

There is minimal difference in stream releases between the WSIP and base settings (which could be either an increase or decrease in the release). The potential difference is attributed to whether the different resulting storage in the reservoir is higher or lower between the two settings. Part of the difference in modeled Crystal Springs Reservoir storage is due to modeling assumptions for the proportionate management of storage among the Bay Area reservoirs, and the coincidence of constrained conveyance flow rates. In actual operations, it is anticipated that system operators would manage the reservoir system such that stream releases would be minimal under any setting and essentially no difference would occur between the WSIP and base settings.

Table 2.8-1 illustrates the stream releases for the WSIP and base-Calaveras constrained settings, and the difference in modeled flows between the two settings. A greater operating range in Crystal Springs Reservoir operation would lead to an increased potential to regulate reservoir inflow, which would lead to less risk in needing to make stream releases. However, as described above, actual system operations will attempt to minimize releases under any setting; thus, the difference in releases between the variant and base setting will be minimal, if any. Table 2.8-2 illustrates the same form of information in comparing modeled stream releases between the WSIP and base-Calaveras unconstrained settings.

San Andreas Reservoir operations would generally be the same between the WSIP and base settings. Reservoir storage would follow a systematic filling and lowering each year in managing runoff. Figure 2.8-4 illustrates the average monthly storage in San Andreas Reservoir for the 82-year simulation, and the range in storage for each month for the WSIP and base-Calaveras constrained settings. Figure 2.8-5 illustrates a chronological trace of the simulation of San Andreas Reservoir storage and stream releases from Springs Dam. Shown in Figure 2.8-5 are the results for the WSIP and base settings. There are no projected stream releases from San Andreas Reservoir in any setting. Notable in Figure 2.8-5 is the difference in storage operation every fifth year. The WSIP setting storage operation differs from the base settings. The differences in operation arise from the assumed difference in Hetch Hetchy conveyance maintenance in each setting. In the WSIP setting, the maintenance occurs systematically every year, and to a greater degree every fifth year, which constrains the amount of Hetch Hetchy water supplied to serve water demands in the Bay Area. As discussed previously, during these winter periods, the Bay Area reservoir system accommodates the reduction in imported supply by serving the Bay Area water deliveries with the local watersheds' runoff and storage. At San Andreas Reservoir, the serving of water demand affects the reservoir when additional required water production at Harry Tracy Water Treatment Plant (Harry Tracy WTP) associated with WSIP or the base-Calaveras unconstrained setting exceeds the ability to maintain San Andreas Reservoir storage with pumping from Crystal Springs Reservoir. The model assumes that the conveyance capacity from Crystal Springs Reservoir is the same among all of the settings. The additional water demand of the WSIP setting and the current demand of the base-Calaveras unconstrained setting require additional production from Harry Tracy WTP to be drawn from San Andreas Reservoir.

2.9 Pilarcitos Reservoir

Coastside County Water District's (Coastside CWD's) water demand and its SFPUC purchase request are projected to increase within the WSIP planning horizon of year 2030. Within the context of the 2030 purchase request of 300 mgd, Coastside CWD's portion has been estimated to amount to about 3 mgd. This projected purchase request is approximately 1 mgd greater that its current purchase request. Considering the current physical constraints to deliveries from the SFPUC to Coastside CWD and the ongoing planning activities in the watershed, the precise means of serving Coastside CWD's additional purchase request (and the resultant potential changes to the operation of SFPUC facilities and their affected environs) are uncertain.[2]

Assuming a range of potential means to serve the additional purchase request from Coastside CWD, the following are potential hydrologic effects to SFPUC facilities and their affected environs:

- Due to limited yield from Pilarcitos Reservoir, additional diversions would be required from Crystal Springs Reservoir.
- If deliveries to Coastside CWD from Pilarcitos Reservoir increase during the winter season, these deliveries could potentially reduce storage in Pilarcitos Reservoir, thereby potentially reducing diversions to the San Mateo Creek watershed. Although the increased delivery would increase releases to Pilarcitos Creek from Pilarcitos Dam for a period of time, the increase would subsequently lead to a reduction in spills past Stone Dam.
- Additional wintertime deliveries could also potentially impair the ability to provide carry-over storage into the summer season from Pilarcitos Reservoir, and subsequently lead to an acceleration of the beginning of the season when releases to Pilarcitos Creek from Pilarcitos Reservoir consist only of the passage of reservoir inflow.
- An increase in summertime deliveries from Pilarcitos Creek could also accelerate the beginning of the season when releases to Pilarcitos Creek from Pilarcitos Reservoir consist only of the passage of reservoir inflow.

APPENDIX H2-2

Memorandum

Subject: **Estimated Effect of WSIP on Daily Releases below Hetch Hetchy Reservoir**
From: **Daniel B. Steiner**
Date: **December 31, 2006**

1. Introduction

The simulation of San Francisco Public Utilities Commission (SFPUC) Regional Water System daily operations over a long-term record of hydrology is currently not available with existing modeling tools. The Hetch Hetchy Local Simulation Model (HH/LSM) performs analyses using a monthly time-step, with input and results depicted by monthly volumes of water. As such, the day-to-day variation of operations, or an operational decision that can occur in less than monthly intervals cannot always be adequately represented or depicted by "monthly" HH/LSM results. One such hydrologic parameter that suggests an alternative interpretation is the stream release that is simulated to occur below O'Shaughnessy Dam. This occurs as either a fairly constant release through the low-level outlet for fishery maintenance or varying controlled releases through the dam's outlet valves and through the spillway. The release from the dam during the year is typically limited to the amount of flow required to meet fishery stream flow commitments. However, during many years, an amount of water above minimum flow commitments requires release to the stream. These flows are managed on a day-to-day basis to balance inflow, reservoir storage, and diversions to water supply and power operations. During the runoff season, operations can change daily as prevailing conditions warrant.

HH/LSM simulations cannot fully depict the within-month changes that can occur. For instance, although the model will accurately depict that several thousand acre-feet of reservoir spill would occur in a month (e.g., 24,000 acre-feet in a month), the model results do not provide sufficient information regarding the daily magnitude or duration of the release during that month. A 24,000-acre-foot release during a month could occur as a constant release of 400 cubic feet per second (cfs) per day, or it could occur as an 800 cfs release during half of the days during a month. By looking solely at the average monthly results provided by HH/LSM, the effects of the operational and system changes may not be fully understood. This memorandum illustrates the adaptation of HH/LSM monthly results into an estimate of the projected change in daily releases to the stream below the dam as a result of the Water System Improvement Program (WSIP).

2. Approach

The record of recent historical operations at O'Shaughnessy Dam serves as the backdrop for this analysis. Also incorporated are the HH/LSM simulated operation of the existing system and the simulation of system operations after implementation of the WSIP. Upon tracing historical operations, the modeled incremental changes between the existing system operation and the operation of the system with the WSIP are layered. The modeled operation captured in the analysis is the change in Hetch Hetchy Reservoir storage that occurs from one year to the next due to the WSIP. That change in storage would be subsequently replenished by a change in diversions to Canyon Tunnel or spills to the river below the dam.

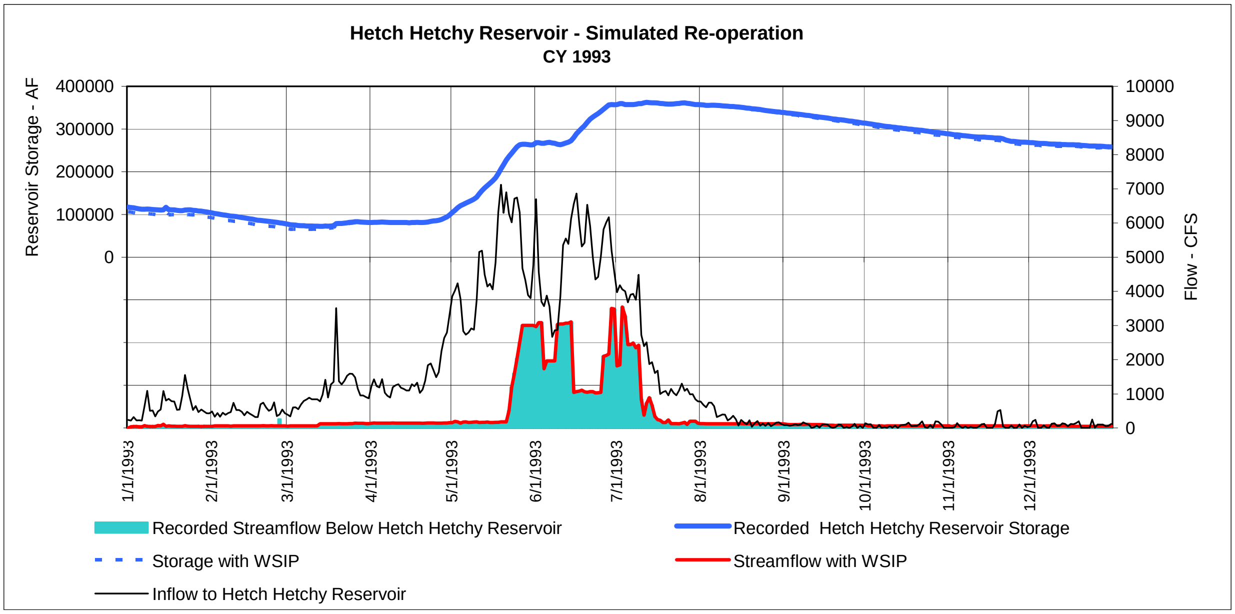
This analysis has been limited to evaluating only the most recent record of operations, those that have occurred since the 1987-1992 drought. Operations subsequent to that period incorporate additional emphasis on carryover storage to safeguard water supply yield, consistent with modeled operations. This period also represents a generally stable level of current system water demand, again consistent with modeled operations. Both of these factors make the modeled results of the existing system a more comparable representation to recent historical operations.

3. Analysis

Analyses of the WSIP have illustrated that additional diversion from Hetch Hetchy Reservoir to provide for additional SFPUC Regional Water System water deliveries would additionally deplete the reservoir in most years. To replenish this storage, spills to the river either from Kirkwood Powerhouse or from the dam would be subsequently reduced.

Figure 1 illustrates a trace of the recorded storage in Hetch Hetchy Reservoir (solid blue line), inflow to the reservoir (daily varying black solid line), and releases to the stream below the dam (area graph shown in aqua blue) for calendar year 1993. Also shown in Figure 1 is the adjusted Hetch Hetchy Reservoir storage (dashed blue line) subsequent to the WSIP. The solid red line depicts the estimated daily release below the dam subsequent to the WSIP.

Figure 1



The adjusted Hetch Hetchy Reservoir storage is depicted by layering onto the historical record of reservoir storage the change in modeled storage between existing conditions and the WSIP condition. The premise is that, although the absolute depiction of reservoir storage through modeling may differ from recorded operations (due to several anomalies that occur in the actual operation that cannot be fully captured by modeling), the relative difference between the two modeled conditions will be adequately representative of the change that would have occurred to historical operations. Because HH/LSM only develops monthly results, the model change in storage in the reservoir was evenly distributed during a month to provide the daily adjustment to the recorded daily historical storage.

The change in storage from month to month is derived from HH/LSM results and is applied to the historical record of storage. In this “re-operation” of 1993, there is approximately 11,000 acre-feet less storage in the reservoir at the end of February, with the deficit eliminated by the end of March (dashed blue line). The deficit is due to additional water supply diversions in the previous year under the WSIP. Both the modeled operation and recorded operation release no more than minimum flows below the dam for this period, indicating that the replenishment of storage in this particular year would have occurred through a reduction in Canyon Tunnel diversions (spills to the river from Kirkwood Powerhouse). With this replenishment occurring prior to the spill period, the remainder of the stream release operation through the spill period (solid red line) would remain the same as the historical operation. In this example, the WSIP would not affect the magnitude or duration of the spill hydrograph for 1993.

The effect of the WSIP varies by year. Calendar year 1994 is another example illustrating that, at times, the WSIP is anticipated to have no effect on the stream releases below the dam. Figure 2 provides a trace of 1994 actual operations. Although reservoir storage is depicted to be diminished prior to and through May, only minimum releases to the stream occurred during the year; therefore, the WSIP would have no effect on stream releases below the dam in this year. During this year of operation, the deficit of storage would be replenished prior to the end of the runoff season by a reduction in Canyon Tunnel diversions. Subsequent to the reservoir being filled, the additional diminishment of storage would begin again and the effect would be carried into the next year.

Figure 2

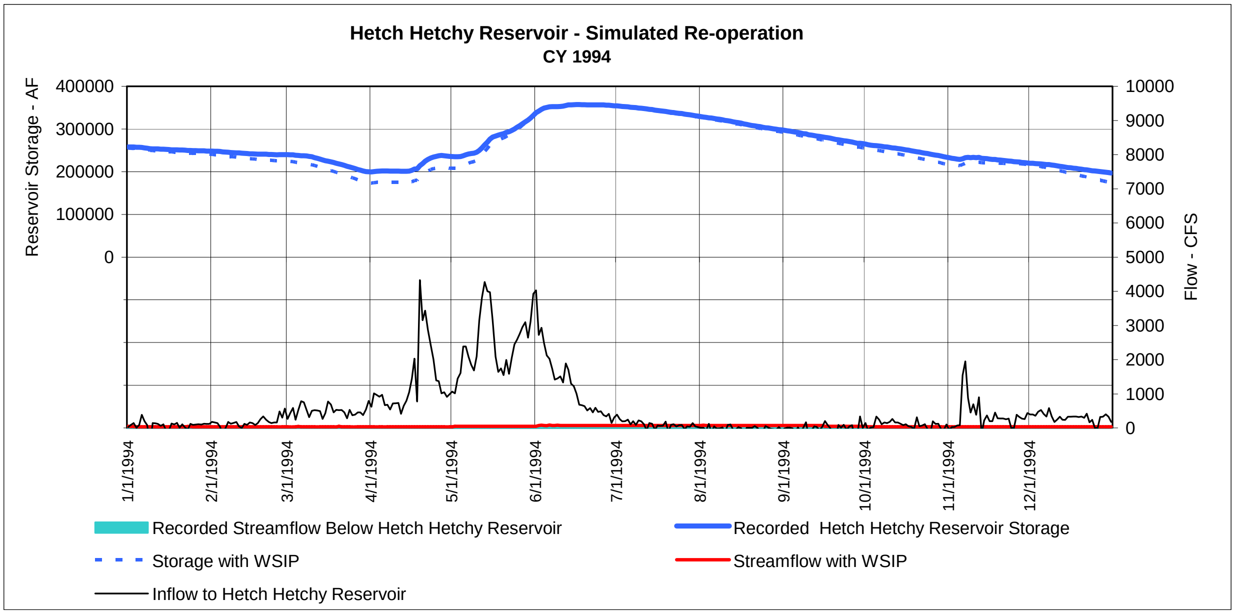


Figure 3 (1995), Figure 4 (1996), Figure 5 (1997), and Figure 6 (1998) each illustrate additional years of actual and projected operations. In each of these example years, there would be no WSIP affect on stream releases below the dam. In each instance, the storage deficit developed by the WSIP would have been replenished by reductions to Canyon Tunnel diversions well prior to spills into the river.

Figure 3

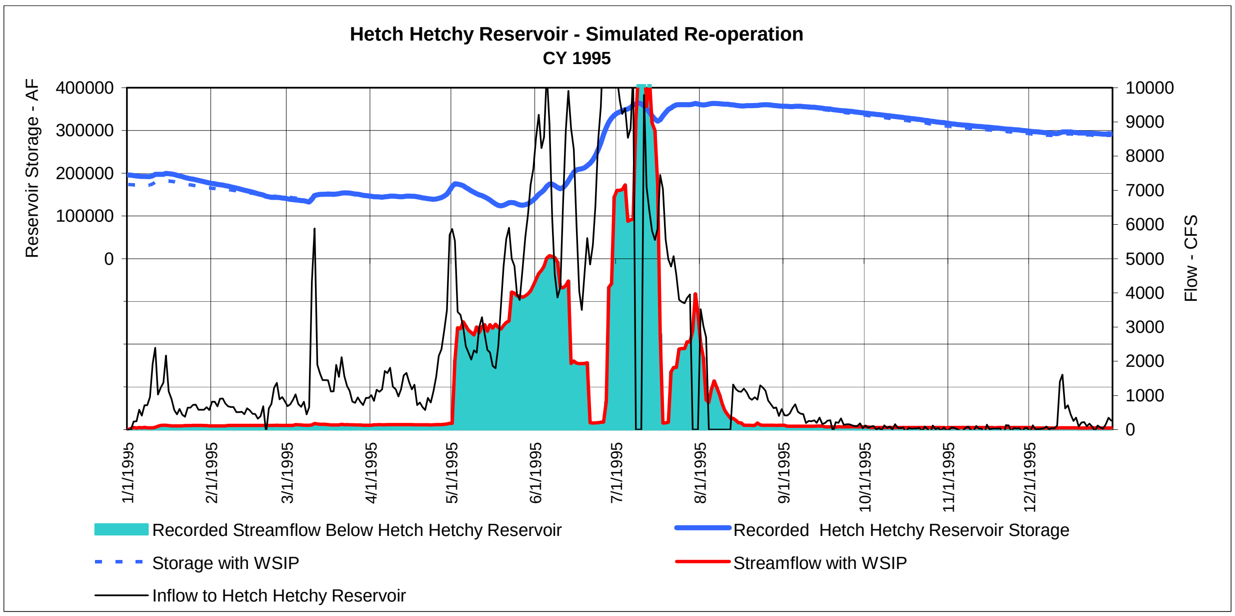

Figure 4

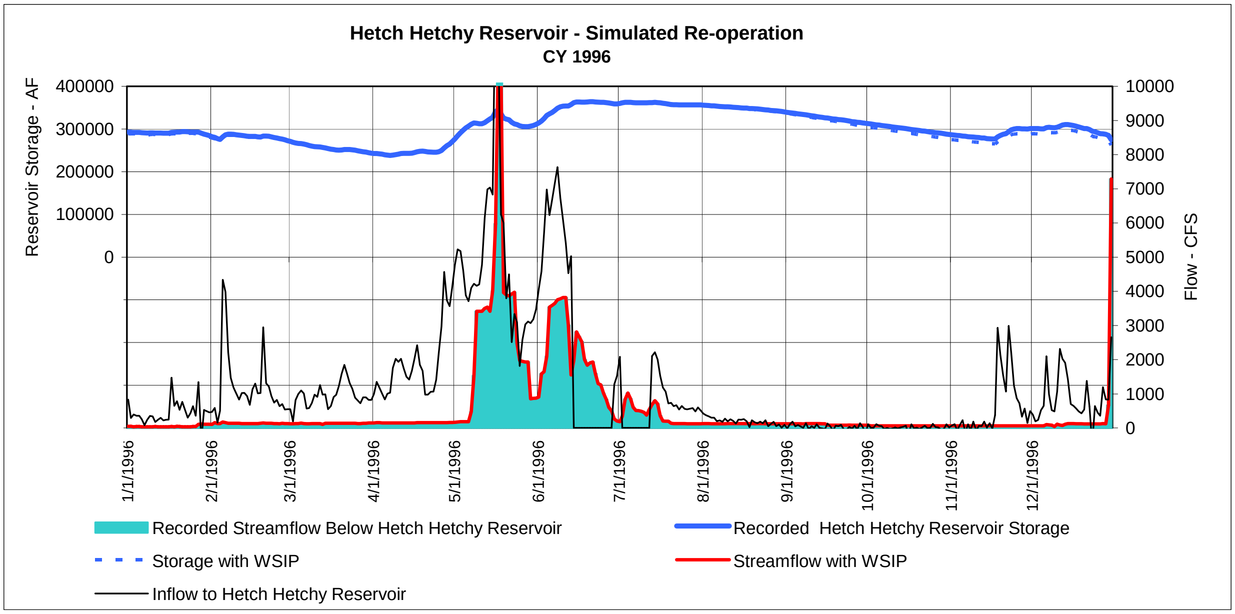

Figure 5

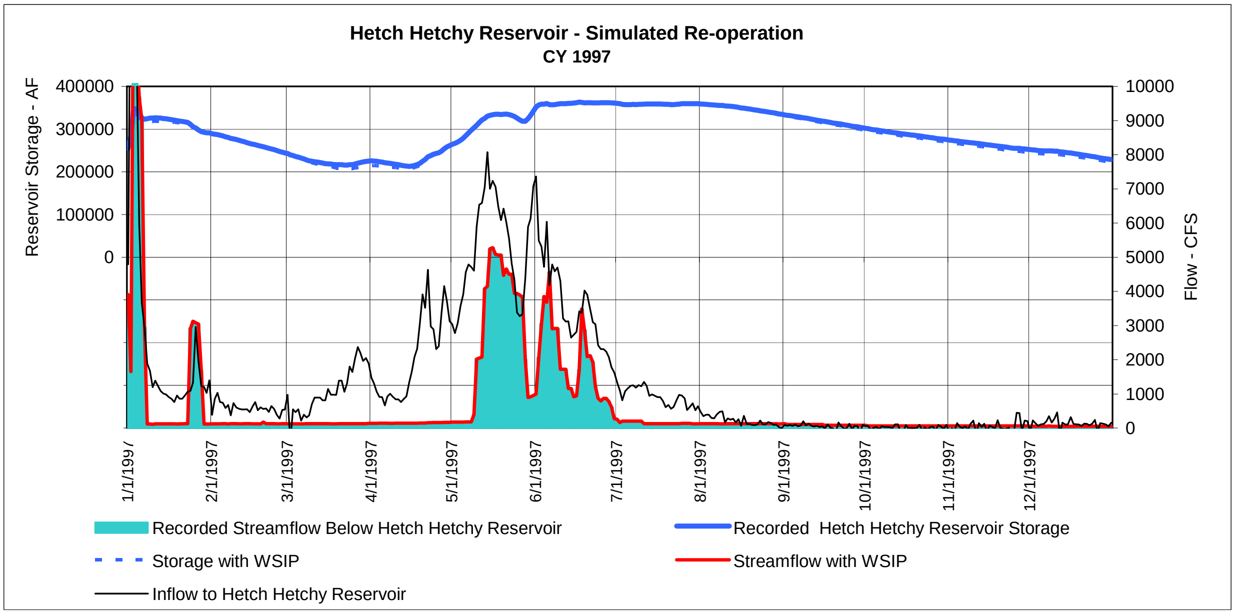

Figure 6

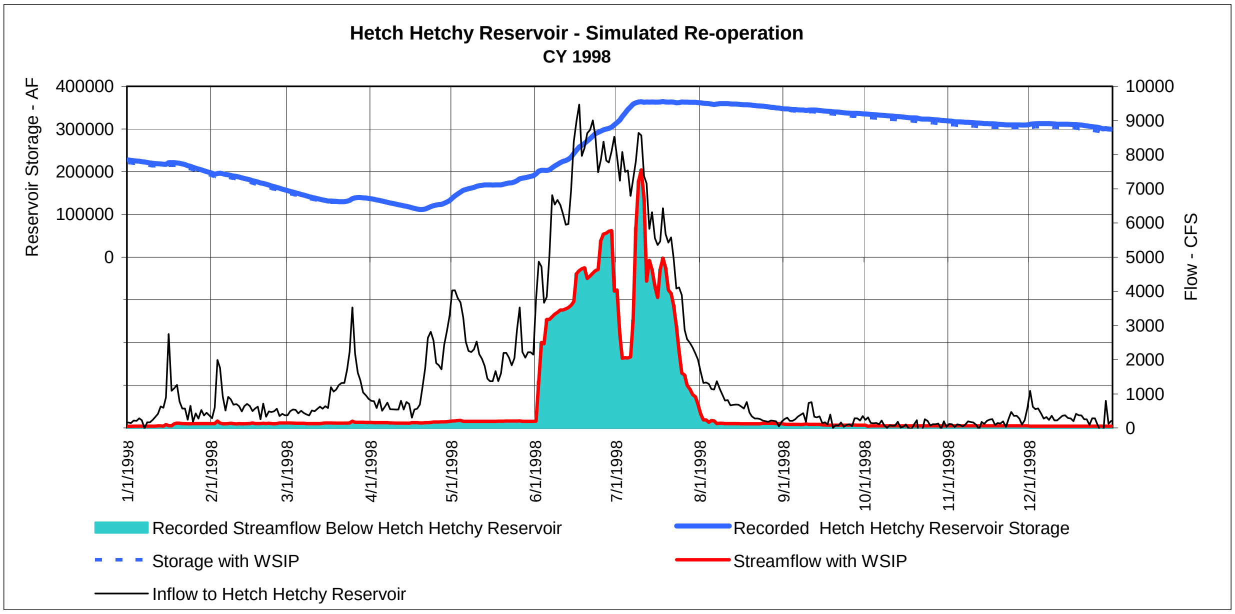

Calendar years 1999 and 2000 illustrate instances when the WSIP may affect stream releases below the dam. Figure 7 illustrates the trace of historical and projected operations for 1999. An incremental storage deficit from the WSIP could occur during the time that the reservoir would otherwise be releasing in excess of minimum flows, leading to a delay in the day that such excess releases would occur (illustrated by the solid red line). In this instance, the analysis indicates a 3-day delay in spills due to the effect of the WSIP. Figure 8 illustrates the same form of effects during calendar year 2000, with a 1 day delay in excess releases due to the WSIP.

Figure 7

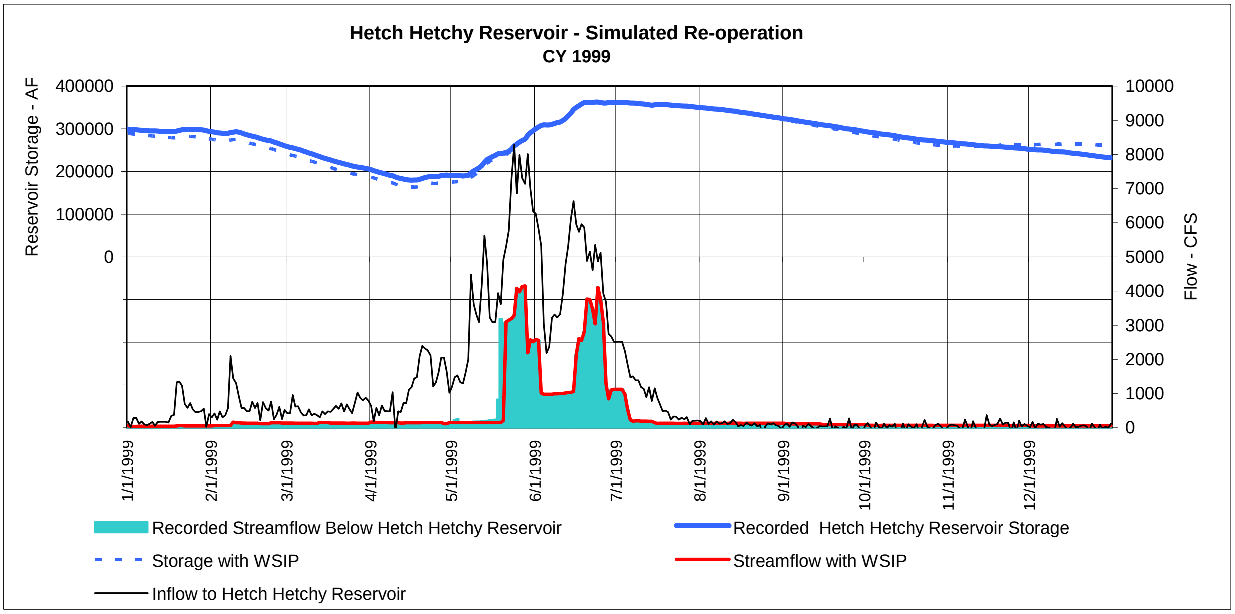

Figure 8

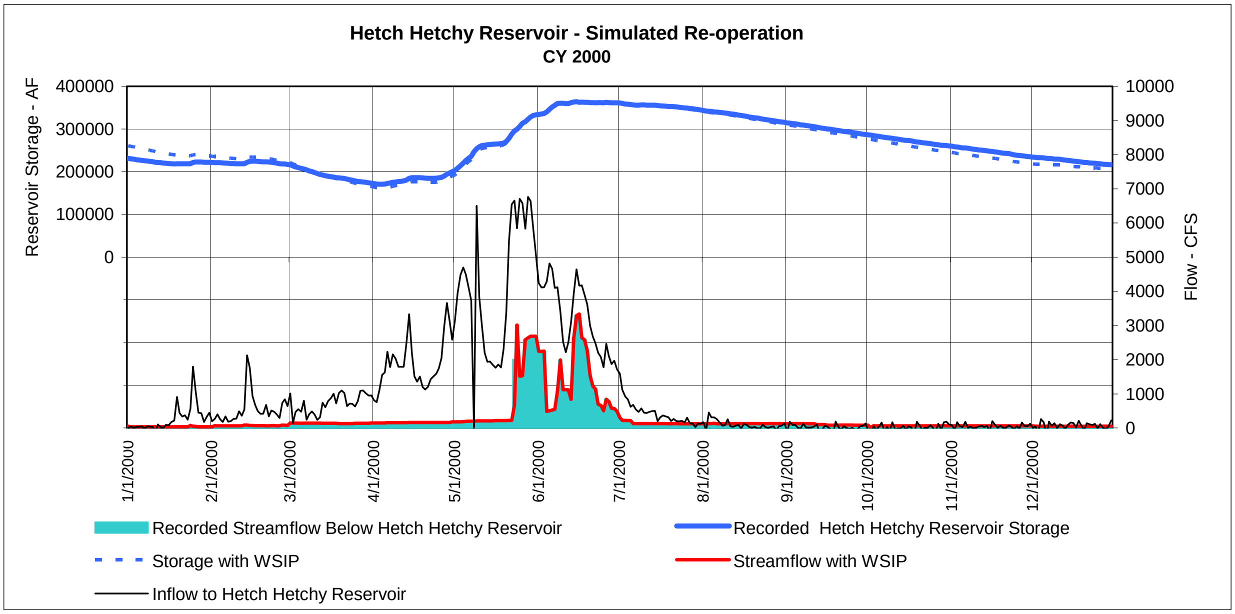
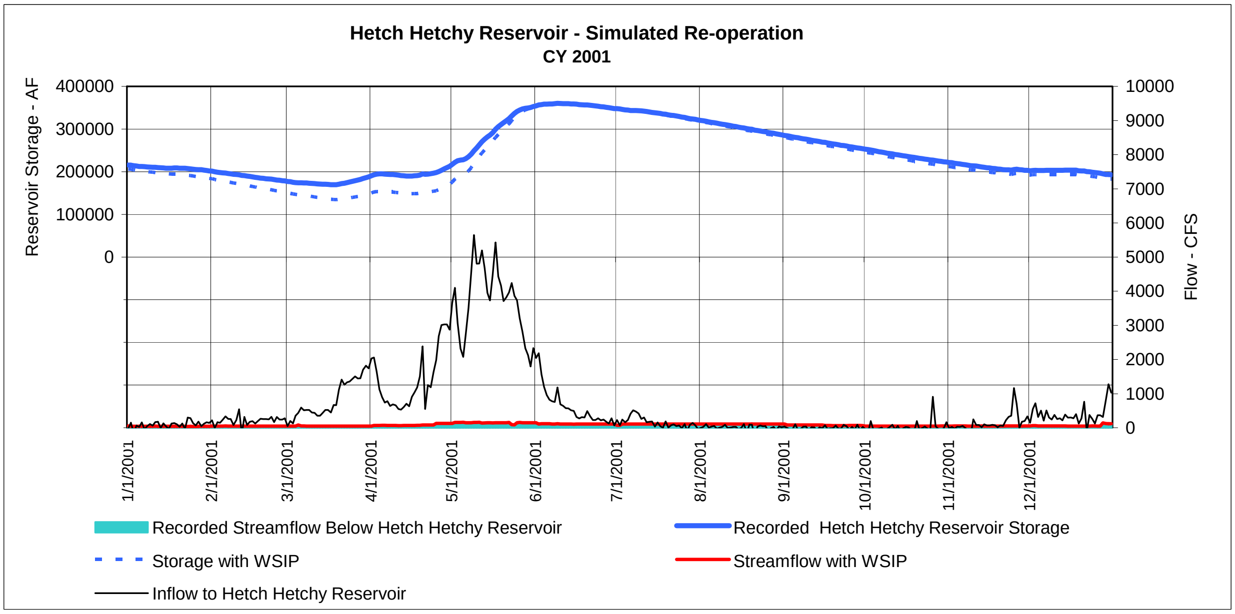


In each of these examples, the spill that would have occurred otherwise was diminished in volume. However, subsequent to storage being replenished, the spill hydrograph returns to what would have occurred regardless of the WSIP, typically for a substantial portion of the time that would have occurred and at a peak magnitude that would be greater than what flows levels were reduced.

Figure 9 illustrates that calendar year 2001 is similar to conditions during 1994. No spills above minimum stream commitments occurred during 2001. Although there is an incremental deficit in storage due to the WSIP, replenishment of the storage by the end of the runoff season would occur through a reduction in Canyon Tunnel diversions. Stream flow below the dam would be unaffected.

Figure 9



Calendar year 2002 (Figure 10) illustrates a low-frequency event in Hetch Hetchy Reservoir operations. During 2002, the reservoir was filled during the early days of June. The spills that occurred were due to the reservoir being full and diversions to Canyon Tunnel maximized. With no ability to store or divert additional water, minor spills occurred at the reservoir until inflow receded. The WSIP would not affect this spill event because reservoir storage would already have been replenished by adjustment of Canyon Tunnel diversions.

Figure 10

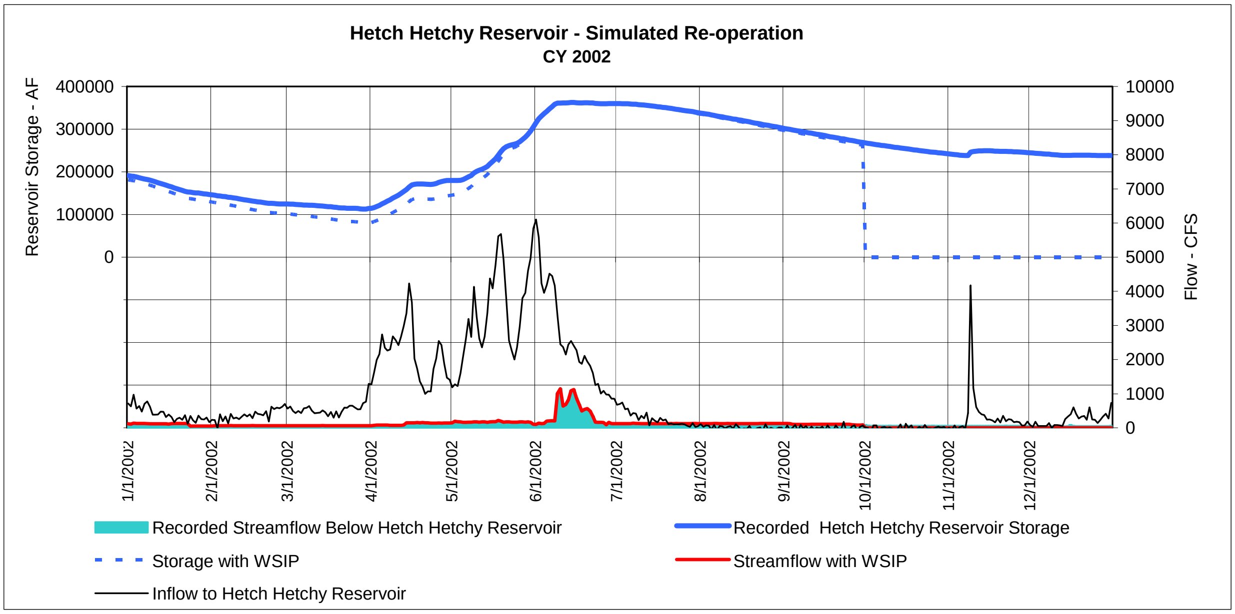


Figure 11 illustrates the annual volume of spill from the dam (releases to the stream in excess of minimum commitments), simulated for existing conditions and with the WSIP. Under existing conditions, the reservoir would not spill in 15 years (out of 82 years); when spilling, the volume normally would exceed 100,000 acre-feet. The spills typically occur during May through July, normally during May and June. With the WSIP, three additional years of spill could be eliminated. During these types of years, there would have been minimal spills otherwise occurring under existing conditions. When a reduction in the volume of spills occurs due to the WSIP in the other years of simulation, it is anticipated that the reduction would occur in the form of a delayed spill period, as demonstrated by this analysis of the historical operation. As an example of the potential delay in releases, recent historical operations have shown that it is typical to initially establish dam releases at 3,000 cfs or more. A 3,000-cfs release would equate to approximately 6,000 acre-feet in a day. With such a release otherwise occurring, a diminished storage effect in the reservoir of 24,000 acre-feet would be ameliorated in about 4 days due to a delay in the release.

APPENDIX H2-3

Memorandum

Subject: **Analysis of SFPUC Pilarcitos and Coastside County Water District Operations**
From: **Daniel B. Steiner**
Date: **March 8, 2007**

1. Introduction

Pilarcitos Creek has provided water supply to San Francisco since the 19th century. Pilarcitos Reservoir, Stone Dam, and associated facilities are an integral part of San Francisco Public Utilities Commission (SFPUC) Regional Water System operations. Watershed runoff regulated at these SFPUC facilities serves the Coastside County Water District (Coastside CWD) purchase request, and is also diverted to the San Mateo Creek watershed for integration into the rest of the SFPUC system.

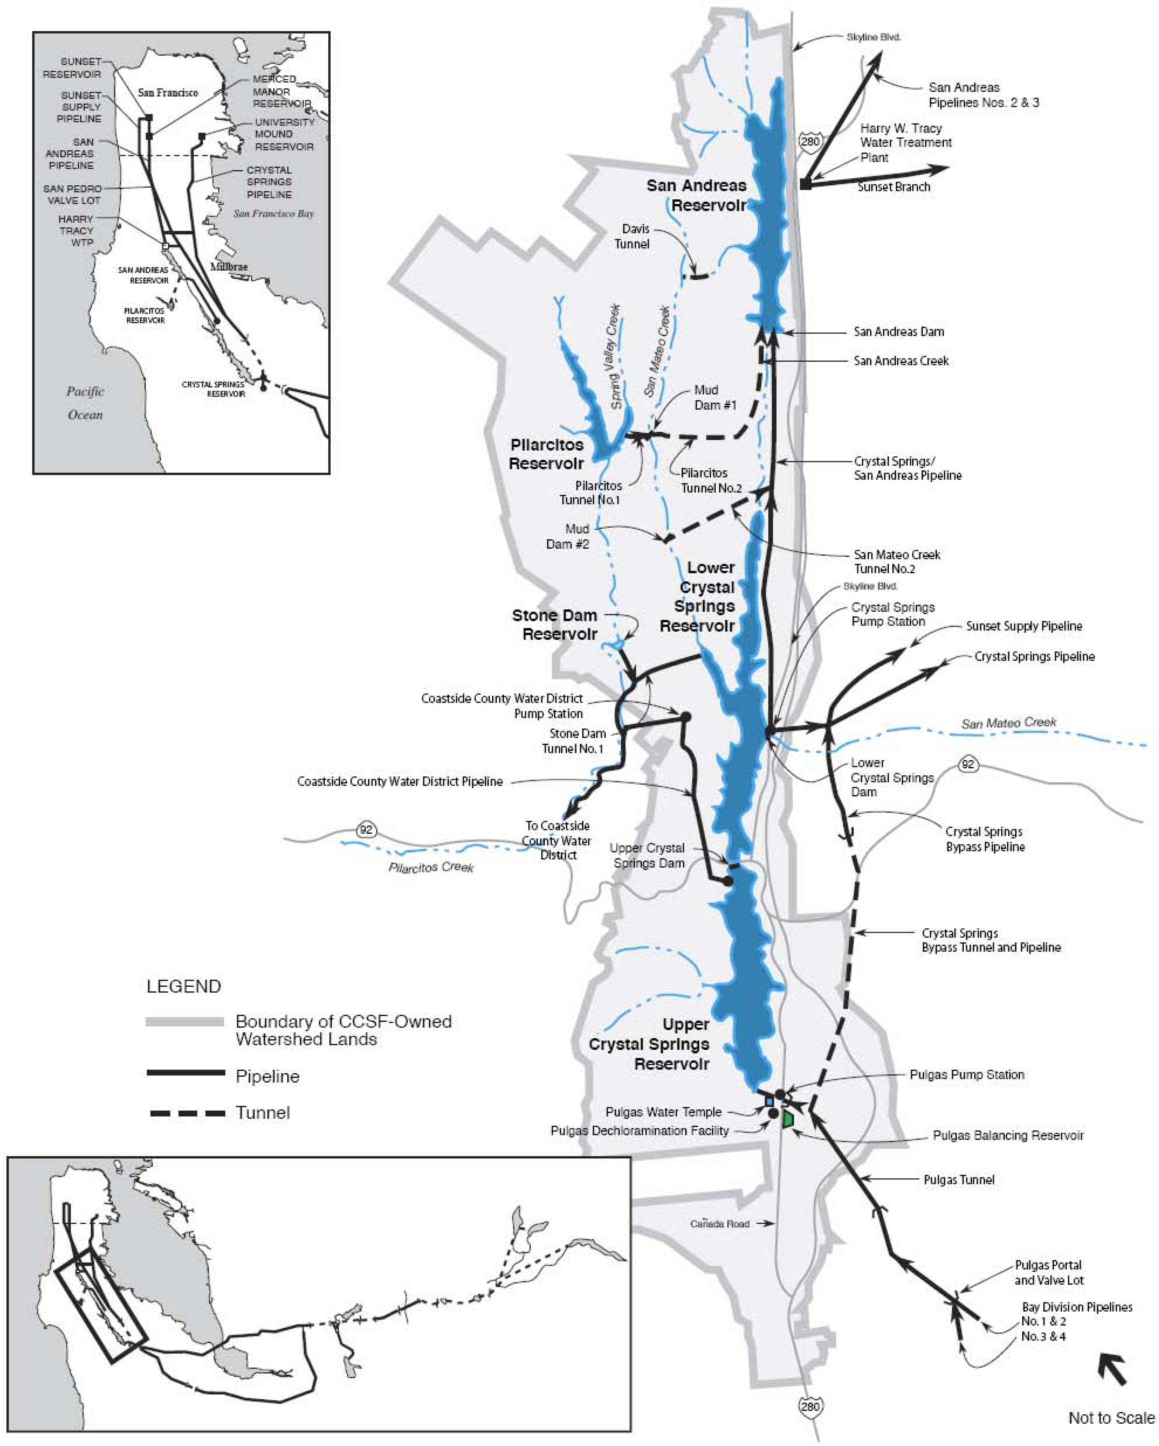
The purpose of this memorandum is to provide a brief description of the operation of SFPUC facilities in the Pilarcitos Creek watershed, both in the context of deliveries to Coastside CWD and integration into the SFPUC Regional Water System. Also described are illustrations of the potential changes in operations and hydrologic outcome that may be associated with implementation of the Water System Improvement Program (WSIP) as it is affected by an increase in Coastside CWD's purchase request.

2. System Description

Major SFPUC facilities located on the peninsula are shown in Figure 1. Pilarcitos Reservoir (maximum storage capacity of approximately 3,000 acre-feet) regulates watershed runoff into the reservoir for release to Pilarcitos Creek for rediversion at Stone Dam. Excess water in the watershed is diverted to the San Mateo watershed from Pilarcitos Reservoir through the Pilarcitos Tunnel No. 1, and at Stone Dam through Stone Dam Tunnel No. 1. The annual average runoff to Pilarcitos Reservoir is estimated to be approximately 3,980 acre-feet per year, and has ranged from little or no runoff to over 15,000 acre-feet in a year. Inflow to the reservoir occurs predominantly from rainfall during December through April. Additional runoff enters the stream reach below Pilarcitos Dam and above Stone Dam from several tributaries. This runoff is estimated to be an average annual 1,849 acre-feet. Flow at Stone Dam that exceeds the diversion needs to Coastside CWD and the ability to divert water to Crystal Springs Reservoir spills over Stone Dam and continues downstream in Pilarcitos Creek.

Current operations of the SFPUC Pilarcitos watershed facilities focus on the management of runoff. The tools available to manage the runoff are Pilarcitos Reservoir and the diversion works at Pilarcitos Reservoir and Stone Dam. An underlying objective for the operation is the conservation of runoff for the delivery of water to Coastside CWD and diversion into the SFPUC Regional Water System, minimizing releases past Stone Dam. This objective is achieved beginning with the drawing of storage in Pilarcitos Reservoir before the rainy season. By early fall, Pilarcitos Reservoir storage will typically be incidentally drawn down to the minimum level that passes water through the stream outlet works. This draw occurs because of releases made for deliveries to Coastside CWD from Pilarcitos Reservoir. During the ensuing rainy season, storm runoff is regulated in the reservoir with diversions made to Coastside CWD deliveries and transfers to the San Mateo Creek watershed via Pilarcitos Tunnel No. 1. Adequate available reservoir storage space in the reservoir is retained to regulate storm runoff, minimizing spills past Stone Dam. At the end of the rainy season, mid-April or sometimes earlier, transfers to the San Mateo Creek watershed will be curtailed in an effort to fill Pilarcitos Reservoir for maximum carry over into the summer season. Releases from Pilarcitos Reservoir will typically be reduced to only those requested by Coastside CWD for diversion at Stone Dam. During the summer, releases continue to be maintained at the request of Coastside CWD for diversion at Stone Dam. Current delivery requests by Coastside CWD can often deplete Pilarcitos Reservoir by late summer to a reservoir level when the outlet gates are opened to pass reservoir inflow. During these times, the reservoir release is typically less than that needed by Coastside CWD and the district exercises its Crystal Springs Reservoir diversion for delivery of the SFPUC supply.

Figure 1
Major SFPUC Peninsula Watershed Facilities



SOURCE: San Francisco Planning Department, 2001

During the wettest of years, storm runoff can exceed the regulation efforts of the SFPUC, and spills past Pilarcitos Dam will occur. These events could be as short as a matter of days to as long as 1 or 2 months. At times, transfers to the San Mateo Creek facilities may cease in circumstances when the SFPUC San Mateo Creek watershed facilities are already operating at maximum capacity managing their own watershed's runoff. Although it is more desirable to transfer water from Pilarcitos Reservoir to the San Mateo Creek watershed directly to San Andreas Reservoir, reservoir or conveyance constraints may warrant that the transfer occur to Crystal Springs Reservoir, either through diversions to Pilarcitos Tunnel No. 1 or from the diversion at Stone Dam.

Accretions and depletions of the stream reach between Pilarcitos Dam and Stone Dam enter the calculus of releases from Pilarcitos Dam and diversions at Stone Dam. Coastside CWD's delivery from Pilarcitos Creek is through the Pilarcitos Canyon Pipeline, which is connected to a SFPUC pipeline connecting to the diversion from Stone Dam. The SFPUC diversion works provide the headwater for Coastside CWD's delivery, with diversions in excess of Coastside CWD's need or capacity flowing to Crystal Springs Reservoir. Releases from Pilarcitos Reservoir are typically established based on the delivery request of Coastside CWD, accounting for the intervening flow or depletion of flow below Pilarcitos Dam. Any estimation errors in the hydrology of the intervening reach result in the delivery request of Coastside CWD slightly shorted at Stone Dam, or in excess flow being diverted to Crystal Springs Reservoir. Flow past Stone Dam to Pilarcitos Creek in either circumstance remains no more than seeps or leaks past the dam, with tributary flows adding to Pilarcitos Creek below the dam. There may be circumstances in which Stone Dam spills to Pilarcitos Creek when Pilarcitos Reservoir is not releasing to the creek. This can occur when the runoff from the intervening reach exceeds the delivery of water to Coastside CWD at Stone Dam and the transfer of water to Crystal Springs Reservoir.

3. Recent Historical Operations

The Figure 2 series of charts illustrate historical hydrologic information (1986-2005) for Pilarcitos Reservoir and deliveries to Coastside CWD from the SFPUC. Also included are observed flow values for Pilarcitos Creek at two locations, below Stone Dam and near Half Moon Bay. Figure 2 illustrates the daily storage in Pilarcitos Reservoir. Evident is the annually cyclic operation of storage, operated to achieve maximum storage in April or May, being drawn during the summer and fall, and then varying in storage throughout the winter in reaction to winter storm runoff and subsequent evacuation of storage until the spring-time filling cycle. Also shown are the deliveries to Coastside CWD from SFPUC facilities. The shaded "bars" illustrate the average daily deliveries to Coastside CWD from Stone Dam for a month. Typically, the pattern of deliveries indicates that Coastside CWD shapes the SFPUC delivery throughout the year in a distribution that reflects their total system demand, greatest during the summer and less during the winter. Periods when no delivery from Stone Dam occur reflect insufficient water deliveries from Pilarcitos Reservoir (typically reflective of minimal reservoir storage to sustain sufficient releases to the creek for subsequent diversion), whereby Coastside CWD opts to switch its SFPUC delivery to pumping from Crystal Springs Reservoir.

The creek flow information shown in Figure 2 is for Pilarcitos Creek just below Stone Dam, and for a downstream location near Half Moon Bay. The flow record below Stone Dam typically indicates a circumstance whereby flow occurring above the dam is diverted to Coastside CWD and Crystal Springs Reservoir. The flow at Half Moon Bay occurs predominantly from tributaries below Stone Dam. Significant flow at either location indicates periods of runoff from storm events. The occurrence of storm events is also reflected in changes in Pilarcitos Reservoir storage.

Deliveries from Crystal Springs Reservoir and total production from Coastside CWD sources are also illustrated in Figure 2. Coastside CWD's portfolio of resources includes deliveries from the SFPUC from Pilarcitos Creek (Stone Dam), from the SFPUC through pumping from Crystal Springs Reservoir, the district's Pilarcitos wells, and surface and groundwater supplies associated with the district's Denniston Project. Recent annual water production from Coastside CWD's non-SFPUC supplies is illustrated in Figure 3. Production from Coastside CWD's Denniston Project sources appears fairly constant for the past several years, with the annual variation generally reactive to the wetness of a year. Annual production from the district's Pilarcitos wells appears to have declined in recent years, with the production occurring during their permitted period of pumping November through March.

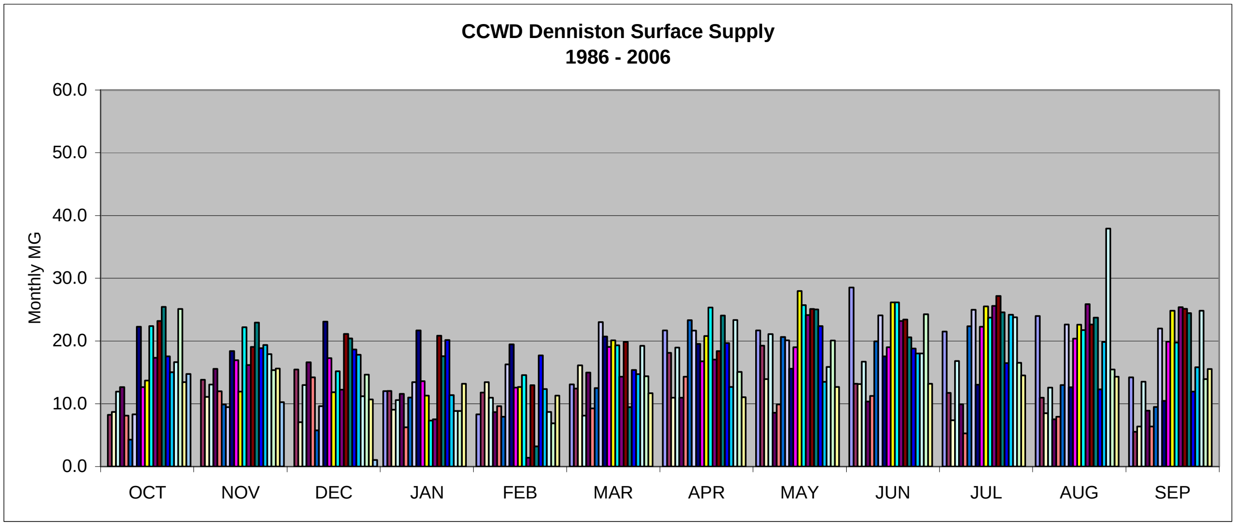
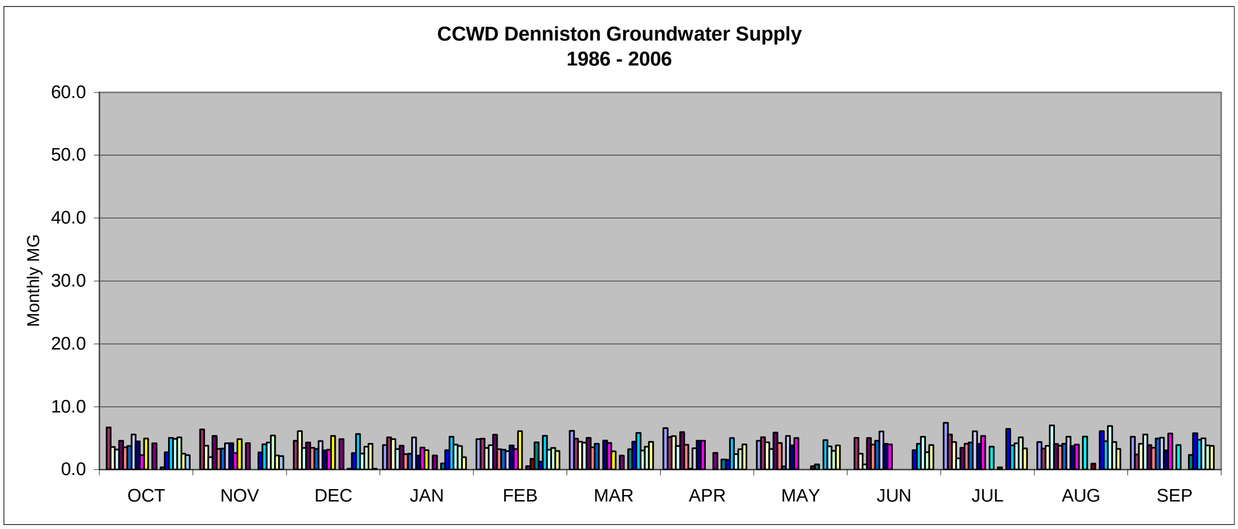
1986-2005





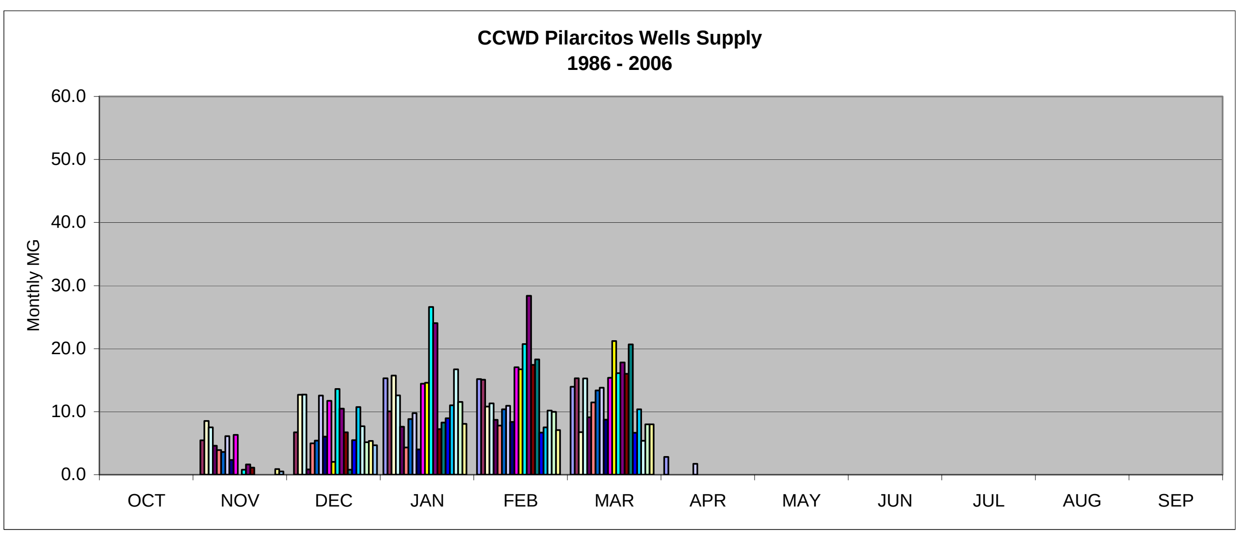


Figure 4 provides an insight to Coastside CWD's total water production (representative of total system demand) and the proportion provided by SFPUC deliveries. Supplementing Figure 4 is Table 1, which reports the district's total production. The district's annual water production has averaged 2.5 million gallons per day (mgd) over the past 5 years. Table 2 illustrates the district's delivery of water from the SFPUC, indicating a fairly constant receipt of about 1.8 mgd over the past 5 years. The delivery of water

from SFPUC sources to Coastside CWD is illustrated in Figure 5, showing the seasonal trend and magnitude of deliveries from Stone Dam and Crystal Springs Reservoir. The data illustrate that deliveries from the Stone Dam diversion have generally peaked in recent years during May through September, typically representing an average monthly delivery rate of 2 mgd. The estimated capacity of the turnout is slightly greater than historical records indicate; however, the record indicates the typical maximum average monthly performance of the diversion facilities. Deliveries during this period may actually be less than the maximum diversion rate due to either limited water availability from Pilarcitos Reservoir or a need to serve a greater rate of delivery that can be accommodated by diversions from Crystal Springs Reservoir. Deliveries from Pilarcitos Reservoir are reduced during the winter as the district's demand is less and the district utilizes other resources. The district's average delivery of SFPUC water from the Stone Dam diversion has averaged about 1 mgd over the past 5 years, with another 0.8 mgd originating from Crystal Springs Reservoir. Table 3 and Table 4 report the SFPUC deliveries to the district from each source.

Long-term planning model (Hetch Hetchy Local Simulation Model) results indicate that, under existing operations and demands, Pilarcitos Reservoir would fill to maximum capacity in the spring during about 50 percent of the years, and, in about 60 percent of the years, Coastside CWD deliveries from Pilarcitos would draw the reservoir down to minimum pool at the stream outlet works by the end of September. The recent record of operations (1998-2005) indicates that the minimum pool was reached during 7 of the past 8 years of operation.

4. Estimation of Potential Effects of Increased Deliveries to Coastside CWD

Coastside CWD's water demand and its SFPUC purchase request are projected to increase within the WSIP planning horizon of year 2030. Within the context of the 2030 purchase request of 300 mgd, Coastside CWD's portion has been estimated to be about 3 mgd.[1] This projected purchase request is approximately 1 mgd greater than its current purchase request.

---

[1] SFPUC Water System Improvement Program EIR, Chapter 3, 2007.

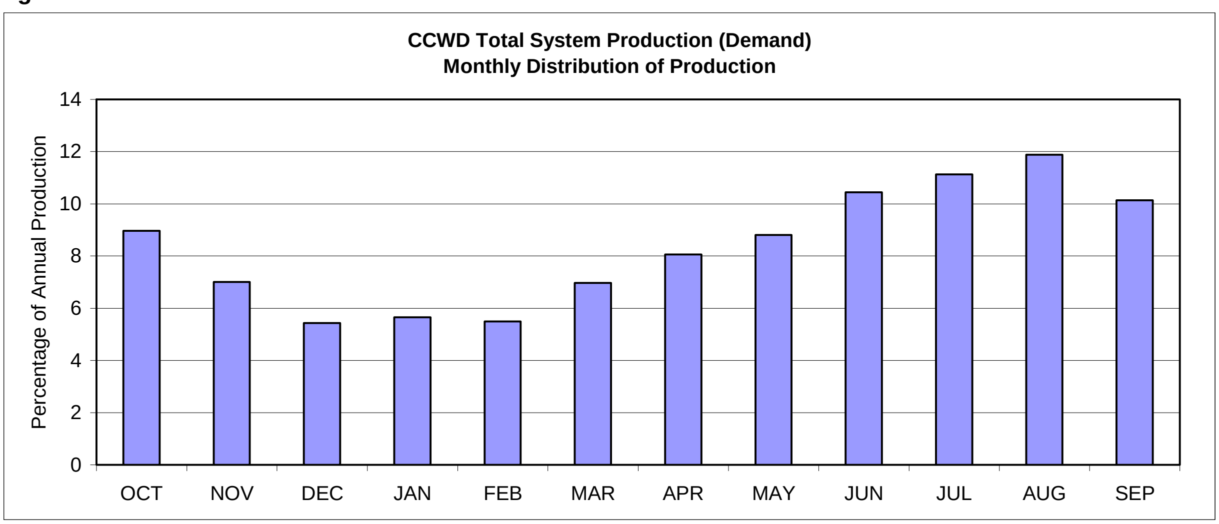
A definitive description for the temporal distribution of Coastside CWD's future SFPUC purchase request is not currently known. The district is currently evaluating how to best manage its future demand with its available resources, and the SFPUC and the district are involved in forums concerning the management of the Pilarcitos Creek watershed. The recent historical record of SFPUC deliveries to the district sheds light on how the current level of delivery affects Pilarcitos Reservoir operation and watershed hydrology. That record also illustrates the hydrologic constraints of the water supply (e.g., the finite amount of water available at Pilarcitos Reservoir) and physical constraints of conveying water to the district (e.g., delivery rate constraint from the Stone Dam diversion). How the additional supply from the SFPUC will manifest as a change in deliveries from the regional system (both source and seasonal pattern) will unfold sometime in the future, and at a minimum be a subject of inquiry during the negotiation of a new water supply contact.

Although it is uncertain how serving Coastside CWD's additional purchase request will specifically change the operation of SFPUC facilities and affect their environs, a range of potential hydrologic effects can be described through development of reasonable assumptions for the manner in which the additional purchase occurs. The following describes several potential postulated delivery scenarios and resultant hydrologic outcomes.

Proportional Load-shape Increase

In this delivery scenario, Coastside CWD's seasonal SFPUC delivery would increase in proportion to the shape of the district's total system production. Figure 6 illustrates the monthly distribution of Coastside CWD's total system production (a surrogate of demand). The temporal shape of the production indicates a demand that is affected by urban use, including domestic irrigation, and irrigation deliveries by the district.

Figure 6



Coastside CWD's current deliveries from the SFPUC are slightly less than those under contract. Recent deliveries (2001-2005) have been approximately 1.9 mgd annually, compared to Coastside CWD's contractual amount of about 2.2 mgd. Figure 7 and Figure 8 illustrate the change in temporal deliveries from current deliveries to the scenario that assumes the district's future purchase request of 2.99 mgd.

Figure 7

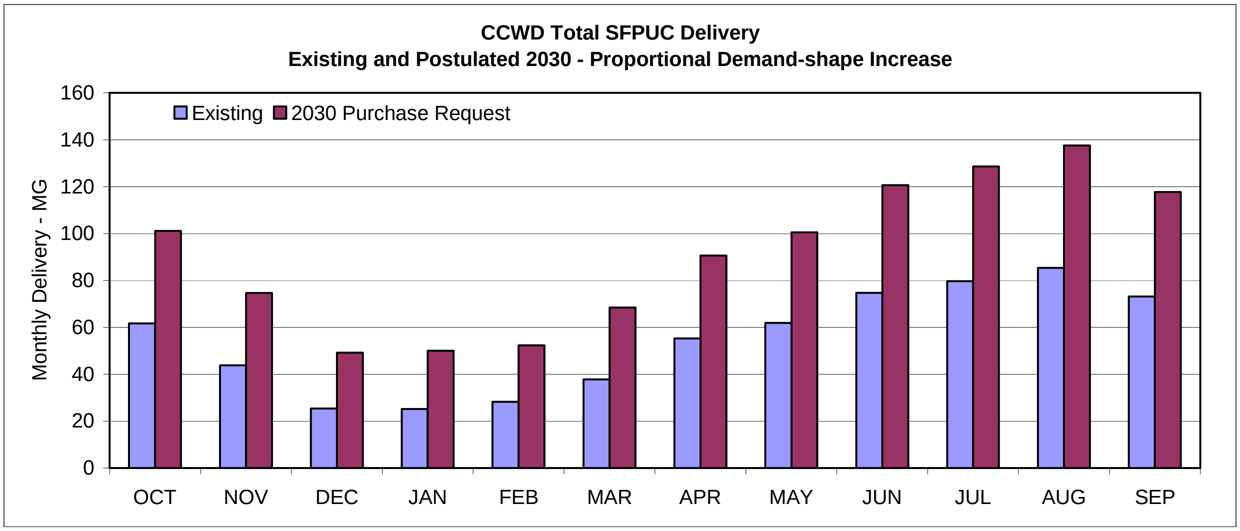


Figure 8

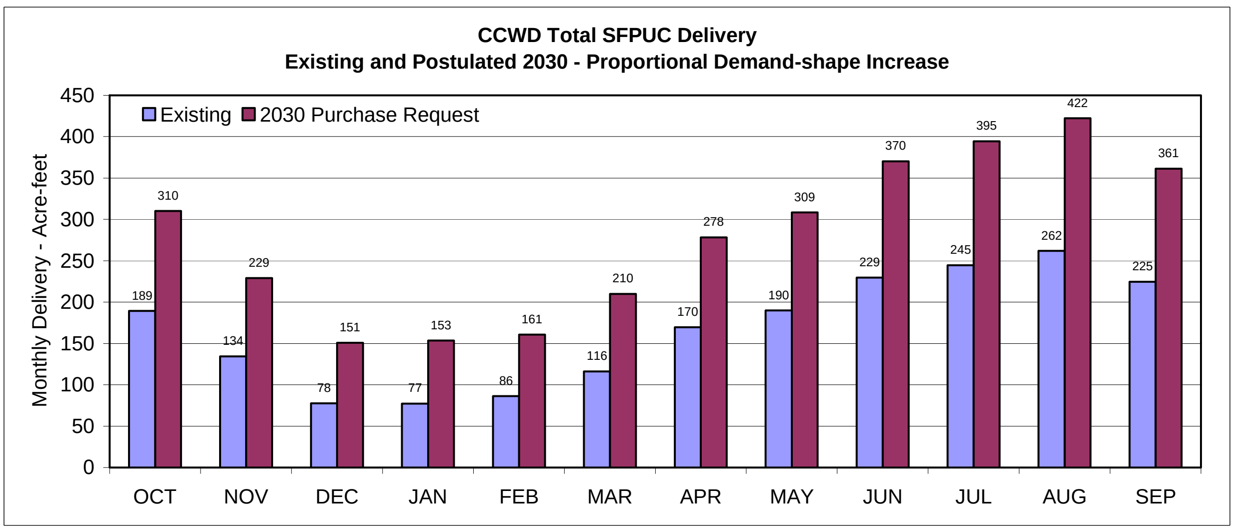
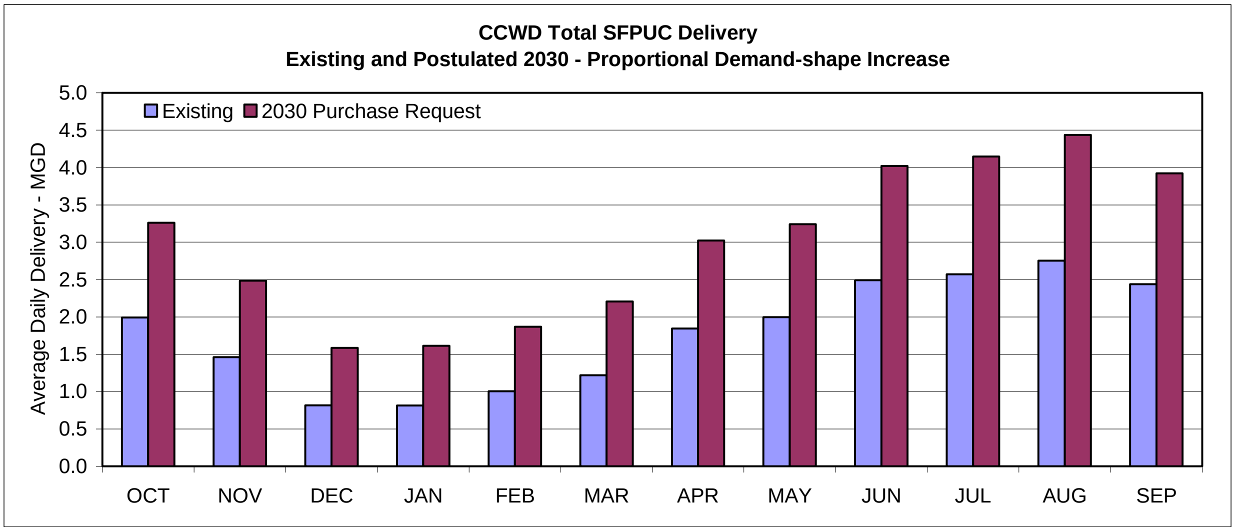


To illustrate potential delivery conveyance constraints, Figure 9 illustrates the average daily flow rate of monthly deliveries associated with current and projected Coastside CWD deliveries from the SFPUC. For recent years, Coastside CWD has been receiving deliveries at a rate of 2 mgd or greater for the period of May through September. This rate of delivery has shown to be a general limitation for deliveries from the Stone Dam diversion, if there is water supply to divert from this source (refer to Figure 5). If Coastside CWD ultimately increases its delivery from the SFPUC in the distribution postulated, the current conveyance constraint of the Stone Dam diversion would require the district to divert the additional water from Crystal Springs Reservoir, possibly requiring facility improvements to effectuate simultaneous deliveries from both sources. Additional deliveries during this season from Crystal Springs Reservoir would not affect the Pilarcitos Reservoir operation if the district is currently already exercising a maximum delivery rate from the Reservoir as constrained by the diversion at Stone Dam. During November through April, Coastside CWD could increase its delivery of Pilarcitos water within the existing capacity of the

Figure 9



Stone Dam diversion. If water was available from Pilarcitos Reservoir (inflow plus storage above the minimum pool of the outlet works), such an increase in delivery would deplete storage in the reservoir or delay the replenishment of the reservoir. While releases from the dam would increase to serve the additional delivery, transfers to the San Mateo Creek watershed would be reduced, and in wetter years the occasional spill to the stream would be delayed if it were to occur at all.

Within any specific year, an additional delivery from Pilarcitos Reservoir could lead to the accelerated draw of storage as compared to current conditions. If, in the current condition, the reservoir is depleted to the minimum pool of the outlet works, the additional delivery would increase the release to the stream until storage is depleted, which would occur at an earlier date. Or, the additional delivery could draw storage to the minimum pool of the outlet works in a year that it would not have occurred in the current condition. Flow in the stream subsequent to this point would be the passage of reservoir inflow, which would occur earlier than in the current condition.

If Coastside CWD were to increase the rate at which it could take delivery of water from Pilarcitos Creek by increasing the size of the Pilarcitos Canyon Pipeline, there would be a potential of an accelerated draw of storage from Pilarcitos Reservoir. The accelerated draw of storage would lead to an increase in the number of days that the stream below Pilarcitos Dam would incur only the passage of inflow to the reservoir. During the period in which the additional level of delivery occurs, the stream flow would increase compared to current conditions. The additional draw of storage could lead to a reduction of water transferred to the San Mateo Creek watershed, and reduce the occasional spill from the reservoir to the stream.

Any purchase request by Coastside CWD not met with Pilarcitos Creek diversions would continue to be met from deliveries from Crystal Springs Reservoir.

Increasing Winter-season Deliveries

An alternative outcome for the postulated temporal distribution of increased water deliveries would be a request that the increase in delivery predominantly occur during the winter season. Assuming the postulated seasonally proportional growth in delivery request, analysis indicates that the distribution of the future level of deliveries would not accommodate the full increase in annual delivery during the winter (November through April) period. Also, if the delivery to Coastside CWD from the Stone Dam diversion continues to be constrained at about 2 mgd, the full future purchase request for the district cannot be fully met from Pilarcitos Creek, even if unlimited water were available from the watershed.

The concentration of additional deliveries to the winter period would increase the draw of water from Pilarcitos Reservoir when it is available. As described previously, an increase in draw during this period would deplete storage in the reservoir or delay the replenishment of the reservoir. While releases from the dam would increase to serve the additional delivery, transfers to the San Mateo Creek watershed would be reduced, and, in wetter years, spill to the stream would be delayed if it occurred at all. During years in which water is not transferred to the San Mateo Creek watershed and water is not spilled from the reservoir (a year when Pilarcitos Reservoir may not fill to maximum carry over storage), the additional draw of water in the winter season would affect the amount of water available for delivery from Pilarcitos Creek during the subsequent summer. Shifting deliveries to earlier in the year would increase flows to meet the increased deliveries, but would accelerate the time when storage is depleted from the reservoir, and the stream would incur only the passage of inflow to the reservoir. Deliveries from Crystal Springs Reservoir would be initiated earlier in the year under these circumstances.

5. Potential Measures to Avoid or Reduce Hydrologic Effects in Pilarcitos Operations

Compared to the current hydrologic condition resulting from the SFPUC's Pilarcitos Creek operations, increased deliveries to Coastside CWD would likely have some level of hydrologic effect to the reservoir and stream. If the basis of comparison is the current condition of the reservoir and stream, and the maintenance of this condition is an objective, several operational measures could avoid or reduce potential hydrologic effects of an increased delivery to Coastside CWD.

- A reservoir operation protocol could be developed that identifies specific storage levels to be retained during seasons of the year. The purpose of the storage levels would be to generally replicate the recent historical operation of the reservoir, leading to a general replication of the frequency and magnitude of stream releases and reservoir storage. Operation to these storage levels could at times limit the seasonal amount of release from Pilarcitos Reservoir and subsequent re-diversion of water to Coastside CWD from Pilarcitos Creek. The purchase request of Coastside CWD not served from Pilarcitos Creek would be served from Crystal Springs Reservoir.

- Rate of delivery constraints within the Coastside CWD contract could be established that would serve as a limitation upon the seasonal or annual amount of water delivered from Pilarcitos Creek. These limitations could be fashioned to reflect recent historical deliveries from the SFPUC from Pilarcitos Creek. For instance, summertime deliveries could be limited to no more than currently delivered, up to about 2 mgd. During the winter, deliveries could be limited to no more than 1 mgd. The effect of limiting deliveries would result in releases for deliveries from Pilarcitos Reservoir no greater than those in recent history. In effect, the increased delivery level would be served from Crystal Springs Reservoir.

APPENDIX H2-4

Memorandum

Subject: **HH/LSM Assumptions and Results – WSIP Variants**
From: **Daniel B. Steiner**
Date: **February 20, 2007**

1. Introduction

This memorandum summarizes assumptions for, and describes the interpretation of, Hetch Hetchy Local Simulation Model (HH/LSM) results for the simulation of the Water System Improvement Program (WSIP) variants that are incorporated into the Program Environmental Impact Report (PEIR). Three WSIP variants have been evaluated: WSIP Variant 1 - All Tuolumne; WSIP Variant 2 - Regional Desalination for Drought; and WSIP Variant 3 - 10% Rationing. Major difference between the variants and the proposed program (WSIP) occur either in the proposed source(s) of water supply or in the drought-year rationing level of service. Table 1-1 and Table 1-2 summarize the components, various modeling assumptions, and performance and hydrologic results for the variants as compared with the modeled existing setting (2005) with Calaveras Reservoir constrained by California Division of Safety of Dams (DSOD) restrictions, the pre-2002 setting (with a Calaveras Reservoir operation prior to DSOD restrictions), and the WSIP setting.

The hydrology of each variant is primarily discussed in terms of a comparison to the proposed program (WSIP) and contrasted to the baseline condition of the PEIR, i.e., the simulated current (2005) operation of the Regional Water System assuming DSOD constraints on operations of both the Calaveras and Crystal Springs Reservoirs. Only primary hydrologic parameters such as projected water deliveries, reservoir storage, and stream flows are compared, and only those parameters identified as key hydrologic factors that lead to environmental impact assessment are illustrated.

Notes for Table 1-1 and Table 1-2

1. Baseline condition represents the existing conditions at the time of NOP publication in September 2005. This is the baseline used to assess WSIP program impact and impact significance. This setting indicates DSOD restrictions on Calaveras and Crystal Springs Reservoirs.

2. This baseline condition represents a system configuration and operation prior to the DSOD storage restriction (pre-2002).

3. These three scenarios are variations on the proposed WSIP. The attributes of these scenarios are largely the same as the proposed WSIP, except for variations in water supply source(s) or objectives for water delivery rationing.

4. The time horizon for the setting of the scenario. The baseline condition scenarios are depicted for recent conditions, while the proposed WSIP, variants, and alternatives are depicted for the future at full buildout and implementation, i.e., conditions in the year 2030.

5. HH/LSM model simulation study name.

6. The customer purchase request (demand) information is based on the demand and request studies prepared by the SFPUC in coordination with the wholesale customers (SFPUC/URS 2004). This demand on the regional water system includes both the SFPUC retail customers and wholesale customers. The current (2005) average annual demand is 265 mgd and the projected 2030 average annual demand is 300 mgd, assuming the SFPUC adopts the updated wholesale customer purchase requests as part of the Master Sales Agreement renewal with these customers (due in 2009).

7. Certain scenarios include the development of additional water supply from a combination of recycled water projects, groundwater projects, and conservation, utilized every year and not subject to reduction during drought.

8. The average annual demand for supplies from the combination of the SFPUC local watershed and Tuolumne River, as well as programs not included in the regional water conservation, reclamation, and groundwater programs shown.

9. Modeled results for SFPUC deliveries, with supplies added for regional water conservation, reclamation, and groundwater programs. Total deliveries and supply will be less than full customer purchase requests due to rationing in some years.

10. Shows only the features that affect hydrologic results of the system operation simulations. Additional projects are included in the WSIP, variants, and alternatives.

11. Illustrates the frequency and severity of water supply action or severity of system-wide rationing. Only years in which variable water supply component is implemented or rationing occurs are shown. "DD" illustrates the shortage results for years included in the prospective drought period of the SFPUC Design Drought. These years contribute to establishing system operation protocols but are not included in the hydrologic assessment analyses.

12. Rationing policy cap: The SFPUC WSIP level of service goal is to maintain rationing on the regional system at no more than 20% during any one year of the drought. Some alternatives do not achieve this level of service goal. Performance is indicated for both the Design Drought ("DD") sequence and "Historical" hydrologic sequence.

13. Water supply elements develop water in different amounts from year to year, and, in some instances, they only develop water during dry years. This information is provided to compare local watershed supplies, Tuolumne River supplies, and other identifiable water supplies used to meet system purchase requests. Values are stated in units of average annual quantities during the simulated historical sequence.

14. Results from HH/LSM analysis of each scenario. Values represent the average annual production of each element of supply during the design drought period.

15. Simplified calculation of system deliveries during the SFPUC design drought. The value represents the application of system-wide shortages to the demand level being met with SFPUC local watershed, Tuolumne, and other developed supplies, and does not include supplies from regional water conservation or from recycled water or groundwater projects. Average value may be slightly misstated (up to 3 mgd) due to metric of analysis that does not account for differences in residual storage between studies. "Nominal" firm yield represents the yield of each scenario after adjustment for minor residual storage differences.

16. Supplemental releases from Calaveras Reservoir for fisheries (1997 MOU) of up to 6,300 AFY and the Alameda Creek Recapture project are tied to implementation of the Calaveras Dam replacement project. When the dam is replaced and capacity restored, both the flow release and recapture will occur. The release requirement is based on the supplementation of other occurring flows below Calaveras Reservoir, sometimes not requiring the full 6,300 acre-feet.

17. SFPUC actions are assumed to leave MID/TID diversions unchanged so that the SFPUC effects on the Tuolumne River below La Grange Dam are isolated and possibly overstated. The Districts' diversions are assumed to be constant among the scenarios to provide comparable results of SFPUC-alone effects.

18. Participation in the San Joaquin River Agreement is assumed. Although the agreement expires after 2010, it is assumed that a subsequent similar agreement or requirement of the Districts will occur. HH/LSM does not explicitly model the Districts' participation in the agreement; however, its participation if modeled would result in only minor differences in results and would not change impact conclusions.

19. From HH/LSM results for modeling the SFPUC Design Drought Period.

20. From HH/LSM results for modeling the system operations for the historical hydrologic period 1921-2002. Values indicate average annual quantities during the simulated historical period.

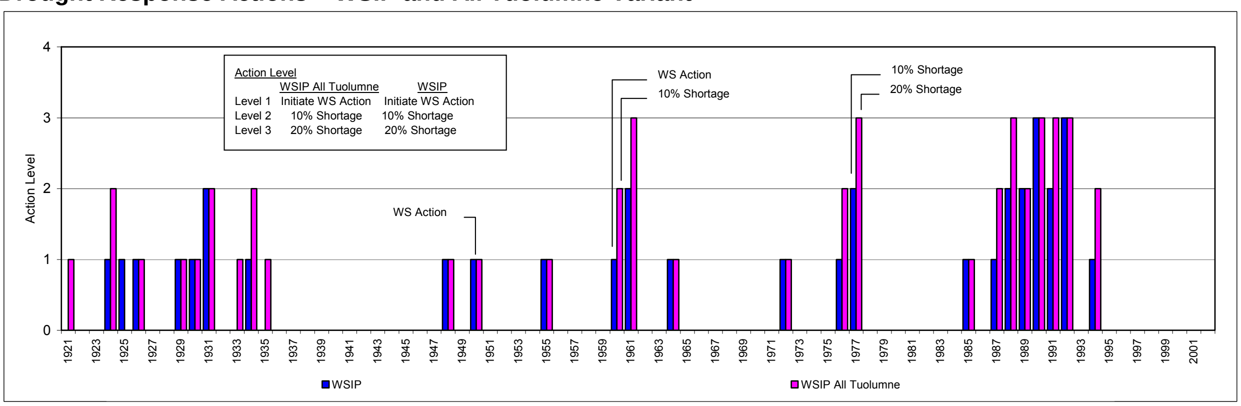
2. WSIP Variant 1 - All Tuolumne

WSIP Variant 1 - All Tuolumne variant would be identical to the proposed program (WSIP), except that the programs used to serve the increase in purchase request (from 265 to 300 million gallons per day [mgd]) and improvement in supply reliability would not include a supply of 10 mgd from implementation of the Recycled Water Projects (SF-3), Local Groundwater Projects (a component of SF-2, Groundwater Projects), and additional conservation programs (collectively referred to in this memorandum as RRGWC). In effect, the absence of the 10 mgd of RRGWC requires the Regional Water System's resources to serve a 300-mgd demand instead of a net 290-mgd demand. In all other aspects, this variant would include the same water supply sources as the WSIP, and would incorporate the same restored storage features of Calaveras and Crystal Springs Reservoir and the integration of the Westside Basin Groundwater Program. Identical to the WSIP, also included is a supplemental water supply for delivery during drought obtained from Tuolumne River diversions through transfers from the Turlock Irrigation District (TID) and Modesto Irrigation District (MID).

2.1 Water Deliveries and Drought Response Actions

The same amount of MID/TID Tuolumne River water transfer (27,000 acre-feet) is modeled for both the proposed program and the variant. With the absence of 10 mgd of RRGWC, the Regional Water System's resources are required to serve a 300-mgd demand instead of a net 290-mgd demand. This greater demand being served with the same amount of supply leads to a more frequent implementation of rationing and a greater severity of rationing during drought periods. This rationing is applied to the 300-mgd level of demand as opposed to the 290-mgd level of demand. Table 1-1 compares the drought response actions of the proposed program and the variant. Figure 2.1-1 illustrates the drought response actions for the simulated 82-year historical period (1921-2002) for the variant and WSIP settings.

Figure 2.1-1
Drought Response Actions – WSIP and All Tuolumne Variant



In Figure 2.1-1, years with bars showing a "1" or greater level of action indicate periods when a supplemental water supply action is initiated. In these scenarios, the water supply action is the use of the Westside Basin Groundwater Program to supplement San Francisco Public Utilities Commission (SFPUC) water deliveries. Action levels greater than "1" indicate the imposition of delivery shortages (rationing) to SFPUC customers. The initiation of supplemental supplies from the Westside Basin Groundwater Program, frequency of imposed delivery shortages, and severity of shortages all increase in the variant setting.

The same form of information is shown in Figure 2.1-2 in comparing the variant and the "Base - Calaveras Constrained" (existing) settings. In modeling parlance, there is no level 1 action level in the base setting. Without supplemental resources, the existing system has only delivery shortage measures available to cope with drought. This shortage measure is imposed during level 2 (10 percent) and level 3 (20 percent). These percentages of shortage are applied to both the variant and base setting for these action levels, although they are applied to different levels of water demand. In the variant, the system's water demand is an average annual net 300 mgd; in the base setting, the water demand is 265 mgd.

Figure 2.1-2
Drought Response Actions – Base and All Tuolumne Variant

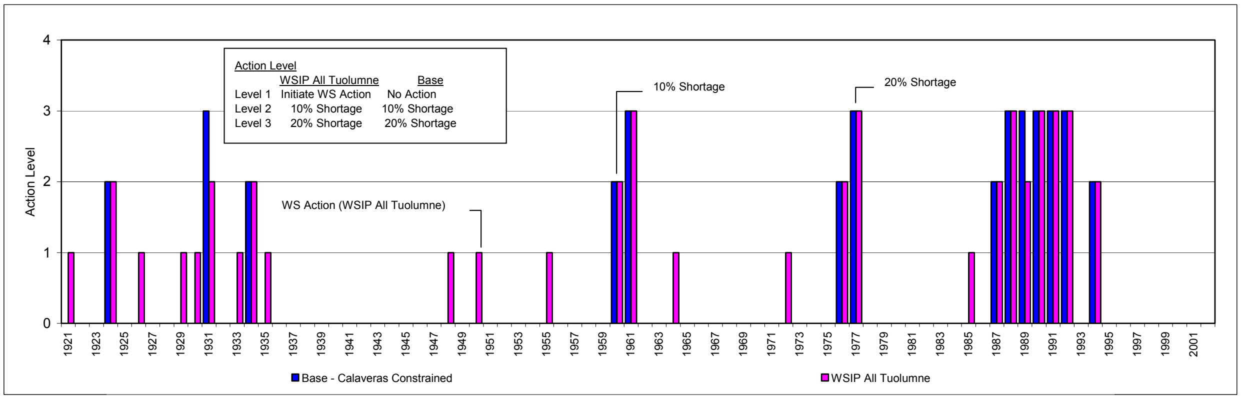


Figure 2.1-2 illustrates that, when compared to the base setting, the variant triggers supplemental resources at an early indication of drought, during periods when in the current setting there is no supplemental resource available to the system. The use of the supplemental resource during these times results in the lessening of (or at least a non-increase in) the severity of delivery shortage, even with an increase in deliveries.

Not illustrated in Figure 2.1-2, but shown in Table 1-1, are the delivery shortages anticipated during the entire SFPUC Design Drought. Shortages during the Design Drought with the variant are maintained within the objective to limit the severity of shortage to no more than 20 percent. This objective is also achieved with the WSIP. However, with the variant, an additional 10 percent of shortage occurs during 3 more years than with the WSIP, but the shortages occur to a larger demand (300 mgd). Over the Design Drought, approximately the same amount of water is delivered to SFPUC customers for the proposed program and the variant. With the existing system, the 20-percent-limitation (cap) objective cannot be achieved during the last 18 months of the Design Drought, and a 25 percent shortage is applied.

The difference in water deliveries between the proposed program and the variant is shown chronologically for the 82-year simulation in Table 2.1-1. The years indicating positive differences amounting to approximately 3,600 million gallons indicate periods when 10 mgd of demand is being met from the regional system (which, in the proposed program, is being met from RRGWC). The years showing positive differences of approximately 6,300 million gallons represent years when additional replenishment of the Westside Basin Groundwater Program was necessary after an additional draw from the program was needed to partially offset the absence of the 10 mgd of RRGWC. The years showing a reduction of deliveries of approximately 7,000 million gallons represent years of additional shortages with the variant.

2.2 Diversions from Tuolumne River

The metric for illustrating the SFPUC diversion from the Tuolumne River Basin is the flow through the San Joaquin Pipeline (SJPL). Inherent to this variant is the draw of additional water from the Tuolumne River Basin to replace the 10 mgd of RRGWC that was included in the proposed program. Table 2.2-1 illustrates the difference in diversions to the SJPL between the proposed program and the variant. The differences appear much less systematic than the system deliveries shown in Table 2.1-1 because system storage buffers the change in deliveries; however, the reductions in SJPL diversions are generally associated with periods of reduced system-wide deliveries, and the increases are due to additional water diversions to offset the absence of the 10 mgd of RRGWC included in the proposed program. The additional diversion typically occurs from October through March when unused capacity is available in the SJPL. During the spring and summer, the SJPL is modeled in both settings to be diverting at maximum capacity to minimize the amount of storage drawn from local Bay Area reservoirs. Table 2.2-2 illustrates the average monthly diversion through the SJPL, by year type, for the 82-year simulation period for the proposed program and the variant.

2.3 Hetch Hetchy Reservoir and Releases

The additional draw of water for the SJPL will cause an increase in draw from Hetch Hetchy Reservoir; however, the additional draw of storage does not occur every year, and the largest differences are due to the accumulation of additional draw over a series of years. Figure 2.3-1 illustrates a chronological trace of the simulation of Hetch Hetchy Reservoir storage and stream releases. Shown in Figure 2.3-1 are the results for the WSIP, variant (“WSIP All Tuolumne”), and base (“Base – Calaveras Constrained”) settings. Supplementing the Figure 2.3-1 representation of Hetch Hetchy Reservoir storage are Table 2.3-1 Hetch Hetchy Reservoir Storage (All Tuolumne), Table 2.3-2 Hetch Hetchy Reservoir Storage (WSIP), and Table 2.3-3 Difference in Hetch Hetchy Reservoir Storage (All Tuolumne minus WSIP). Table 2.3-4 illustrates the difference in Hetch Hetchy Reservoir storage between the base and variant settings.

Table 2.3-3 illustrates that, throughout the summer and into the fall, storage in Hetch Hetchy Reservoir in the variant setting would differ from the storage in the WSIP setting only in some years, and this difference could be more or less storage. Although Hetch Hetchy Reservoir would typically be lower in storage during the fall and winter, generally coincident with the additional diversion to the SJPL, Hetch Hetchy Reservoir normally fills by the end of May, which would negate the additional draw from storage carrying into the next summer. The greatest draw from reservoir storage occurs during the droughts of the 1930s and 1976-1977, which is not coincident with the year of greatest difference in reservoir draw between the base setting and either the WSIP or variant setting. There are exceptions to the additional draw when the variant causes a greater level of rationing (e.g., 1987-1988), which then reduces diversion from Hetch Hetchy. This results in greater storage in the variant setting than in the WSIP setting. Figure 2.3-2 illustrates the difference in reservoir storage, averaged by year type, to compare the variant to the WSIP setting. Also shown is the average difference in storage for the two settings. Figure 2.3-3 illustrates the same information in comparing the variant and base settings. Figure 2.3-4 illustrates the average monthly storage in Hetch Hetchy Reservoir for the 82-year simulation, and the range in storage for each month for the variant and base settings.

The difference in storage in Hetch Hetchy Reservoir attributed to the diversion effects of the variant would manifest into differences in releases from the reservoir to the stream. A different amount of available reservoir space in the winter and spring due to the variant would lead to a different ability to regulate inflow, thus potentially changing the amount of water released to the stream (which is above minimum release requirements). Figure 2.3-1 illustrates the stream release from the dam for the WSIP, variant, and base settings. Table 2.3-5 illustrates the difference in stream releases between the variant and WSIP settings. Compared to the WSIP setting, the variant typically exhibits an incrementally larger reduction in stream releases, predominantly during May or June, which reflects the months when releases to the stream above minimum release requirements are made in anticipation of filling the reservoir. There are exceptions to the reductions (increases) during periods when the variant causes incrementally greater delivery shortages, thereby leaving greater storage in the reservoir.

Table 2.3-5 illustrates the difference in stream release between the variant and WSIP settings, expressed in terms of a monthly volume (acre-feet) of flow. Table 2.3-6 illustrates the same information and the average monthly stream release for the variant and WSIP setting, expressed in average monthly flow (in cubic feet per second [cfs]). Table 2.3-7 illustrates the same form of information in comparing the variant and base settings.

Table 2.3-5 illustrates that the difference in monthly flow below O'Shaughnessy Dam could range from an increase of approximately 24,000 acre-feet to a decrease of approximately 18,000 acre-feet. Considering the manner in which releases are determined and made to the stream, quantifying the effect of these changes in terms of average monthly flow (cfs) is not always meaningful.[1] When comparing the variant to the WSIP setting, a change in the volume of release from O'Shaughnessy Dam to the stream would likely result in the delay or earlier initiation of the release by a matter of days. Typical springtime releases, when initiated, amount to a release up to 3,000 cfs (approximately 6,000 acre-feet over the span of a day). Assuming that a change in release volume equates to a delay or earlier initiation of a 6,000 acre-feet-per-day release, the difference in stream release from O'Shaughnessy Dam between the variant and WSIP would be a delay up to 3 days or up to an added 4 days of release. Normally, the effect of the delay in release would not affect the year's peak stream release rate during a year. Comparing the variant and WSIP setting, a change (increase or decrease) in stream release would occur in approximately 60 percent of the years simulated.

Compared to the base setting, the variant's effect to stream flow is very similar to the effect caused by the WSIP, but at times slightly greater. Table 2.3-8 illustrates the difference in stream release between the variant and base settings, expressed in terms of a month-to-month volume (acre-feet) of flow. Assuming the type of effect to releases described above, the releases above minimum requirements below the dam could be delayed by up to 9 days or initiated earlier by up to 2 days.

2.4 Lake Lloyd and Lake Eleanor

Compared to the operation of the WSIP, the operation of Lake Lloyd and Lake Eleanor are simulated to be only slightly different in the variant. Figure 2.4-1 illustrates a chronological trace of the simulation of Lake Lloyd storage and stream releases. Shown in Figure 2.4-1 are the results for the WSIP, variant, and base setting. The operation resulting from the variant is essentially the same as the WSIP, except during the prolonged drought of 1987-1992. The difference is explained by modeling assumptions for the discretionary judgment used by system operations to balance reservoir operations within the system, and the modeled differences are not likely to occur. HH/LSM model logic estimates the amount of water to be released from Lake Lloyd based on the condition of Hetch Hetchy Reservoir, the Don Pedro Water Bank Account, and Lake Eleanor and Lake Lloyd storage in comparison to demands. In this instance, Hetch Hetchy Reservoir storage is slightly lower in the variant at the later stage of the drought, and larger demands are anticipated within the variant. The model logic retains more storage in Lake Lloyd (in anticipation of a larger need) than in the WSIP setting. The model logic is not very refined, and a small change in computation can result in a large difference in Lake Lloyd release (in this instance, through Holm Powerhouse). Overall, the Lake Lloyd operation would be discretionary, and the outcome would likely be very similar if not the same between the variant and the WSIP settings.

Figure 2.4-2 illustrates the almost identical operation of Lake Eleanor for the variant and WSIP settings. Also shown in Figure 2.4-2 is the operation for the base setting. Any difference that occurs in the Lake Eleanor operation would be caused by a small change in operation at Lake Lloyd that would affect the operation of the Cherry-Eleanor Tunnel between the two watersheds. Any difference that occurs in the simulations is associated more with modeling discretion than with any substantive difference in operation.

Supplementing the Figure 2.4-1 representation of Lake Lloyd stream releases is Table 2.4-1, which illustrates releases for the variant and WSIP settings and the difference in releases between the two. Table 2.4-2 provides the same form of information for the variant and base settings.

[1] See "Estimated Effect of WSIP on Daily Releases below Hetch Hetchy Reservoir", Memorandum by Daniel B. Steiner, December 31, 2006.

2.5 Don Pedro Reservoir and La Grange Releases

A change in Don Pedro Reservoir operation is caused by changes in inflow to the reservoir. The changes in inflow to the reservoir are the result of net changes within the operation of the upstream SFPUC facilities, described previously, and other changes in SFPUC operations associated with diversions to the Holm, Kirkwood, and Moccasin Powerhouses. Figure 2.5-1 illustrates a chronological trace of the simulation of Don Pedro Reservoir storage and Tuolumne River stream releases from La Grange Dam. Shown in Figure 2.5-1 are the results for the WSIP, variant, and base settings.

Supplementing the Figure 2.5-1 representation of Don Pedro Reservoir storage are Table 2.5-1 Don Pedro Reservoir Storage (All Tuolumne), Table 2.5-2 Don Pedro Reservoir Storage (WSIP), and Table 2.5-3 Difference in Don Pedro Reservoir Storage (All Tuolumne minus WSIP). Table 2.5-4 illustrates the difference in Hetch Hetchy Reservoir storage between the base and variant settings.

Table 2.5-3 illustrates that, throughout many years, the storage in Don Pedro Reservoir associated with the variant setting would differ from the storage in the WSIP setting, and that this difference could be more or less storage. When there is a change, the change occurs because inflow to the reservoir differs between the two settings in a month or series of months when Don Pedro Reservoir is below the flood control storage limitation and can regulate inflow with storage. When no storage difference occurs for months or other periods of time, either inflow to the reservoir did not change between the settings or (if inflow was different while storage was at the flood control storage limitation) the change in inflow manifests as a change in release to the Tuolumne River below La Grange Dam (discussed later).

The greatest draw from reservoir storage occurs during the drought of 1976-1977, which does not coincide with the year of greatest difference in reservoir draw between the base setting and either the WSIP or variant settings, the drought of the 1930s. There are exceptions to reductions in storage (due to a reduction in inflow) when the variant causes a greater level of SFPUC rationing (e.g., 1987-1988), which then reduces the SFPUC's upstream diversion from the Tuolumne and leads to greater inflow to Don Pedro Reservoir in a subsequent period. Figure 2.5-2 illustrates the difference in reservoir storage, averaged by year type, in comparing the variant to the WSIP settings. Also shown is the average difference in storage for the two settings during the 82-year simulation. Figure 2.5-3 illustrates the same information in comparing the variant and base settings.

Figure 2.5-4 illustrates the average monthly storage in Don Pedro Reservoir for the 82-year simulation, and the range in storage for each month for the variant and base settings.

The difference in storage in Don Pedro Reservoir attributed to the upstream effects of the variant would manifest into differences in releases from La Grange Dam to the stream. A different amount of available reservoir space in the winter and spring due to the variant would lead to a different ability to additionally regulate inflow, thus potentially changing the amount of water released to the stream, which is above minimum release requirements. During periods when inflow differs and Don Pedro Reservoir is at maximum storage capacity within the flood control storage limitation, a change in inflow directly manifests as a change in release from La Grange Dam (a change in either more or less flow). Figure 2.5-1 illustrates the stream release from La Grange Dam for the WSIP, variant, and base settings.

Figure 2.5-2

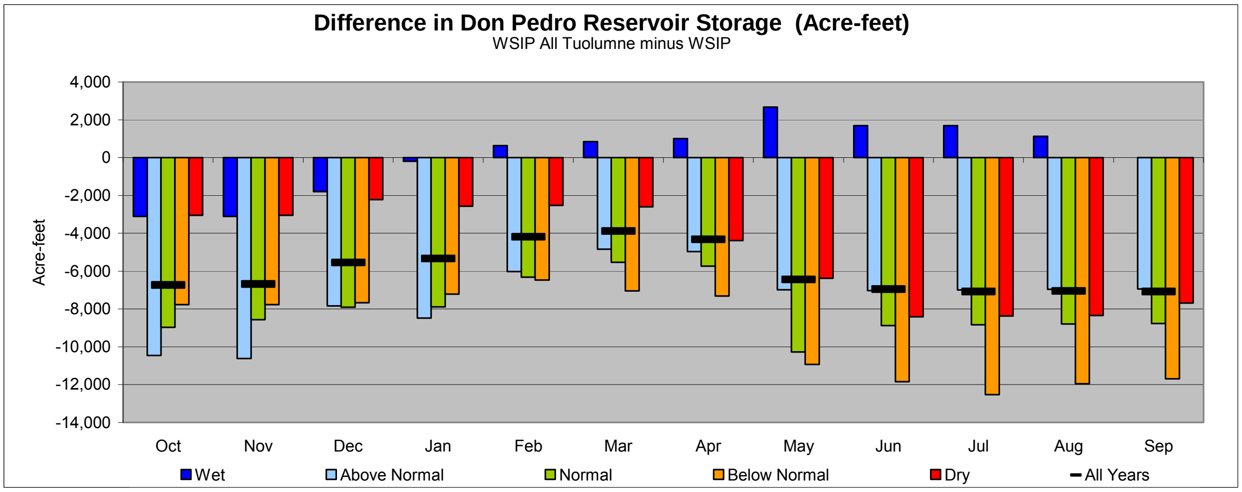

Figure 2.5-3

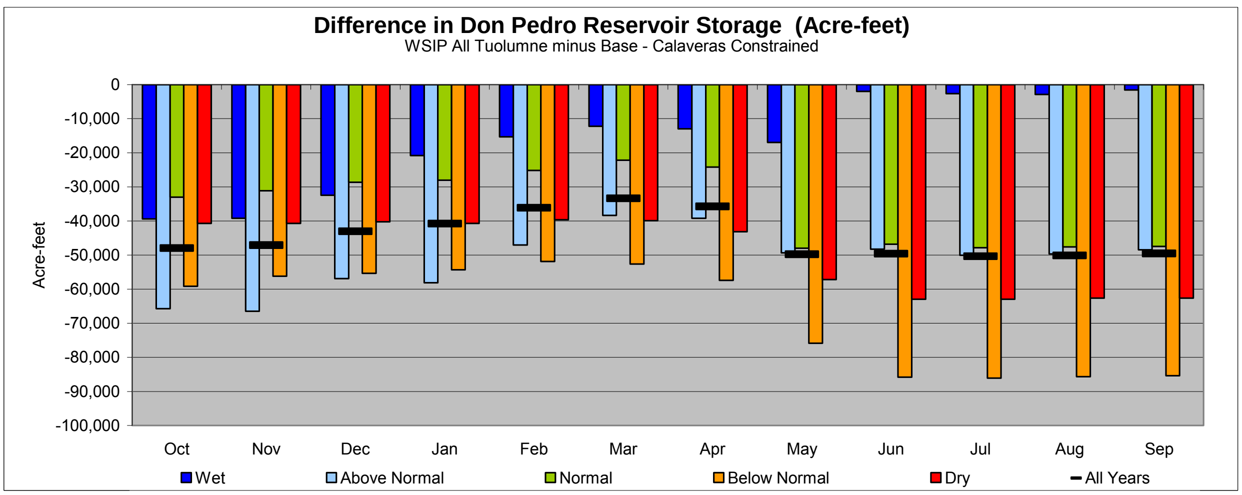

Figure 2.5-4

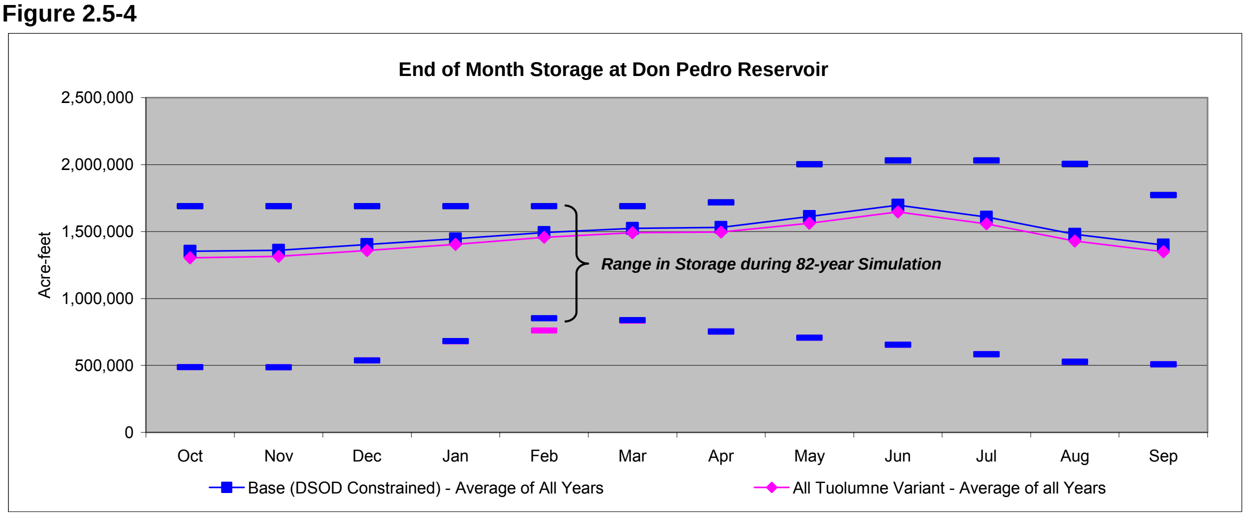

Table 2.5-5 illustrates the difference in stream releases between the variant and WSIP settings. Compared to the WSIP setting, the variant typically exhibits an incrementally larger reduction in stream releases, predominantly during early winter through June, which reflects the months when releases to the stream above minimum release requirements are made, due to flood control or in anticipation of filling the reservoir. Increase in releases to the stream sometimes occur, during periods when the variant causes incrementally greater delivery shortages, which thereby provides greater inflow to the reservoir (and subsequent additional release) as compared to the WSIP setting. Table 2.5-6 illustrates the same information in comparing the variant and WSIP settings, with years ranked by descending order of the San Joaquin River Index. The table shows the finding that differences in releases to the Tuolumne River from La Grange Dam would occur only with releases above minimum Federal Energy Regulatory Commission (FERC) flow requirements. This circumstance typically occurs only in above normal and wet years, and predominantly during early winter through June. During other year types and during the summer and fall, releases would be maintained at minimum FERC flow requirements regardless of the setting.

Table 2.5-5 illustrates the difference in stream release between the variant and WSIP settings, expressed in terms of a monthly volume (acre-feet) of flow. Table 2.5-7 illustrates the same information and the average monthly stream release for the variant and WSIP settings, expressed in average monthly flow (cfs). Table 2.5-5 illustrates that the difference in monthly flow below La Grange Dam could range from an increase of approximately 21,000 acre-feet to a decrease of approximately 54,000 acre-feet. Considering the manner in which releases are determined and made to the stream, quantifying the effect of these changes in terms of average monthly flow (cfs) is not always meaningful. Similar to the operation of releases below O'Shaughnessy Dam, a change in the volume of release from La Grange Dam to the stream would likely result in the delay or earlier initiation of the release by a matter of days. Assuming that a change in release volume equates to a delay or earlier initiation of releasing 6,000 acre-feet per day, the difference in stream release from La Grange Dam between the variant and WSIP would be a delay in releases up to 9 days or up to an added 3 days of release. Normally, the effect of the delay in release would not affect the year's peak stream release rate during a year. However, infrequently, the variant's effect on stream releases could manifest as an elimination of all flows above minimum FERC flow requirements within a year. This would occur after the experience of an extended drought period. Comparing the variant and WSIP settings, a change (increase or decrease) in stream release would occur in approximately 50 percent of the years simulated.

Table 2.5-8 illustrates the releases to the Tuolumne River below La Grange Dam and their differences for the variant and base settings, provided in terms of average monthly flow (cfs) averaged within year types. Table 2.5-9 illustrates the results for the comparison of the variant and the base settings, in the same format as Table 2.5-5, showing the simulated month-to-month flow (volume) changes between the two settings. Compared to the base setting, the variant's effect to stream flow is very similar to the effect caused by the WSIP, but at times slightly greater. Assuming that a change in release volume equates to a delay or earlier initiation of releasing 6,000 acre-feet per day, the difference in stream release from La Grange Dam between the variant and base would typically be a delay in releases up to a few days. Normally, the effect of the delay in release would not affect the year's peak stream release rate during a year. However, infrequently, following a prolonged multi-year drought period, the variant's effect on stream releases could manifest as an elimination of all flows above minimum FERC flow requirements within a year.

Table 2.5-5

Difference in Total La Grange Release to River (Acre-feet)

WSIP All Tuolumne minus WSIP

2.6 Calaveras and San Antonio Reservoirs, Alameda Creek and Downstream

There is only a slight difference in Calaveras Reservoir operations between the variant and WSIP settings. Figure 2.6-1 illustrates a chronological trace of the simulation of Calaveras Reservoir storage and stream releases from Calaveras Dam. Shown in Figure 2.6-1 are the results for the WSIP, variant, and base settings. The difference in Calaveras Reservoir storage between the variant and WSIP settings is mostly caused by the interaction of the increased demand served by the system's resources (300 mgd for the variant and a net 290 demand for the WSIP) and the operation of the SJPL. Generally, the systematic minor decrease in reservoir storage in most years is due to the additional demand drawing slightly more water from Calaveras Reservoir during the summer when the SJPL is operating at maximum capacity. In a few instances, storage is greater in the variant setting. This occurs when greater water delivery reductions are required in the variant setting, thus reducing the draw from Calaveras Reservoir as compared to the WSIP setting. The difference in storage between the variant and WSIP settings and the base setting is due to the restoration of the operational capacity of Calaveras Reservoir. Figure 2.6-2 illustrates the average monthly storage in Calaveras Reservoir for the 82-year simulation, and the range in storage for each month for the variant and base settings.

There is essentially no change (i.e., change occurs infrequently) in releases to Calaveras Creek below Calaveras Dam between the variant and WSIP settings. Both settings have fishery releases that are not included in the base setting. Table 2.6-1 illustrates the difference in releases to Calaveras Creek between the variant and WSIP settings. Supplementing the Figure 2.6-1 representation of Calaveras Dam stream releases and Table 2.6-1 is Table 2.6-2, illustrating releases for the variant and WSIP settings, and the difference in releases between the two. Table 2.6-3 provides the same form of information for the variant and base settings. The notable difference in releases between the variant and base settings is the addition of the flows associated with the 1997 Memorandum of Understanding (MOU) and the reduction of stream releases during wetter-year/wetter-season flows due to the restoration of Calaveras Reservoir operational capacity.

There is essentially no change (i.e., minor difference occur during 2 months of the 82-year simulation) in Alameda Creek diversions to Calaveras Reservoir between the variant and the WSIP settings. With almost no change in Calaveras Reservoir storage between the two settings, there would be no change in the diversion operation at the Alameda Creek Diversion Dam. Water would only be diverted to Calaveras Reservoir when the diversion would not contribute to releases below Calaveras Dam that are above minimum required flows . Coincidentally, with no change in the diversion at Alameda Creek Diversion Dam, flow spilling past the diversion dam would be the same in both the variant and WSIP settings. Table 2.6-4 illustrates the flow below the Alameda Creek Diversion Dam for the variant and base settings. The notable difference between the variant and the base settings is the reduction of wetter-year water flowing past the diversion dam. This occurs because, in the variant setting, the restoration of Calaveras Reservoir storage allows a greater frequency of diversion from Alameda Creek to Calaveras Reservoir.

Comparing the variant and WSIP settings, with no differences in releases from Calaveras Dam to the stream, and no differences to spills at Alameda Creek Diversion Dam, flow below the Alameda Creek and Calaveras Creek confluence will be the same for each setting. Table 2.6-5 illustrates the flow below the confluence for the variant and WSIP settings, and the similarity in flow between the two. Table 2.6-6 provides the same form of information for the variant and base settings. The notable differences between the variant and the base settings (comparable to the difference between the WSIP and base settings) are the addition of required stream flows for the 1997 MOU and the reduction of wetter-year/wet-season flows due to the restoration of Calaveras Reservoir storage.

A flow recapture facility in Alameda Creek below Calaveras Reservoir is incorporated in the variant and WSIP settings. This facility is assumed to recapture flows explicitly released from Calaveras Dam for the 1997 MOU. The effect of the recapture is a reduction in the flow that occurs below the confluence of Alameda and Calaveras Creeks, but only to the extent that releases were explicitly made from Calaveras Reservoir for the 1997 MOU. Table 2.6-7 illustrates the flow below the confluence and upstream of the Alameda and San Antonio Creek confluence for the variant and WSIP settings, and the similarity in flow between the two. Table 2.6-8 provides the same form of information for the variant and base settings. The flows at this location are indicative of flow occurring below the confluence of Alameda and Calaveras Creeks (described above), with the addition of estimated stream accretions between the Alameda and Calaveras Creek confluence and the Alameda and San Antonio Creek confluence, minus the water assumed to be recaptured (diverted) from the creek by the SFPUC.

Compared to the WSIP setting, San Antonio Reservoir operations in the variant setting generally mirror the changes experienced for Calaveras Reservoir operations. Figure 2.6-3 illustrates a chronological trace of the simulation of San Antonio Reservoir storage and stream releases from the dam. Shown in Figure 2.6-3 are the results for the WSIP, variant, and base settings. The difference in San Antonio Reservoir storage between the variant and WSIP settings is mostly caused by the interaction of the increased demand served by the system's resources (300 mgd for the variant and a net 290 demand for the WSIP) and the operation of the SJPL. Mirroring the Calaveras Reservoir effect, the systematic minor decrease in reservoir storage in most years is due to the additional demand drawing slightly more water from the Bay Area reservoirs during the summer when the SJPL is operating at maximum capacity. In a few instances, storage is greater in the variant setting. This occurs when greater water delivery reductions are required in the variant setting, thus reducing the draw from Bay Area reservoirs as compared to the WSIP setting.

The effect of the difference in San Antonio Reservoir storage depends on modeling assumptions for the balancing of total Bay Area reservoir storage among the five major SFPUC reservoirs. The model balances storage between reservoirs by way of an input file by the modeler concerning the relative draw (percentage) from each reservoir under various storage conditions. These are discretionary input in the model, and the logic and relative percentages are meant to mimic the current practice and

Figure 2.6-3

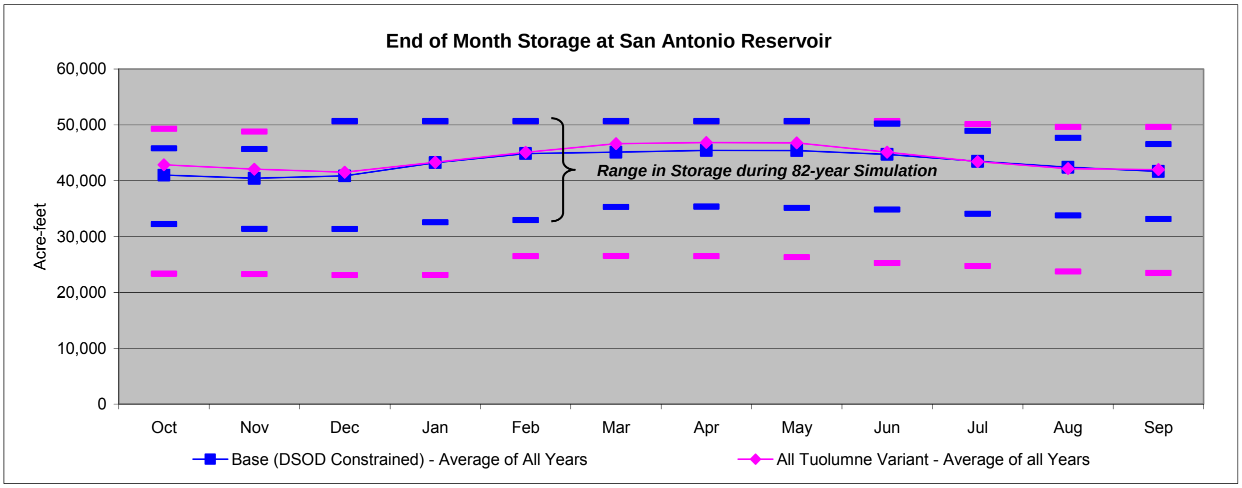
discretion of the system operators based on recognition of the physical conveyance constraints within the system and the ability of each reservoir to provide yield and water delivery security.

The difference in storage between the variant and WSIP settings and the base setting is due to the restoration of the operational capacity of Calaveras Reservoir. In the base setting, the limited operating storage capacity at Calaveras leads to a different operation at San Antonio Reservoir, one that provides relatively more stored water for system demands when the draw from Calaveras Reservoir is constrained because of limited storage. There is also a notable difference in storage operation between the variant and WSIP settings and the base setting every fifth year. Assumed systematic maintenance of Hetch Hetchy conveyance facilities occurs in the simulation that constrains diversions to the Bay Area from Hetch Hetchy every fifth year. The reduction in diversion from Hetch Hetchy during these periods is accommodated in the system by additional water draws from the Bay Area reservoirs. The proportionate share of this operation is evident in the tracing of San Antonio Reservoir storage for the variant and WSIP settings. Figure 2.6-4 illustrates the average monthly storage in Calaveras Reservoir for the 82-year simulation, and the range in storage for each month for the variant and base settings.

Figure 2.6-4



There would very little change in stream releases below San Antonio Reservoir between the variant and WSIP settings. Table 2.6-9 illustrates the modeled release to San Antonio Creek from San Antonio Reservoir for the two settings and the differences for the average release during a year type. With a slightly lower reservoir operation at times during the winter, as seen in Figure 2.6-4, an increase in the ability to regulate reservoir inflow and avoid stream releases would be expected. Given the sometimes rigid constraints of the modeling assumptions, the model will overestimate the frequency and magnitude of stream releases from San Antonio Reservoir under any of the investigated settings. The flexibility that occurs in actual operations would likely serve to avoid most of the releases represented by the model. The modeled stream releases from San Antonio Reservoir and difference between releases for the variant and base setting are shown in Table 2.6-10. The differences among the two settings range from increases to decreases in flow. This modeled circumstance reflects the different resulting storage operation between the two settings, as seen in Figure 2.6-3. In some circumstances, the base setting storage at San Antonio Reservoir could be higher than projected for the variant setting during the same period. This circumstance could lead to an occasionally greater modeled release for the base setting, which would be reflected in the results. As described above, the model will overestimate the frequency and magnitude of releases from San Antonio Reservoir, and the actual releases from San Antonio Reservoir in any setting and the difference between settings are expected to be minor.

Flow below the confluence of Alameda and San Antonio Creeks is influenced by releases from San Antonio Creek and flow arriving at the location from Alameda Creek, which includes upstream impairment by SFPUC operations and facilities. Table 2.6-11 illustrates the flow below the confluence for the variant and WSIP settings, and the differences in flow between the two.

Table 2.6-12 illustrates the same information in comparing the variant and base settings. Table 2.6-11 illustrates the minor modeled differences in flow that occur between the variant and WSIP settings, while Table 2.6-12 illustrates the relatively larger differences in flow that could occur between the variant and base settings. The difference is particularly due to the effects of the restoration of Calaveras Reservoir operating capacity in the variant setting.

2.7 Crystal Springs and San Andreas Reservoirs

There are differences in Crystal Springs Reservoir operations between the variant and WSIP settings. Figure 2.7-1 illustrates a chronological trace of the simulation of Crystal Springs Reservoir storage and stream releases from Crystal Springs Dam. Shown in Figure 2.7-1 are the results for the WSIP, variant, and base settings. The difference in Crystal Springs Reservoir storage between the variant and WSIP setting is caused by the interaction of the increased demand served by the system's resources (300 mgd for the variant and a net 290 demand for the WSIP) and the operation of the SJPL and Bay Diversion Pipelines (BDPL). Generally, the systematic decrease in reservoir storage is due to the additional demand drawing more water from the Bay Area system reservoirs during the summer when the SJPL is operating at maximum capacity. A portion of this additional draw is focused on Crystal Springs Reservoir. Subsequent to the additional draw of storage, Hetch Hetchy would attempt to replenish the Bay Area system reservoirs. However, there are modeled circumstances in which the coincidence of SJPL or BDPL capacity constraints would inhibit the ability to replenish Crystal Springs Reservoir storage. During these periods, Crystal Springs Reservoir storage would be lower in the variant setting than in the WSIP setting. The exception to the lower storage condition would be during periods when the variant condition leads to greater delivery shortages (rationing, and therefore less delivery) or the initiation of drought water supplies (in this setting, the offset of demand with the Westside Groundwater Program). During these periods, Crystal Springs Reservoir storage becomes greater in the variant setting than in the WSIP setting because of the lesser need for water from the reservoirs. The magnitude of the additional draw of storage from Crystal Springs Reservoir and the lesser draw from storage during drought partially depends on the discretionary assumptions of the model that proportion the use of storage among the Bay Area system reservoirs. In actual operations, some of the differences in result may not occur as system operators and prevailing hydraulic and hydrologic conditions may direct the operational effect of the different demand to an alternative apportionment of effect among the reservoirs. Figure 2.7-2 illustrates the average monthly storage in Crystal Springs Reservoir for the 82-year simulation, and the range in storage for each month for the variant and WSIP settings.

Figure 2.7-3 illustrates the average monthly storage in Crystal Springs Reservoir for the 82-year simulation, and the range in storage for each month for the variant and base settings. Consistent with the comparison of the WSIP and base settings, the variant setting would result in reservoir storage operating at a higher

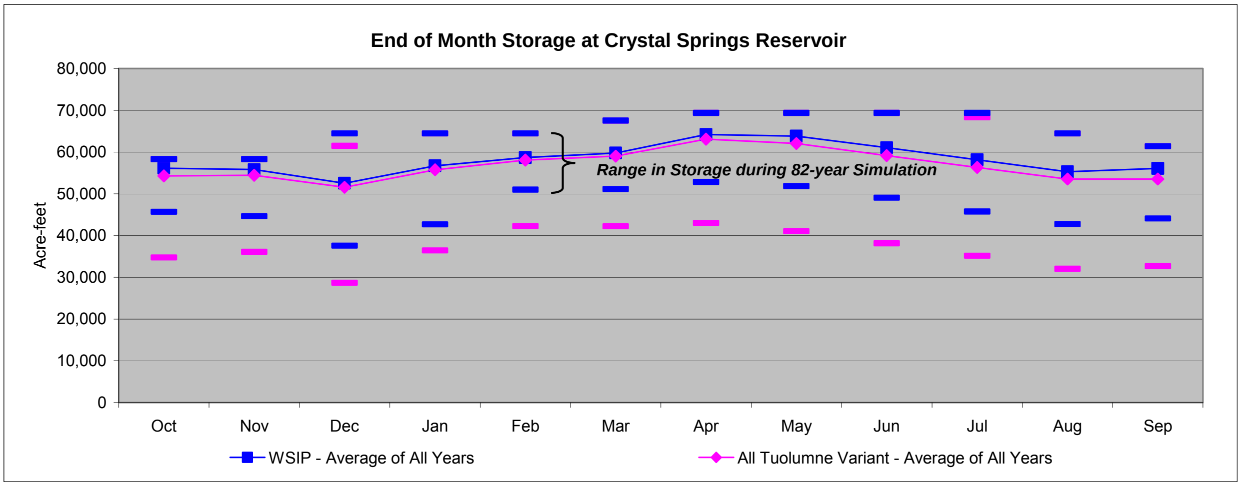

Figure 2.7-3

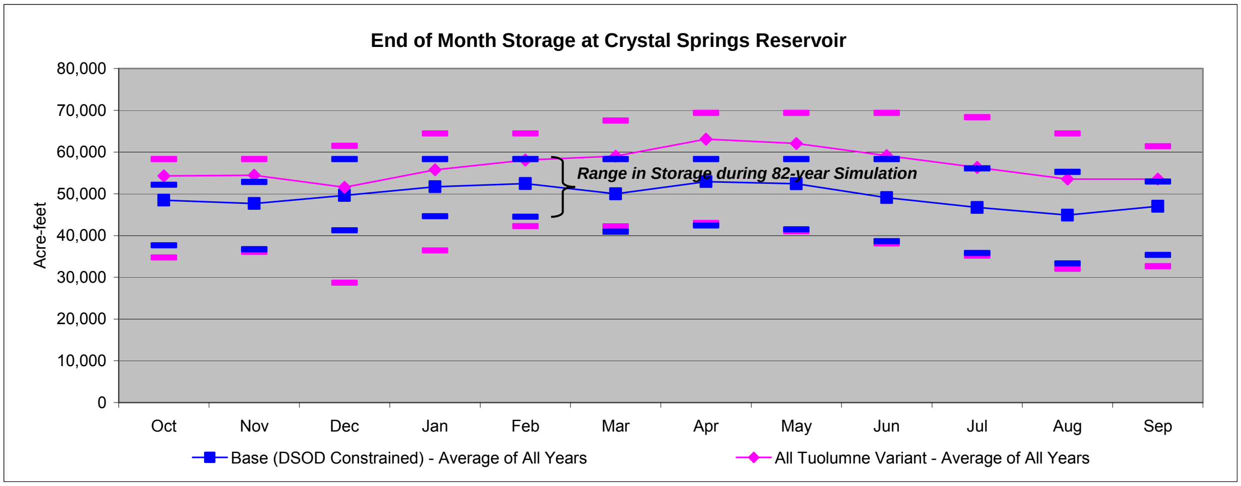

average and higher upper-range than the base setting. This occurs due to the restoration of the operating capacity of Crystal Springs Reservoir.

Table 2.7-1 illustrates the modeled variant and WSIP stream releases from Crystal Springs Reservoir and the differences between the two settings. Modeling results indicate that, within a month, either an increase or decrease in the occasional release could occur. The potential difference is attributed to whether the different resulting storage in the reservoir is higher or lower between the two settings. Part of the difference in modeled Crystal Springs Reservoir storage is due to modeling assumptions for the proportionate balancing of storage among the Bay Area reservoirs, and the coincidence of assumed system-wide maintenance with less than favorable hydrologic conditions. In actual operations, it is anticipated that system operators would manage the reservoir system such that stream releases would be minimal under any setting, with the effect of essentially no difference between the variant and WSIP settings. Modeling results indicate that there would be releases in only 16 months of the 6-month January-through-May period of the 82-years of simulation.

Table 2.7-2 illustrates the stream releases for the variant and base settings and the difference in modeled flows between the two settings. A greater operating range in Crystal Springs Reservoir operation would lead to an increased potential to regulate reservoir inflow, which would lead to less risk in needing to make stream releases. However, as described above, actual system operations would attempt to minimize releases under any setting; thus, the difference in releases between the variant and base setting would be minimal, if any.

San Andreas Reservoir operations would generally be the same between the variant and WSIP settings. Reservoir storage would follow a systematic filling and lowering each year. Figure 2.7-4 illustrates a chronological trace of the simulation of San Andreas Reservoir storage and stream releases from San Andreas Dam. Shown in Figure 2.7-4 are the results for the WSIP, variant, and base settings. There are no projected stream releases from San Andreas Reservoir in any setting. Notable in Figure 2.7-4 is the difference in storage operation every fifth year. Both the variant and WSIP setting storage operation differ from the base setting. This is due to the assumption that Hetch Hetchy conveyance maintenance occurs systematically every fifth year, which constrains the amount of Hetch Hetchy water supplied to serve water demands in the Bay Area. As discussed previously, during these winter periods, the Bay Area reservoir system accommodates the reduction in imported supply by serving the Bay Area water deliveries with the local watersheds' runoff and storage. At San Andreas Reservoir, the serving of water demand affects the reservoir when additional required water production at Harry Tracy Water Treatment Plant (Harry Tracy WTP) associated with WSIP or the variant exceeds the ability to maintain San Andreas Reservoir storage with pumping from Crystal Springs Reservoir. In the modeling, the conveyance capacity from Crystal Springs Reservoir is assumed to be the same among all of the settings. The additional water demand of the WSIP and variant require additional production from Harry Tracy WTP to be drawn from San Andreas Reservoir. Figure 2.7-5 illustrates the average monthly storage in San Andreas Reservoir for the 82-year simulation, and the range in storage for each month for the variant and base settings.

1980 - 2002

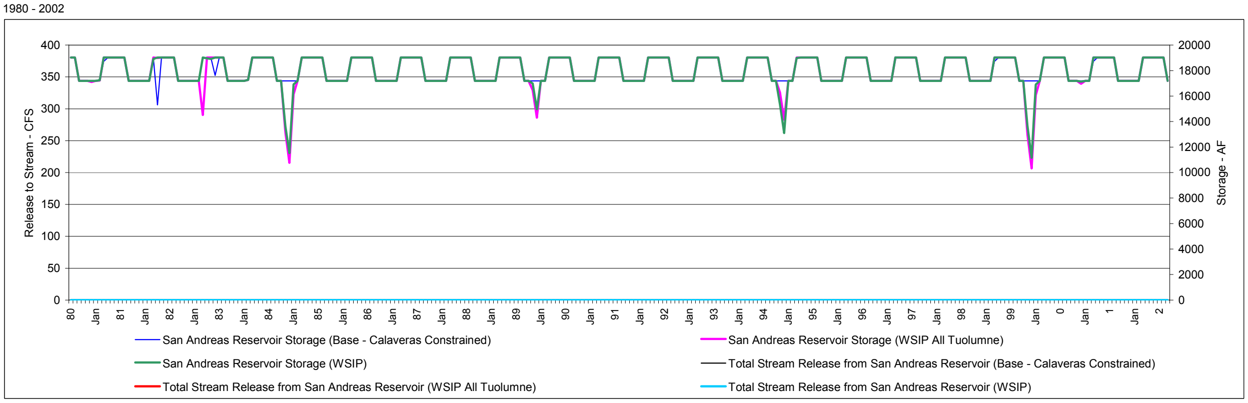

Figure 2.7-5

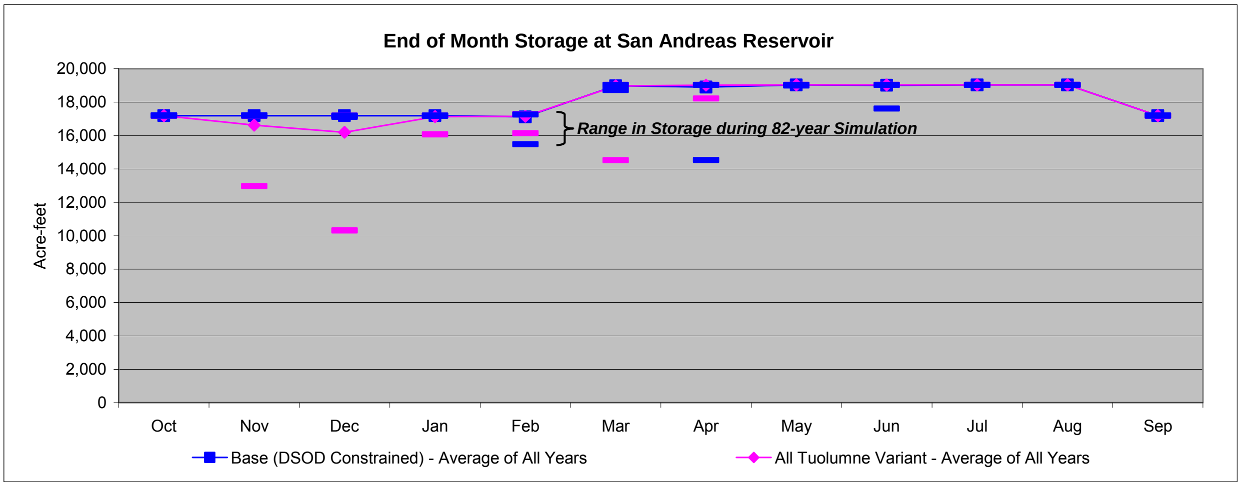


2.8 Pilarcitos Reservoir

Coastside County Water District's (Coastside CWD's) water demand and its SFPUC purchase request are projected to increase within the WSIP planning horizon of year 2030. Within the context of the 2030 purchase request of 300 mgd, Coastside CWD's portion has been estimated to amount to about 3 mgd. This projected purchase request is approximately 1 mgd greater than its current purchase request. Recognizing the current physical constraints to deliveries from the SFPUC to Coastside CWD and the ongoing planning activities in the watershed, there is uncertainty as to the precise manner in which Coastside CWD's additional purchase request would be served and the resultant potential changes to the operation of SFPUC facilities and their affected environs.[2]

Assuming a range of potential means to serve the additional purchase request from Coastside CWD, the following potential hydrologic effects to SFPUC facilities and their affected environs are identified:

- Due to limited yield from Pilarcitos Reservoir, additional diversions would be required from Crystal Springs Reservoir.
- If deliveries to Coastside CWD from Pilarcitos Reservoir increase during the winter season, these deliveries could potentially reduce storage in Pilarcitos Reservoir, thereby potentially reducing diversions to the San Mateo Creek watershed. Although the increased delivery would increase releases to Pilarcitos Creek from Pilarcitos Dam for a period of time, the increase would subsequently lead to a reduction in spills past Stone Dam.
- Additional wintertime deliveries could also potentially impair the ability to provide carry-over storage into the summer season from Pilarcitos Reservoir, and subsequently lead to an acceleration of the beginning of the season when releases to Pilarcitos Creek from Pilarcitos Reservoir consist only of the passage of reservoir inflow.
- An increase in summertime deliveries from Pilarcitos Creek could also accelerate the beginning of the season when releases to Pilarcitos Creek from Pilarcitos Reservoir consist only of the passage of reservoir inflow.

The variant setting could result in the same potential effects to the Pilarcitos Creek watershed as the WSIP setting.

[2] See "Analysis of SFPUC PIlarcitos/Coastside County Water District Operations", Memorandum by Daniel B. Steiner, March 8, 2007.

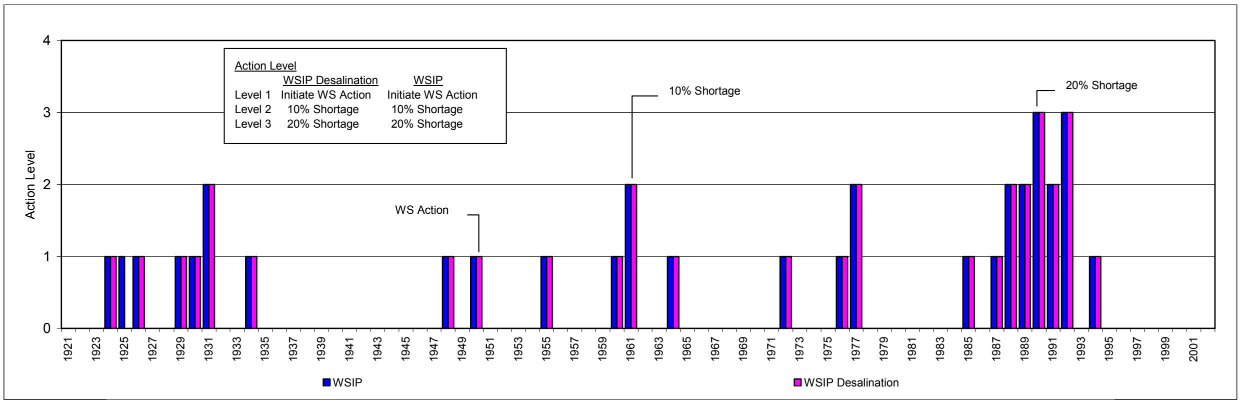
3. WSIP Variant 2 – Regional Desalination for Drought

WSIP Variant 2 – Regional Desalination for Drought (Desalination) variant programs would be the same as the WSIP programs, except that water production during drought from a desalination plant would substitute for the purchase from TID/MID. As with the WSIP, the purchase request increases from 265 mgd to 300 mgd and increase in delivery reliability would be served with a supply of 10 mgd from implementation of the Recycled Water Projects (SF-3), Local Groundwater Projects (a component of SF-2, Groundwater Projects), and additional conservation programs (RRGWC). In effect, the 10 mgd of RRGWC requires the Regional Water System's resources to serve a net 290 mgd demand. In all other aspects, this variant would include the same water supply sources as the proposed program, and integrate the same restored storage features of Calaveras and Crystal Springs Reservoirs and the incorporation of the Westside Basin Groundwater Program.

3.1 Water Deliveries and Drought Response Actions

In the WSIP, the MID/TID Tuolumne River water transfer (27,000 acre-feet) is modeled to occur each year. In the variant, this transfer does not occur, but instead 27,000 acre-feet of water offsets demand during the onset of anticipated drought. Table 1-1 compares the drought response actions for the proposed program and variant. Figure 3.1-1 illustrates the drought response actions for the simulated 82-year historical period (1921-2002).

Figure 3.1-1
Drought Response Actions – WSIP and All Tuolumne Variant



In Figure 3.1-1, years with bars showing a "1" or greater level of action indicate periods when a supplemental water supply action is initiated. In both scenarios, the action is the use of the Westside Basin Groundwater Program to supplement SFPUC water deliveries. In the variant setting, demand offset by desalination production also occurs. Action levels greater than "1" indicate the imposition of delivery shortages (rationing) to SFPUC customers. The initiation of supplemental supplies from the groundwater project and desalination occur one additional time during the 82-year simulation. The frequency of imposed delivery shortages and the severity of shortages remain the same between the variant and WSIP settings.

The same form of information is shown in Figure 3.-1-2 in comparing the variant and "Base - Calaveras Constrained" (existing) settings. In modeling parlance, there is no level 1 action level in the base setting. Without supplemental resources, the existing system only has the delivery shortage measure available to cope with drought. This shortage measure is imposed during level 2 (10 percent) and level 3 (20 percent). These percentages of shortage are applied to both the variant and the base setting for these action levels.

Figure 3.1-2
Drought Response Actions – Base and All Tuolumne Variant

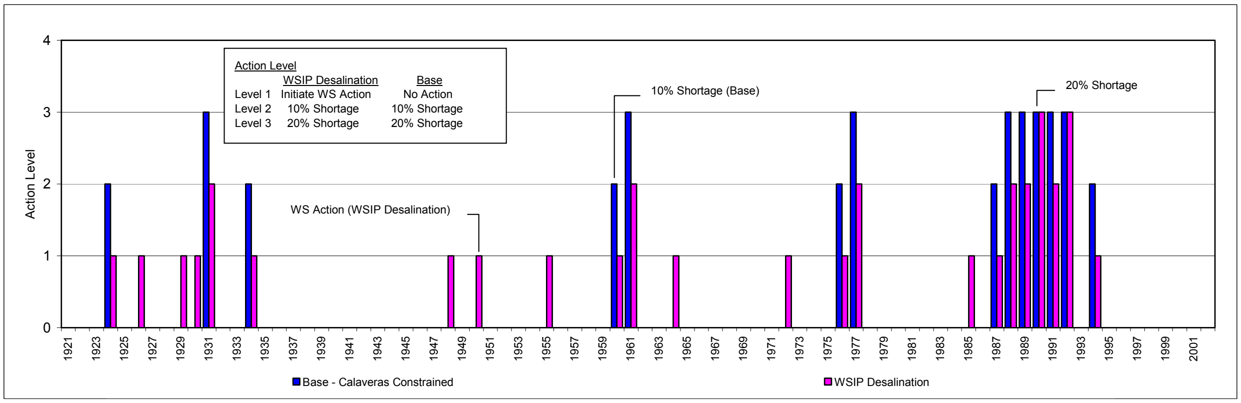


Figure 3.1-2 illustrates that, when compared to the base setting, the variant triggers the supplemental resources at an early indication of drought, during periods when in the current setting no supplemental resource is available to the system. The utilization of the supplemental resource during these times results in the lessening of (or at least a non-increase in) the severity of delivery shortage.

Not illustrated in Figure 3.1-2, but shown in Table 1-1, are the delivery shortages anticipated during the entire SFPUC Design Drought. Shortages during the Design Drought with the variant are maintained within the objective to limit the severity of shortage to no more than 20 percent, and the frequency and severity of shortages during the Design Drought are identical between the variant and WSIP settings. With the existing system, the 20 percent limitation (cap) objective cannot be achieved during the last 18 months of the Design Drought, and a 25 percent shortage is applied.

The difference in water deliveries between the proposed program and the variant is shown chronologically for the 82-year simulation in Table 3.1-1. Deliveries are almost identical between the variant and WSIP settings. The differences occur during 1925-1926 when an additional year of supplemental supply through the Westside Groundwater Program provides an offset to deliveries, and then an “increase” in demand during immediate subsequent years (1928-1929 and 1937-1938), indicating replenishment of the groundwater basin through additional deliveries to the program’s participants.

3.2 Diversions from Tuolumne River

The metric for illustrating the SFPUC diversion from the Tuolumne River Basin is the flow through the SJPL. Table 3.2-1 illustrates the difference in diversions to the SJPL between the proposed program and the variant settings. As demonstrated in Table 3.1-1, water deliveries do not substantially differ between the two scenarios. However, the water supplies for the deliveries differ. During non-drought periods, the increase in deliveries associated with the WSIP would still predominantly be met with increased diversion from the Tuolumne River in both the WSIP and variant setting. The absence of the MID/TID transfer during these years does not affect the amount of water the SFPUC can divert from the Tuolumne River, because the SFPUC has adequate rights and entitlements to do so without the TID/MID transfer water. Thus, the diversions to the SJPL during non-drought periods remain essentially the same between the two settings. The differences would occur during years when the water supply action is triggered during drought. When triggered, the offset in deliveries provided by the desalination supply reduces the need for diversions from the Tuolumne River, and thus reduces the diversion to the SJPL as compared to the WSIP setting. The effect of substituting the variant’s month-to-month desalination supply for the WSIP’s transfer supply does not directly modify the corresponding SJPL month-to-month diversion. Other system-wide storage and conveyance factors affecting the SJPL diversion rate result in the difference in diversion manifesting in less than every month in the year, but the effect would occur over the course of several years within the drought period. Table 3.2-2 illustrates the average monthly diversion through the SJPL, by year type, for the 82-year simulation period for the proposed program and the variant. Table 3.2-3 illustrates the average monthly diversion through the SJPL, by year type, for the variant and the base settings.

The results shown in Table 3.2-3 illustrate that, when comparing the variant setting to the base setting, similar to the WSIP setting, additional diversions from the Tuolumne River would occur to serve the increase in purchase request and improvement in delivery reliability. The difference between the variant and WSIP results would occur during drier years, when less increase in deliveries and reliability would manifest as increases in diversions from the Tuolumne River.

3.3 Hetch Hetchy Reservoir and Releases

The difference between the variant and WSIP operation of Hetch Hetchy during non-drought years is inconsequential, consistent with the similarity occurring in SJPL operation. However, during drought periods, there is less draw of storage because of the reduction in SJPL diversion due to the substitution of the desalination supply in the variant setting. Figure 3.3-1 illustrates a chronological trace of the simulation of Hetch Hetchy Reservoir storage and stream releases. Shown in Figure 3.3-1 are the results for the WSIP, variant (“WSIP All Tuolumne”), and base (“Base – Calaveras Constrained”) settings. Supplementing the Figure 3.3-1 representation of Hetch Hetchy Reservoir storage are Table 3.3-1 Hetch Hetchy Reservoir Storage (Desalination) and Table 3.3-2 Difference in Hetch Hetchy Reservoir Storage (Desalination minus WSIP). Table 3.3-3 is provided to illustrate the difference in Hetch Hetchy Reservoir storage between the base and variant settings.

Table 3.3-2 illustrates that, throughout the summer and into the fall in some years, storage in Hetch Hetchy Reservoir associated with the variant would differ from that of the WSIP,

and that this difference could be more or less storage, but typically would be more storage. These years would be associated with drought periods. During drought periods, Hetch Hetchy Reservoir would typically have greater storage during the fall and winter, generally coincident with less diversion to the SJPL. Even during drought, Hetch Hetchy Reservoir could fill by the end of May, which would negate the relative gain in storage from carrying into the following summer. Figure 3.3-2 illustrates the difference in reservoir storage, averaged by year type, in comparing the variant to the WSIP setting. Also shown is the average difference in storage for the two settings during the 82-year simulation. Figure 3.3-3 illustrates the same information in comparing the variant and base settings.

Figure 3.3-2

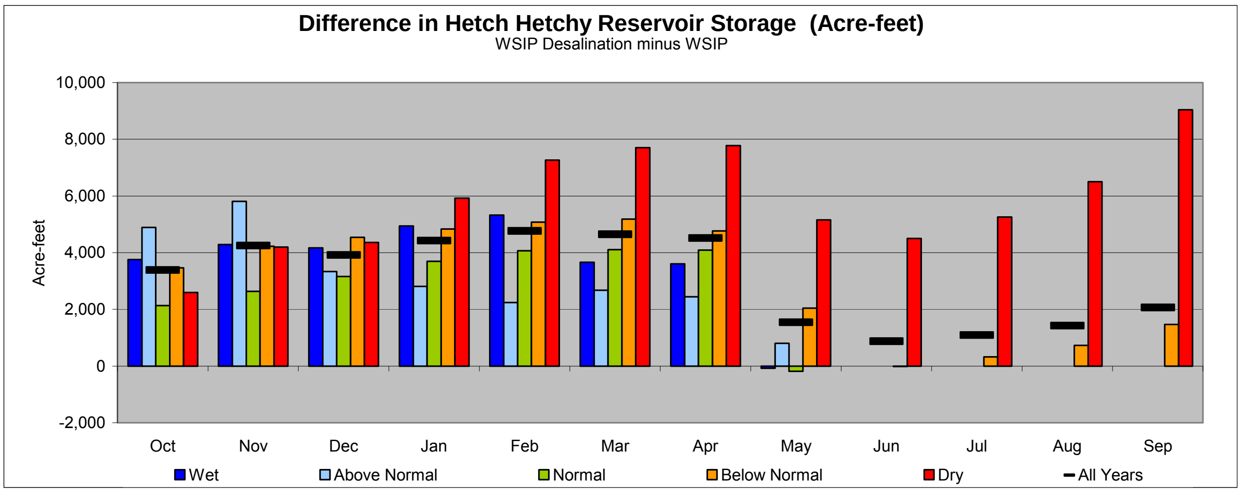

Figure 3.2-3

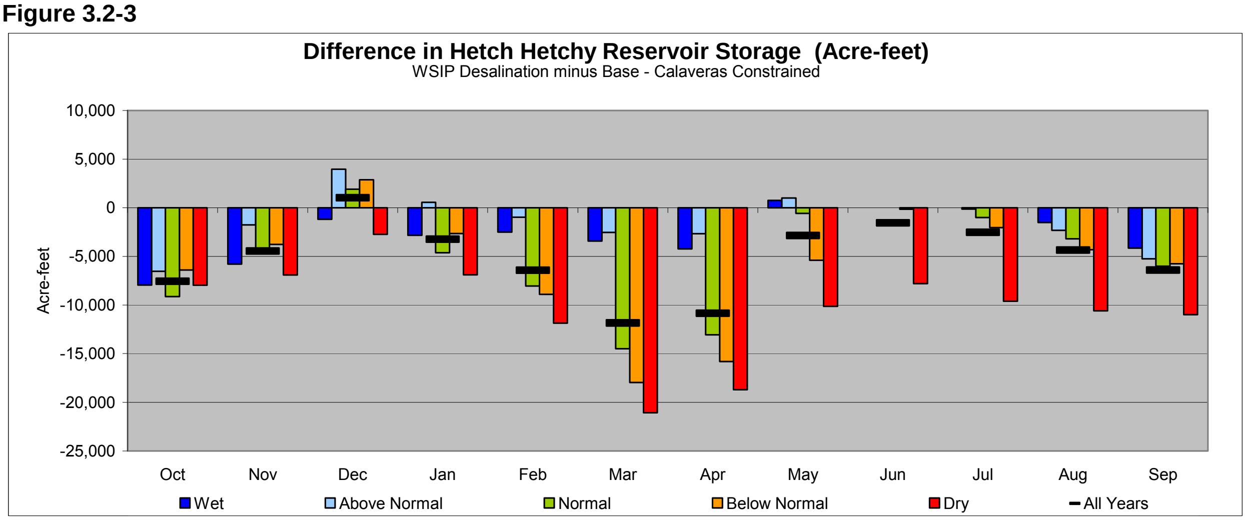
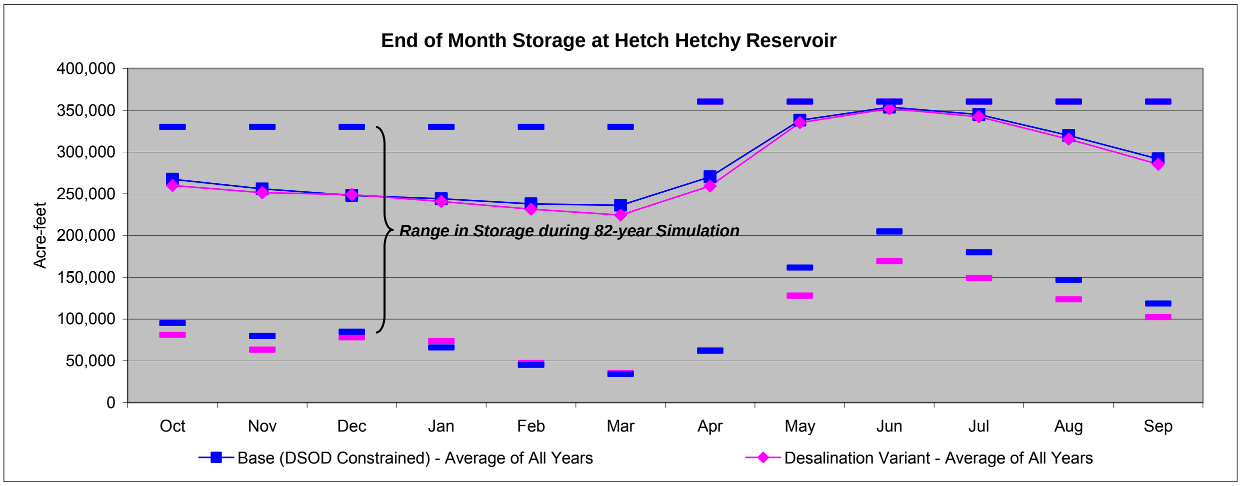


Compared to the base setting, Hetch Hetchy Reservoir storage would normally be the same during the summer, as diversions for the SJPL are at maximum in both settings. Similar to the WSIP setting, storage begins to be systematically lower in early fall into early winter as the effects of increased system purchases draw additional water from the reservoir. Average storage during the early winter would be approximately the same in both settings as system-wide maintenance in the variant setting decreases diversions to the SJPL compared to the base setting. During late winter and during spring, the variant would typically draw additional water from Hetch Hetchy to serve a larger purchase request and replenish Bay Area reservoirs. Figure 3.3-4 illustrates the average monthly storage in Hetch Hetchy Reservoir for the 82-year simulation, and the range in storage for each month for the variant and base settings.

Figure 3.3-4



The difference in storage in Hetch Hetchy Reservoir attributed to the diversion effects of the variant would then manifest into differences in releases from O'Shaughnessy Dam to the stream. Compared to the WSIP, a lesser amount of available reservoir space in the winter and spring of some years due to the variant would lead to a lesser ability to regulate inflow, thus potentially increasing the amount of water released to the stream above minimum release requirements. Figure 3.3-1 illustrates the stream release from O'Shaughnessy Dam for the WSIP, variant, and base settings. Table 3.3-4 illustrates the difference in stream releases between the variant and WSIP settings. Compared to the WSIP setting, the variant typically exhibits an incrementally larger stream release, predominantly during May or June, which reflects the months when releases to the stream above minimum release requirements are made in anticipation of filling the reservoir.

Table 3.3-4 illustrates the difference in stream release between the variant and WSIP settings, expressed in terms of a monthly volume (acre-feet) of flow. Table 3.3-5 illustrates the same form of information for the difference in stream release between the variant and base settings. Table 3.3-6 illustrates the same information and the average monthly stream release for the variant and WSIP settings, expressed in average monthly flow (cfs), and Table 3.3-7 illustrates the same form of information for the variant and base settings.

Table 3.3-4 illustrates that the difference in monthly flow below O'Shaughnessy Dam could range from an increase of approximately 30,000 acre-feet to a decrease of approximately 4,000 acre-feet. Considering the manner in which releases are determined and made to the stream, quantifying the effect of these changes in terms of average monthly flow (cfs) is not always meaningful.[3] When comparing the variant to the WSIP setting, a change in the volume of release from O'Shaughnessy Dam to the stream would likely result in the release being delayed or initiated earlier by a matter of days. Assuming that a change in release volume equates to a delay or acceleration of releasing 6,000 acre-feet per day, the difference in stream release from O'Shaughnessy Dam between the variant and WSIP would be an earlier release up to 5 days or a delay of up to an added day. Normally, the effect of the delay in release would not affect the year's peak stream release rate during a year. Comparing the variant and WSIP settings, a change (increase or decrease) in stream release would occur in approximately 32 percent of the years simulated.

Compared to the base setting, the variant's effect to stream flow is very similar to the effect caused by the WSIP, but for years following drought the effect would be less. Assuming the type of effect to releases described above, releases above minimum requirements below the dam could be delayed by up to 7 days or initiated earlier by up to 2 days.

[3] See "Estimated Effect of WSIP on Daily Releases below Hetch Hetchy Reservoir", Memorandum by Daniel B. Steiner, December 31, 2006.

3.4 Lake Lloyd and Lake Eleanor

Compared to the operation of the WSIP, the operation of Lake Lloyd and Lake Eleanor are simulated to be only slightly different in the variant setting. Figure 3.4-1 illustrates a chronological trace of the simulation of Lake Lloyd storage and stream releases. Shown in Figure 3.4-1 are the results for the WSIP, variant, and base settings. The operation resulting from the variant is essentially the same as the WSIP, except during the prolonged drought of 1987-1992, and to a small extent during the other drought periods. The difference is explained as modeling discretion, and is not likely a difference that would occur in actual operations. HH/LSM model logic estimates the amount of water to be released from Lake Lloyd based on the condition of Hetch Hetchy Reservoir, Don Pedro Water Bank Account, and Lake Eleanor and Lake Lloyd storage in comparison to demands. In these instances, Hetch Hetchy Reservoir storage is different between the variant and the WSIP settings, typically slightly higher in the variant during drought. The model logic is not very refined, and a small change in computation result can result in a large difference in Lake Lloyd release (in this instance, through Holm Powerhouse). Overall, the Lake Lloyd operation would be discretionary and the outcome would likely be the same among the variant and the WSIP settings.

Figure 3.4-2 illustrates the almost identical operation of Lake Eleanor for the variant and WSIP settings. Also shown in Figure 3.4-2 is the operation for the base setting. Any difference that occurs in the Lake

Eleanor operation would be caused by a small change in operation at Lake Lloyd that would affect the operation of the Cherry-Eleanor Tunnel between the two watersheds. Any difference that occurs in the simulations is more associated with modeling discretion as opposed to any substantive difference in operation.

Supplementing the Figure 3.4-1 representation of Lake Lloyd stream releases is Table 3.4-1, illustrating releases for the variant and WSIP settings, and the difference in releases between the two. Table 3.4-2 provides the same form of information for the variant and base settings.

3.5 Don Pedro Reservoir and La Grange Releases

A change in Don Pedro Reservoir operation is caused by changes in inflow to the reservoir. The changes in inflow to the reservoir are the result of net changes within the operation of the upstream SFPUC facilities described previously, and other changes in SFPUC operations associated with diversions to the Holm, Kirkwood, and Moccasin Powerhouses. Figure 3.5-1 illustrates a chronological trace of the simulation of Don Pedro Reservoir storage and Tuolumne River stream releases from La Grange Dam. Shown in Figure 3.5-1 are the results for the WSIP, variant, and base settings.

Supplementing the Figure 3.5-1 representation of Don Pedro Reservoir storage are Table 3.5-1 Don Pedro Reservoir Storage (Desalination) and Table 3.5-2 Difference in Don Pedro Reservoir Storage (Desalination minus WSIP). Table 3.5-3 illustrates the difference in Hetch Hetchy Reservoir storage between the base and variant settings.

Figure 3.5-1 and Table 3.5-2 illustrate that, throughout many years, the storage in Don Pedro Reservoir in the variant setting would not differ greatly from storage in the WSIP setting. These periods generally occur during non-drought periods when the upstream operation of SFPUC facilities does not differ due to the absence of the TID/MID transfer. The differences primarily occur during periods of drought when a substitution of the desalination supply for the TID/MID transfer occurs. Any changes that do occur are due to the different inflow to the reservoir between the two settings in a month or series of months when Don Pedro Reservoir is below the flood control storage limitation and has an ability to regulate inflow with storage. When no storage difference occurs for months or other periods of time, either inflow to the reservoir did not change between the settings or the flood control storage limitation was reached and the change in inflow resulted in a change in release to the Tuolumne River below La Grange Dam (discussed later). As described above, the variant would divert less water from the Tuolumne River during drought than would occur in the WSIP setting, thus leading to less accumulated depletion of storage from Don Pedro Reservoir. However, the additional depletion effect in Don Pedro Reservoir is not completely eliminated when compared to the base setting.

The greatest draw down of reservoir storage occurs during the drought of the 1976-1977, which is not coincident with the year of greatest difference in reservoir draw between the base setting and either the WSIP or variant settings, the drought of the 1930s. Figure 3.5-2 illustrates the difference in reservoir storage, averaged by year type, in comparing the variant to the WSIP setting. Also shown is the average difference in storage for the two settings during the 82-year simulation. Figure 3.5-3 illustrates the same information in comparing the variant and base settings.

Figure 3.5-4 illustrates the average monthly storage in Don Pedro Reservoir for the 82-year simulation, and the range in storage for each month for the variant and base settings.

The difference in storage in Don Pedro Reservoir attributed to the upstream effects of the variant would manifest in differences in releases from La Grange Dam to the stream. As opposed to the WSIP setting, less available reservoir space in the winter and spring due to the variant would lead to greater frequency of water released to the stream at levels above minimum release requirements. During periods when inflow differs and Don Pedro Reservoir is at maximum storage capacity within the flood control storage limitation, a change in inflow would directly manifest as a change in release from La Grange Dam. Figure 3.5-1 illustrates the stream release from La Grange Dam for the WSIP, variant, and base settings.

Table 3.5-4 illustrates the difference in stream releases between the variant and WSIP settings. Compared to the WSIP setting, the variant typically exhibits an incrementally larger stream release, predominantly during early winter through June, which reflects the months when releases to the stream above minimum release requirements are made due to flood control or in anticipation of filling the reservoir. Table 3.5-5 illustrates the same information in comparing the variant and WSIP settings, with years ranked in descending order of the San Joaquin River Index. The table shows that differences in releases to the Tuolumne River from La Grange Dam occur only when there are releases above minimum FERC flow requirements. This typically occurs only in above normal and wet years, and predominantly during early winter through June. During other year types and during the summer and fall, releases would be maintained at minimum FERC flow requirements regardless of the setting. Table 3.5-6 illustrates the difference in stream releases between the variant and base settings.

Table 3.5-4 illustrates the difference in stream release between the variant and WSIP settings, expressed in terms of a monthly volume (acre-feet) of flow. Table 3.5-7 illustrates the same information and the average monthly stream release for the variant and WSIP setting, expressed in average monthly flow (cfs). Table 3.5-4 illustrates that the difference in monthly flow below La Grange Dam could range from an increase of approximately 105,000 acre-feet to a minor decrease of approximately 3,000 acre-feet. Considering the manner in which releases are determined and made to the stream, quantifying the effect of these changes in terms of average monthly flow (cfs) is not always meaningful. Assuming that a change in release volume equates to a delay or earlier initiation of a 6,000 acre-feet release per day, the difference in stream release from La Grange Dam between the variant and WSIP settings would be an almost unnoticeable delay in release or up to an added 18 days of release when compared to the WSIP (and possibly more, depending on the management of spills at Don Pedro Reservoir over a period of time).

Normally, the effect of reduced releases would not affect the year's peak stream release rate during a year. However, infrequently, the variant's effect on stream releases could manifest as an elimination of all flow above minimum FERC flow requirements within a month. This would occur after the experience of an extended drought period. Comparing the variant and WSIP settings, a change (increase or decrease) in stream release would occur in approximately 28 percent of the years simulated. Compared to the base setting, the variant's effect to stream flow is similar to the effect caused by the WSIP, but following drought would be less.

Compared to the base setting, there would be some reduction of release, but a lesser effect than occurs in the WSIP setting. Table 3.5-6 illustrates that the difference in monthly flow below La Grange Dam could range from an increase of approximately 13,000 acre-feet to a decrease of approximately 43,000 acre-feet. Using the same assumption described above for the effect of a changed release, compared to the base setting, the variant setting would result in release changes ranging from an additional 2 days of release to a decrease of 7 days of release in excess of minimum release requirements. Table 3.5-8 illustrates the releases to the Tuolumne River below La Grange Dam and their differences for the variant and base settings, provided in terms of average monthly flow (cfs) averaged within year types.

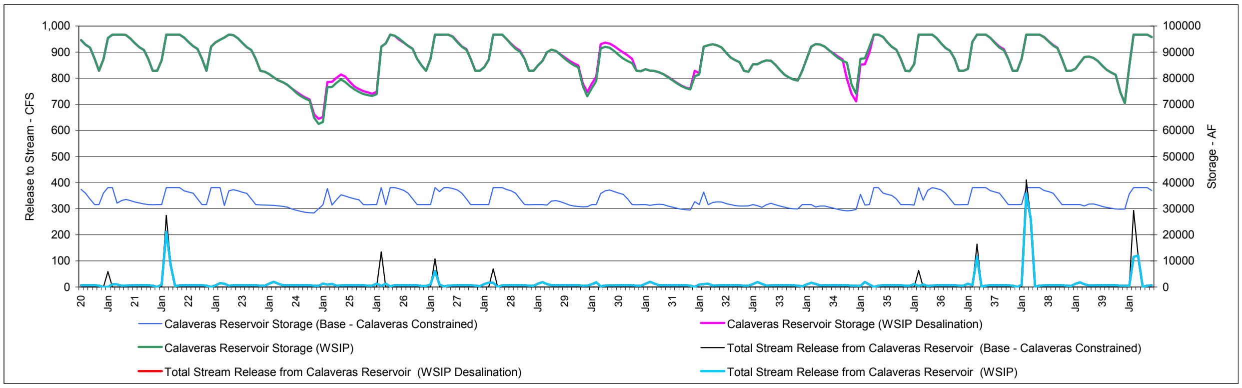
3.6 Calaveras and San Antonio Reservoirs, Alameda Creek and Downstream

There are only a few modeled differences in Calaveras Reservoir operations between the variant and WSIP settings. Figure 3.6-1 illustrates a chronological trace of the simulation of Calaveras Reservoir storage and stream releases from Calaveras Dam. Shown in Figure 3.6-1 are the results for the WSIP, variant, and base settings. Generally, the differences in reservoir storage are partially due to the dependence on modeling assumptions to balance total Bay Area reservoir storage among the five major SFPUC reservoirs and to balance storage between the Bay Areas reservoirs and Hetch Hetchy. The model balances storage between reservoirs by way of an input file by the modeler concerning the relative draw (percentage) from each reservoir under various storage conditions. These are discretionary input in the model, and the logic and relative percentages are meant to mimic the current practice and discretion of the system operators based on recognition of the physical conveyance constraints within the system and the ability of each reservoir to provide yield and water delivery security. Generally, during drought, the draw of water for deliveries from Hetch Hetchy is lessened with the variant (compared to the WSIP setting), leaving Bay Area reservoir storage less drawn upon due to conveyance limitations. During these circumstances, some of the storage gain is proportionately left in Calaveras Reservoir.

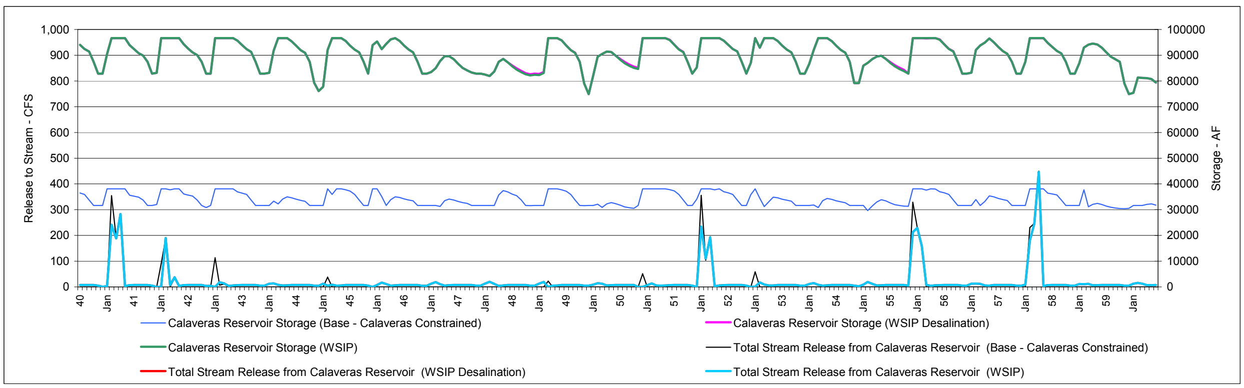
The notable difference in storage between the variant and WSIP settings is during the drought of the 1960s; Calaveras Reservoir storage is modeled to be lower in the variant than in the WSIP setting. This circumstance is primarily the result of modeling assumptions for the balancing of storage among Calaveras Reservoir and San Antonio Reservoir. For the results that indicate Calaveras Reservoir storage is lower than the WSIP setting, the results will coincidentally indicate that San Antonio Reservoir storage is higher than in the WSIP setting. There is little net difference in combined storage for the two reservoirs in comparison to the WSIP setting. It is concluded that little, if any, difference in Calaveras Reservoir storage occurs between the variant and WSIP settings, except for slight increases during drought. The difference in storage between the variant and WSIP settings and the base setting is due to the restoration of the operational capacity of Calaveras Reservoir. Figure 3.6-2 illustrates the average monthly storage in Calaveras Reservoir for the 82-year simulation, and the range in storage for each month for the variant and base settings.

Figure 3.6-1
Calaveras Reservoir Storage and Stream Release

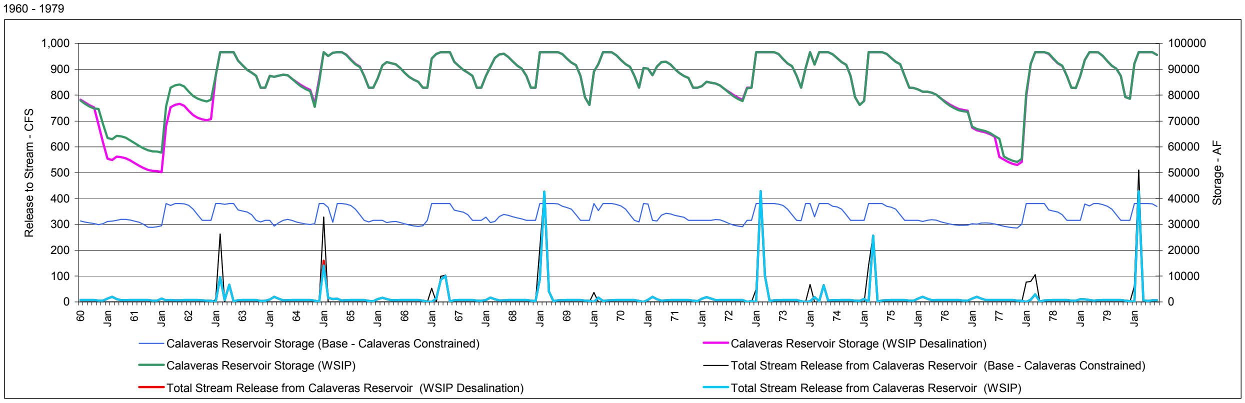
1920 - 1939



1940 - 1959



1960 - 1979



1980 - 2002

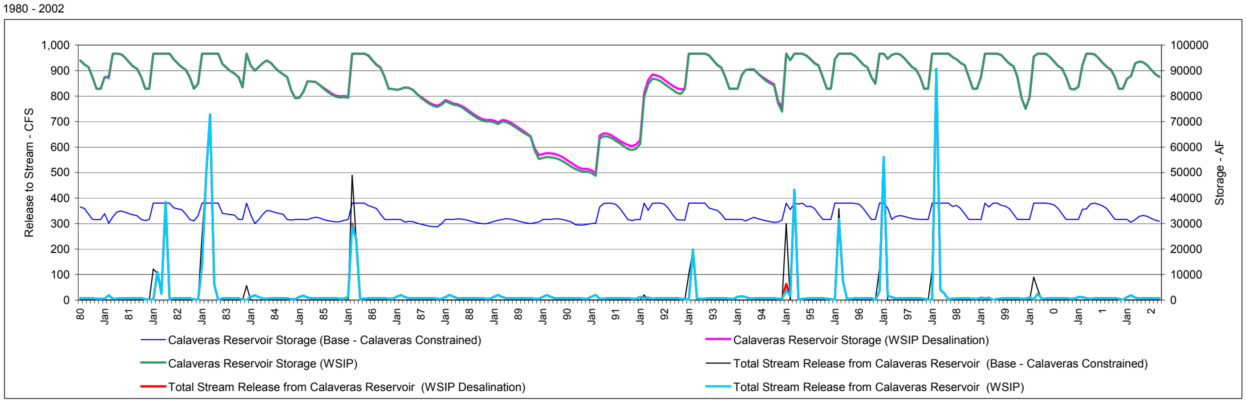


Figure 3.6-2

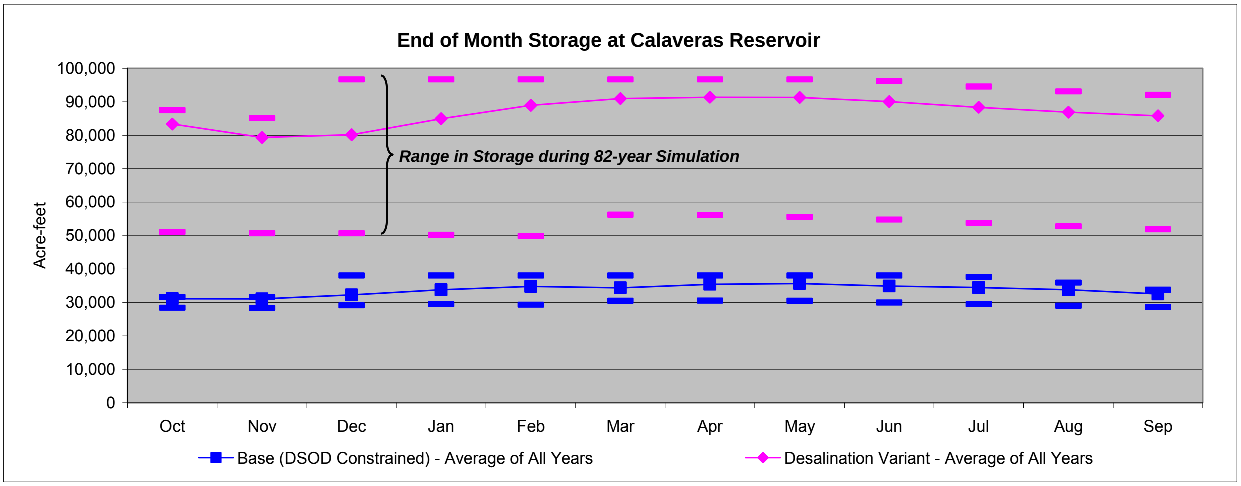

There is essentially no change in releases (i.e., infrequent slight increases) to Calaveras Creek below Calaveras Dam between the variant and WSIP settings. Both settings have fishery releases that are not included in the base setting. Table 3.6-1 illustrates the difference in releases to Calaveras Creek between the variant and WSIP settings. Supplementing the Figure 3.6-1 representation of Calaveras Dam stream releases and Table 3.6-1 is Table 3.6-2, illustrating releases for the variant and WSIP settings, and the difference in releases between the two. Table 3.6-3 provides the same form of information for the variant and base settings. The notable difference in releases between the variant and base settings is the addition of the flows representing the 1997 MOU and the reduction of stream releases during wetter-year/wetter-season flows due to the restoration of Calaveras Reservoir operational capacity.

There is essentially no change (minor differences during 5 months of the 82-year simulation) in Alameda Creek diversions to Calaveras Reservoir between the variant and the WSIP settings. With almost no change in Calaveras Reservoir storage between the two settings, there would be no change in the diversion operation at the Alameda Creek Diversion Dam. Water would only be diverted to Calaveras Reservoir when the diversion would not contribute to releases in excess of minimum required flows below Calaveras Dam. Coincidentally, with no change in the diversion at Alameda Creek Diversion Dam, flow spilling past the diversion dam would experience no differences between the variant and WSIP settings. Table 3.6-4 illustrates the flow below the Alameda Creek Diversion Dam for the variant and base settings. The notable difference between the variant and base settings is the reduction of wetter-year water flowing past the diversion dam. This occurs because, in the variant setting, the restoration of Calaveras Reservoir storage allows a greater frequency of diversion from Alameda Creek to Calaveras Reservoir.

Comparing the variant and WSIP settings, with essentially no differences (albeit slight increases) in releases from Calaveras Dam to the stream and no differences to spills at Alameda Creek Diversion Dam (albeit slight increases), flow below the Alameda Creek and Calaveras Creek confluence will be the same for each setting, or slightly larger for the variant setting. Table 3.6-5 illustrates the flow below the confluence for the variant and WSIP settings, and the near similarity in flow between the two. Table 3.6-6 provides the same form of information for the variant and base settings. The notable differences between the variant and base settings (comparable to the difference between the WSIP and base settings) are the addition of required stream flows for the 1997 MOU and the reduction of wetter-year/wet-season flows due to the restoration of Calaveras Reservoir storage.

A flow recapture facility in Alameda Creek below Calaveras Reservoir is incorporated in the variant and WSIP settings. This facility is assumed to recapture flows explicitly released from Calaveras Dam for the 1997 MOU. The effect of the recapture is a reduction in the flow that occurs below the confluence of Alameda and Calaveras Creeks, but only to the extent that releases were explicitly made from Calaveras Reservoir for the 1997 MOU. Table 3.6-7 illustrates the flow below the confluence and above the Alameda and San Antonio Creek confluence for the variant and WSIP settings, and the near similarity in flow between the two. Table 3.6-8 provides the same form of information for the variant and base settings. The flows identified at this location are indicative of flow occurring below the confluence of Alameda and Calaveras Creeks (described above), with the addition of estimated stream accretions between the Alameda and Calaveras Creek confluence and the Alameda and San Antonio Creek confluence, minus the water assumed to be recaptured (diverted) by the SFPUC from the creek.

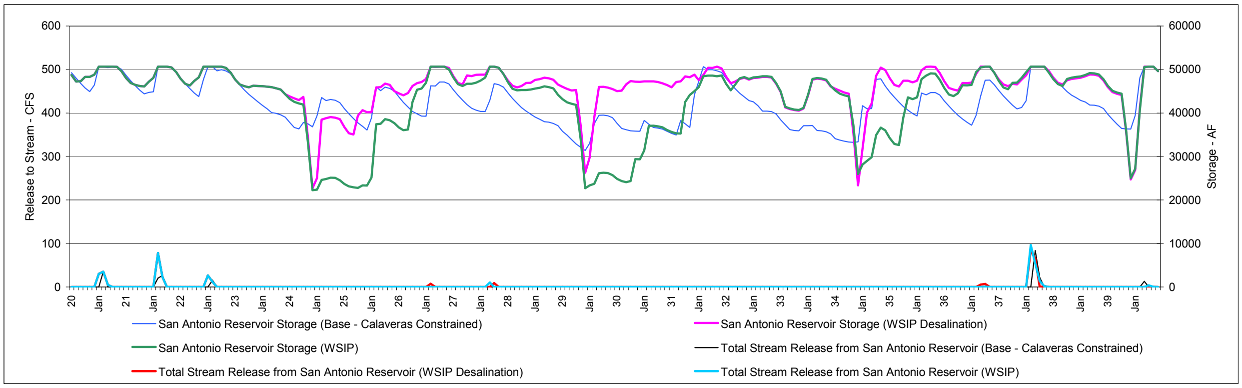
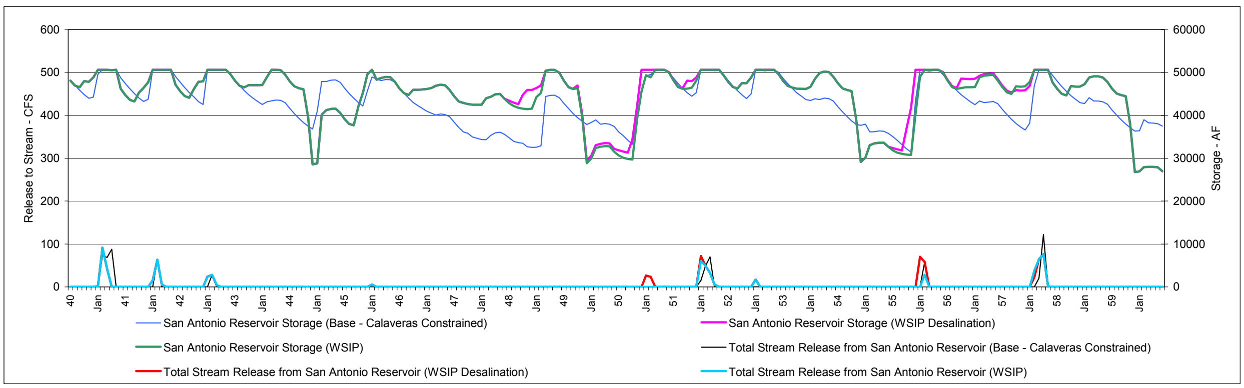
Compared to the WSIP setting, San Antonio Reservoir operations in the variant setting generally mirror the changes experienced for Calaveras Reservoir operations. Figure 3.6-3 illustrates a chronological trace of the simulation of San Antonio Reservoir storage and stream releases from the dam. Shown in Figure 3.6-3 are the results for the WSIP, variant, and base settings. The difference in San Antonio Reservoir storage between the variant and WSIP setting is mostly caused by the increase in Bay Area reservoir storage due to the desalination supply offsetting some of the draw of reservoir storage during drought periods when Hetch Hetchy imports are at maximum capacity. The magnitude of effect in the difference in San Antonio Reservoir storage depends on modeling assumptions to balance total Bay Area reservoir storage among the five major SFPUC reservoirs. The model balances storage between reservoirs by way of an input file by the modeler concerning the relative draw (percentage) from each reservoir under various storage conditions. These are discretionary input in the model, and the logic and relative percentages are meant to mimic the current practice and discretion of the system operators based on recognition of the physical conveyance constraints within the system and the ability of each reservoir to provide yield and water delivery security.

Figure 3.6-3
San Antonio Reservoir Storage and Stream Release

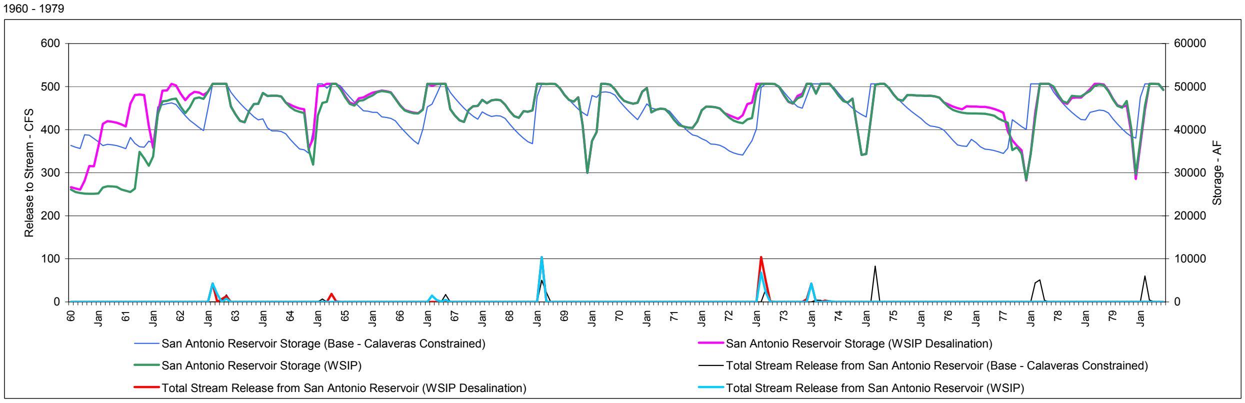
1920 - 1939



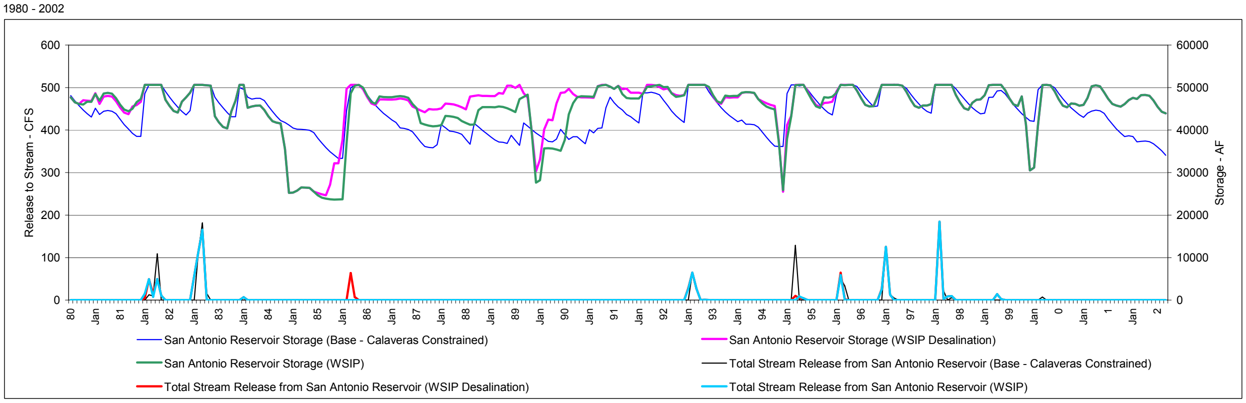
1940 - 1959



1960 - 1979

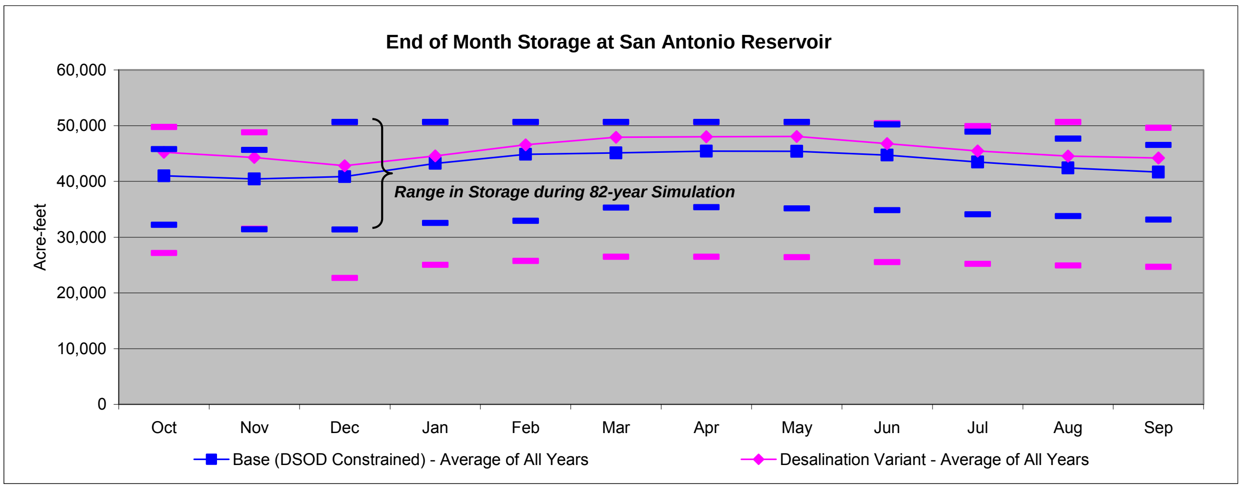


1980 - 2002



The difference in storage between the variant and WSIP settings and the base settings is due to the restoration of the operational capacity of Calaveras Reservoir. In the base setting, the limited operating storage capacity at Calaveras leads to a different operation at San Antonio Reservoir, one that provides relatively more stored water for system demands when the draw from Calaveras Reservoir is constrained due to limited storage. There is also a notable difference in storage operation between the variant and WSIP settings and the base setting every fifth year. Assumed systematic maintenance of Hetch Hetchy conveyance facilities occurs in the simulation that constrains diversions to the Bay Area from Hetch Hetchy every fifth year. The reduction in diversion from Hetch Hetchy during these periods is accommodated in the system by drawing additional water from the Bay Area reservoirs. The proportionate share of this operation is evident in the tracing of San Antonio Reservoir storage for the variant and WSIP settings. Figure 3.6-4 illustrates the average monthly storage in Calaveras Reservoir for the 82-year simulation, and the range in storage for each month for the variant and base settings.

Figure 3.6-4



There would be very little change in stream releases below San Antonio Reservoir between the variant and WSIP settings. Table 3.6-9 illustrates the modeled release to San Antonio Creek from San Antonio Reservoir for the two settings and the differences for the average release during a year type. With a slightly higher reservoir operation at times during the winter, as seen in Figure 3.6-4, a greater frequency in stream releases is expected. Given the sometimes rigid constraints within the modeling assumptions, the model will overestimate the frequency and magnitude of stream releases from San Antonio Reservoir under any of the investigated settings. The flexibility that occurs in actual operations would likely avoid most of the releases represented by the model. The modeled stream releases from San Antonio Reservoir and difference between releases for the variant and base settings are shown in Table 3.6-10. The differences between the two settings range from increases to decreases in flow. This modeled circumstance reflects the different resulting storage operation between the two settings, as seen in Figure 3.6-3. In some circumstances, the base setting storage at San Antonio Reservoir could be higher than projected for the variant setting during the same period. This circumstance could lead to an occasionally greater modeled release for the base setting, which would be reflected in the results. As described above, the model will overestimate the frequency and magnitude of releases from San Antonio Reservoir, and the actual releases from San Antonio Reservoir in any setting, and the difference between settings are expected to be minor.

Flow below the confluence of Alameda and San Antonio Creeks is influenced by releases from San Antonio Creek and flow arriving at the location from Alameda Creek, which includes upstream impairment by SFPUC operations and facilities. Table 3.6-11 illustrates the flow below the confluence for the variant and WSIP settings, and the differences in flow between the two.

Table 3.6-12 illustrates the same information in comparing the variant and base settings. Table 3.6-11 illustrates the minor modeled differences in flow that occur between the variant and WSIP settings, while Table 3.6-12 illustrates the relatively larger differences in flow that could occur between the variant and base settings. The difference is particularly due to the effects of the restoration of Calaveras Reservoir operating capacity in the variant setting.

3.7 Crystal Springs and San Andreas Reservoirs

There are differences in Crystal Springs Reservoir operations between the variant and WSIP setting. Figure 3.7-1 illustrates a chronological trace of the simulation of Crystal Springs Reservoir storage and stream releases from Springs Dam. Shown in Figure 3.7-1 are the results for the WSIP, variant, and base settings.

The difference in Crystal Springs Reservoir storage between the variant and WSIP settings is largely due to the increase in Bay Area reservoir storage that results from the desalination supply offsetting some of the draw during drought periods (when Hetch Hetchy imports are at maximum capacity). The effect of the difference in storage at Crystal Springs Reservoir depends on modeling assumptions for balancing total Bay Area reservoir storage among the five major SFPUC reservoirs. The model balances storage between reservoirs by way of an input file by the modeler concerning the relative draw (percentage) from each reservoir under various storage conditions. These are discretionary input in the model, and the logic and relative percentages are meant to mimic the current practice and discretion of the system operators based on recognition of the physical conveyance constraints within the system and the ability of each reservoir to provide yield and water delivery security. In actual operations, some of the differences in result may not occur, as system operators and prevailing hydraulic and hydrologic conditions may direct the operational effect of the different demand to an alternative apportionment of effect among the reservoirs. Figure 3.7-2 illustrates the average monthly storage in Crystal Springs Reservoir for the 82-year simulation, and the range in storage for each month for the variant and WSIP settings. Figure 3.7-3 illustrates the average monthly storage in Crystal Springs Reservoir for the 82-year simulation, and the range in storage for each month for the variant and base settings. Consistent with the comparison of the WSIP and base settings, the variant setting would result in reservoir storage operating at a higher average and higher upper-range than the base setting. This is due to the restoration of the operating capacity of Crystal Springs Reservoir.

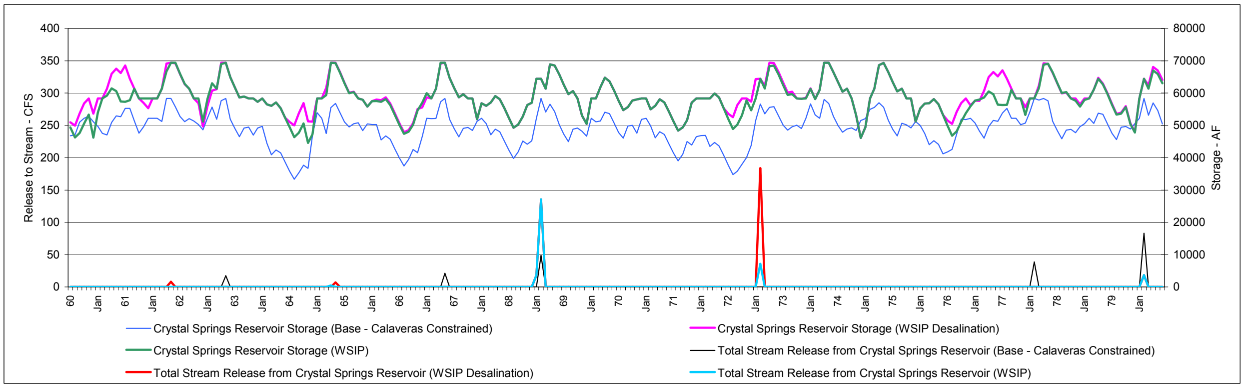
1960 - 1979



1980 - 2002

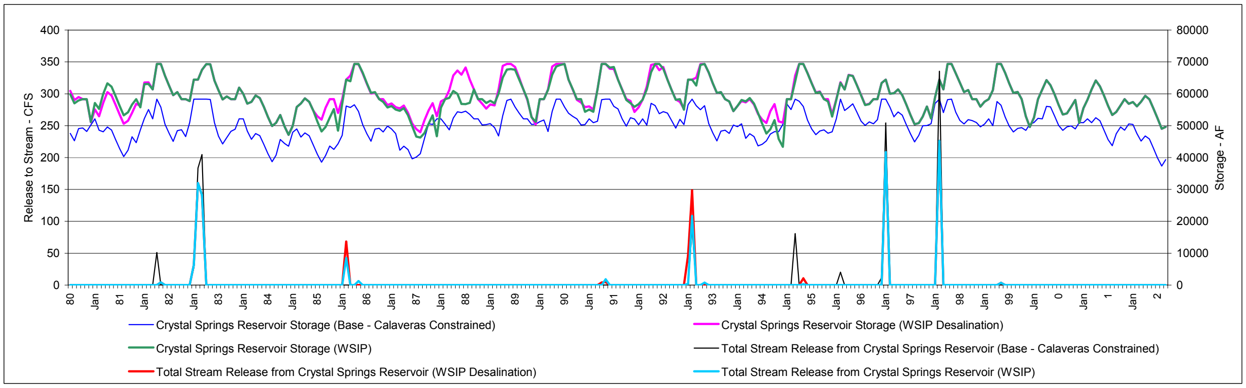


Figure 3.7-2

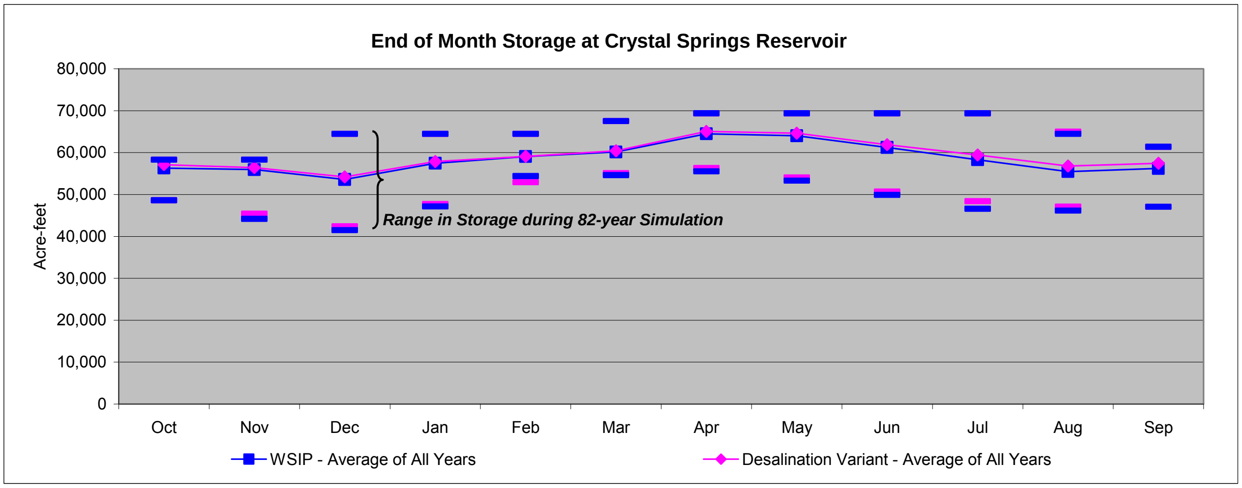

Figure 3.7-3

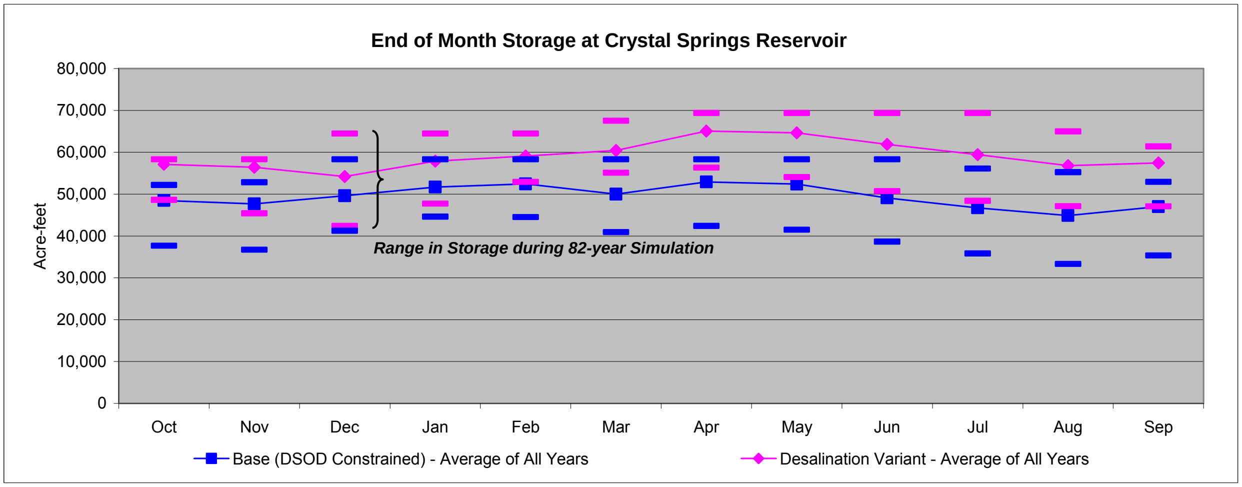

Table 3.7-1 illustrates the modeled variant and WSIP stream releases from Crystal Springs Reservoir and the differences between the two settings. Modeling results indicate that an occasional increase in releases could occur. The potential difference is attributed to slightly higher reservoir storage in the variant setting. Part of the difference in modeled Crystal Springs Reservoir storage is due to modeling assumptions for the proportionate management of storage among the Bay Area reservoirs, and the coincidence of assumed system-wide maintenance with less than favorable hydrologic conditions. In actual operations, it is anticipated that system operators would manage the reservoir system such that stream releases would be minimal under any setting, with the effect of essentially no difference between the variant and WSIP settings. Modeling results indicate that there would be releases in only 23 months (in the 6-month January-through-May period) during the 82-year simulation.

Table 3.7-2 illustrates the stream releases for the variant and base settings, and the difference in modeled flows between the two settings. A greater operating range in Crystal Springs Reservoir operation would lead to an increased potential to regulate reservoir inflow, which would lead to less risk in making needed stream releases. However, as described above, actual system operations would attempt to minimize releases under any setting; thus, the difference in releases between the variant and base setting would be minimal, if any.

San Andreas Reservoir operations would generally be the same between the variant and WSIP settings. Reservoir storage would follow a systematic filling and lowering each year. Figure 3.7-4 illustrates a chronological trace of the simulation of San Andreas Reservoir storage and stream releases from Springs Dam. Shown in Figure 3.7-4 are the results for the WSIP, variant, and base settings. There are no projected stream releases from San Andreas Reservoir in any setting. Notable in Figure 3.7-4 is the difference in storage operation every fifth year. Both the variant and WSIP setting storage operation differ from the base setting. This operation is based on the assumption that Hetch Hetchy conveyance maintenance occurs systematically every fifth year, which constrains the amount of Hetch Hetchy water supplied to serve water demands in the Bay Area. As discussed previously, during these winter periods, the Bay Area reservoir system accommodates the reduction in imported supply by serving the Bay Area water deliveries with the local watersheds' runoff and storage. At San Andreas Reservoir, the serving of water demand affects the reservoir when additional required water production at Harry Tracy WTP associated with WSIP or the variant exceeds the ability to maintain San Andreas Reservoir storage with pumping from Crystal Springs Reservoir. In the modeling, the conveyance capacity from Crystal Springs Reservoir is assumed to be the same among all of the settings. The additional water demand of the WSIP and variant requires additional production from Harry Tracy WTP to be drawn from San Andreas Reservoir. The draw down of storage due to the variant would be slightly less than for the WSIP setting. Figure 3.7-5 illustrates the average monthly storage in San Andreas Reservoir for the 82-year simulation, and the range in storage for each month for the variant and base settings.

Figure 3.7-4

3.8 Pilarcitos Reservoir

Coastside County Water District's (Coastside CWD) water demand and its SFPUC purchase request are projected to increase within the WSIP planning horizon of year 2030. Within the context of the 2030 purchase request of 300 mgd, Coastside CWD's portion has been estimated at about 3 mgd. This projected purchase request is approximately 1 mgd greater that its current purchase request. Recognizing the current physical constraints to deliveries from the SFPUC to Coastside CWD and the ongoing planning activities in the watershed, there is uncertainty as to the precise manner in which Coastside CWD's additional purchase request would be served and the resultant potential changes to the operation of SFPUC facilities and their affected environs.[4]

Assuming a range of potential means to serve the additional purchase request from Coastside CWD, the following potential hydrologic effects to SFPUC facilities and their affected environs are identified:

- Due to limited yield from Pilarcitos Reservoir, additional diversions would be required from Crystal Springs Reservoir.
- If deliveries to Coastside CWD from Pilarcitos Reservoir increase during the winter season, these deliveries could potentially reduce storage in Pilarcitos Reservoir, thereby potentially reducing diversions to the San Mateo Creek watershed. Although the increased delivery would increase releases to Pilarcitos Creek from Pilarcitos Dam for a period of time, the increase would subsequently lead to a reduction in spills past Stone Dam.
- Additional wintertime deliveries could also potentially impair the ability to provide carry-over storage into the summer season from Pilarcitos Reservoir, and subsequently lead to an acceleration of the beginning of the season when releases to Pilarcitos Creek from Pilarcitos Reservoir consist only of the passage of reservoir inflow.
- An increase in summertime deliveries from Pilarcitos Creek could also accelerate the beginning of the season when releases to Pilarcitos Creek from Pilarcitos Reservoir consist only of the passage of reservoir inflow.

The variant setting could result in the same potential effects to the Pilarcitos Creek watershed as the WSIP setting.

[4] See "Analysis of SFPUC PIlarcitos/Coastside County Water District Operations", Memorandum by Daniel B. Steiner, March 8, 2007.

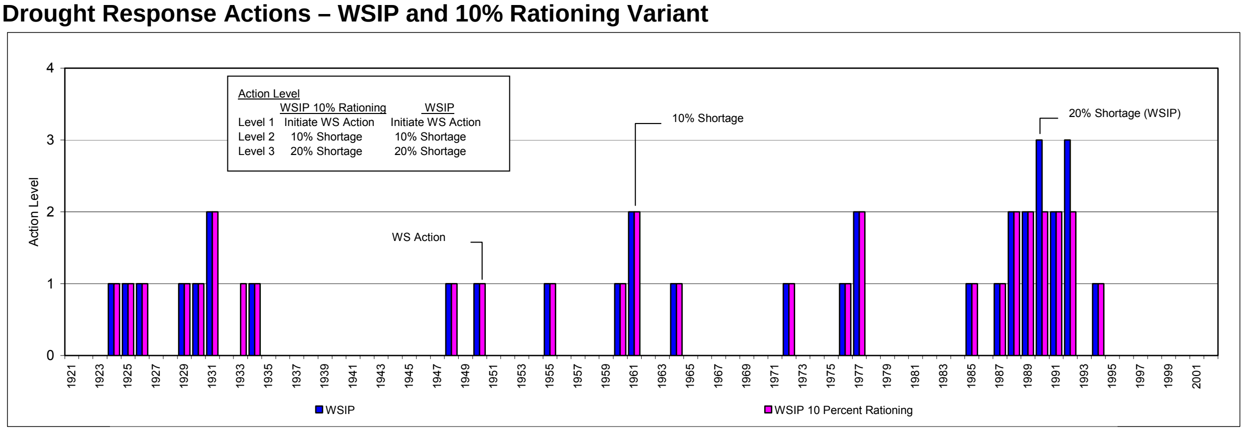
4. WSIP Variant 3 – 10% Rationing

WSIP Variant 3 – 10% Rationing variant programs would be identical to the programs proposed for the WSIP, except that the drought response program would limit delivery shortages (rationing) to no more than 10 percent. The resources that would be needed to serve the increase in purchase request (from 265 to 300 mgd) and the improvement in supply reliability include: 1) a supply of 10 mgd from implementation of the Recycled Water Projects (SF-3), Local Groundwater Projects (a component of SF-2, Groundwater Projects), and additional conservation programs (RRGWC); 2) the same restored storage features of Calaveras and Crystal Springs Reservoirs; and 3) the incorporation of the Westside Basin Groundwater Program. Also included is a supplemental water supply for delivery during drought obtained from Tuolumne River diversions through transfers from the TID and MID.

4.1 Water Deliveries and Drought Response Actions

The same form of MID/TID Tuolumne River water transfer is modeled for both the proposed program and the variant. However, the volume of water transferred is increased from 27,000 acre-feet per year (afy) to 42,000 afy for use during drought. The additional transfer volume is needed in the variant setting to provide the supplemental water necessary to accommodate the goal of limiting delivery shortages to no more than 10 percent in any year including during the Design Drought. Table 1-1 compares the drought response actions for the WSIP and variant. Figure 4.1-1 illustrates the drought response actions for the simulated 82-year historical period (1921-2002).

Figure 4.1-1
Drought Response Actions – WSIP and 10% Rationing Variant



In Figure 4.1-1, years with bars showing a “1” or greater level of action indicate periods when a supplemental water supply action is initiated. In these scenarios, the action is the use of the Westside Basin Groundwater Program to supplement SFPUC water deliveries. Action levels greater than “1” indicate the imposition of delivery shortages (rationing) to SFPUC customers. Rationing is not greater than 10 percent in the variant setting. Compared to the WSIP setting, the 10-percent rationing limit of the variant requires the triggering of an additional year of utilization of supplemental water from the Westside Basin Groundwater Program; this rationing limit could not be achieved without the increase in transfer from MID/TID.

The same form of information is shown in Figure 4.1-2 in comparing the variant and “Base - Calaveras Constrained” (existing) settings. In modeling parlance, there is no level 1 action level in the base setting. Without supplemental resources, the existing system has only the delivery shortage measure available to cope with drought. This shortage measure is imposed during level 2 (10 percent) and level 3 (20 percent). These percentages of shortage are applied to both the variant and base setting for these action levels.

Figure 4.1-2
Drought Response Actions – Base and 10% Rationing Variant

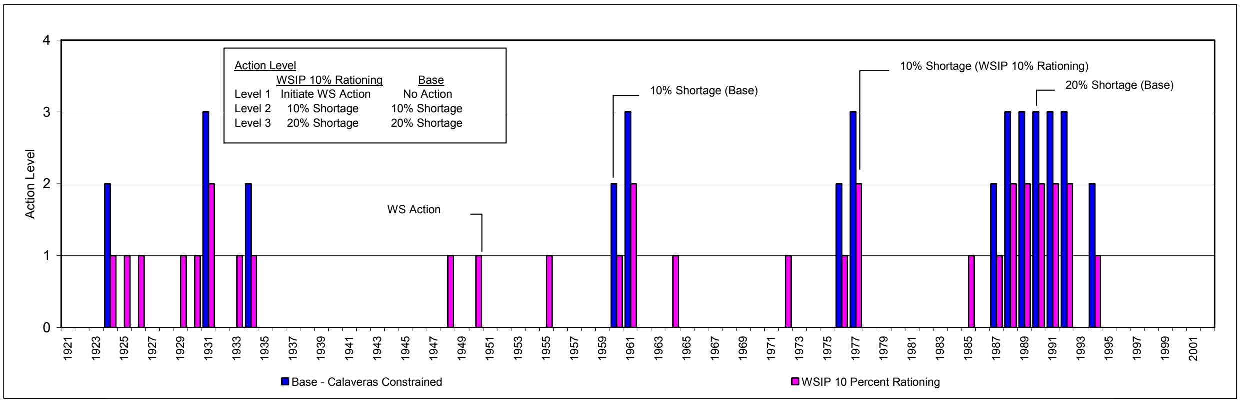


Figure 4.1-2 illustrates that, when compared to the base setting, the variant triggers the supplemental resource (Westside Basin Groundwater Program) at an early indication of drought, during periods when in the current setting there is no supplemental resource available to the system. The utilization of the supplemental resource during these times results in the lessening of (or at least a non-increase in) the severity of delivery shortage.

Not illustrated in Figure 4.1-2, but shown in Table 1-1, are the delivery shortages anticipated during the entire SFPUC Design Drought. Shortages during the Design Drought with the variant are maintained within the objective of limiting the severity of shortage to no more than 10 percent. With the existing system, the WSIP's 20 percent limitation (cap) objective cannot be achieved during the last 18 months of the Design Drought, and a 25 percent shortage is applied.

The difference in water deliveries between the proposed program and the variant is shown chronologically for the 82-year simulation in Table 4.1-1. The negative differences indicated for 1934-1935 reflect the triggering of an additional year of supplement supply from the Westside Groundwater Program. In effect, the use of the resource offsets the demand needed from other SFPUC resources. The positive differences following this period of approximately 2,600 million gallons per year represent years when additional replenishment of the Westside Basin Groundwater Program was necessary after the additional draw from the program. The years showing additional deliveries of approximately 10,000 million gallons during the 1990s represent years when shortages were reduced to 10 percent in the variant setting.

4.2 Diversions from Tuolumne River

The metric for illustrating the SFPUC diversion from the Tuolumne River Basin is the flow through the SJPL. Table 4.2-1 illustrates the difference in diversions to the SJPL between the proposed program and the variant settings. The year-to-year shift in diversions to the SJPL during the 1930s reflects the minor change in system deliveries shown in Table 4.1-1 that are due to the additional operation of the Westside Groundwater Program. The net difference during the period is negligible. A similar shifting of diversions between years is modeled to occur during the 1960s and 1970s, both attributable to modeling assumptions that balance storage among SFPUC reservoirs and the setting of the flow rate of the SJPL. These changes are not considered to be meaningful. The additional diversions indicated during the 1990s represent the additional water supply provided from the Tuolumne River to serve the additional deliveries associated with the 10 percent rationing limit. In the WSIP setting, the diversion would be less because its 20-percent rationing goal requires fewer water deliveries. Table 4.2-2 illustrates the average monthly diversion through the SJPL, by year type, for the 82-year simulation period for the proposed program and the variant settings.

4.3 Hetch Hetchy Reservoir and Releases

The additional draw of water for the additional deliveries of the variant would increase the draw from Hetch Hetchy Reservoir; however, this draw essentially only occurs during one period of the simulation. Figure 4.3-1 illustrates a chronological trace of the simulation of Hetch Hetchy Reservoir storage and stream releases. Shown in Figure 4.3-1 are the results for the WSIP, variant ("WSIP All Tuolumne"), and base ("Base – Calaveras Constrained") settings. Supplementing the Figure 4.3-1 representation of Hetch Hetchy Reservoir storage are Table 4.3-1 Hetch Hetchy Reservoir Storage (10% Rationing) and Table 4.3-2 Difference in Hetch Hetchy Reservoir Storage (10% Rationing minus WSIP). Table 4.3-3 illustrates the difference in Hetch Hetchy Reservoir storage between the base and variant settings.

Table 4.3-2 illustrates that, throughout the summer and into the fall, storage in Hetch Hetchy Reservoir associated with the variant would differ from the storage in the WSIP setting only in some years, and this difference could be more or less storage. The occasional difference in storage at Hetch Hetchy Reservoir is coincident with the changes that are modeled for the SJPL diversion. Only the changes associated with the difference in Westside Groundwater Program operations (1930s) and the diversion of additional water for the 10 percent rationing objective (1990s) are meaningful. The other modeled differences are attributable to assumptions for reservoir balancing and flow rates of the SJPL, which are discretionary in the model, and the differences may not occur in actual operations. The minor changes that would occur to Hetch Hetchy Reservoir storage during the winter and spring would typically be negated by the end of May with the filling of the reservoir. Figure 4.3-1 illustrates that the greatest draw from reservoir storage occurs during the droughts of the 1930s and 1976-1977 for both the variant and the base settings, and that there is not much difference between the two. Figure 4.3-2 illustrates the difference in reservoir storage, averaged by year type, in comparing the variant and WSIP settings. Also shown is the average difference in storage for the two settings during the 82-year simulation. Figure 4.3-3 illustrates the same information in comparing the variant and base setting. Figure 4.3-4 illustrates the average monthly storage in Hetch Hetchy Reservoir for the 82-year simulation, and the range in storage for each month for the variant and base settings.

The infrequent minor differences in storage in Hetch Hetchy Reservoir attributed to the diversion effects of the variant manifest into differences in releases from O'Shaughnessy Dam to the stream. A difference in the amount of available reservoir space in the winter and spring would lead to a difference in how inflow is regulated at O'Shaughnessy Dam. Figure 4.3-1 illustrates the stream release from O'Shaughnessy Dam for the WSIP, variant, and base settings. Table 4.3-4 illustrates the difference in stream releases between the variant and WSIP settings. Compared to the WSIP setting, the variant exhibits almost no change in stream releases. The one meaningful exception occurs during the drought of the 1990s, when additional water is diverted for additional deliveries and the effect manifests as a reduction to releases to the stream in one subsequent month (June). Table 4.3-5 illustrates the same information in comparing the variant and base settings.

Table 4.3-4 illustrates the difference in stream release between the variant and WSIP settings, expressed in terms of a month-to-month change in volume (acre-feet) of flow. The one notable difference in monthly flow below O'Shaughnessy Dam indicates a potential decrease of approximately 29,000 acre-feet between the variant and WSIP settings. Considering the manner in which releases are determined and made to the stream, quantifying the effect of these changes in terms of average monthly flow (cfs) is not always meaningful.[5] Assuming that a change in release volume equates to a delay or earlier initiation of releasing 6,000 acre-feet per day, the difference in stream release from O'Shaughnessy Dam between the variant and WSIP would be a delay in releases up to 5 days. Normally, the effect of a delay in release would not affect the year's peak stream release rate during a year. Compared to the base setting, the variant's effect to stream flow is almost identical to the effect caused by the WSIP.

Compared to the base setting, Table 4.3-5 illustrates that the variant could potentially decrease releases by up to 58,000 acre-feet in one monthly instance, or increase releases by up to 10,000 acre-feet during a month. These changes would equate to an effect ranging from a delay in release of up to 10 days to an earlier initiation of releases by 2 days.

4.4 Lake Lloyd and Lake Eleanor

Compared to the operation of the WSIP, the operation of Lake Lloyd and Lake Eleanor are simulated to be only slightly different in the variant. Figure 4.4-1 illustrates a chronological trace of the simulation of Lake Lloyd storage and stream releases. Shown in Figure 4.4-1 are the results for the WSIP, variant, and base settings. The operation resulting from the variant is essentially the same as in the WSIP setting, except during the prolonged drought of 1987-1992. The difference is explained as modeling discretion, and would not likely occur. HH/LSM model logic estimates the amount of water to be released from Lake Lloyd based on the condition of Hetch Hetchy Reservoir, the Don Pedro Water Bank Account, and Lake Eleanor and Lake Lloyd storage in comparison to demands. In this instance, the model logic retains more water in Lake Lloyd as compared to the WSIP setting. By the end of the drought, this water is utilized, and the storage between the two settings is comparable. The end result is the same storage at the end of the period, and only the rate at which it changes is different. The model logic is not very refined, and a small change in computation result can result in a large difference in Lake Lloyd release (in this instance, through Holm Powerhouse). Overall, the Lake Lloyd operation would be discretionary, and the outcome would likely be the same among the variant and the WSIP settings.

Figure 4.4-2 illustrates an almost identical operation of Lake Eleanor for the variant and WSIP settings. Also shown in Figure 4.4-2 is the operation for the base setting. Any difference that occurs in the Lake Eleanor operation would be caused by a small change in operation at Lake Lloyd that would affect the operation of the Cherry-Eleanor Tunnel between the two watersheds. Any difference that occurs in the simulations is more associated with modeling discretion than with any substantive likely difference in operation.

Supplementing the Figure 4.4-1 representation of Lake Lloyd stream releases is Table 4.4-1, which illustrates releases for the variant and WSIP settings and the almost no difference in releases between the two. Table 4.4-2 provides the same form of information for the variant and base settings, also showing almost no difference between the variant and the base settings.

4.5 Don Pedro Reservoir and La Grange Releases

A change in Don Pedro Reservoir operation is caused by changes in inflow to the reservoir. The changes in inflow to the reservoir are the result of net changes within the operation of the upstream SFPUC facilities described previously, and other changes in SFPUC operations associated with diversions to the Holm, Kirkwood, and Moccasin Powerhouses. Figure 4.5-1 illustrates a chronological trace of the simulation of Don Pedro Reservoir storage and Tuolumne River stream releases from La Grange Dam. Shown in Figure 4.5-1 are the results for the WSIP, variant, and base settings.

Supplementing the Figure 4.5-1 representation of Don Pedro Reservoir storage are Table 4.5-1 Don Pedro Reservoir Storage (10% Rationing) and Table 4.5-2 Difference in Don Pedro Reservoir Storage (10% Rationing minus WSIP). Table 4.5-3 is provided to illustrate the difference in Hetch Hetchy Reservoir storage between the base and variant settings.

Table 4.5-2 illustrates that, throughout many years, the storage in Don Pedro Reservoir associated with the variant would not differ from the storage in the WSIP setting. Minor changes in storage occur during

the 1930s and 1960s, and then sporadically in other years. These changes are due to slight changes in the upstream operation of SFPUC facilities, which have previously been described as modeling discretion; this has led to the conclusion that little or no change in actual operations would occur during these periods. The one notable change in Don Pedro Reservoir storage occurs during the 1990s, while the variant's 10% shortage limitation requires additional diversion from the Tuolumne River. The storage difference manifesting in Don Pedro Reservoir is the result of the MID/TID transfer facilitating the addition diversion of water to the SJPL.

The greatest draw from reservoir storage occurs during the drought of the 1976-1977, which is the same for the variant, WSIP, and base settings. The year of greatest difference in reservoir draw between the base setting and variant occurs during the 1987-1992 drought. Figure 4.5-2 illustrates the difference in reservoir storage, averaged by year type, in comparing the variant to the WSIP setting; almost no difference between the two settings is illustrated, except during dry years (associated with the 1987-1992 drought period). Also shown is the average difference in storage for the two settings during the 82-year simulation. Figure 4.5-3 illustrates the same information in comparing the variant and base setting. These results are almost identical to the comparison of the WSIP and base settings.

Figure 4.5-2

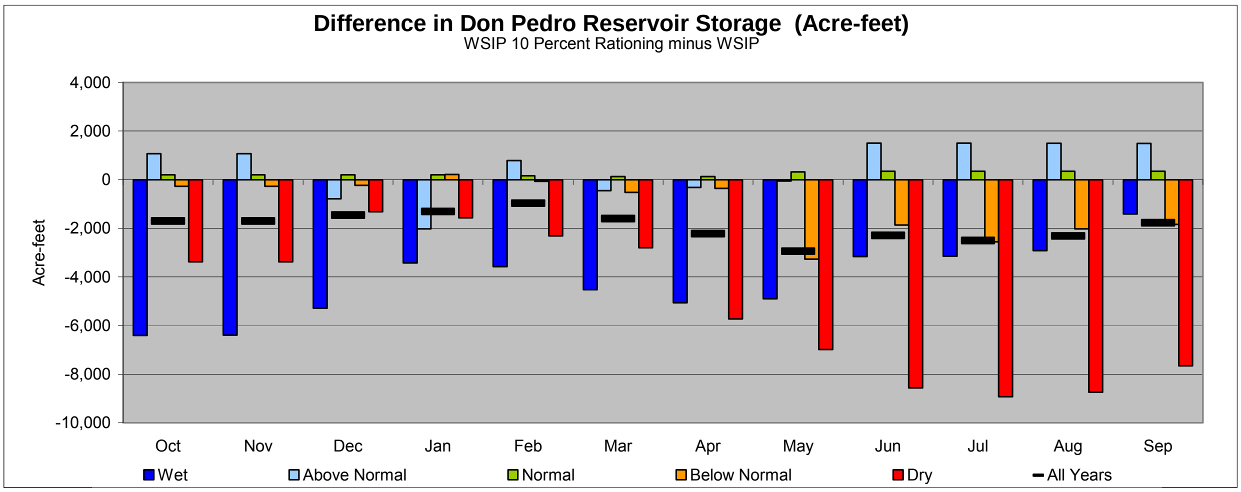

Figure 4.5-3

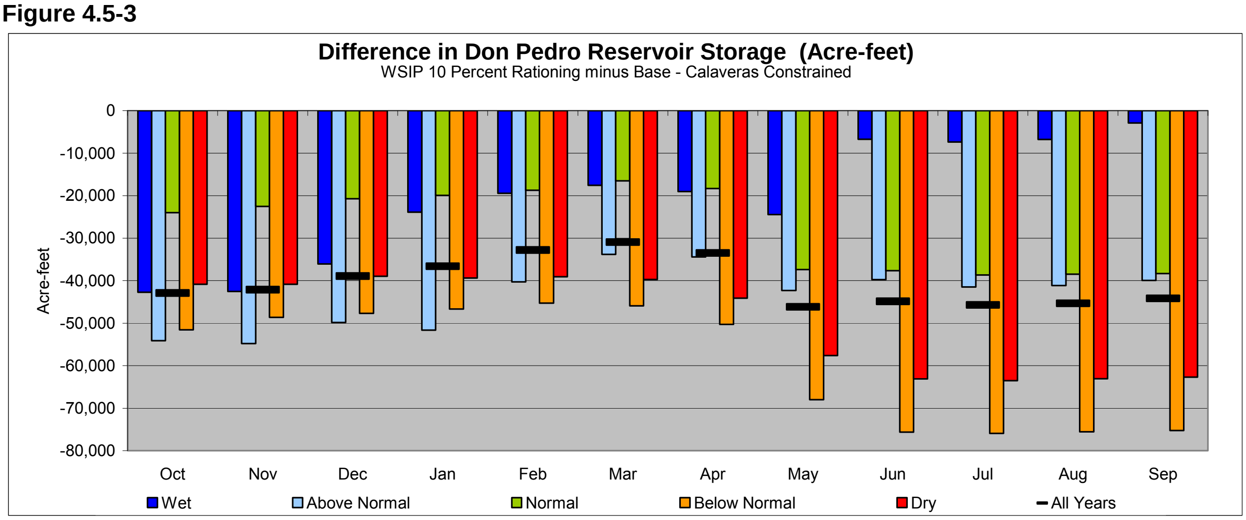

Figure 4.5-4 illustrates the average monthly storage in Don Pedro Reservoir for the 82-year simulation, and the range in storage for each month for the variant and base settings. The difference in storage in Don Pedro Reservoir attributed to the upstream effects of the variant would manifest into differences in releases from La Grange Dam to the stream. A difference in the amount of available reservoir space in

the winter and spring due to the variant would lead to a difference in the ability to regulate inflow, thus potentially changing the amount of water released to the stream, which is above minimum release requirements. During periods when inflow differs and Don Pedro Reservoir is at maximum storage capacity within the flood control storage limitation, a change in inflow would directly manifest as a change in release from La Grange Dam (a change in either more or less flow). Figure 4.5-1 illustrates the stream release from La Grange Dam for the WSIP, variant, and base settings.

Figure 4.5-4

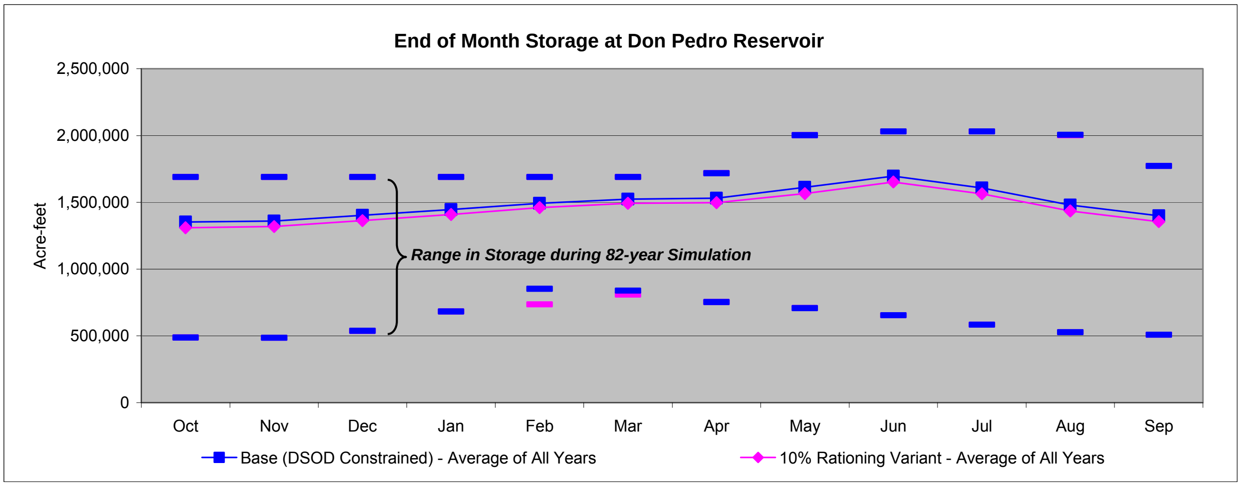

Table 4.5-4 illustrates the difference in stream releases between the variant and WSIP settings. Consistent with the near absence of changes in Don Pedro Reservoir storage, stream releases between the variant and WSIP settings are almost identical, except for a period following the droughts of the 1930s and 1987-1992. In both instances, additional diversions to the SJPL lead to additional depletion of Don Pedro Reservoir storage. The additional depletion of reservoir storage manifests as a reduction in subsequent releases below La Grange Dam to replenish the reservoir storage. The differences in releases to the Tuolumne River from La Grange Dam would occur only when there are releases above minimum FERC flow requirements. Table 4.5-4 illustrates that the difference in monthly flow below La Grange Dam ranged up to a decrease of approximately 23,000 acre-feet in one month. Assuming that a change in release volume equates to a delay or earlier initiation of releasing 6,000 acre-feet per day, the difference in stream release from La Grange Dam between the variant and WSIP would be a delay in releases up to 4 days in that month. Normally, the effect of the delay in release would not affect the year's peak stream release rate during a year. However, infrequently, the variant's effect on stream releases could manifest as an elimination of all flows above minimum FERC flow requirements within a month or year. This would occur after the experience of an extended drought period.

Table 4.5-5 illustrates differences in releases between the variant and base settings. Compared to the base setting, the variant's effect on stream flow is very similar to the effect caused by the WSIP, but at times slightly greater. Using the same assumption that a change in release volume equates to a delay or earlier initiation of releasing 6,000 acre-feet per day, the difference in stream release from La Grange Dam between the variant and base would typically be a delay in releases up to a few days. Normally, the effect of the delay in release would not affect the year's peak stream release rate during a year. However, infrequently, following a prolonged multi-year drought period, the variant's effect on stream releases could manifest as an elimination of all flows above minimum FERC flow requirements within a year.

Table 4.5-6 illustrates releases to the Tuolumne River below La Grange Dam and their differences, in terms of average monthly flow (cfs) averaged within year types, in comparing the variant and WSIP settings. The same form of information is provided for the variant and base settings in Table 4.5-7.

4.6 Calaveras and San Antonio Reservoirs, Alameda Creek and Downstream

There are only slight differences in Calaveras Reservoir operations between the variant and WSIP settings. Figure 4.6-1 illustrates a chronological trace of the simulation of Calaveras Reservoir storage and stream releases from Calaveras Dam. Shown in Figure 4.6-1 are the results for the WSIP, variant, and base settings. The differences in Calaveras Reservoir storage between the variant and WSIP settings during the 1930s, 1960s, and 1976-1977 are due to the modeled difference in SJPL diversions during those periods. These differences are mostly due to model logic that selects the rate at which diversions occur to the pipelines, and to reservoir balancing logic. During each of these periods, results indicate that the differences are negated prior to reservoir spill, which indicates that the differences are due to discretionary logic and may not occur in actual operations. The operation of Calaveras Reservoir between the variant and WSIP settings would be the essentially the same.

The difference in storage between the variant and WSIP settings and the base setting is due to the restoration of the operational capacity of Calaveras Reservoir. Figure 4.6-2 illustrates the average monthly storage in Calaveras Reservoir for the 82-year simulation, and the range in storage for each month for the variant and base settings.

There is essentially no change in releases to Calaveras Creek below Calaveras Dam between the variant and WSIP settings. A change was indicated in only one month of the 82-year simulation, and that was attributed to discretionary modeling assumptions. The difference is almost unnoticeable during February 1940, as shown in Figure 4.6-1. Both settings have fishery releases that are not included in the base setting. Supplementing the Figure 4.6-1 representation of Calaveras Dam stream releases is Table 4.6-1, illustrating releases for the variant and base settings, and the difference in releases between the two. The notable difference in releases between the variant and base settings is the addition of the flows representing the 1997 MOU and the reduction of stream releases during wetter-year/wetter-season flows due to the restoration of Calaveras Reservoir operational capacity.

There is essentially no change (one month of minor change during the 82-year simulation) in Alameda Creek diversions to Calaveras Reservoir between the variant and the WSIP settings. With almost no change in Calaveras Reservoir storage between the two settings, there would be no change in the diversion operation at the Alameda Creek Diversion Dam. Water would only be diverted to Calaveras Reservoir when the diversion would not contribute to releases in excess of minimum required flows below Calaveras Dam. Coincidentally, with no change in the diversion at Alameda Creek Diversion Dam, flow spilling past the diversion dam would experience no differences between the variant and WSIP settings. Table 4.6-2 illustrates the flow below the Alameda Creek Diversion Dam for the variant and base settings. The notable difference between the variant and the base settings is the reduction of wetter-year water flowing past the diversion dam. This occurs because, in the variant setting, the restoration of Calaveras Reservoir storage allows a greater frequency of diversion from Alameda Creek to Calaveras Reservoir.

Comparing the variant and WSIP setting, with no differences in releases from Calaveras Dam to the stream, and no differences to spills at Alameda Creek Diversion Dam, flow below the Alameda Creek and Calaveras Creek confluence will be the same for each setting. Table 4.6-3 illustrates the flow below the confluence for the variant and base settings, and the difference in flow between the two. The notable differences between the variant and the base settings (comparable to the difference between the WSIP and base settings) are the addition of stream flows for the 1997 MOU and the reduction of wetter-year/wet season flows due to the restoration of Calaveras Reservoir storage.

A flow recapture facility in Alameda Creek below Calaveras Reservoir is incorporated in the variant and WSIP settings. This facility is assumed to recapture flows explicitly released from Calaveras Dam for the 1997 MOU. The effect of the recapture is a reduction in the flow that occurs below the confluence of Alameda and Calaveras Creeks, but only to the extent that releases were explicitly made from Calaveras Reservoir for the 1997 MOU. Flows below this diversion have been estimated and noted as the flow above the Alameda and San Antonio Creek confluence. With no changes noted for stream releases from Calaveras Reservoir or flow past Alameda Creek Diversion Dam between the variant and WSIP settings, the flow at this location will be the same among the variant and WSIP settings. Table 4.6-4 illustrates the flow at this location for the variant and base settings. The flows identified at this location indicate flow below the confluence of Alameda and Calaveras Creeks (described above), with the addition of estimated stream accretions between the Alameda-Calaveras Creek confluence and the Alameda-San Antonio Creek confluence, minus the water assumed to be recaptured (diverted) by the SFPUC from the creek.

Compared to the WSIP setting, San Antonio Reservoir operations in the variant setting generally mirror the changes experienced for Calaveras Reservoir operations. Figure 4.6-3 illustrates a chronological trace of the simulation of San Antonio Reservoir storage and stream releases from the dam. Shown in Figure 4.6-3 are the results for the WSIP, variant, and base settings. The difference in San Antonio Reservoir storage between the variant and WSIP settings during the 1930s, 1960s, and 1976-1977 are due to the same modeling nuances described for Calaveras Reservoir differences. These differences are mostly due to model-selected flow rates for the SJPL and to reservoir balancing logic. During each of these periods, results indicate that the differences are negated prior to reservoir spill, indicating that the differences are due to discretionary logic and may not occur in actual operations. The operation of San Antonio Reservoir between the variant and WSIP settings would be essentially the same.

The magnitude of effect in the difference in San Antonio Reservoir storage depends on modeling assumptions for the balancing of total Bay Area reservoir storage among the five major SFPUC reservoirs. The model balances storage between reservoirs by way of an input file by the modeler concerning the relative draw (percentage) from each reservoir under various storage conditions. These are discretionary input in the model, and the logic and relative percentages are meant to mimic the current practice and discretion of the system operators based on recognition of the physical conveyance constraints within the system and the ability of each reservoir to provide yield and water delivery security.

The logic currently favors the retention of storage in the peninsula reservoirs for security reasons; thus, the provision of additional water between the settings is balanced between San Antonio and Calaveras Reservoir.

The difference in storage between the variant and WSIP settings and the base setting is due to the restoration of the operational capacity of Calaveras Reservoir. In the base setting, the limited operating storage capacity at Calaveras leads to a different operation at San Antonio Reservoir, one that provides relatively more stored water for system demands when the draw from Calaveras Reservoir is constrained due to limited storage. There is also a notable difference in storage operation between the variant and WSIP settings and the base setting every fifth year. Assumed systematic maintenance of Hetch Hetchy conveyance facilities occurs in the simulation, and constrains diversions to the Bay Area from Hetch Hetchy every fifth year. The reduction in diversion from Hetch Hetchy during these periods is accommodated in the system by the drawing of additional water from the Bay Area reservoirs. The proportionate share of this operation is evident in the tracing of San Antonio Reservoir storage for the variant and WSIP settings. Figure 4.6-4 illustrates the average monthly storage in Calaveras Reservoir for the 82-year simulation, and the range in storage for each month for the variant and base settings.

There would very little change in stream releases below San Antonio Reservoir between the variant and WSIP settings. Table 4.6-5 illustrates the modeled release to San Antonio Creek from San Antonio Reservoir for the two settings and the differences for the average release during a year type. With a slightly lower reservoir operation at times, an increase in the ability to regulate reservoir inflow and avoid stream releases would be expected. Given the sometimes rigid constraints within the modeling assumptions, the model overestimates the frequency and magnitude of stream releases from San Antonio Reservoir under any of the investigated settings. The flexibility that occurs in actual operations would likely avoid most of the releases represented by the model. The modeled stream releases from San Antonio Reservoir and difference between releases for the variant and base settings are shown in Table 4.6-6. The differences among the two settings range from increases to decreases in flow. This modeled circumstance reflects the different resulting storage operation between the two settings, as seen in Figure 4.6-3. In some circumstances, the base setting storage at San Antonio Reservoir during a period could be higher than projected for the variant setting during the same period. This could lead to an occasionally greater modeled release for the base setting, which would be reflected in the results. As described above, the model overestimates the frequency and magnitude of releases from San Antonio Reservoir; the actual releases from San Antonio Reservoir in any setting and the difference between settings are expected to be minor.

Flow below the confluence of Alameda and San Antonio Creeks is influenced by releases from San Antonio Creek and flow arriving at the location from Alameda Creek, which includes upstream impairment by SFPUC operations and facilities. Table 4.6-7 illustrates the flow below the confluence for the variant and base settings, and the differences in flow between the two. The differences are particularly due to the effects of the restoration of Calaveras Reservoir operating capacity in the variant setting.

4.7 Crystal Springs and San Andreas Reservoirs

There are essentially no differences in Crystal Springs Reservoir operations between the variant and WSIP settings. Figure 4.7-1 illustrates a chronological trace of the simulation of Crystal Springs Reservoir storage and stream releases from Crystal Springs Dam. Shown in Figure 4.7-1 are the results for the WSIP, variant, and base settings. The slight differences in Crystal Springs Reservoir storage between the variant and WSIP setting are caused by the coincidence of reservoir balancing logic in the model, conveyance constraints, and selected flow rates for the SJPL. In actual operations, results may not differ as system operators and prevailing hydraulic and hydrologic conditions may direct the operational effect of the different demand to an alternative apportionment of effect among the reservoirs.

Figure 4.7-2 illustrates the average monthly storage in Crystal Springs Reservoir for the 82-year simulation, and the range in storage for each month for the variant and base settings. Consistent with the comparison of the WSIP and base settings, the variant setting would result in reservoir storage operating at a higher average and higher upper-range than the base setting. This is due to the restoration of the operating capacity of Crystal Springs Reservoir.

Comparing the variant to WSIP settings, differences in stream releases are infrequent (9 months during the 82-year simulation), and could be either an increase or decrease in the release. The potential difference is attributed to whether the different resulting storage in the reservoir was higher or lower between the two settings. Part of the difference in modeled Crystal Springs Reservoir storage is due to modeling assumptions for the proportionate management of storage among the Bay Area reservoirs, and the coincidence of constrained conveyance flow rates. In actual operations, it is anticipated that system operators would manage the reservoir system, whereby stream releases would be minimal under any setting, with the result of essentially no difference between the variant and WSIP settings.

Table 4.7-1 illustrates the stream releases for the variant and base settings, and the difference in modeled flows between the two settings. A greater operating range in Crystal Springs Reservoir operation would lead to an increased potential to regulate reservoir inflow, which would lead to less risk in needing to make stream releases. However, as described above, actual system operations would attempt to minimize releases under any setting; thus, the difference in releases between the variant and base setting would be minimal, if any.

San Andreas Reservoir operations would generally be the same between the variant and WSIP settings. Reservoir storage would follow a systematic filling and lowering each year. Figure 4.7-3 illustrates a chronological trace of the simulation of San Andreas Reservoir storage and stream releases. Shown in Figure 4.7-3 are the results for the WSIP, variant, and base settings. There are no projected stream

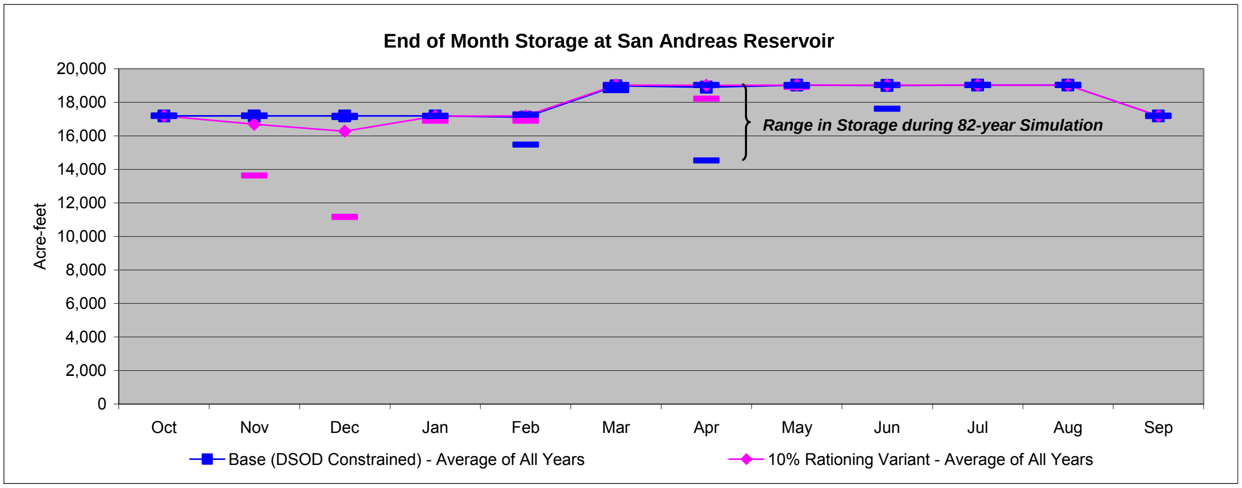
releases from San Andreas Reservoir in any setting. Notable in Figure 4.7-3 is the difference in storage operation every fifth year. Both the variant and WSIP setting storage operation differ from the base setting. This operation is the result of the assumption that Hetch Hetchy conveyance maintenance occurs systematically every fifth year, which constrains the amount of Hetch Hetchy water supplied to serve water demands in the Bay Area. As discussed previously, during these winter periods, the Bay Area reservoir system accommodates the reduction in imported supply by serving the Bay Area water deliveries with the local watersheds' runoff and storage. At San Andreas Reservoir, the serving of water demand affects the reservoir when additional required water production at Harry Tracy WTP associated with WSIP or the variant exceeds the ability to maintain San Andreas Reservoir storage with pumping from Crystal Springs Reservoir. In the modeling, the conveyance capacity from Crystal Springs Reservoir is assumed to be the same among all of the settings. The additional water demand of the WSIP and variant require additional draw from Harry Tracy WTP to the San Andreas Reservoir. Figure 4.7-4 illustrates the average monthly storage in San Andreas Reservoir for the 82-year simulation, and the range in storage for each month for the variant and base settings.

Figure 4.7-4



4.8 Pilarcitos Reservoir

Coastside County Water District's (Coastside CWD) water demand and its SFPUC purchase request are projected to increase within the WSIP planning horizon of year 2030. Within the context of the 2030 purchase request of 300 mgd, Coastside CWD's portion has been estimated at about 3 mgd. This projected purchase request is approximately 1 mgd greater that its current purchase request. Recognizing the current physical constraints to deliveries from the SFPUC to Coastside CWD and the ongoing planning activities in the watershed, there is uncertainty as to the precise manner in which Coastside CWD's additional purchase request would be served and the resultant potential changes to the operation of SFPUC facilities and their affected environs.[6]

Assuming a range of potential means to serve the additional purchase request from Coastside CWD, the following potential hydrologic effects to SFPUC facilities and their affected environs have been identified:

- Due to limited yield from Pilarcitos Reservoir, additional diversions would be required from Crystal Springs Reservoir.
- If deliveries to Coastside CWD from Pilarcitos Reservoir increase during the winter season, these deliveries could potentially reduce storage in Pilarcitos Reservoir, thereby potentially reducing diversions to the San Mateo Creek watershed. Although the increased delivery would increase releases to Pilarcitos Creek from Pilarcitos Dam for a period of time, the increase would subsequently lead to a reduction in spills past Stone Dam.

[6] See "Analysis of SFPUC PIlarcitos/Coastside County Water District Operations", Memorandum by Daniel B. Steiner, March 8, 2007.

- Additional wintertime deliveries could also potentially impair the ability to provide carry-over storage into the summer season from Pilarcitos Reservoir, and subsequently lead to an acceleration of the beginning of the season when releases to Pilarcitos Creek from Pilarcitos Reservoir consist only of the passage of reservoir inflow.
- An increase in summertime deliveries from Pilarcitos Creek could also accelerate the beginning of the season when releases to Pilarcitos Creek from Pilarcitos Reservoir consist only of the passage of reservoir inflow.

The variant setting could result in essentially the same potential effects to the Pilarcitos Creek watershed as under the WSIP setting. In the variant setting, there would be a slightly higher delivery to Coastside CWD during prolonged drought due to the greater reliability of 10 percent maximum rationing. In contrast to the WSIP setting, during these periods, the effect on the Pilarcitos Creek watershed could be slightly greater.

APPENDIX H2-5

Memorandum

Subject: **HH/LSM Assumptions and Results – CEQA Alternatives**
From: **Daniel B. Steiner**
Date: **April 2, 2007**

1. Introduction

This memorandum summarizes assumptions for and describes the interpretation of Hetch Hetchy Local Simulation Model (HH/LSM) results for the simulation of the California Environmental Quality Act (CEQA) Alternatives that are incorporated into the Program Environmental Impact Report (PEIR). Five CEQA alternatives are analyzed: 1) No Program; 2) No Purchase Request Increase; 3) Aggressive Conservation and Water Recycling; 4) Lower Tuolumne River Diversion; and 5) Desalination within San Francisco. A sixth alternative, Regional Desalination for Drought, was identified as a CEQA alternative; its hydrologic analysis is described in a separate memorandum.[1] These scenarios represent CEQA program alternatives that vary from the proposed program (Water System Improvement Program [WSIP]) on key program components in a manner expected to avoid or reduce potentially significant effects of the proposed program. Table 1-1 and Table 1-2 summarize the components, various modeling assumptions, and performance and hydrologic results for Alternatives 1, 2, and 3 in comparison to the modeled existing setting (2005) with Calaveras Reservoir constrained by California Division of Safety of Dams (DSOD) restrictions, the pre-2002 setting (with a Calaveras Reservoir operation prior to DSOD restrictions), and the WSIP setting. Alternative 3, Aggressive Conservation, has additionally been analyzed in terms of alternative objectives of performance (level of service [LOS]) and effect to Tuolumne River hydrology, with those results mostly described qualitatively. Alternative 4, Lower Tuolumne River Diversion, and Alternative 5, Desalination within San Francisco, are discussed partly quantitatively and partly qualitatively.

The hydrology of each alternative is primarily compared to the proposed program and contrasted to the baseline condition of the PEIR, namely the simulated current (2005) operation of the regional system, assuming the Calaveras and Crystal Springs Reservoirs operation being constrained by DSOD restrictions. Only primary hydrologic parameters such as projected water deliveries, reservoir storage, and stream flows are compared, and only those parameters that have been identified as key hydrologic factors that lead to environmental impact assessment are illustrated.

<u>Note Regarding Crystal Springs Reservoir Modeling Assumptions</u>

This memorandum describes results for several studies performed with HH/LSM during the past several years. A number of the HH/LSM studies concerning the CEQA Alternatives considered for the WSIP PEIR reflect an assumption that the WSIP Lower Crystal Springs Dam Improvements (LCSDI) project would not be implemented. These modeling studies were conducted in such a manner because early drafts of those alternatives proposed this assumption. Upon further investigation, the SFPUC concluded that the LCSDI project is required in all future scenarios due to a number of factors such as DSOD regulations and public health and safety, in addition to its role in meeting WSIP reliability objectives.

When illustrated for the CEQA Alternatives described in this memorandum, the results for the Crystal Springs Reservoir operation may reflect the assumed constraint to operations that limits the reservoir's maximum storage to approximately 58,300 acre-feet. Some results of those operations would be different when assuming that under each CEQA Alternative the reservoir would be operated to its restored operational capacity of 69,300 acre-feet. Little or no change would occur in hydrologic effects for almost all of the hydrologic parameters compared. The substantive change to the alternative's operation would be the range of Crystal Springs Reservoir storage, which would be comparable to the range which occurs in the WSIP. The text and illustrations contained in this memorandum, for some of the alternatives, have not been modified to reflect this revised assumption for the LCSDI project.

Notes for Table 1-1 and Table 1-2

1. Baseline condition represents the existing conditions at the time of NOP publication in September 2005. This is the baseline used to assess WSIP program impact and impact significance. This setting indicates DSOD restrictions on Calaveras and Crystal Springs Reservoirs.

2. This baseline condition represents a system configuration and operation prior to the DSOD storage restriction (pre-2002).

3. These scenarios represent CEQA program alternatives that vary from the proposed WSIP program on key components in a manner expected to avoid or reduce potentially significant effects of the proposed program.

4. The time horizon for the setting of the scenario. The baseline condition scenarios are depicted for recent conditions, while the proposed WSIP, variants, and alternatives are depicted for the future at full buildout and implementation, i.e., conditions in the year 2030.

5. HH/LSM model simulation study name.

6. The customer purchase request (demand) information is based on the demand and request studies prepared by the SFPUC in coordination with the wholesale customers (SFPUC/URS 2004). This demand on the regional water system includes both the SFPUC retail customers and wholesale customers. The current (2005) average annual demand is 265 mgd, and the projected 2030 average annual demand is 300 mgd, assuming the SFPUC adopts the updated wholesale customer purchase requests as part of the Master Sales Agreement renewal with these customers (due in 2009).

7. Certain scenarios include the development of additional water supply from a combination of recycled water projects, groundwater projects, and conservation, utilized every year and not subject to reduction during drought.

8. The average annual demand for supplies from the combination of the SFPUC local watershed and Tuolumne River, as well as programs not included in the regional water conservation, reclamation, and groundwater programs shown.

9. Modeled results for SFPUC deliveries, with supplies added for regional water conservation, reclamation, and groundwater programs. Total deliveries and supply will be less than full customer purchase requests due to rationing in some years.

10. Shows only the features that affect hydrologic results of the system operation simulations. Additional projects are included in the WSIP, variants, and alternatives.

11. Illustrates the frequency and severity of water supply action or severity of system wide rationing. Only years in which variable water supply component is implemented or rationing occurs are shown. "DD" illustrates the shortage results for years included in the prospective drought period of the SFPUC Design Drought. These years contribute to establishing system operation protocols, but are not included in the hydrologic assessment analyses.

12. Rationing policy cap: The SFPUC WSIP level of service goal is to maintain rationing on the regional system at no more than 20% during any one year of drought. Some alternatives do not achieve this level of service goal. Performance is indicated for both the Design Drought ("DD") sequence and for the "Historical" hydrologic sequence.

13. Water supply elements develop water in different amounts from year-to-year, and in some instances, they only develop water during dry years. This information is provided to compare local watershed supplies, Tuolumne River supplies, and other identifiable water supplies used to meet system purchase requests. Values are stated in units of average annual quantities during the simulated historical sequence.

14. Results from HH/LSM analysis of each scenario. Values represent the average annual production of each element of supply during the design drought period.

15. Simplified calculation of system deliveries during the SFPUC design drought. The value represents the application of system-wide shortages to the demand level being met with SFPUC local watershed, Tuolumne, and other developed supplies, and does not include supplies from regional water conservation, or from recycled water or groundwater projects. Average value may be slightly misstated (up to 3 mgd) due to metric of analysis that does not account for differences in residual storage between studies. "Nominal" firm yield represents the yield of each scenario after adjustment for minor residual storage differences.

16. Supplemental releases from Calaveras Reservoir for fisheries (1997 MOU) of up to 6,300 AFY and the Alameda Creek Recapture project are tied to implementation of the Calaveras Dam replacement project. When the dam is replaced and capacity restored, both the flow release and recapture will occur. The release requirement is based on the supplementation of other occurring flows below Calaveras Reservoir, sometimes not requiring the full 6,300 acre-feet.

17. SFPUC actions are assumed to leave MID/TID diversions unchanged so that the SFPUC effects on the Tuolumne River below La Grange Dam are isolated and possibly overstated. The Districts' diversions are assumed to be constant among the scenarios to provide comparable results of SFPUC-alone effects.

18. Participation in the San Joaquin River Agreement is assumed. Although the agreement expires after 2010, it is assumed that a subsequent similar agreement or requirement of the Districts will occur. HH/LSM does not explicitly model the Districts' participation in the agreement; however, its participation if modeled would result in only minor differences in results and would not change impact conclusions.

19. From HH/LSM results for modeling the SFPUC Design Drought Period.

20. From HH/LSM results for modeling the system operations for the historical hydrologic period 1921-2002. Values indicate average annual quantities during the simulated historical period.

21. Modeling did not include inclusion of LSCDI project. Inclusion of the project in alternatives would develop 1 mgd of system firm yield.

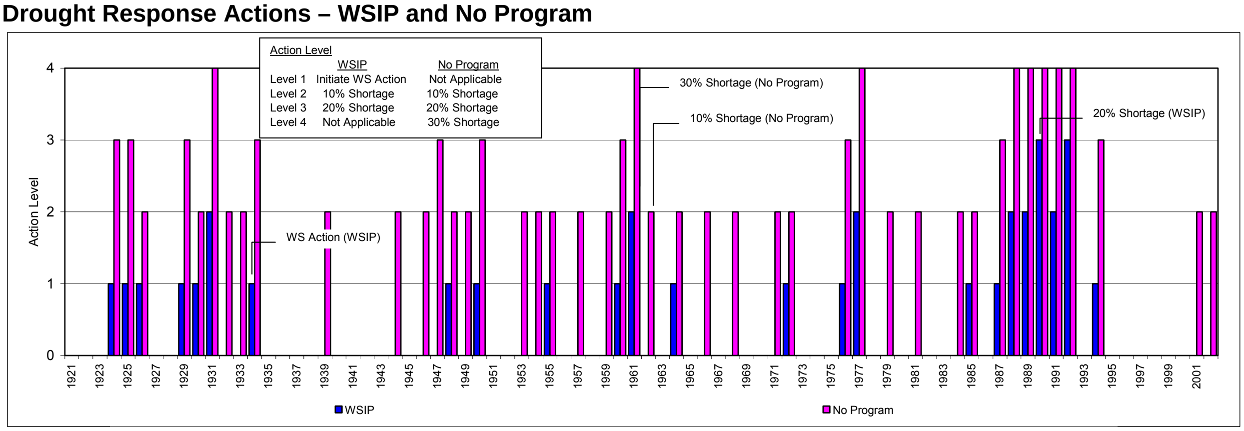
2. CEQA Alternative 1 – No Program

CEQA Alternative 1 – No Program Alternative would implement only those WSIP facility improvement projects that are mandated by, or previously agreed upon with, regulatory agencies. Those projects affecting hydrology include Alameda Creek Fishery Enhancement (SV-1) and Calaveras Dam Replacement (SV-2).[2] Under the No Program Alternative, customer purchase requests for water from the San Francisco Public Utilities Commission (SFPUC) (water demand) would increase from an average annual demand of 265 million gallons per day (mgd) in 2005 to 300 mgd in 2030. There would be no supplemental water supply sources from regional groundwater development, recycled water projects or conservation (collectively referred herein for the WSIP as Regional Recycled/Ground Water and Conservation [RRGWC]), restoration of Crystal Springs Reservoir capacity, water transfers, or the Westside Basin Groundwater Program. The additional water demand would be served, to the extent possible, from increased diversions from the Tuolumne River, as well as from the increased use of local watershed supplies, primarily associated with the restoration of Calaveras Reservoir.

2.1 Water Deliveries and Drought Response Actions

Compared to the WSIP setting, with the absence of 10 mgd of RRGWC, the regional system's resources are required to serve a 300-mgd demand instead of a net 290-mgd demand. Combined with a lesser supply as compared to the WSIP setting, this circumstance leads to a more frequent implementation of rationing and a greater severity of rationing during drought periods. The rationing is applied to the 300-mgd level of demand as opposed to a 290-mgd level of demand. Table 1-1 compares the drought response actions for the proposed program and the alternative. Figure 2.1-1 illustrates the occurrence of drought response actions for the simulated 82-year historical period (1921-2002).

Figure 2.1-1
Drought Response Actions – WSIP and No Program



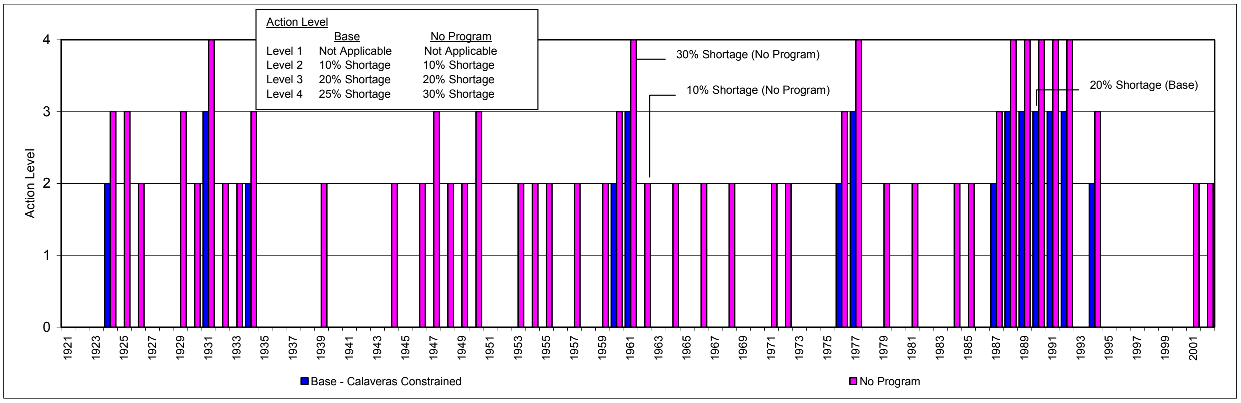
In Figure 2.1-1, years with bars showing a "1" or greater level of action indicate periods when a supplemental water supply action is initiated. In the WSIP setting, the water supply action is the use of the Westside Basin Groundwater Program to supplement SFPUC water deliveries. Also occurring in the WSIP setting is the water transfer supplemental supply from MID/TID. Action levels greater than "1" indicate the imposition of delivery shortages (rationing) to SFPUC customers. Without supplemental resources, the alternative only has delivery shortage measures available to cope with drought. This shortage measure is imposed during level 2 (10 percent), level 3 (20 percent), and level 4 (an assumed 30 percent shortage). The frequency of imposed delivery shortages and severity of shortages all increase in the alternative setting.

The same form of information is shown in Figure 2.1-2 in comparing the alternative and "Base - Calaveras Constrained" (existing) settings. As illustrated above, there is no level 1 action level in the alternative setting or base setting. Without supplemental resources, the existing system only has delivery shortage

[2] The Lower Crystal Springs Dam Improvements project is also included in the No Program Alternative but was not included in the HH/LSM modeling.

measures available to cope with drought. In the base setting, the shortage measure is imposed during level 2 (10 percent) and level 3 (20 percent). These percentages of shortage are applied to both the alternative and the base setting for these action levels, although they are applied to different levels of water demand. In the alternative, the system's water demand is an average annual 300 mgd; in the base setting, the water demand is 265 mgd. Rationing above 20 percent is not required in the base setting; however, for the same simulation period, a 30-percent level of rationing is needed for the alternative to be viable.

Figure 2.1-2
Drought Response Actions – Base and No Program



Not illustrated in Figure 2.1-2 but shown in Table 1-1 are the delivery shortages anticipated during the entire SFPUC Design Drought. During the Design Drought, neither the base setting nor the alternative setting has a viable operation without exceeding a 20-percent shortage level. The base setting exceeds the 20-percent shortage level (requires 25 percent rationing) during the last 18 months of the Design Drought. The alternative exceeds the 20-percent shortage level (requires 35 percent rationing) 6½ years out of the 8½ year Design Drought, and 3 other years within the simulation.

The difference in water deliveries between the proposed program and the alternative is shown chronologically for the 82-year simulation in Table 2.1-1. The years indicating positive differences amounting to approximately 3,600 million gallons illustrate 10 mgd of demand being met from the regional system, which, in the proposed program, was being met from RRGWC. This indicates that the regional system serves an average annual demand of 300 mgd in the alternative setting compared to the regional system serving an average annual net demand of 290 mgd in the WSIP setting. During about 23 percent of the years, the alternative can fully serve the 300 mgd of demand. During another 23 percent of the years, the alternative would provide some amount of additional water greater than base setting deliveries, but not the full amount associated with a 300-mgd level of demand. During the remaining 50 percent of years, water deliveries in the alternative setting would be less than the deliveries provided in the base setting. This reduction in reliability is due to the need to initiate shortages on the higher level of demand in many more years in anticipation of potential prolonged drought. Comparing the alternative setting to the base setting, Table 2.1-2 illustrates the difference in water deliveries between the two settings. The alternative setting would provide greater deliveries in most years. This indicates that an increase in system deliveries can be accommodated with the existing system.

2.2 Diversions from Tuolumne River

The metric for illustrating the SFPUC diversion from the Tuolumne River Basin (Tuolumne) is the flow through the San Joaquin Pipeline (SJPL). Inherent to this alternative is the draw of additional water from the Tuolumne. Table 2.2-1 illustrates the difference in diversions to the SJPL between the proposed program and the alternative settings. Compared to the base setting, the constrained conveyance capacity of the SJPL in the alternative (only equal to the existing capacity) is evident. During the summer, the SJPL would convey less water in the alternative setting. In some years, this reduction in flow is offset during the winter with an increase in diversion when capacity is available in the SJPL. With only the

existing capacity of the SJPL available in the alternative, and with scheduled maintenance for the facility, the additional demand on the system would require the SJPL to operate on an average annual basis of approximately 95 percent of it capacity, and in many years full capacity. Overall, compared to the WSIP setting, the alternative setting would divert less water from the Tuolumne.

Table 2.2-2 illustrates the difference in diversions to the SJPL between the alternative and base settings. During many springs and summers, there is little or no difference in diversions to the SJPL alternative and base settings. This indicates that the SJPL is conveying water at maximum capacity in both settings, attempting to retain storage in the Bay Area reservoirs. During the fall and winter, the increase in diversions to the SJPL indicates the system's need to serve additional demand and replenish Bay Area reservoirs. The reduction in diversion during December indicates the implementation of annual system-wide maintenance within the Hetch Hetchy conveyance facilities that currently does not occur. Overall, there would be an increase in average annual diversions to the SJPL in the alternative setting.

The average monthly diversion through the SJPL by year type for the 82-year simulation period for the proposed program and the alternative settings, and the difference between the two settings, are illustrated in Table 2.2-3. Table 2.2-4 presents the same information for the alternative and base settings.

2.3 Hetch Hetchy Reservoir and Releases

Compared to the WSIP setting, the alternative setting would draw less water from the Tuolumne in most years. This circumstance would lead to less draw from Hetch Hetchy Reservoir in most years. Figure 2.3-1 illustrates a chronological trace of the simulation of Hetch Hetchy Reservoir storage and stream releases. Shown in Figure 2.3-1 are the results for the WSIP, alternative ("No Program"), and base ("Base – Calaveras Constrained") settings. Supplementing the Figure 2.3-1 representation of Hetch Hetchy Reservoir storage are Table 2.3-1 Hetch Hetchy Reservoir Storage (No Program), Table 2.3-2 Hetch Hetchy Reservoir Storage (WSIP), and Table 2.3-3 Difference in Hetch Hetchy Reservoir Storage (No Program minus WSIP). Table 2.3-4 illustrates the difference in Hetch Hetchy Reservoir storage between the base and alternative settings.

Table 2.3-3 shows that, by the end of summer, storage in Hetch Hetchy Reservoir associated with the alternative setting would be greater than the storage in the WSIP setting, albeit typically an increase of less than 10,000 acre-feet. In about 16 percent of the years, storage would be greater by 10,000 acre-feet or more. The relatively minor increases in storage are attributable to less water being diverted during the summer to the SJPL due to a lesser conveyance capacity. The lesser capacity does not always lead to an increase in storage because, in many years, the same release from Hetch Hetchy Reservoir (via Canyon Tunnel) occurs regardless of the diversion to the SJPL, with any flow not being diverted to the SJPL flowing to Don Pedro Reservoir. The larger increases in storage are associated with years or periods during which the increase in severity of water delivery shortages between the WSIP and alternative settings require less water to be diverted to the SJPL. Through the fall and winter, storage in Hetch Hetchy Reservoir would typically be higher, but could be lower depending on the system's need to replenish Bay Area reservoir storage, which is lower due to the lesser conveyance capacity of the SJPL. Hetch Hetchy Reservoir would fill by the end of May during approximately 61 percent of the years, which would negate any difference in storage from carrying into the next summer. Figure 2.3-2 illustrates the difference in reservoir storage averaged by year type for the comparison of the alternative to the WSIP setting. Also shown is the average difference in storage for the two settings during the 82-year simulation.

Table 2.3-4 illustrates the difference in Hetch Hetchy Reservoir storage between the alternative and base settings. Throughout the summer and early fall, there would be very little difference in storage levels between the two settings. Beginning in fall, storage would slightly decrease in the alternative setting, as additional diversions to the SJPL would be needed to replenish Bay Area reservoir storage, which would be affected by the additional demand of the alternative setting during the summer. Storage becomes greater in December of the alternative setting due to the assumed system-wide maintenance that occurs in the alternative (no water being conveyed through the SJPL), which does not occur in the base setting. After December, storage in the alternative setting again becomes affected as Bay Area reservoir storage begins to replenish. In most years, there is a difference in storage between the alternative and base settings; the alternative setting results in a lower storage in the reservoir by the end of April.

Table 2.2-2

Difference in Total SJPL (Acre-feet)

No Program minus Base - Calaveras Constrained

Figure 2.3-2

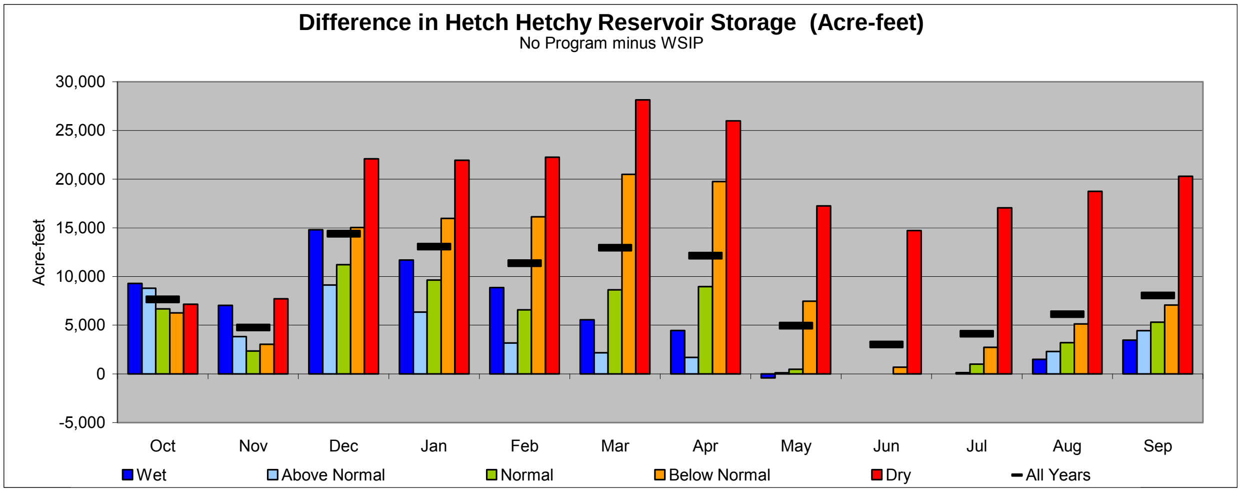

Figure 2.3-3 illustrates the difference in reservoir storage averaged by year type for the comparison of the alternative to the base setting. Also shown is the average difference in storage for the two settings during the 82-year simulation. Figure 2.3-4 illustrates the average monthly storage in Hetch Hetchy Reservoir for the 82-year simulation, and the range in storage for each month for the variant and base settings.

Figure 2.3-3

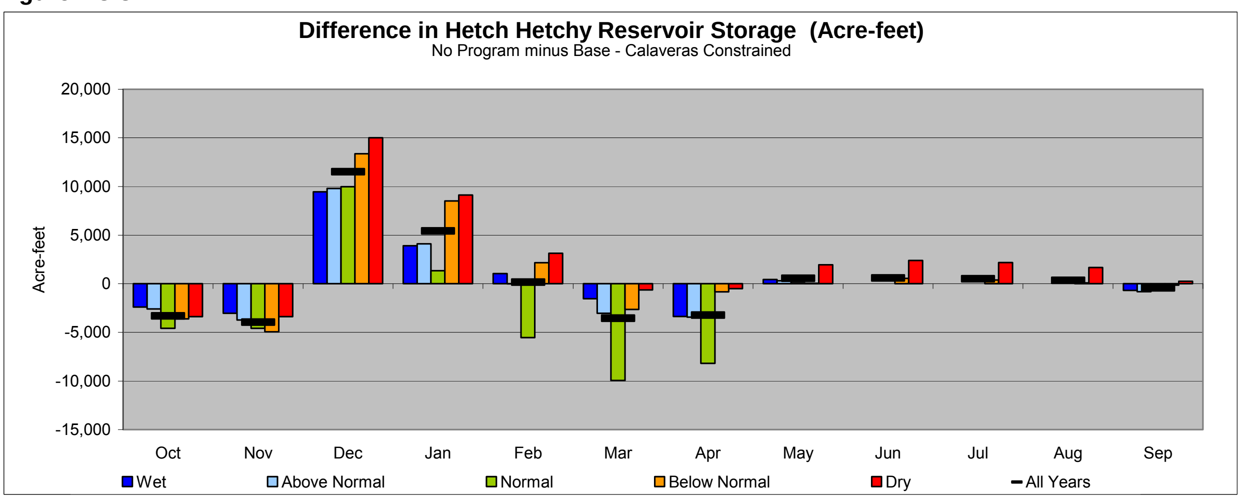

Figure 2.3-4

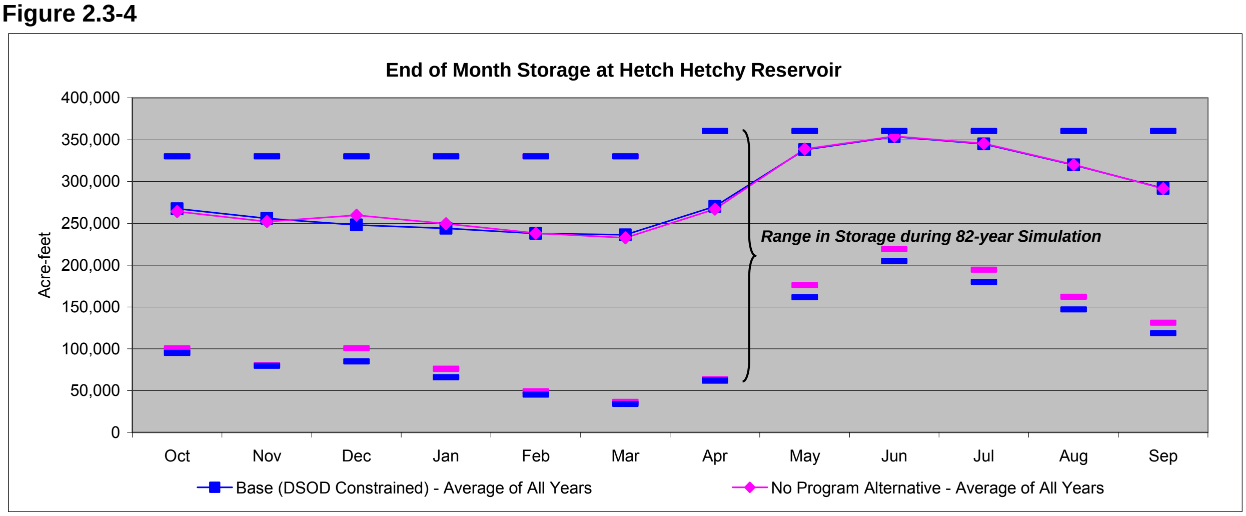

The difference in storage in Hetch Hetchy Reservoir attributed to the diversion effects of the alternative would manifest in differences in releases from O'Shaughnessy Dam to the stream. A different amount of available reservoir space in the winter and spring due to the alternative would lead to a different ability to regulate inflow, thus potentially changing the amount of water released to the stream that is above minimum release requirements. Figure 2.3-1 illustrates the stream release from O'Shaughnessy Dam for the WSIP, alternative, and base settings. Table 2.3-5 illustrates the difference in stream releases between the alternative and WSIP settings. Compared to the WSIP setting, the alternative typically exhibits an incrementally greater stream release, predominantly during May or June, which reflects the months when releases to the stream are made above minimum release requirements in anticipation of the reservoir being filled. However, there are exceptions to this circumstance during which incrementally larger reductions in releases to the stream occurs. Whether the change is an increase in releases or a decrease in releases is a matter of whether the reservoir is higher or lower in storage compared to the WSIP setting, which is a matter of coincidence of greater or lesser demands between the settings and the hydrologic sequence of years that leads to the need for Bay Area reservoir storage replenishment from the Tuolumne.

Table 2.3-6 illustrates the difference in stream release between the alternative and base settings. Consistent with the lower storage in Hetch Hetchy Reservoir by the end of April for the alternative setting, releases to the stream below Hetch Hetchy Reservoir would be less compared to the base setting. This circumstance occurs in 32 percent of the years of the 82-year simulation. There are a few exceptions when an increase in release would occur.

Table 2.3-5 illustrates the difference in stream release between the alternative and WSIP settings, expressed in terms of a monthly volume (acre-feet) of flow. Table 2.3-7 illustrates the same information and the average monthly stream release for the alternative and WSIP setting, expressed in average monthly flow (in cubic feet per second [cfs]) for each year type. Table 2.3-5 illustrates that the difference in monthly flow below O'Shaughnessy Dam could range from an increase of approximately 30,000 acre-feet to a decrease of approximately 10,000 acre-feet. Considering the manner in which releases are determined and made to the stream, quantifying the effect of these changes in terms of monthly flow (acre-feet or average cfs) is not always meaningful.[3] When comparing the alternative to the WSIP setting, a change in the volume of release from O'Shaughnessy Dam to the stream would likely result in the initiation of the release being delayed or initiated earlier by a matter of days. Typical spring-time releases, when initiated, amount to a release up to 3,000 cfs (approximately 6,000 acre-feet over the span of a day). Assuming that a change in release volume equates to a delay or acceleration of releasing 6,000 acre-feet per day, the difference in stream release between the alternative and WSIP settings would be a delay in releases up to 2 days or up to an added 5 days of release. Normally, the effect of the delay in release would not affect the year's peak stream release rate during a year. Comparing the alternative and WSIP settings, a change (increase or decrease) in stream release would occur in approximately 70 percent of the years simulated. Compared to the base setting, the alternative's effect to stream flow is typically less than the effect caused by the WSIP, but at times could be greater.

Table 2.3-8 illustrates the average monthly stream release for the alternative and base setting, expressed in average monthly flow (cfs), and the differences between the two. Table 2.3-6 illustrates that the difference in monthly flow below O'Shaughnessy Dam between the alternative and base settings could range from an increase of approximately 8,000 acre-feet to a decrease of approximately 33,000 acre-feet. Using the same metric as described above to estimate the delay or addition in the number days of release to the stream, the alternative could lead to an effect ranging from an increase of 1 day of release to a decrease of up to 6 days, compared to the base setting.

[3] See "Estimated Effect of WSIP on Daily Releases below Hetch Hetchy Reservoir", Memorandum by Daniel B. Steiner, December 31, 2006.

Table 2.3-5

Difference in Hetch Hetchy Release to Stream (Acre-feet)

No Program minus WSIP

2.4 Lake Lloyd and Lake Eleanor

Compared to the operation of the WSIP, the operation of Lake Lloyd and Lake Eleanor are simulated to be only slightly different for the alternative. Figure 2.4-1 illustrates a chronological trace of the simulation of Lake Lloyd storage and stream releases. Shown in Figure 2.4-1 are the results for the WSIP, alternative, and base settings. The operation resulting from the alternative is essentially the same as the WSIP, except during the prolonged drought of 1987-1992. The difference in operation during that drought stems from the delivery of additional water from Hetch Hetchy Reservoir in the WSIP setting. The additional draw of water reduced the amount of water released from Hetch Hetchy Reservoir to Don Pedro Reservoir in the WSIP setting, which, for satisfaction of MID/TID entitlements to inflow, was met with additional releases from Lake Lloyd. In the alternative setting, SFPUC deliveries during the 1987-1992 drought are nearly identical to the base setting; thus, an additional release from Lake Lloyd is not needed and the reservoir's operation would essentially be identical to the operation in the base setting.

Figure 2.4-2 illustrates the almost identical operation of Lake Eleanor for the alternative and WSIP settings. Also shown in Figure 2.4-2 is the operation for the base setting. Any difference that occurs in the Lake Eleanor operation would be caused by a small change in operation at Lake Lloyd that would affect the operation of the Cherry-Eleanor Tunnel between the two watersheds. Any difference that occurs in the simulations is more associated with modeling discretion than with any substantive difference in operation.

Supplementing the Figure 2.4-1 representation of Lake Lloyd stream releases is Table 2.4-1, illustrating releases for the alternative and WSIP settings and the difference in releases between the two settings. Table 2.4-2 provides the same form of information for the alternative and base settings.

2.5 Don Pedro Reservoir and La Grange Releases

A change in Don Pedro Reservoir operation is caused by changes in inflow to the reservoir. The changes in inflow to the reservoir are the result of net changes within the operation of the upstream SFPUC facilities described previously, and other changes in SFPUC operations associated with diversions to the Holm, Kirkwood, and Moccasin Powerhouses. Figure 2.5-1 illustrates a chronological trace of the simulation of Don Pedro Reservoir storage and Tuolumne River stream releases from La Grange Dam. Shown in Figure 9 are the results for the WSIP, alternative, and base settings.

Supplementing the Figure 2.5-1 representation of Don Pedro Reservoir storage are Table 2.5-1 Don Pedro Reservoir Storage (No Program), Table 2.5-2 Don Pedro Reservoir Storage (WSIP), and Table 2.5-3 Difference in Don Pedro Reservoir Storage (No Program minus WSIP). Table 2.5-4 illustrates the difference in Don Pedro Reservoir storage between the base and alternative settings.

Table 2.5-3 illustrates that, throughout many years, the storage in Don Pedro Reservoir associated with the alternative setting would differ from the storage in the WSIP setting, and that this difference would almost always be more storage. Table 2.5-4 illustrates that the alternative setting results for Don Pedro Reservoir storage are close to the storage results depicted for the base setting. Compared to the WSIP setting, the differences in storage are indicative of the increases to the inflow of Don Pedro Reservoir that are due to lesser SJPL diversions in the alternative setting. The increases in inflow typically occur during winter through early summer. Comparing to the base setting, the alternative would result in typically less inflow to Don Pedro Reservoir, and thus less reservoir storage. As described above concerning SFPUC deliveries and SJPL diversions, when compared to the base setting, the alternative would divert additional water from the Tuolumne in many years. The greatest draw from reservoir storage for both the base and alternative settings occurs during the droughts of the 1930s, 1960s, and 1976-1977.

Figure 2.5-2 illustrates the difference in reservoir storage averaged by year type in comparing the alternative to the WSIP settings. Also shown is the average difference in storage for the two settings during the 82-year simulation. Figure 2.5-3 illustrates the same information in comparing the alternative and the base settings.

Figure 2.5-2

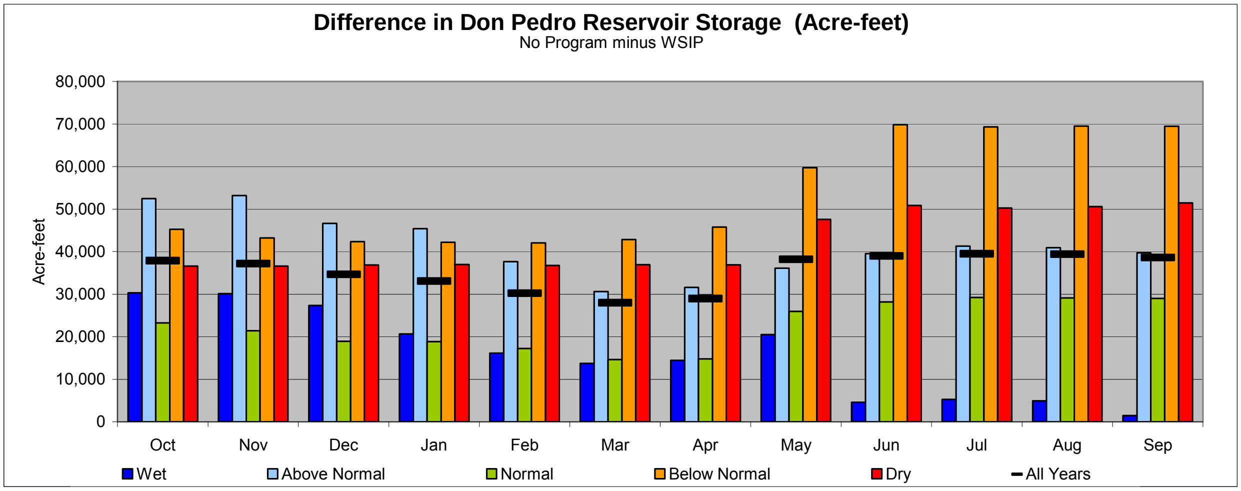

Figure 2.5-3

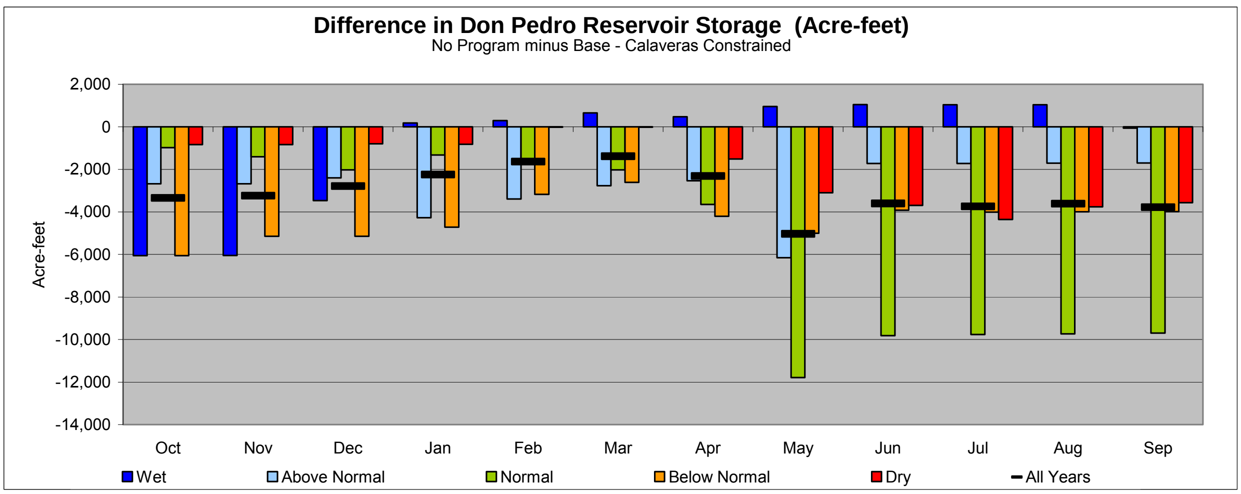

Figure 2.5-4 illustrates the average monthly storage in Don Pedro Reservoir for the 82-year simulation, and the range in storage for each month for the alternative and base settings.

The difference in storage in Don Pedro Reservoir attributed to the upstream effects of the alternative would manifest in differences in releases from La Grange Dam to the stream. A different amount of available reservoir space in the winter and spring due to the alternative would lead to a different ability to regulate inflow, thus potentially changing the amount of water released to the stream that is above minimum release requirements. During periods when inflow differs and Don Pedro Reservoir is at maximum storage capacity within the flood control storage limitation, a change in inflow directly manifests as a change in release from La Grange Dam (a change of either more or less flow). Figure 2.5-1 illustrates the stream release from La Grange Dam for the WSIP, alternative, and base settings.

Figure 2.5-4

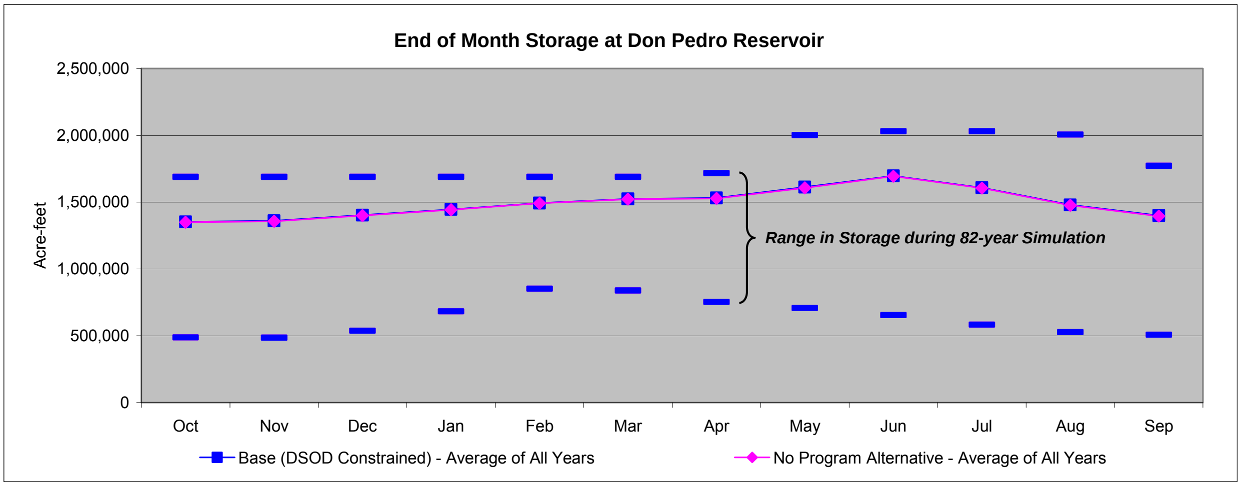

Table 2.5-5 illustrates the difference in stream releases between the alternative and WSIP settings. Compared to the WSIP setting, the alternative typically exhibits an incrementally larger stream release, predominantly during some months in early winter through June, which reflects the months when releases to the stream are made above minimum release requirements due to flood control or in anticipation of the reservoir being filled. There are exceptions, a decrease in releases to the stream, during certain years when the alternative diverts more water the SJPL to serve more demand as compared to the WSIP setting. Table 2.5-6 illustrates the same information in comparing the alternative and WSIP settings, with years ranked in descending order of the San Joaquin River Index. Illustrated is the finding that differences in releases to the Tuolumne River from La Grange Dam would occur only when there are releases in excess of minimum Federal Energy Regulatory Commission (FERC) flow requirements. This circumstance typically occurs only in above normal and wet years, and predominantly during early winter through June. During July of the wettest of years, additional releases could be associated with the alternative setting. During other year types and during the summer and fall, releases would be maintained at minimum FERC flow requirements regardless of the setting. Compared to the WSIP setting, the large potential reduction in flow following an extended drought period is ameliorated with the alternative because the amount of water delivered by the SFPUC during these periods is typically about the same as delivered in the base setting, thereby not exacerbating the draw down of Don Pedro Reservoir.

As described above concerning Don Pedro inflow and storage, compared to the base setting, the alternative setting would lead to an additional draw of storage due to SFPUC diversions that are greater than in the base setting in many years. Although the reduction in storage would not greatly accumulate over several years, greater replenishment of Don Pedro Reservoir storage is needed in over 40 percent of the years of the 82-year simulation. Table 2.5-7 illustrates the difference in stream releases between the alternative and base settings, depicting the predominance of reductions to flow. Table 2.5-8 illustrates the same information ranked in descending order of the San Joaquin River Index.

Table 2.5-6 and Table 2.5-7 illustrate the difference in stream release between the alternative, WSIP, and base settings, expressed in terms of a monthly volume (acre-feet) of flow. Table 2.5-9 illustrates the same information and the average monthly stream release for the alternative and WSIP settings, expressed in average monthly flow (cfs). Table 2.5-10 illustrates the same information in comparing the alternative and base settings. For the comparison of the alternative to the WSIP setting, the difference in monthly flow below La Grange Dam could range from an increase of approximately 197,000 acre-feet to a decrease of approximately 25,000 acre-feet. Considering the manner in which releases are determined and made to the stream, quantifying the effect of these changes in terms of average monthly flow (cfs) is not always meaningful. Similar to the operation of releases below O'Shaughnessy Dam, a change in the volume of release from La Grange Dam to the stream would likely result in the initiation of the release being delayed or accelerated by a matter of days. Assuming that a change in release volume equates to a delay or acceleration of releasing 6,000 acre-feet per day, the difference in stream release from La Grange Dam between the alternative and WSIP would be a delay in releases up to 4 days or up to an added month of release.

Normally, the effect of the delay in release would not affect the year's peak stream release rate during a year. However, infrequently, the alternative's effect on stream releases could manifest as an elimination of all flows during a year above minimum FERC flow requirements. Compared to the base setting, the alternative's effect to stream flow ranges from a slight reduction to releases (a potential delay in release of 6 days) to a slight increase in releases (a potential additional day of release).

2.6 Calaveras and San Antonio Reservoirs, Alameda Creek, and Downstream

Compared to the WSIP setting, Calaveras Reservoir storage is utilized to a greater extent in the alternative setting. Figure 2.6-1 illustrates a chronological trace of the simulation of Calaveras Reservoir storage and stream releases from Calaveras Dam. Shown in Figure 2.6-1 are the results for the WSIP, alternative, and base settings. The difference in Calaveras Reservoir storage between the alternative and WSIP settings is mostly caused by the interaction of the increased demand served by the system's resources (300 mgd for the alternative and a net 290-mgd demand for the WSIP for many years), and by the difference in conveyance capacity of the SJPL. Generally, the systematic decrease in reservoir storage beginning in spring and lasting through fall is due to the additional demand and less SJPL conveyance capacity drawing more water from Calaveras Reservoir during the period. This additional draw down occurs each year between annual filling events, and accumulates during drought sequences
